Line style of the line connecting the markers. Default is 'none'.

- **lineWidth** ↑

Line width of line if plotted. Must be a scalar double.

- **marker** ↑

Sets the marker of the plot. Either {'o'} | 'x' | '+' | '*' | 's' | 'd' | '.' | '^' | '<' | '>' | 'v' | 'p' | 'h'. Must be a string or a cellstr with size 1 x size(yData,2).

- **markerSize** ↑

Sets the size of the markers. Must be a scalar.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is of class nb_axes. (Which is the default)

- **type** ↑

nb_scatter/type is a property.

- **visible** ↑

Sets the visibility of the radar plot. {'on'} | 'off'.

- **xData** ↑

A double matrix. Each column will be match against the corresponding column of th yData property. If it is given as a vector it will be expanded to fit the number of columns of the yData property.

- **yData** ↑

A double matrix. Each column will be match against the corresponding column of the xData property. If it is given as a vector it will be expanded to fit the number of columns of the xData property.

-

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get ↑**

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_scatter

Input:

- obj : An object of class nb_scatter
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('cData');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÅ;terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

set(obj,varargin)

Description:

Sets the properties of an object of class nb_scatter. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_scatter
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_scatter with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_table

Go to: [Properties](#) | [Methods](#)

This is a class for making tables.

Superclasses:

nb_plotHandle, nb_cursorTracker

Constructor:

```
obj = nb_table(data, varargin)
```

Input:

- data : Table cell contents as m x n cell array

Optional input:

- varargin : 'propertyName', PropertyValue,...

Output:

- obj : An object of class nb_table (handle).

Examples:

```
data = asCell(nb_cs.rand);
t = nb_table(data);
t.BackgroundColor(1, :) = {'blue'};
```

Written by Henrik Halvorsen Hortemo and Kenneth Sæterhagen Paulsen

- **[BackgroundColor](#)** ↑

m x n cell array. Cell contents: [R G B] | color name as string

- **[BorderBottom](#)** ↑

Line width of bottom border
m x n cell array. Cell contents: Integer

- **[BorderColor](#)** ↑

[R G B] or color name

- **[BorderLeft](#)** ↑

Line width of left border
m x n cell array. Cell contents: Integer

- **[BorderRight](#)** ↑

Line width of right border
m x n cell array. Cell contents: Integer

- **[BorderTop](#)** ↑

Line width of top border
m x n cell array. Cell contents: Integer

- **[Color](#)** ↑

m x n cell array. Cell contents: [R G B] | color name as string

- **[ColumnSizes](#)** ↑

Normalized 1 x n vector

- **ColumnSpan** ↑

Sets how many columns a cell should span.
Cells expand downwards and to the right.
m x n cell array. Cell contents: Integer

- **DateFormat** ↑

m x n cell array. Cell contents: char

- **Editing** ↑

m x n cell array. Cell contents: logical

- **FontSize** ↑

m x n cell array. Cell contents: double

- **FontUnits** ↑

m x n cell array. Cell contents: string

- **FontWeight** ↑

m x n cell array. Cell contents: 'bold' | 'normal'

- **HorizontalAlignment** ↑

m x n cell array. Cell contents: 'left' | 'center' | 'right'

- **Interpreter** ↑

m x n cell array. Cell contents: 'none' | 'tex' | 'latex'

- **Margin** ↑

Margin from left/right border to text
m x n cell array. Cell contents: Integer

- **RowSizes** ↑

Normalized 1 x m vector

- **RowSpan** ↑

Sets how many rows a cell should span
Cells expand downwards and to the right.
m x n cell array. Cell contents: Integer

- **String** ↑

m x n cell array. Cell contents: cellstr

- **VerticalAlignment** ↑

m x n cell array. Cell contents: 'left' | 'center' | 'right'

- **allowDimensionChange** ↑

Boolean indicating whether or not adding/removing rows/columns is allowed

- **children** ↑

Cell array of object handles

- **data** ↑

A cell of the unformatted data of the table.

- **decimals** ↑

Round numbers to the number of digits. Default is not to round numbers. Either as an integer with the number of digits, or a string with the printed format. See num2str function.

- **defaultContextMenu** ↑

The default context menu to add to each cell. Add, Delete and Format menus will be appended. If empty only these three menus are added.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **language** ↑

Sets the language of the date format given by the DateFormat property. Only important for the Monthtext and Quartertext options.

- **mode** ↑

Which type of edit mode the table is in. Either 'even' (default) or 'neighbour'. This affect how the rest of the rows or columns of the table is resizes given the change in one of the row or column. If 'even' all the rest of the rows or columns of the table share the adjustment in the row or column evenly, otherwise the next row column in the line take all the adjustment.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **size** ↑

[m n]

- **stylingPatterns** ↑

Styling patterns. See nb_table.stylingPatternsTemplate method.

- **updateOnChange** ↑

Turn automatic updates on/off. Used for performance enhancements and to avoid recursion traps

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scal factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj, propertyName)
```

Description:

Get a property of an object of class nb_table

Input:

- obj : An object of class nb_table
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **getDefaultColors ↑**

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvít','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÅ!terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set** ↑

```
set(obj, varargin)
```

Description:

Set properties of the nb_table class

Input:

- varargin : Property name property value pairs.

Written by Henrik Halvorsen Hortemo

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct

Input:

- obj : An object of class nb_table

Output:

- s : A struct

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

obj = nb_table.unstruct(s)

Description:

Convert struct to object

Input:

- s : A struct

Output:

- obj : An object of class nb_table

See also:

[nb_table.struct](#)

■ nb_tableTextUpdateEvent

Go to: [Properties](#) | [Methods](#)

The data that get sent when the updatedTableText event is notified.

Superclasses:

event.EventData

See also:

[nb_table](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [EventName](#)
- [Index](#)
- [Source](#)
- [String](#)

- [EventName](#) ↑

event.EventData.EventName - Name of event

Documentation for event.EventData.EventName
doc event.EventData.EventName

- [Index](#) ↑

The index of the edited cell of the nb_table object.

- [Source](#) ↑

event.EventData.Source - Event source

Documentation for event.EventData.Source
doc event.EventData.Source

- [String](#) ↑

A char with the string property of the edited cell of the nb_table object

Methods:

■ nb_textArrow

Go to: [Properties](#) | [Methods](#)

`nb_lineAnnotation, nb_movableAnnotation, nb_textAnnotation,
nb_annotation, handle`

Description:

A class for adding a arrow with a text box to a plot.

Constructor:

`obj = nb_textArrow(varargin)`

Input:

Optional input ('propertyName', PropertyValue):

> You can set some properties of the class. See the list below.

Output

- `obj` : An object of class `nb_textArrow`

Examples:

See also:

`nb_textAnnotation, nb_annotation, handle, nb_graph_ts
nb_graph_cs`

Written by Kenneth Sætherhagen Paulsen

Properties:

- `children`
- `color`
- `copyOption`
- `deleteOption`
- `fontAngle`
- `fontName`
- `fontSize`
- `fontUnits`
- `fontWeight`
- `headLength`
- `headStyle`
- `headWidth`
- `horizontalAlignment`
- `interpreter`
- `lineStyle`
- `lineWidth`
- `listeners`
- `normalized`
- `parent`
- `pointer`
- `selected`
- `side`
- `string`
- `textBackgroundColor`
- `textColor`
- `textEdgeColor`
- `textLineWidth`
- `textMargin`
- `textRotation`
- `units`
- `verticalAlignment`
- `xData`
- `yData`

- **`children`** ↑

The children of the handle.

Inherited from superclass `NB_ANNOTATION`

- **color** ↑

The color data of the line plotted. Must be of size; 1x3. With the RGB colors. Or a string with the name of the color. See the method `interpretColor` of the `nb_plotHandle` class for more on the supported color names.

- **copyOption** ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass `NB_ANNOTATION`

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass `NB_ANNOTATION`

- **fontAngle** ↑

{'normal'} | 'italic' | 'oblique'

- **fontName** ↑

Name of the font to use. Must be a string. Default is 'arial'.

Inherited from superclass `NB_TEXTANNOTATION`

- **fontSize** ↑

Sets the font size in the units given by the `fontUnits` property. Must be a scalar. Default is 12.

Inherited from superclass `NB_TEXTANNOTATION`

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the `fontSize` property.

normalized - Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `fontSize` accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

Inherited from superclass `NB_TEXTANNOTATION`

- **fontWeight** ↑

Weight of text characters. {'normal' | 'bold' | 'light'
| 'demi'

Inherited from superclass NB_TEXTANNOTATION

- **headLength** [↑](#)

Length of first arrowhead. Size in points. As a scalar.
Specify in points.1 point = 1/72 inch. The default value
is 8.

The first arrowhead is located at the start defined by
the point xData(1), yData(1).

- **headStyle** [↑](#)

Style of first arrowhead. As a string. Specify this
property as one of the strings from the following table.

```
> 'none'  
> 'plain'  
> 'ellipse'  
> 'vback1'  
> 'vback2' (default)  
> 'vback3'  
> 'cback1'  
> 'cback2'  
> 'cback3'  
> 'star4'  
> 'rectangle'  
> 'diamond'  
> 'rose'  
> 'hypocycloid'  
> 'astroid'  
> 'deltoid'
```

- **headWidth** [↑](#)

Width of first arrowhead. Specify in points.
1 point = 1/72 inch. As a scalar. The default value is
8.

The arrowhead is located at the start defined by the
point xData(1), yData(1).

- **horizontalAlignment** [↑](#)

Horizontal alignment of text. Specifies the horizontal
justification of the text string. Must be a string.
'left' | 'center' | 'right' | {'default'}. When 'default'
is given this class will try to find the best
alignment.

- **interpreter** [↑](#)

Interpret TeX instructions. Must be a string. 'latex' |
{'tex'} | 'none'.

- **lineStyle** ↑

The line style of the plotted data. Must be a string.
{'-' } | '--' | ':' | '-' | 'none'. '---' is not supported.

- **lineWidth** ↑

The line width of the plotted arrow. As an integer.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **normalized** ↑

Indicate if the font when fontUnits is set to 'normalized' should be normalized to the axes ('axes') or to the figure ('figure'), i.e. the default axes position [0.1 0.1 0.8 0.8].

Inherited from superclass NB_TEXTANNOTATION

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object. When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **side** ↑

The axes to plot against. 'left' or 'right'. 'left' is default.

- **string** ↑

Sets the text of the textbox. Must be a char. Each vertical element of the given char will result in a new line of text.

- **textBackgroundColor** ↑

Color of text background rectangle. Must be of size; 1x3. With the RGB colors. Or a string with the name of the color. See the method interpretColor of the nb_plotHandle class for more on the supported color names. Can also be set to 'none'.

- **textColor** ↑

Color of text. Must be of size; 1 x 3. With the RGB colors. Or a string with the name of the color. See the method interpretColor of the nb_plotHandle class for more on the supported color names.

- **textEdgeColor** ↑

Color of edge of text rectangle. Must be of size; 1 x 3. With the RGB colors. Or a string with the name of the color. See the method interpretColor of the nb_plotHandle class for more on the supported color names. Can also be set to 'none'.

- **textLineWidth** ↑

Width of text rectangle edge. Must be a scalar. Default is 0.5.

- **textMargin** ↑

Space around text. A value in pixels that defines the space around the text string, but within the rectangle. Default value is 5 pixels.

- **textRotation** ↑

Text orientation. Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation). Must be a scalar. Default is 0.

- **units** ↑

The coordinates system to plot in. Either {'data'} : xy-coordinates | 'normalized' : figure coordinates.

- **verticalAlignment** ↑

Vertical alignment of text. Specifies the vertical justification of the text string. Must be a string. 'top' | 'cap' | 'middle' | 'baseline' | 'bottom' | 'default'. When 'default' is given this class will try to find the best alignment.

- **xData** ↑

The x-axis data. As a double. E.g: [x_begin, x_end].

- **yData** ↑

The y-axis data. As a double. E.g: [y_begin, y_end].

Methods:

- [set](#)

► **set** ↑

`set(obj,varargin)`

Description:

Sets the properties of an object of class nb_textArrow. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- `obj` : An object of class nb_textArrow
- `varargin` : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- `obj` : The same object of class nb_arrow with the given properties reset

Examples:

`obj.set('propertyName',PropertyValue,...);`

Written by Kenneth Sæterhagen Paulsen

■ **nb_textBox**

Go to: [Properties](#) | [Methods](#)

`nb_textAnnotation, nb_movableAnnotation, nb_lineAnnotation,
nb_annotation, handle`

Description:

A class for adding a text box to a plot.

Constructor:

```
obj = nb_textBox(varargin)
```

Input:

Optional input ('propertyName', PropertyValue):

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_textBox

Examples:

See also:

[nb_textAnnotation](#), [nb_lineAnnotation](#), [nb_annotation](#), handle

Written by Kenneth Sætherhagen Paulsen

Properties:

- | | | | |
|-----------------------------------|-------------------------------------|------------------------------|---------------------------------------|
| • backgroundColor | • children | • color | • copyOption |
| • deleteOption | • edgeColor | • fontAngle | • fontName |
| • fontSize | • fontUnits | • fontWeight | • horizontalAlignment |
| • interpreter | • lineStyle | • lineWidth | • listeners |
| • margin | • normalized | • parent | • pointer |
| • rotation | • selected | • side | • string |
| • units | • verticalAlignment | • xData | • yData |

- **backgroundColor** ↑

Color of text background rectangle. Must be of size; 1x3. With the RGB colors. Or a string with the name of the color. See the method `interpretColor` of the `nb_plotHandle` class for more on the supported color names. Can also be set to 'none'.

- **children** ↑

The children of the handle.

Inherited from superclass NB_ANNOTATION

- **color** ↑

Color of text. Must be of size; 1x3. With the RGB colors. Or a string with the name of the color. See the method `interpretColor` of the `nb_plotHandle` class for more on the supported color names.

- **copyOption** ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass NB_ANNOTATION

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass NB_ANNOTATION

- **edgeColor** ↑

Color of edge of text rectangle. Must be of size; 1x3. With the RGB colors. Or a string with the name of the color. See the method interpretColor of the nb_plotHandle class for more on the supported color names. Can also be set to 'none'.

- **fontAngle** ↑

{'normal'} | 'italic' | 'oblique'

- **fontName** ↑

Name of the font to use. Must be a string. Default is 'arial'.

Inherited from superclass NB_TEXTANNOTATION

- **fontSize** ↑

Sets the font size in the units given by the font units property. Must be a scalar. Default is 12.

Inherited from superclass NB_TEXTANNOTATION

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the fontSize property.

normalized - Interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen fontSize accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

Inherited from superclass NB_TEXTANNOTATION

- **fontWeight** ↑

Weight of text characters. {'normal'} | 'bold' | 'light'
| 'demi'

Inherited from superclass NB_TEXTANNOTATION

- **horizontalAlignment** ↑

Horizontal alignment of text. Specifies the horizontal justification of the text string. Must be a string.
{'left'} | 'center' | 'right'.

- **interpreter** ↑

Interpret TeX instructions. Must be a string.
'latex' | {'tex'} | 'none'.

- **lineStyle** ↑

The line style of the plotted box. Must be a string.
{'-' } | '--' | ':' | '-' | 'none'. '---' is not supported.

- **lineWidth** ↑

Width of text rectangle edge. Must be a scalar. Default is 0.5.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **margin** ↑

Space around text. A value in pixels that defines the space around the text string, but within the rectangle. Default value is 5 pixels.

- **normalized** ↑

Indicate if the font when fontUnits is set to 'normalized' should be normalized to the axes ('axes') or to the figure ('figure'), i.e. the default axes position [0.1 0.1 0.8 0.8].

Inherited from superclass NB_TEXTANNOTATION

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **rotation** [↑](#)

Text orientation. Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation). Must be a scalar. Default is 0.

- **selected** [↑](#)

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **side** [↑](#)

The axes to plot against. 'left' or 'right'. 'left' is default.

- **string** [↑](#)

Sets the text of the textbox. Must be a char. Each vertical element of the given char will result in a new line of text.

- **units** [↑](#)

The coordinates system to plot in. {'data'} : xy-coordinates. 'normalized' : Axes are normalized to have length 1.

- **verticalAlignment** [↑](#)

Vertical alignment of text. Specifies the vertical justification of the text string. Must be a string. 'top' | 'cap' | {'middle'} | 'baseline' | 'bottom'.

- **xData** [↑](#)

The x-axis data. As a scalar.

- **yData** [↑](#)

The y-axis data. As a scalar.

Methods:

- [set](#)

► **set** [↑](#)

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_textArrow. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_textArrow
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_arrow with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_title

Go to: [Properties](#) | [Methods](#)

```
obj = nb_title(parent,string,varargin)
```

Superclasses:

handle

Description:

This is a class for adding a title to a nb_axes handle

Constructor:

```
obj = nb_title(parent,string,varargin)
```

Input:

- parent : An object of class nb_axes
- string : The title as a string

Optional input:

- varargin : ...,'propertyName',PropertyValue,...

Output:

- obj : An object of class nb_title

Examples:

First you need to make the nb_axes handle
ax = nb_axes();

Then you can add the title
nb_title(ax,'A title');

nb_title(ax,'A title','propertyName',PropertyValue,...);
titleHandle = nb_title(ax,'A title','propertyName',...
PropertyValue,...);

same as

nb_title('A title','parent',ax,'propertyName',...
PropertyValue,...);

titleHandle = nb_title('A title','parent',ax,...
'propertyName',PropertyValue,...);

Make new axes for the given title:

nb_title('A title','propertyName',PropertyValue,...);
titleHandle = nb_title('A title','propertyName',...
PropertyValue,...);

[title](#), [nb_axes](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- alignment
- children
- deleteOption
- fontName
- fontSize
- fontUnits
- fontWeight
- interpreter
- normalized
- parent
- placement
- string
- visible

- **alignment** ↑

The figure title text alignment, default is 'center'. You also have 'left' and 'right'.

- **children** ↑

The children will consist of one MATLAB title handle.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **fontName** ↑

The font name to use. As a string. Default is 'arial'

- **fontSize** ↑

The size of the font. As a scalar.

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the `fontSize` property.

normalized - Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `fontSize` accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

The weight of the font, {'bold'} | 'normal' | 'light'.

- **interpreter** ↑

{'none'} | 'tex' | 'latex'

- **normalized** ↑

Indicate if the font when `fontUnits` is set to 'normalized' should be normalized to the axes ('axes') or to the figure ('figure'), i.e. the default axes position [0.1 0.1 0.8 0.8].

- **parent** ↑

The parent, as a nb_axes handle (object).

- **placement** ↑

The placement of the title. {'center'} | 'left' | 'right' | 'lefttaxes'

- **string** ↑

The text of the title. As a char. Multi-lined char gives a multi-lined title.

- **visible** ↑

Sets the visibility of the radar plot. {'on'} | 'off'.

Methods:

- **get**
 - **set**
-

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_fanLegend

Input:

- **obj** : An object of class nb_fanLegend
- **propertyName** : A string with the propertyName

Output:

- **propertyValue** : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_title. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_title
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_title with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_verticalLine

Go to: [Properties](#) | [Methods](#)

```
obj = nb_verticalLine(xData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for making vertical lines which spans all of the y-axis.

If the parent is a nb_axes object:

- The line will automatically update the length of the line, so it spans all the y-axis.

If the parent is a MATLAB axes handle (object):

- The line will not update itself automatically and you need to use the update() method of the object to make it fit to the axes handle (If it is changed)

Constructor:

```
obj = nb_verticalLine(xData,varargin)
```

Input:

- xData : The x-axis value for where to place the vertical line. As a scalar.

Optional input:

- varargin : ...,'propertyName',PropertyValue,...

Output:

- obj : An object of class nb_verticalLine

Examples:

```
nb_verticalLine(xData)
obj = nb_verticalLine(xData)
obj = nb_verticalLine(xData,varargin)
```

[nb_line](#), [line](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- cData
- children
- deleteOption
- legendInfo
- lineWidth
- marker
- markerEdgeColor
- markerFaceColor
- parent
- side
- visible
- xData
- **lineStyle**
- **markerSize**

- **cData** [↑](#)

The color data of the line plotted. Must be of size; 1x3. With the RGB colors. or a string with the color name. See the method `interpretColor` of the `nb_plotHandle` class for more on the supported color names.

- **children** [↑](#)

The children of this object. As an `nb_line` object.

- **deleteOption** [↑](#)

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **legendInfo** [↑](#)

{'off'} : Not included in the legend. 'on' : included in the legend

- **lineStyle** ↑

The line style of the plotted data. Either a string or a cell array with size as the number of lines to be plotted. {'-' } | '--' | '---' | ':' | '-' | 'none'

- **lineWidth** ↑

The line width of the plotted data. Must be a scalar.
Default is 1.

- **marker** ↑

The markers of the lines. Either a string or a cell array with size as the number of lines to be plotted. See marker property of the MATLAB line function for more on the options of this property

- **markerEdgeColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **markerFaceColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **markerSize** ↑

Size of the markers. Must be a integer. Default is 9.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'.

- **xData** ↑

A scalar with the x-axis value for where to place the vertical line.

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefauleColors](#)
 - [interpretColor](#)
 - [set](#)
-

► **[findClosestNiceNumber](#)** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **[findLimitsAlgo](#)** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow, dataHigh, method, fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get ↑**

propertyValue = get(obj,propertyName)

Description:

Get a property of an object of class nb_verticalLine

Input:

- obj : An object of class nb_verticalLine
- propertyName : A string with the propertyName

Output:

- `propertyValue` : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the `nb_plotHandle` class.

Get the default colors given the number of plotted variables.

Input:

- `dataSize` : Number of plotted variables.

Output:

- `defaultColors` : The default colors, as a $M \times 3$ double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_PLOTHANDLE`

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the `nb_plotHandle` class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blå','b'
```

```

> 'red','rÃ,d','r'
> 'green','grÃ,nn','g'
> 'orange','o'
> 'light blue','lys blÃ¥','lb'
> 'black','svart','k'
> 'grey','grÃ¥','gr'
> 'purple','lilla','p'
> 'yellow','gul','y'
> 'magenta','m'
> 'white','hvit','w'
> 'cyan','c'
> 'burgundy','burgunder'
> 'sky blue','himmelblÃ¥','hb'
> 'deep blue','mÃ,rk blÃ¥','db'
> 'water blue','vannblÃ¥','vb'
> 'cool grey','kald grÃ¥','cgr'
> 'sand','s'
> 'pink','rosa','pi'
> 'turquoise','turkis','t'

```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_verticalLine. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_verticalLine
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_verticalLine with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_xlabel

Go to: [Properties](#) | [Methods](#)

```
obj = nb_xlabel(parent,string,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for adding a x-label to a nb_axes handle

Constructor:

```
obj = nb_xlabel(parent,string,varargin)
```

Input:

- parent : An object of class nb_axes
- string : the label as string

Optional input:

- varargin : 'propertyName',PropertyValue,...

Output:

- obj : A handle to the plot.

Examples:

First you need to make the nb_axes handle
ax = nb_axes();

Then you can add the x-label
nb_xlabel(ax,'A label');

Other examples:

```
nb_xlabel(ax,'A label','propertyName',PropertyValue,...);
```

```
titleHandle = nb_xlabel(ax,'A label','propertyName',...
                           PropertyValue,...);
```

same as

```
nb_xlabel('A label','parent',ax,'propertyName',...
    'propertyValue,...');

xlabelHandle = nb_xlabel('A label','parent',ax,...
    'propertyName',propertyValue,...);
```

Make new axes for the given x-label:

```
nb_xlabel('A label','propertyName',propertyValue,...);

xlabelHandle = nb_xlabel('A label','propertyName',...
    'propertyValue,...');
```

`nb_axes`, `xlabel`

Written by Kenneth Sætherhagen Paulsen

Properties:

- `alignment`
- `children`
- `deleteOption`
- `extent`
- `fontName`
- `fontSize`
- `fontUnits`
- `fontWeight`
- `interpreter`
- `normalized`
- `offset`
- `parent`
- `placement`
- `string`
- `visible`

- **alignment** ↑

The figure title text alignment, default is 'center'. You also have 'left' and 'right'.

- **children** ↑

The children will consist of one MATLAB text handle.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **extent** ↑

position rectangle (read-only)

Position and size of text. A four-element vector that defines the size and position of the text string:

[left,bottom,width,height]

left and bottom are the x- and y-coordinates of the lower left corner of the text extent. The units are normalized.

- **fontName** ↑

The font name to use. As a string. 'arial' is default.

- **fontSize** ↑

The size of the font. As a scalar. Default is 14.

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' |
'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the fontSize property.

normalized - Interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen fontSize accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

The weight of the font, {'bold'} | 'normal' | 'light'

- **interpreter** ↑

{'none'} | 'tex' | 'latex'.

- **normalized** ↑

Indicate if the font when fontUnits is set to 'normalized' should be normalized to the axes ('axes') or to the figure ('figure'), i.e. the default axes position [0.1 0.1 0.8 0.8].

- **offset** ↑

A scalar which manage the space between the x-axis tick mark labels and the x-label.

- **parent** ↑

The parent, as a nb_axes handle (object).

- **placement** ↑

The placement of the title. {'center'} | 'left' | 'right' | 'leftaxes'

- **string** ↑

The text of the x-label. As a string or a char.

- **visible** ↑

{'on'} | 'off'.

Methods:

- [get](#)
 - [set](#)
-

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_xlabel

Input:

- obj : An object of class nb_xlabel
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_xlabel. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_xlabel
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_xlabel with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_ylabel

Go to: [Properties](#) | [Methods](#)

```
obj = nb_ylabel(parent,string,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for adding a y-label to a nb_axes handle

Constructor:

```
obj = nb_ylabel(parent,string,varargin)
```

Input:

- parent : An object of class nb_axes
- string : The y-axis label as a string

Optional input:

- varargin : 'propertyName',PropertyValue,...

Output:

- obj : An object of class nb_ylabel

Examples:

First you need to make the nb_axes handle
ax = nb_axes();

```
Then you can add the y-label  
nb_ylabel(ax,'A label');
```

Other examples:

```
nb_ylabel(ax,'A label','propertyName',PropertyValue,...);
```

```
titleHandle = nb_ylabel(ax,'A label','propertyName',...  
                           PropertyValue,...);
```

same as

```
nb_ylabel('A label','parent',ax,'propertyName',...  
                           PropertyValue,...);
```

```
ylabelHandle = nb_ylabel('A label','parent',ax,...  
                           'propertyName',PropertyValue,...);
```

Make new axes for the given y-label:

```
nb_ylabel('A label','propertyName',PropertyValue,...);
```

```
ylabelHandle = nb_ylabel('A label','propertyName',...  
                           PropertyValue,...);
```

As an nb_textBox object

Methods:

■ **nb_editCurlyBrace**

Go to: [Properties](#) | [Methods](#)

A class for editing an object of class nb_curlyBrace interactively.

Constructor:

gui = nb_editCurlyBrace(parent)

Input:

- parent : An object of class nb_curlyBrace.

Output:

- gui : An object of class nb_editCurlyBrace

See also:

[nb_arrow](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- defaultColors • figureHandle • parent

- [defaultColors ↑](#)

Default colors

- [figureHandle ↑](#)

A handle to the GUI window

- [parent ↑](#)

As an nb_drawPatch object

Methods:

■ [nb_editDrawLine](#)

Go to: [Properties](#) | [Methods](#)

A class for editing an object of class nb_editDrawLine interactively.

Constructor:

gui = nb_editDrawLine(parent)

Input:

- parent : An object of class nb_drawLine.

Output:

- gui : An object of class nb_editDrawLine

See also:

[nb_drawLine](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- defaultColors • figureHandle • parent

- [defaultColors ↑](#)

Default colors

- **figureHandle** ↑
A handle to the GUI window

- **parent** ↑
As an nb_drawPatch object

Methods:

■ **nb_editDrawPatch**
Go to: [Properties](#) | [Methods](#)

A class for editing an object of class nb_drawPatch interactivly.

Constructor:

gui = nb_editDrawPatch(parent)

Input:

- parent : An object of class nb_drawPatch.

Output:

- gui : An object of class nb_editDrawPatch

See also:

[nb_drawPatch](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

• defaultColors • figureHandle • parent

- **defaultColors** ↑

Default colors

- **figureHandle** ↑

A handle to the GUI window

- **parent** ↑

As an nb_drawPatch object

Methods:

■ **nb_editPlotLabels**
Go to: [Properties](#) | [Methods](#)

A class for editing an object of class nb_plotLabels interactively.

Constructor:

gui = nb_editPlotLabels(parent, class, index)

Input:

- parent : An object of class nb_barAnnotation.

Output:

- gui : An object of class nb_editPlotLabels.

See also:

[nb_barAnnotation](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

• class • defaultColors • figureHandle • index • parent

• type

- **class** ↑

Class for the underlying object to add labels to. Some options may be affected by this.

- **defaultColors** ↑

Default colors

- **figureHandle** ↑

A handle to the GUI window

- **index** ↑

The index of the label that is being edited.

- **parent** ↑

As an nb_barAnnotation object

- **type** ↑

The level of editing. Either 'all', 'row', 'column' or 'cell'

Methods:

■ **nb_editRegressLine**

Go to: [Properties](#) | [Methods](#)

A class for editing an object of class nb_regressLine interactivly.

Constructor:

gui = nb_editRegressLine(parent)

Input:

- parent : An object of class nb_regressLine.

Output:

- gui : An object of class nb_editRegressLine

See also:

[nb_regressLine](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

• defaultColors • figureHandle • parent

- **defaultColors** ↑

Default colors

- **figureHandle** ↑

A handle to the GUI window

- **parent** ↑

As an nb_drawPatch object

Methods:

■ **nb_editTextArrow**

Go to: [Properties](#) | [Methods](#)

A class for editing an object of class nb_textArrow interactivly.

Constructor:

gui = nb_editTextArrow(parent)

Input:

- parent : An object of class nb_textArrow.

Output:

- gui : An object of class nb_editTextArrow.

See also:

[nb_textArrow](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- defaultColors • figureHandle • parent

- [defaultColors ↑](#)

Default colors

- [figureHandle ↑](#)

A handle to the GUI window

- [parent ↑](#)

As an nb_textBox object

Methods:

■ [nb_editTextBox](#)

Go to: [Properties](#) | [Methods](#)

A class for editing an object of class nb_textBox interactively.

Constructor:

```
gui = nb_editTextBox(parent)
```

Input:

- parent : An object of class nb_textBox.

Output:

- gui : An object of class nb_editTextBox.

See also:

[nb_textBox](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- defaultColors • figureHandle • parent

- [defaultColors ↑](#)

Default colors

- **figureHandle** ↑

A handle to the GUI window

- **parent** ↑

As an nb_textBox object

Methods:

◆ **nb_alpha**

c = nb_alpha(c1,c2,alpha1,alpha2)

Description:

Alpha blending of two colors.

Input:

- c1 : A 1x3 double with the RGB color.
- c2 : A 1x3 double with the RGB color.
- alpha1 : A 1x1 double between 0 and 1.
- alpha2 : A 1x1 double between 0 and 1.

Output:

- c : A 1x3 double with the alpha blended RGB color.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_breakText**

nb_breakText(textObj, fitTo)

Description:

Wrap text of a object given some area to fit to. The object is already assumed to be included in the area fitTo, and therefore only the extent of the text is checked to not cross the right border.

Input:

- textObj : Handle to a text object
- fitTo : A 1x4 double with position to fit the text to.

Written by Kenneth Sæterhagen Paulsen and Henrik Halvorsen Hortemo

◆ nb_breakTextAfterEdit

```
index = nb_breakTextAfterEdit(textObj, fitTo, index)
```

Description:

Break text of a object given some area to fit to, after editing. I.e. after one string element is added to the string property of the object. The object is already assumed to be included in the area fitTo, and therefore only the extent of the text is checked to not cross the right border.

Input:

- textObj : Handle to a text object
- fitTo : A 1x4 double with position to fit the text to.
- index : A 1x2 double with the index for where the string property of the text handle is breaked. index(1) is the current row, and index(2) is the current column. Will be updated if the breakpoint is before the current position in a line. I.e. the current point must then be switched to the next line

Written by Kenneth Sæterhagen Paulsen

◆ nb_colormap

```
nb_colormap(ax, map)
```

Description:

Set the color map used by an object of class nb_axes. The color map of an nb_axes object may be used when a nb_image object assign the nb_axes object as it parent.

Input:

- ax : An object of class nb_axes.
- map : A n x 3 double with the color map to use.

See also:

[nb_axes.colorMap](#), [nb_axes.set](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_defaultColors

```
defaultColors = nb_defaultColors()
defaultColors = nb_defaultColors(number,isNB)
```

Description:

Gets the default colors used by the NB toolbox.

To change the default colors set the environment variable 'defaultColors' to the name of a .m file (fully specified path!) that creates a variable defaultColors. This variable must have size N x 3, and be a double array.

Example;

```
setenv('C:\yourDefaultColors.m')
```

Where the file is on the format;

```
defaultColors = [
    0, 0, 0;
    0.8, 0.8, 0.8
];
```

Output:

defaultColors : A n x 3 double with the RGB colors.

Written by Kenneth Sæterhagen Paulsen

◆ nb_displayValue

```
nb_displayValue(hObject, event)
```

Description:

Callback function which can be used to display the value of the data point in a nb_notifiesMouseOverObject object.

Input:

- hObject : An object of class nb_axes.
- event : A nb_mouseOverObjectEvent object
- variables : A nested cellstr with the same size as the maximum value of event.h (Number of children of the axes). And each element must have size event.y (Number of plotted variables by the child).
- variablesX : A nested cellstr with the same size as the maximum value of event.h (Number of children of the axes). And each element must have size event.y (Number of plotted observation by the child).

Output:

- A text box on screen displaying the data value.

Example:

```
d      = rand(10,2);
d(2,2) = -0.2;
d(2,1) = -0.1;
bar    = nb_bar(d,'style','stacked');
func   = @(src,event) nb_displayValue(src,event,{{'Var1','Var2'}});
addlistener(bar.parent,'mouseOverObject',func);
```

See also:

[nb_notifiesMouseOverObject](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_dpos2dpos**

```
x = nb_dpos2dpos(x,oldPos,newPos,oldScale,newScale)
```

Description:

Convert the matrix *x* from the old units to the new units value.

Input:

- *x* : Old value(s). As a double matrix.
- *oldPos* : Old positions. As a 1x2 double.
- *newPos* : New positions. As a 1x2 double.
- *oldScale* : New scale. Either 'normal' or 'log'.
- *newScale* : Old scale. Either 'normal' or 'log'.

Output:

- *x*

Written by Kenneth Sæterhagen Paulsen

◆ **nb_getCurrentPointInAxesUnits**

```
[cPoint,cAxPoint] = nb_getCurrentPointInAxesUnits(fig,ax)
```

Description:

Get current point of the mouse in the axes units of an nb_axes object.

Input:

- fig : Either a figure, a nb_figure or a nb_graphPanel object.
- ax : As a nb_axes or axes object.

Output:

- cPoint : Current point in figure or panel units. Will depend on if the fig input is an nb_figure or an nb_graphPanel object.
- cAxPoint : Current point of the mouse in the axes units of an nb_axes object. (in normalized units).

Written by Kenneth Sæterhagen Paulsen

◆ nb_getFanColors

```
cData = nb_getFanColors(cData,percentiles)
```

Description:

Get fan colors

Input:

- cData : A string with the base color to use. {'nb'} | 'yellow' | 'magenta' | 'cyan' | 'red' | 'green' | 'blue' | 'grey' | 'white'
- percentiles : The percentiles as 1 x numberofPercentiles double. E.g: [.3,.5,.7,.9] (Which is default)

Output:

- cData : A numberofPercentiles x 3 double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_getFontSize

```
fontSize = nb_getFontSize(fontSize,newFontUnits,oldFontUnits,...  
                           normalizeFactor)
```

Description:

Transform the given font size from a font units from a old to a new one while keeping the font size on the plot. (See below for an exception)

Caution : If you transform from 'points','inches' and

'centimeters' to 'normalized' this function will not keep the font size, it will normalize the font size to how the given font size would have been plotted on a axes with positions [0.13 0.11 0.775 0.815] on a screen with resolution 1680x1050 pixels.

Adjust the normalizeFactor to change which axes positions and screen resolution to normalize against.

Input:

- fontSize : The font size to convert. As a scalar.
- newFontUnits : The font units to convert to.
Either 'points', 'inches', 'centimeters' or 'normalized'.
- oldFontUnits : The font to convert from.
Either 'points', 'inches', 'centimeters' or 'normalized'.
- normalizeFactor : The factor that transform the font size in 'points' to the font size in 'normalized' units. The default factor is 0.001787310098302, which will normalize the font size to how the given font size would have been plotted on a axes with positions [0.13 0.11 0.775 0.815] on a screen with resolution 1680x1050 pixels.

Output:

- fontSize : The converted font size. As a scalar.

Examples:

```
fontSize = nb_getFontSize(12,'normalized','points');
```

See also:

Written by Kenneth Sæterhagen Paulsen

◆ **nb_htmlColors**

```
colors = nb_htmlColors(endc)
```

Description:

Create a color list for use in colored pop-up menus

Input:

- endc : A n x 3 double with the RGB colors.

Output:

- colors : A cell array with size n.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_interpretKeyPress**

```
[index,special] = nb_interpretKeyPress(textObj,index,event)
```

Description:

Update a text object given a index and a event triggered by KeyReleaseFcn
KeyPressFcn or a nb_keyEvent.

Input:

- textObj : A MATLAB text handle (object).
- index : A 1x2 double with the index for where the string property of
the text handle is edited. index(1) is the current row, and
index(2) is the current column.
- event : Either a struct thrown by KeyReleaseFcn or KeyPressFcn, or a
nb_keyEvent.

Output:

- index : The updated index. May change due to arrow being pressed.
- special : Either:
 - '' : No special key is pressed.
 - 'escape' : Esc is pressed.
 - 'tab' : Tab is pressed.
 - struct : If the special field is set to
'multilinePaste', a multilined element
is pasted into the given location. See
the pasted field for the pasted element.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_isAxes**

```
ret = nb_isAxes(value)
```

Description:

Test if an object is of class axes.

Input:

- value : Any

Output:

- ret : True if value is a handle to a axes.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isColorProp

```
ret = nb_isColorProp(in,log)
```

Description:

Evaluates the color properties. Must have dimension size N x 3 with the RGB colors or a cellstr with size 1 x N with the color names.

N == 1 if mult is set to false, else N can be > 1.

Input:

- in : The property value to be evaluated.

- mult : Allow for multiple colors.

Output:

- ret : Logical. Returns true if the property is evaluated to be a valid color property as stated in the description above.

Written by Tobias Ingebrigtsen

◆ nb_isContextMenu

```
ret = nb_isContextMenu(value)
```

Description:

Test if an object is of class ContextMenu.

Input:

- value : Any

Output:

- ret : True if value is a handle to a figure.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isFigure

```
ret = nb_isFigure(value)
```

Description:

Test if an object is of class figure.

Input:

- value : Any

Output:

- ret : True if value is a handle to a figure.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isPanel

```
ret = nb_isPanel(value)
```

Description:

Test if an object is of class panel.

Input:

- value : Any

Output:

- ret : True if value is a handle to a figure.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isRGB

```
ret = nb_isRGB(in)
ret = nb_isRGB(in,moreRows)
```

Description:

Test if the input in is a RGB color.

Input:

```
- in      : The value to be evaluated.  
- moreRows : Give true to also tolerate a N x 3 RGB color matrix for  
N > 1. Default is false.
```

Output:

```
- ret      : Logical. Returns true if the input is a RGB color.
```

Written by Tobias Ingebrigtsen

◆ **nb_isUipanel**

```
ret = nb_isUipanel(value)
```

Description:

Test if an object is of class ContextMenu.

Input:

```
- value : Any
```

Output:

```
- ret    : True if value is a handle to a figure.
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_islineStyle**

```
ret = nb_islineStyle(in,allowCell)
```

Description:

Test if an input is a valid lineStyle property.

Input:

```
- in      : Any input
```

```
- allowCell : True if we allow for cellstring.
```

Output:

```
- ret : true if in is a valid lineStyle property.
```

Written by Tobias Ingebrigtsen

◆ nb_ismarker

```
ret = nb_ismarker(in)
```

Description:

Test if an input is a valid marker property.

Input:

- in : Any input.
- log : True if we allow for cellstr.

Output:

- ret : true if in is a valid marker property.

Written by Tobias Ingebrigtsen

◆ nb_istype

```
ret = nb_istype(in)
```

Description:

Test if an input is a valid type property.

Input:

- in : Any input

Output:

- ret : true if in is a valid type property.

Written by Tobias Ingebrigtsen

◆ nb_pos2pos

```
x = nb_pos2pos(x,oldPos,newPos,oldScale,newScale)
```

Description:

Convert the value x from the old units to the new units value.

Input:

```
- x           : Old value. As a double.  
- oldPos     : Old positions. As a 1x2 double.  
- newPos     : New positions. As a 1x2 double.  
- oldScale   : New scale. Either 'normal' or 'log'.  
- newScale   : Old scale. Either 'normal' or 'log'.
```

Output:

```
- x
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_scaleLineWidth**

```
lineWidth = nb_scaleLineWidth(obj, lineWidth)
```

Description:

Scale a line width property.

Input:

```
- obj        : An object of class nb_plotHandle  
- lineWidth : The value of a property that represent the width of some  
               type of line. As a double.
```

Output:

```
- lineWidth : The scaled or non-scaled line width.
```

See also:

[nb_axes.scaleLineWidth](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_setDefinedColorAnnotation**

```
nb_setDefinedColorAnnotation(hObject, event, gui, popupmenu)
```

Description:

Make the user able to define a color and add it to the popupmenu handle.

Input:

- hObject : The MATLAB handle triggering the event
- event : The event structure.
- gui : An gui objects thots edit the nb_annotation objects. Must have a property defaultColors.
- varargin : Handle to the popupmenu handle to assign the defined color. Can be given more handles as seperate inputs

Written by Kenneth Sætherhagen Paulsen

◆ nb_subplot

```
nb_axesObject = nb_subplot(m,n,p,varargin)
```

Description:

Create axes in tiled positions.

obj = nb_subplot(m,n,p), breaks the Figure window into an m-by-n matrix of small axes, selects the p-th axes for the current plot, and returns the nb_axes handle. The axes are counted along the top row of the Figure window, then the second row, etc.

Input:

- m : Number of axes rows of current figure
- n : Number of axes columns of current figure
- p : The p-th axes of the subplot
- varargin : ..., 'propertyName', 'PropertyValue', ... combination given to the initialized nb_axes handles. Should not include the property name 'position', because then you overrule the position given by this function. See the nb_axes class for more on the properties to set.

Caution : If you want to add more sub axes to one figure it is important to provide the 'parent' property. E.g. if you want two axes in one figure, do the following:

```
fig = nb_figure;
axes1 = nb_subplot(2,1,1,'parent',fig);
axes2 = nb_subplot(2,1,2,'parent',fig);
```

Output:

- nb_axesObject : An object of class nb_axes

Examples:

```
nb_axesObject = nb_subplot(2,2,1);
nb_axesObject = nb_subplot(2,2,1,'shading','grey');
```

See also:

[nb_axes](#), [axes](#), [subplot](#), [nb_subplotSpecial](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_subplotSpecial**

```
nb_axesObject = nb_subplotSpecial(m,n,p,varargin)
```

Description:

Create axes in tiled positions. Contrary to the `nb_subplot` function this function will tile the `1x2` and `2x1` subplot in positions better fitted for inclusion in presentations.

`obj = nb_subplotSpecial(m,n,p)`, breaks the Figure window into an `m`-by-`n` matrix of small axes, selects the `p`-th axes for the current plot, and returns the `nb_axes` handle. The axes are counted along the top row of the Figure window, then the second row, etc.

Input:

- `m` : Number of axes rows of current figure
- `n` : Number of axes columns of current figure
- `p` : The `p`-th axes of the subplot
- `varargin` : ..., 'propertyName', `PropertyValue`, ... combination given to the initialized `nb_axes` handles. Should not include the property name 'position', because then you overrule the position given by this function. See the `nb_axes` class for more on the properties to set.

Caution : If you want to add more sub axes to one figure it is important to provide the 'parent' property. E.g. if you want two axes in one figure, do the following:

```
fig = nb_figure;
axes1 = nb_subplotSpecial(2,1,1,'parent',fig);
axes2 = nb_subplotSpecial(2,1,2,'parent',fig);
```

Output:

- `nb_axesObject` : An object of class `nb_axes`

Examples:

```
nb_axesObject = nb_subplotSpecial(2,2,1);
nb_axesObject = nb_subplotSpecial(2,2,1,'shading','grey');
```

See also:

[nb_axes](#), [axes](#), [subplot](#), [nb_subplot](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_subplot_position**

```
position = nb_subplot_position(m,n,p)
```

Description:

Get the axes position when divided into subplots.

`obj = nb_subplot(m,n,p)`, breaks the Figure window into an m-by-n matrix of small axes, selects the p-th axes for the current plot, and returns the nb_axes handle. The axes are counted along the top row of the Figure window, then the second row, etc.

Input:

- m : Number of axes rows of current figure
- n : Number of axes columns of current figure
- p : The p-th axes of the subplot

Output:

- position : A 1x4 double. [xLow,yLow,xWidth,yWidth].

Examples:

```
position = nb_subplot(2,2,1);
```

See also:

[subplot](#), [nb_subplot](#), [nb_subplotSpecial](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_unitsRatio**

Calculate ratio between different units

Examples:

```
nb_unitsRatio('Characters', 'Normalized', axes);
```

Written by Henrik Halvorsen Hortemo

◆ **nb_wrapFigureText**

```
nb_wrapFigureText(obj,t,place)
```

Description:

Wrap footer or figure title.

Input:

- obj : An object of class nb_figure or nb_figureTitle.
- t : A text handle of the displayed footer or figure title.
- place : x-axis position of where the text is positioned.

See also:

[nb_footer](#), [nb_figureTitle](#)

Written by Kenneth Sæterhagen Paulsen

25.5 Utils graphics classes and functions

- [nb_getInUnits](#)
- [nb_gobjects](#)
- [nb_oldGraphVersion](#)

◆ **nb_getInUnits**

```
position = nb_getInUnits(object, property, units)
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_gobjects**

```
array = nb_gobjects(varargin)
```

Description:

Preallocate array for storing graphical objects that are robust to different versions of MATLAB.

Input:

- See gobjects or nan.

Output:

- array : Either a matrix of nan or a matrix of default graphics objects. See gobjects or nan. If nb_oldGraphVersion returns true then doubles are returned.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_oldGraphVersion**

```
ret = nb_oldGraphVersion()
```

Description:

MATLAB handle graphical objects in a new way since version 8.4. This return true if the version the user is using is less than this.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

25.6 Cell functions

- RemoveDuplicates
- nb_appendIndexes
- cell2charTable
- nb_cell2latex
- nb_appendLagPostfix
- nb_cell2String
- nb_cellstr2file
- nb_cellfind
- nb_cellstr2String
- nb_cellstrlead
- nb_compareCell2TXT
- nb_cellstrlag
- nb_convertContexts
- nb_nestedCell2Cell
- nb_contains
- nb_scellstrlag
- nb_strcomb
- nb_obj2cell

◆ **RemoveDuplicates**

```
out = RemoveDuplicates(in,dim)
```

Description:

Remove duplicates of a sorted cellstr array (also a matrix)

Input:

- in : A cellstr which are sorted in the dimesnion to remove the duplicates.
- dim : The dimesnion to remove the duplicates.

Output:

- out : A cellstr with the duplicates removed.

Written by Junior Maih

◆ **cell2charTable**

```
tableAsChar = cell2charTable(table)
```

Description:

Convert a cell matrix to a printable char vector.

Input:

- table : A cellstr matrix.

Output:

- tableAsChar : A char vector.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_appendIndexes**

```
c = nb_appendIndexes(str,indexes)
```

Description:

Append indexes to a string, and return those strin in an cellstr array.

Input:

- str : A one line char (string).

- indexes : The index to append. E.g. 1:10.

Output:

- c : A cellstr.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_appendLagPostfix**

```
newNames = nb_appendLagPostfix(c,nLags)
```

Description:

Append '_lagX' postfix to a cellstr.

Input:

- nLags : A cell. E.g. {1,2,4,8}
- c : A cellstr.

Output:

- xout : A cellstr

See also:

[nb_cellstrlag](#)

Written by Kenneth S. Paulsen

◆ **nb_cell2String**

string = nb_cell2String(c)

Description:

Convert a cell to a string. Each element will be called with the `toString` method.

Input:

- c : A cell.

Output:

- string : A string.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_cell2latex**

code = nb_cell2latex(c,varargin)

Description:

Make latex table of one or more cellstr matrices. Please see the preamble for the packages needed to make the latex code work.

Input:

- c : A cellstr matrix.

Optional input:

- 'caption' : Adds a caption to the table. Must be a string.
If the 'tables' input is given this input must be a cell array with same length as that input. (or empty)
- 'colors' : Set it to 0 if the colored rows of the table should be turned off. Default is 1.
- 'columnOrientation' : A cellstr with size 1 x size(c,2). Each element must be either 'l', 'c', 'r', 'R{Xcm}', 'C{Xcm}' or 'R{Xcm}'.
If the 'tables' input is given this input must be a cell array with same length as that input. (or empty)
- 'firstRowColor' : A string with the color, e.g. 'blue','white','black','blue!20!white'. Default is 'nbblue'.
- 'fontSize' : Sets the font size of the table. Either:
'Huge', 'huge', 'LARGE', 'Large', 'large',
'normalsize' (default), 'small',
'footnotesize', 'scriptsize','tiny'.

Caution : This option is case sensitive.
- 'justification' : Sets the justification of the caption of the table. Must be a string.
Either 'justified','centering' (default),
'raggedright', 'RaggedRight', 'raggedleft'.

Caution : This option is case sensitive.
- 'language' : Either 'english' (default) or 'norwegian'
('norsk').
- 'lookUpMatrix' :

Sets how the given mnemonics (variable names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
 'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
lookUpMatrix = {  
  
'mnemonics1','englishDescription1','norwegianDescription1';
 'mnemonics2','englishDescription2','norwegianDescription2'};
```

Be aware : Each of the given description can be multi-lined char, which will result in multi-line text of the table.

- 'preamble' : Give 0 if you don't want to include the preamble in the returned output. Default is to include the preamble, i.e. 1.
- 'rotation' : The rotation of the table in LaTeX. Either:
 - > 'sidewaystable' : A sideways table
 - > 'landscape' : Rotate the whole page
 - > '' : No rotation
- 'rowColor1' : Color of every second row of the table starting from the second row. Same options as was the case for the 'firstRowColor' option.
- 'rowColor2' : Color of every second row of the table starting from the third row. Same options as was the case for the 'firstRowColor' option.
- 'lineBreak' : The maximum number of characters before line break. The line breaking take place at white spaces. Default is no line break.
- 'maxRows' : Maximum number of rows of a table in one page. If c has more rows than this number the table will start over again in the next page. Default is [], i.e. tables will not be broken even if not fit to one page.
- 'space' : Number of lines between multiple tables. Default is 5.
- 'tables' : A cell array with more cellstr matrices to produce latex tables of. Important for nice breaking of many huge cell matrices. The c input will be discarded in this case.

Output:

- code : A char with the code.

Written by Kenneth Sætherhagen Paulsen

◆ **nb_cellfind**

```
ind = nb_cellfind(c,pattern)
```

Description:

Check if the given pattern is found in the cells of the cellstr array. Will return a logical array of same size. Return true for

all cells where the pattern is found.

Input:

- c : A cellstr array
- pattern : The pattern to look for. As a string

Output:

- ind : Logical array

Examples:

```
c = {'dfsdf','dfdf.df','sdfs'};  
ind = nb_cellfind(c,'.')
```

Written by Kenneth S. Paulsen

◆ nb_cellstr2String

```
str = nb_cellstr2String(c)  
str = nb_cellstr2String(c,sep,sepLast)
```

Description:

Convert a cellstr array to a string using the sep input to separate the elements of the cellstr.

Input:

- c : A cellstr.
- sep : A string. Default is ','
- sepLast : A string. Default is ','

Output:

- str : A string.

Example:

```
c = {'dfdfddf','dfdffdf','dfdfdf'};  
str = nb_cellstr2String(c,', ','')
```

Gives str = 'dfdfddf, dfdffdf, dfdfdf'

Written by Kenneth Sætherhagen Paulsen

◆ nb_cellstr2file

```
nb_cellstr2file(string,filename)
nb_cellstr2file(string,filename,breakLine)
```

Description:

Write a cellstr to a file.

Input:

- string : A cellstr or char array.
- filename : The name of the saved file. If the extension is not provided the default is '.m'.
Can also be a file identifier.
- breakLine : true || false. Add '\r\n' at the end of each line or not.
Default is true.

Written by Kenneth SÃ¶therhagen Paulsen

◆ **nb_cellstrlag**

```
cflag = nb_cellstrlag(c,nlag,type)
```

Description:

Type = 'lagFast':

Creates a array of size 1 x size(c,2)*nlag. I.e.
{'var1_lag1', 'var1_lag2', ... 'var1_lagN', ...
'var2_lag1', ... 'var2_lagN'}

Type = 'varFast':

Creates a matrix of size 1 x size(c,2)*nlag. I.e.
['var1_lag1', ... 'varp_lag1', ..., 'var1_lagN', ...
'varp_lagN']

Input:

- c : A cellstr
- nlag : The number of lags. Default is 1. Could be a 1 x nvar double.
- type : Either 'lagFast' (default) or 'varFast'

Output:

- xout : A cellstr

Written by Kenneth S. Paulsen

◆ nb_cellstrlead

```
clag = nb_cellstrlead(c,nlead,type,reverse)

Description:
Type = 'leadFast':
Creates a matrix of size(x,1) x size(x,2)*nlead. I.e.
{'var1_lead1', 'var1_lead2', ... 'var1_leadN', ...
 'var2_lead1', ... 'var2_leadN'}
Type = 'varFast':
Creates a matrix of size 1 x size(c,2)*nlag. I.e.
['var1_lead1', ... 'varp_lead1', ..., 'var1_leadN', ...
 'varp_leadN']
```

Input:

- c : A cellstr
- nlead : The number of lead. Default is 1. Could be a 1 x nvar double.
- type : Either 'leadFast' (default) or 'varFast'

Output:

- xout : A cellstr

Written by Kenneth S. Paulsen

◆ nb_COMPARECell2TXT

```
nb_COMPARECell2TXT(cell,file)
```

Description:

Check to see if the cell is equal to the contents of the .TXT file. This function assumes that the .TXT file has be written by nb_cellstr2file.

Input:

- cell : A cellstr.
- filename : The name of the saved file with the full path.
- breakLine : true || false. Add '\r\n' at the end of each line or not. Default is true.

Ouput:

- bool : Logical. True if contents (and formatting) is equal. False if they are different. Will also return false if file cannot be opened / found.

Written by Per Bjarne Bye

◆ nb_contains

```
ind = nb_contains(s,pattern,varargin)
```

Description:

Robust implementation of the MATLAB function contains over different versions of MATLAB.

Input:

- s : A M x N cellstr or a M x 1 char.
- pattern : A one line char with the pattern to look for.

Optional input:

- 'ignoreCase' : Set to true to ignore case.

Output:

- ind : A M x N logical if input is cellstr, otherwise M x 1. true if pattern found, otherwise false.

Written by Kenneth Sæterhagen Paulsen

◆ nb_convertContexts

```
contexts = nb_convertContexts(contexts)
```

Description:

Convert from a cellstr of elements on the format 'yyyymmdd' to a double vector.

Input:

- contexts : Either a 1 x N or N x 1 cellstr, where all the elements are on the format 'yyyymmdd'.

Output:

- contexts : A N x 1 double vector.

Written by Kenneth Sæterhagen Paulsen

◆ nb_nestedCell2Cell

c = nb_nestedCell2Cell(nested)

Description:

Transform a nested cell array to a cell array

Input:

- nested : A nested cell array. E.g. {{'Var1','Var2'},{'Var3'}}

Output:

- c : A cell array. E.g. {'Var1','Var2','Var3'}

Written by Kenneth Sæterhagen Paulsen

◆ nb_obj2cell

cout = nb_obj2cell(obj)

Description:

Convert object matrix to cell matrix

Input:

- obj : An user defined object of size M x N x P

Output:

- c : A cell of size M x N x P

Written by Kenneth Sæterhagen Paulsen

◆ nb_scellstrlag

clag = nb_scellstrlag(c, lags)

Description:

```
Creates a array of nObs x total number of lags. I.e.  
[x1(t-1), x1(t-2), ... x1(t-max([lags{1}]), x2(t-1), ... ,  
x2(t-max([lags{1}]))]
```

Input:

- c : A cellstr
- nlag : The number of lags. Default is 1. Could be a 1 x nvar double.
- type : Either 'lagFast' (default) or 'varFast'

Output:

- xout : A cellstr

Examples:

```
cflag = nb_scellstrlag({'Var1','Var2'}, {1,[1,2]})
```

Written by Kenneth S. Paulsen

◆ **nb_strcomb**

```
c = nb_strcomb(c1,c2)  
c = nb_strcomb(c1,c2,sep)
```

Description:

Create all combinations of two cellstr.

Input:

- c1 : A cellstr with size N x 1
- c2 : A cellstr with size M x 1
- sep : A string with the separator between the two concatenated strings. Default is '_'.

Output:

- c : A cellstr with size N*M

Examples:

```
c1 = {'T';'G';'F'};  
c2 = {'a';'b';'c'};  
c = nb_strcomb(c1,c2)
```

25.7 Char functions

- nb_any2String
 - nb_breakChar
 - nb_createChar
 - nb_dash
 - nb_getMatchingParentheses
 - nb_isOneLineChar
 - nb_newLine
 - nb_splitIntoTerms
 - nb_str2double
 - toString
-

◆ nb_any2String

```
string = toString(anyObject)
```

Description:

Same as `toString`, but `cellstr` and one line char are converted to the way they are displayed by MATLAB instead of using `nb_cellstr2String`.

Input:

- `anyObject` : A double, logical, `nb_ts`, `nb_cs`, `nb_data` or cell.

Output:

- `string` : A string

See also:

`num2str`, `int2str`, `nb_cellstr2String`, `toString`

Written by Kenneth Sæterhagen Paulsen

◆ nb_breakChar

```
s = nb_breakChar(s,numChar)
```

Description:

Break char so that `size(s,2) <= numChar`

Input:

- `s` : A char.
- `numChar` : An integer > 0 .

Output:

- `s` : A char.

Written by Kenneth Sæterhagen Paulsen

◆ nb_createChar

```
out = nb_createChar(r,c)
```

Description:

Create a empty r x c char array.

Input:

- r : Number of rows.
- c : Number of columns.

Output:

- out : A r x c char array.

Written by Kenneth Sæterhagen Paulsen

◆ nb_dash

```
d = nb_dash(type,printing2PDF)
```

Description:

Get dash type.

Input:

- type : Either 'dash', 'en-dash' or 'em-dash'. Default is 'dash'.

Output:

- d : A char with the given dash type.

Written by Kenneth Sæterhagen Paulsen

◆ nb_getMatchingParentheses

```
match = nb_getMatchingParentheses(expr,reverse)
```

Description:

Find index of matching parentheses.

Input:

- expr : A one-line char that starts with (.
- reverse : Set to true to match in from end to start. Default is false.

Output:

- match : A 1 x 2 integer with the index of the matching parentheses in expr. Will be given as [0,0], if not located.

Examples:

```
match = nb_getMatchingParentheses(' (y*x+(1-y)*x) ')
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_isOneLineChar**

```
ret = nb_isOneLineChar(str)
```

Description:

Test if an input is a one line (row) char.

Input:

- in : Any input

Output:

- ret : true if in is a one line char, otherwise false.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_newLine**

```
nl = nb_newLine
nl = nb_newLine(num)
```

Description:

Returns the new line character, same as char(10). Same as newline, but added to be robust to different versions of MATLAB. The num input is also added compared to newline.

Input:

- num : The number of new line characters to make. Default is 1.

Output:

- nl : A one line char with the new line characters.

See also:

[newline](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_splitIntoTerms

```
breaks          = nb_splitIntoTerms(expr)
[breaks,split,addPar] = nb_splitIntoTerms(expr,op,notOp)
```

Description:

Split a mathematical expression into separate terms.

Input:

- expr : A one-line char that include a mathematical expression.
- op : Operators to split at. Default is {'+', '-'} . Must be a cellstr.
- notOp : Operators that will invalidates break-points if just in front of any operator in op. Default is {'*', '^', '/'}. Must be a cellstr.

Output:

- breaks : The indexes of '+' and '-' signs.
- split : A nBreaks + 1 cell array.
- addPar : The expression should be enclosed with parentheses again.

Examples:

```
[breaks,split,addPar] = nb_splitIntoTerms('y*x+(1-y)*x')
[breaks,split,addPar] = nb_splitIntoTerms(' (y*x+(1-y)*x)')
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_str2double

```
num = nb_str2double(string)
```

Description:

Convert a string to double. Added the possibility to convert a interval from a string to a double compared to str2double. See examples

Input:

- string : A string.

Output:

- num : A double

Examples:

```
nb_str2double('2')
nb_str2double('1:3')
nb_str2double('[1,3]')
nb_str2double('[1:3,6]')
```

See also:

[str2double](#)

Written by Kenneth Sætherhagen Paulsen

◆ **toString**

```
string = toString(anyObject)
```

Description:

Converts object into a string.

Input:

- anyObject : A double, logical, nb_ts, nb_cs, nb_data or cell.

Output:

- string : A string

See also:

[num2str](#), [int2str](#), [nb_cellstr2String](#), [nb_any2String](#)

Written by Kenneth Sætherhagen Paulsen

25.8 Help Classes

- [nb_logicalInExpr](#)

■ **nb_logicalInExpr**
Go to: [Properties](#) | [Methods](#)

A class representing a logical array that can be used in nb_eval to get the resulting logical array from an expression.

Constructor:

obj = nb_logicalInExpr(data)

Input:

- data : Logical array.

Output:

- obj : An object of class nb_logicalInExpr.

Examples:

```
obj = nb_logicalInExpr(true);
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- data • type

- **data** ↑

The date the object represents.

- **type** ↑

The type of logical operator to use. Default is '||' (or).

Methods:

► **abs** ↑

```
obj = abs(obj)
```

Description:

Absolute value

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = abs(in);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acos** ↑

```
obj = acos(obj)
```

Description:

Take inverse cosine, result in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = acos(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acosd** ↑

```
obj = acosd(obj)
```

Description:

acosd(obj) is the inverse cosine, expressed in degrees

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acosd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acosh** ↑

```
obj = acosh(obj)
```

Description:

acosh(obj) is the inverse hyperbolic cosine

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acosh(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acot** ↑

```
obj = acot(obj)
```

Description:

Take inverse cotangent

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = acot(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acotd** ↑

```
obj = acotd(obj)
```

Description:

acotd(obj) is the inverse cotangent, expressed in degrees

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acotd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acoth** ↑

```
obj = acoth(obj)
```

Description:

acoth(obj) is the inverse hyperbolic cotangent of the elements of obj

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acoth(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acsc** ↑

```
obj = acsc(obj)
```

Description:

Take acsc

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = acsc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acsqd** ↑

```
obj = acscd(obj)
```

Description:

acscd(obj) is the inverse cosecant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acscd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acsch** ↑

```
obj = acsch(obj)
```

Description:

acsch(obj) is the inverse hyperbolic cosecant

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acsch(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **and** ↑

```
a = and(a,b)
```

Description:

The and operator (&).

Input:

- a : An object of class nb_objectInExpr
- b : An object of class nb_objectInExpr

Output:

- a : An object of class nb_objectInExpr.

Examples:

```
a = a & b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **append ↑**

```
obj = append(obj,aObj)
obj = append(obj,aObj,priority)
```

Description:

Append aObj to obj with a given priority.

Input:

- obj : A nb_objectInExpr object.
- aObj : A nb_objectInExpr object.
- priority : 'first' or 'second'. If 'first' all the observations from obj is used before the observations from aObj, otherwise it is reverse. 'first' is default.

Output:

- obj : A nb_objectInExpr object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asec** ↑

```
obj = asec(obj)
```

Description:

Inverse secant, result in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = asec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asecd** ↑

```
obj = asecd(obj)
```

Description:

asecd(obj) is the inverse secant, expressed in degrees

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = asecd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asech** ↑

```
obj = asech(obj)
```

Description:

asech(obj) is the inverse hyperbolic secant

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = asech(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asin** ↑

```
obj = asin(obj)
```

Description:

Take inverse sine, result in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = asin(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asind** ↑

```
obj = asind(obj)
```

Description:

asind(obj) is the inverse sine, expressed in degrees

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = asind(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asinh** ↑

```
obj = asinh(obj)
```

Description:

asinh(obj) is the inverse hyperbolic sine

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = asinh(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **atan** ↑

```
obj = atan(obj)
```

Description:

Take the tangent

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = atan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **atand** ↑

```
obj = atand(obj)
```

Description:

atand(obj) is the inverse tangent, expressed in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = atand(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **atanh** ↑

```
obj = atanh(obj)
```

Description:

atanh(obj) is the inverse hyperbolic tangent

Input:

```
- obj : An object of class nb_objectInExpr
```

Output:

```
- obj : An object of class nb_objectInExpr
```

Examples:

```
out = atanh(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **avgOAF** ↑

```
obj = avgOAF(obj,avgFreq)
```

Description:

Take the average over a lower frequency.

Input:

```
- obj : An object of class nb_objectInExpr  
- avgFreq : Any
```

Output:

```
- obj : An object of class nb_objectInExpr
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **bkfilter** ↑

```
obj = bkfilter(obj,low,high)
```

Description:

Do band pass filtering

Input:

- obj : An object of class nb_objectInExpr
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **bkfilterls** ↑

```
obj = bkfilterls(obj,low,high)
```

Description:

Do one sided band pass-filtering.

Input:

- obj : An object of class nb_objectInExpr
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **callfun** ↑

```
obj      = callfun(obj,'func',func)
obj      = callfun(obj,another,'func',func)
obj      = callfun(obj,varargin,'func',func)
varargout = callfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the object.

Input:

- obj : An object of class nb_logicalInExpr.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function $\theta(x)x$ will be used.
- 'frequency' : Any
- 'interpolateDate' : Any
- varargin : Optional inputs given as extra inputs to the function func. May be of any class.

Output:

- varargout : The output will be given as return by the func function when applied to the input objects.

Examples:

```
d1 = callfun(d,'func',@sin); % Same as d1 = sin(d) !
d2 = callfun(d,d,'func','plus') % Same as d2 = d + d !
```

Written by Kenneth Sæterhagen Paulsen

► ceil ↑

```
obj = ceil(obj)
```

Description:

ceil(obj) rounds the elements of obj to the nearest integers towards infinity.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = ceil(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **conj** ↑

```
obj = conj(obj)
```

Description:

conj(obj) is the complex conjugate

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = conj(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **convert** ↑

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_logicalInExpr object

Input:

- obj : An object of class nb_logicalInExpr
- freq : Any
- method : Any

Optional input:

- Any

Output:

- obj : An nb_logicalInExpr object.

Written by Kenneth S. Paulsen

► **corr ↑**

obj = corr(obj)

Description:

Correlation

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cos ↑**

obj = cos(obj)

Description:

Cosine

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = cos(obj);  
  
Written by Kenneth S. Paulsen  
  
Inherited from superclass NB_OBJECTINEXPR
```

► **cosd** ↑

```
obj = cosd(obj)
```

Description:

`cosd(obj)` is the cosine of the elements of `obj`, expressed in degrees.

Input:

- `obj` : An object of class `nb_objectInExpr`

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
out = cosd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cosh** ↑

```
obj = cosh(obj)
```

Description:

`cosh(obj)` is the hyperbolic cosine.

Input:

- `obj` : An object of class `nb_objectInExpr`

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
out = cosh(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR
```

► **cot** ↑

```
obj = cot(obj)
```

Description:

Cotangent

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = cot(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cotd** ↑

```
obj = cotd(obj)
```

Description:

cotd(obj) is the cotangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = cotd(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR
```

► **coth** ↑

```
obj = coth(obj)
```

Description:

coth(obj) is the hyperbolic cotangent of the elements of obj.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = coth(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cov** ↑

```
obj = cov(obj)
```

Description:

Covariance

Input:

obj : An object of class nb_objectInExpr

Output:

d : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **csc** ↑

```
obj = csc(obj)
```

Description:

Cosecant of argument in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = csc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cscd** ↑

```
obj = cscd(obj)
```

Description:

cscd(obj) is the cosecant, expressed in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = cscd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **csch** ↑

```
obj = csch(obj)
```

Description:

`csch(obj)` is the hyperbolic cosecant of the elements of `obj`

Input:

- `obj` : An object of class `nb_objectInExpr`

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
out = csch(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **cumprod** ↑

```
obj = cumprod(obj, dim)
```

Description:

Cumulativ product

Input:

- `obj` : An object of class `nb_objectInExpr`
- `dim` : In which dimension the cumulativ product should be calculated. Default is the first dimension.

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
obj = cumprod(obj, 1);
```

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **cumsum** ↑

```
obj = cumsum(obj,dim)
```

Description:

Cumulative sum

Input:

- obj : An object of class nb_objectInExpr
- dim : In which dimension the cumulative sum should be calculated. Default is the first dimension.

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = cumsum(obj,1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **demean** ↑

```
obj = demean(data,~)
```

Description:

- Demeans along the dimension you choose.

Input:

- obj : A nb_objectInExpr object
- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- obj : A nb_objectInExpr object.

See also:

[sgrowth](#), [subAvg](#).

Written by Tobias Ingebrigtsen

Inherited from superclass NB_OBJECTINEXPR

► **demeanMoving** ↑

```
obj = demeanMoving(obj,backward)
obj = demeanMoving(obj,backward,forward)
```

Description:

- Demeans data with a moving average process.

Input:

- obj : A nb_objectInExpr object
- backward : Number of periods backward in time to calculate the moving average
- forward : Number of periods forward in time to calculate the moving average

Output:

- obj : A nb_objectInExpr object.

See also:

[nb_logicalInExpr.demean](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **denton** ↑

```
obj = denton(obj,z,k,type,d)
```

Description:

The Denton method of transforming a series from low to high frequency.

See Denton (1971), Adjustment of Monthly or Quarterly Series to Annual Totals: An Approach Based on Quadratic Minimization.

Input:

- obj : A nb_logicalInExpr object.
- z : Any
- k : Any
- type : Any
- d : Any

Output:

- x : A nb_logicalInExpr object.

See also:

[nb_denton](#)

Written by Kenneth Sæterhagen Paulsen

► **deptcat** ↑

obj = deptcat(a,b,varargin)

Description:

Depth concatenation (add pages of different nb_objectInExpr objects)
(No short hand notation)

Input:

- a : An object of class nb_objectInExpr
- b : An object of class nb_objectInExpr
- varargin : Optional number of nb_objectInExpr objects

Output:

obj : An object of class nb_objectInExpr.

Examples:

```
obj = deptcat(a,b);  
obj = deptcat(a,b,c);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **detrend** ↑

```
obj = detrend(obj,method,output,varargin)
```

Description:

De-trend.

Input:

- obj : A nb_objectInExpr object.
- method : Any
- output : Any

Optional input:

Any

Output:

- obj : A nb_objectInExpr object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **diff ↑**

```
obj = diff(obj)
obj = diff(obj,lag)
obj = diff(obj,lag,skipNaN)
```

Description:

Diff method.

Input:

- obj : An object of class nb_objectInExpr
- lag : Any
- skipNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = diff(obj);
obj = diff(obj,4);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **disp** ↑

```
disp(obj)
```

Description:

Display object (On the commandline)

Input:

obj : An object of class nb_logicalInExpr

Output:

The object display on the command line. (When not ending the command with an semicolon)

Examples:

```
obj
```

Written by Kenneth S. Paulsen

► **egrowth** ↑

```
obj = egrowth(obj,lag,stripNaN)
```

Description:

Calculate exact growth, using the formula: $(x(t) - x(t-1))/x(t-1)$.

Input:

- obj : An object of class nb_objectInExpr
- lag : Any
- stripNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = egrowth(obj);
obj = egrowth(obj, 4);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **epcn** ↑

```
obj = epcn(obj, lag, stripNaN)
```

Description:

Calculate exact percentage growth, using the formula:
 $100 * (x(t) - x(t-1)) / x(t-1)$.

Input:

- obj : An object of class nb_objectInExpr
- lag : Any
- stripNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = epcn(obj); % period-on-period growth
obj = epcn(obj, 4); % 4-periods growth
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **eq** ↑

```
a = eq(a, b)
```

Description:

This method is intended to test if two nb_math_ts objects are equal. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar.
- b : An object of class nb_objectInExpr or a scalar.

Output:

- a : An object of class nb_objectInExpr

Examples:

```
obj = a == b;  
obj = 2 == b;  
obj = a == 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **exp ↑**

```
obj = exp(obj)
```

Description:

Exponential function.

Input:

- obj : An object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr.

Examples:

```
obj = exp(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **expand ↑**

```
obj = expand(obj,newStartDate,newEndDate,type,warningOff)
```

Description:

This method expands a nb_math_ts object, which means we need to take max of existing end date and the new end date.

Input:

- obj : An object of class nb_logicalInExpr
- newStartDate : Any
- newEndDate : Any
- type : Any
- warningOff : Any

Output:

- obj : An nb_logicalInExpr object.

Written by Kenneth S. Paulsen

► **expml** ↑

obj = expml(obj)

Description:

expml(obj) computes $\exp(\text{obj}) - 1$, compensating for the roundoff in $\exp(\text{obj})$.

(For small real X, expml(X) should be approximately X, whereas the computed value of EXP(X)-1 can be zero or have high relative error.)

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = expml(obj);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **extrapolate** ↑

```
obj = extrapolate(obj,toDate)
obj = extrapolate(obj,toDate,varargin)
```

Description:

Extrapolate the time-series.

Input:

- obj : An object of class nb_logicalInExpr
- toDate : Any

Optional inputs:

- Any

Output:

- obj : An nb_logicalInExpr object.

Written by Kenneth S. Paulsen

► **fillNaN ↑**

```
obj = fillNaN(obj)
obj = fillNaN(obj,date)
```

Description:

Fill in for nan values with last valid observation.

Input:

- obj : An object of class nb_logicalInExpr.
- date : Any

Output:

- obj : An object of class nb_logicalInExpr.

Examples:

```
d2 = fillNaN(d);
```

Written by Kenneth Sæterhagen Paulsen

► **floor** ↑

```
obj = floor(obj)
```

Description:

`floor(obj)` rounds the data elements of `obj` to the nearest integers towards minus infinity

Input:

- `obj` : An object of class `nb_objectInExpr`

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
out = floor(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **ge** ↑

```
a = ge(a,b)
```

Description:

This method is intended to test if a `nb_math_ts` object is greater than or equal to another. We therefore just return the `a` object here as the date the objects represent does not change in this case.

Input:

- `a` : An object of class `nb_objectInExpr` or a scalar

- `b` : An object of class `nb_objectInExpr` or a scalar

Output:

- `a` : An `nb_objectInExpr` object.

Examples:

```
obj = a >= b;  
obj = 2 >= b;  
obj = a >= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► growth ↑

```
obj = growth(obj)  
obj = growth(obj,lag,stripNaN)
```

Description:

Calculate approx growth, using the formula: $\log(x(t)) - \log(x(t-1))$.

Input:

- obj : An object of class nb_objectInExpr
- lag : Any
- stripNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = growth(obj);  
obj = growth(obj,4);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► gt ↑

```
a = gt(a,b)
```

Description:

This method is intended to test if a nb_math_ts object is greater than another. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- a : An nb_objectInExpr object.

Examples:

```
obj = a > b;  
obj = 2 > b;  
obj = a > 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **h21** ↑

```
obj = h21(obj,freq,type)
```

Description:

Map high 2 low frequency observation with converting the frequency of the object.

Input:

- obj : An object of class nb_objectInExpr
- freq : Any
- type : Any

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **horzcat** ↑

```
obj = horzcat(a,b,varargin)
```

Description:

Horizontal concatenation ([a,b])

Input:

- a : An object of class nb_objectInExpr
- b : An object of class nb_objectInExpr
- varargin : Optional number of nb_objectInExpr objects

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = [a,b];  
obj = [a,b,c];
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **horzcatfast** ↑

```
obj = horzcatfast(varargin)
```

Description:

Horizontal concatenation

Input:

- a : An object of class nb_objectInExpr
- b : An object of class nb_objectInExpr
- varargin : Optional number of nb_objectInExpr objects

Output:

- obj : An object of class nb_objectInExpr

See also
nb_logicalInExpr.horzcat

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **hpfilter** ↑

```
obj = hpfilter(obj,lambda)
```

Description:

HP-filtering.

Input:

- obj : An object of class nb_objectInExpr
- lambda : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
gap = hpfilter(data,3000);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **hpfilterls** ↑

```
obj = hpfilterls(obj,lambda)
```

Description:

Do one-sided hp-filtering.

Input:

- obj : An object of class nb_objectInExpr
- lambda : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
gap = hpfilterls(data,3000)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **iegrowth** ↑

```
obj = iegrowth(obj,initialValues,periods)
```

Description:

Inverse of exact growth, i.e. the inverse method of the egrowth method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = iegrowth(obj);  
obj = iegrowth(obj,100);  
obj = iegrowth(obj,[78,89]);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **iegrowthnan** ↑

```
obj = iegrowthnan(obj)  
obj = iegrowthnan(obj,initialValues,periods)
```

Description:

Inverse of exact growth, i.e. the inverse method of the egrowth method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **iepcn** ↑

```
obj = iepcn(obj,initialValues,periods)
```

Description:

Inverse of exact percentage growth, i.e. the inverse method of the epcn method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = iepcn(obj);  
obj = iepcn(obj,100);  
obj = iepcn(obj,[78,89]);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **iepcnnan** ↑

```
obj = iepcnnan(obj)  
obj = iepcnnan(obj,initialValues,periods)
```

Description:

Inverse of exact percentage growth, i.e. the inverse method of the epcn method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► igrowth ↑

```
obj = igrowth(obj,initialValues,periods)
```

Description:

Inverse of log approx. growth, i.e. the inverse method of the growth method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = igrowth(obj);  
obj = igrowth(obj,100);  
obj = igrowth(obj,[78,89]);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► igrowthnan ↑

```
obj = igrowthnan(obj)  
obj = igrowthnan(obj,initialValues,periods)
```

Description:

Inverse of log approx. growth, i.e. the inverse method of the growth method

Input:

```
- obj : An object of class nb_objectInExpr  
- InitialValues : Any  
- periods : Any
```

Output:

```
- obj : An nb_objectInExpr object.
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **interpolate** ↑

```
obj = interpolate(obj,method)
```

Description:

Interpolate.

Input:

```
- data : A nb_objectInExpr object.  
- method : Any
```

Output:

```
- data : A nb_objectInExpr object.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ipcn** ↑

```
obj = ipcn(obj)  
obj = ipcn(obj,initialValues,periods,startAtNaN)
```

Description:

Inverse of percentage log approx. growth, i.e. the inverse method of the pcn method

Input:

```
- obj : An object of class nb_objectInExpr  
- InitialValues : Any  
- periods : Any  
- startAtNaN : Any
```

Output:

```
- obj : An nb_objectInExpr object.
```

Examples:

```
obj = ipcnn(obj);  
obj = ipcnn(obj,100);  
obj = ipcnn(obj,[78,89]);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ipcnnan** ↑

```
obj = ipcnnan(obj)  
obj = ipcnnan(obj,initialValues,periods)
```

Description:

Inverse of percentage log approx. growth, i.e. the inverse method of the pcn method

Input:

```
- obj : An object of class nb_objectInExpr  
- InitialValues : Any  
- periods : Any
```

Output:

```
- obj : An nb_objectInExpr object.
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **isfinite** ↑

```
obj = isfinite(obj)
```

Description:

Is finite.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = isfinite(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **isnan** ↑

```
obj = isnan(obj)
```

Description:

Is nan.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = isnan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **kurtosis** ↑

```
obj = kurtosis(obj,flag,dim,outputType)
```

Description:

Calculate the kurtosis.

Input:

- obj : An object of class nb_objectInExpr
- flag : Any
- dim : Any
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **lag** ↑

obj = lag(obj,periods)

Description:

Lag method.

Input:

- obj : An object of class nb_objectInExpr
- periods : Any

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = lag(obj,1);

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ldivide** ↑

```
obj = ldivide(a,b)
```

Description:

Left element-wise division (.\ \backslash). Same as right element-wise (./) division. See rdivide for more.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = a.\b;  
obj = 2.\b;  
obj = a.\2;
```

See also:

[rdivide](#), [mldivide](#), [mrdivide](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **le ↑**

```
a = le(a,b)
```

Description:

This method is intended to test if a nb_math_ts object is less than or equal to another. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- a : An nb_objectInExpr object.

Examples:

```
obj = a <= b;  
obj = 2 <= b;  
obj = a <= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **lead** ↑

```
obj = lead(obj,periods)
```

Description:

Lead method.

Input:

- obj : An object of class nb_objectInExpr
- periods : Any

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = lead(obj,1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **log** ↑

```
obj = log(obj)
```

Description:

Log operator

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = log(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **log10** ↑

```
obj = log10(obj)
```

Description:

Take the common (base 10) log

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = log(obj);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **log1p** ↑

```
obj = log1p(obj)
```

Description:

log1p(obj) computes $\text{LOG}(1+xi)$, where xi are the elements of obj.
Complex results are produced if $xi < -1$.

For small real xi, log1p(xi) should be approximately xi, whereas the computed value of $\text{LOG}(1+xi)$ can be zero or have high relative error.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = log1p(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► log2 ↑

```
obj = log2(obj)
```

Description:

log2(obj) is the base 2 logarithm of the elements of obj.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = log2(obj);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► lt ↑

```
a = lt(a,b)
```

Description:

This method is intended to test if a nb_math_ts object is less than another. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- a : An nb_objectInExpr object.

Examples:

```
obj = a < b;  
obj = 2 < b;  
obj = a < 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mavg** ↑

```
obj = mavg(obj,backward,forward,flag)
```

Description:

Taking moving avarage

Input:

- obj : An object of class nb_objectInExpr
- backward : Any
- forward : Any
- flag : Any

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **max** ↑

```
obj = max(obj,dim,outputType)
```

Description:

Max

Input:

- obj : An object of class nb_objectInExpr
- dim : Any
- outputType : - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mean** ↑

obj = mean(obj,dim,outputType)

Description:

Mean

Input:

- obj : An object of class nb_objectInExpr
- dim : Any
- outputType : - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **median** ↑

```
obj = median(obj,dim,outputType)
```

Description:

Median.

Input:

- obj : An object of class nb_objectInExpr
- dim : Any
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **merge2Series** ↑

```
obj = merge2Series(obj,other,method,varargin)
```

Description:

Merge 2 series.

Input:

- obj : An object of class nb_objectInExpr.
- other : An object of class nb_objectInExpr.
- method : Any

Optional input:

- Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **min** ↑

```
obj = min(obj, dim, outputType)
```

Description:

Min

Input:

- obj : An object of class nb_objectInExpr
- dim : Any
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **minus** ↑

```
obj = minus(a, b)
```

Description:

Binary subtraction (-).

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = a-b;
obj = 2-b;
obj = a-2;
```

See also:

[plus](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **mldivide** ↑

```
obj = mldivide(a,b)
```

Description:

Matrix left division (\backslash).

Input:

- `a` : An object of class `nb_objectInExpr` or a scalar
- `b` : An object of class `nb_objectInExpr` or a scalar

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
obj = 2\obj;
obj = obj\2;
```

See also:

[rdivide](#), [ldivide](#), [mrdivide](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **mpower** ↑

```
obj = power(a,b)
```

Description:

Element-wise power (.^)

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = 2^b;  
obj = a^2;
```

See also:

[power](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mrddivide** ↑

obj = mrddivide(a,b)

Description:

Matrix left division (/).

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = 2/obj;  
obj = obj/2;
```

See also:

[rdivide](#), [ldivide](#), [mlddivide](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mstd** ↑

obj = mstd(obj,backward,forward)

Description:

Moving standard deviation

Input:

- obj : An object of class nb_objectInExpr
- backward : Number of periods backward in time to calculate the moving std
- forward : Number of periods forward in time to calculate the moving std

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mtimes** ↑

obj = power(a,b)

Description:

Matrix multiplication (*).

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = 2*b;  
obj = a*2;
```

See also:

[times](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **ne** ↑

```
a = ne(a,b)
```

Description:

This method is intended to test if two `nb_math_ts` objects are not equal. We therefore just return the `a` object here as the date the objects represent does not change in this case.

Input:

- `a` : An object of class `nb_objectInExpr` or a scalar.
- `b` : An object of class `nb_objectInExpr` or a scalar.

Output:

- `a` : An object of class `nb_objectInExpr`

Examples:

```
obj = a ~= b;  
obj = 2 ~= b;  
obj = a ~= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **not** ↑

```
obj = not(obj)
```

Description:

The `not` operator (`~`)

Input:

- a : An object of class nb_objectInExpr

Output:

- a : An object of class nb_objectInExpr

Examples:

obj = ~obj;

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► or ↑

a = or(a,b)

Description

The or operator (|)

Input:

- a : An object of class nb_objectInExpr

- b : An object of class nb_objectInExpr

Output:

- a : An object of class nb_objectInExpr

Examples:

a = a | b;

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► pca ↑

F = pca(obj)
[F,LAMBDA,R,varF,expl,c,sigma,e,Z] = pca(obj,r,method,varargin)

Description:

Principal Component Analysis.

Input:

- obj : An object of class nb_objectInExpr.
- The rest not important

Output:

- F : A nb_objectInExpr object.
- LAMBDA : A empty nb_objectInExpr object.
- R : A empty nb_objectInExpr object.
- varF : A empty nb_objectInExpr object.
- expl : A empty nb_objectInExpr object.
- c : A empty nb_objectInExpr object.
- sigma : A empty nb_objectInExpr object.
- e : A nb_objectInExpr object.
- Z : A nb_objectInExpr object.

See also:

[nb_pca](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **pca_func** ↑

factors = pca_func(varargin)

Description:

Principal Component of selected number of series represented by a set of nb_objectInExpr.

Optional input:

- varargin : Optional number of nb_objectInExpr objects.
- 'numFactors' : Determine number of Factors to report. Standard is first factor only.
- 'unbalanced' : true or false.
- 'whichFactor' : Select the factor to return.

Output:

- factors : An object of class nb_objectInExpr.

See also:

[nb_logicalInExpr.pca](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **pcn** ↑

obj = pcn(obj,lag,stripNaN)

Description:

Calculate log approximated percentage growth. Using the formula
 $(\log(t+lag) - \log(t)) * 100$

Input:

- obj : An object of class nb_objectInExpr
- lag : The number of lags. Default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = pcn(obj); % period-on-period log approx. growth
obj = pcn(obj,4); % 4-periods log approx. growth
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **plus** ↑

obj = plus(a,b)

Description:

Binary addition (+).

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = a+b;  
obj = 2+b;  
obj = a+2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **pow2** ↑

```
obj = pow2(obj)
```

Description:

pow2(obj) raises the number 2 to the object

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = pow2(obj);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **power** ↑

```
obj = power(a,b)
```

Description:

Element-wise power (.^)

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = a.^b;
obj = 2.^b;
obj = a.^2;
```

See also:

[mpower](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **q2y** ↑

obj = q2y(obj)

Description:

Cumulative sum over the last 4 periods.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = q2y(obj)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **rdivide** ↑

```
obj = rdivide(a,b)
```

Description:

Right element-wise division (./)

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = a./b;
obj = 2./b;
obj = a./2;
```

See also:

[mrdivide](#), [mldivide](#), [ldivide](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **reIndex** ↑

```
obj = reIndex(obj,date)
```

Description:

Reindex the data of the object to a new date.

Input:

- obj : An object of class nb_objectInExpr
- date : Any

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **real** ↑

obj = real(obj)

Description:

real(obj) returns the real part

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **reallog** ↑

obj = reallog(obj)

Description:

The real natural logarithm

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = reallog(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **realpow** ↑

```
obj = realpow(a,b)
```

Description:

Real power.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

See also:

[mpower](#), [power](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **realsqrt** ↑

```
obj = realsqrt(obj)
```

Description:

realsqrt(obj) is the the real square root

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = realsqrt(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ret** ↑

```
obj = ret(obj)
obj = ret(obj,nlag)
obj = ret(obj,nlag,skipNaN)
```

Description:

Calculate return, using the formula: $x(t)/x(t-lag)$.

Input:

- obj : An object of class nb_objectInExpr
- nlag : Any
- skipNaN : Any

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = ret(obj);
obj = ret(obj,4);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **rlag** ↑

```
obj = rlag(obj,lags)
obj = rlag(obj,lags,periods)
```

Description:

Roll a pattern in the data forward with a given lag.

Input:

- obj : An object of class nb_objectInExpr
- lags : Any
- periods : The extrapolated periods. The end date of the object will be the current end date plus these number of periods. Be aware that trailing nan values in the data will be filled in for even if periods == 0, which is the default.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► round ↑

```
obj = round(obj,value,startDate,endDate,pages)
```

Description:

Round to closes value. I.e. if value is 0.25 it will round to the closes 0.25. E.g. 0.67 will be rounded to 0.75.

Input:

- obj : A nb_objectInExpr object
- value : Any
- startDate : Any
- endDate : Any
- variables : Any

Output:

- obj : A nb_objectInExpr object

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► sec ↑

```
obj = sec(obj)
```

Description:

Secant of argument in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr.

Examples:

obj = sec(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **secd** ↑

obj = secd(obj)

Description:

Secant of argument in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

out = secd(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sech** ↑

obj = sech(obj)

Description:

Hyperbolic secant.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = sech(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **set2Value** ↑

```
obj = set2Value(obj,func,value)
```

Description:

Set all values applying to the restriction given by the input func to the provided value.

Input:

- obj : An object of class nb_objectInExpr.
- func : Any
- value : Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **setNan2Zero** ↑

```
obj = setNan2Zero(obj)
```

Description:

Set all nan values of the data of the object to 0.

Input:

- obj : An object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sgrowth** ↑

obj = sgrowth(obj,horizon)

Description:

Calculates smoothed 12 or 6 months growth.

$x(*) = ((x13+x14+x15)/(x1+x2+x3)-1)*100$

$x(*) = ((x7+x8+x9)/(x1+x2+x3)-1)*100$

Input:

- obj : A nb_objectInExpr object

- horizon : Any

Output:

- out : A nb_objectInExpr object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sin** ↑

obj = sin(obj)

Description:

Sine of argument in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr.

Examples:

```
obj = sin(obj);  
  
Written by Kenneth S. Paulsen  
  
Inherited from superclass NB_OBJECTINEXPR
```

► **sind** ↑

```
obj = sind(obj)
```

Description:

Sine of argument in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = sind(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sinh** ↑

```
obj = sinh(obj)
```

Description:

Hyperbolic sine.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = sinh(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR
```

► **skewness** ↑

```
obj = skewness(obj,flag,dim,outputType)
```

Description:

Calculate the skewness

Input:

- obj : An object of class nb_objectInExpr
- flag : Any
- dim : Any
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sqrt** ↑

```
obj = sqrt(obj)
```

Description:

Square root.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = sqrt(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **std** ↑

```
obj = std(obj,flag,dim,outputType)
```

Description:

Standard deviation

Input:

- obj : An object of class nb_objectInExpr
- flag : Any
- dim : Any
- outputType : - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **stdise** ↑

```
obj = stdise(obj,flag)
```

Description:

Standardise

Input :

- obj : An object of class nb_objectInExpr
- flag : Any

Output:

- obj : An nb_objectInExpr object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **subAvg** ↑

obj = subAvg(obj, k, w)

Description:

- Will for the last k periods (including the present) calculate the cumulative sum and then divide by the amount of periods, which gives you the average over those periods.

Input:

- obj : An object of class nb_objectInExpr.
- k : Any
- w : Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **subSum** ↑

obj = subSum(obj, k, w)

Description:

Calculates the cumulative sum over the last k periods (including the present period).

Input:

- obj : An object of class nb_objectInExpr.
- k : Any
- w : Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sum** ↑

obj = sum(obj,dim)

Description:

Takes the sum of the object data in the wanted dimension

Input:

- obj : An object of class nb_objectInExpr
- dim : Any

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = sum(obj,1)
obj = sum(obj,2)
obj = sum(obj,3)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sumOAF** ↑

obj = sumOAF(obj,sumFreq)

Description:

Take the sum over a lower frequency.

Input:

- obj : An object of class nb_objectInExpr
- sumFreq : Any

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **tan ↑**

obj = tan(obj)

Description:

Tangent

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr.

Examples:

obj = tan(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **tand ↑**

obj = tand(obj)

Description:

tand(obj) is the tangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = tand(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR
```

► **tanh** ↑

```
obj = tanh(obj)
```

Description:

Hyperbolic tangent.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = tanh(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **times** ↑

```
obj = times(a,b)
```

Description:

Element-wise multiplication (.*)

Input:

- a : An object of class nb_objectInExpr or a scalar double
- b : An object of class nb_objectInExpr or a scalar double

Output:

- obj : An object of class nb_objectInExpr

See also:

mtimes

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **uminus** ↑

obj = uminus(obj)

Description:

Unary minus

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = -obj;

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **undiff** ↑

obj = undiff(obj,initialValues,periods)

Description:

Inverse of the diff method.

Input:

- obj : An object of class nb_objectInExpr.
- InitialValues : Any.
- periods : Any.

Output:

- Output : An object of class nb_objectInExpr.

See also
nb_logicalInExpr.diff

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **uplus** ↑

obj = uplus(obj)

Description:

Unary plus

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = +obj;

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **var** ↑

obj = var(obj, dim, outputType)

Description:

Variance

Input:

- obj : An object of class nb_objectInExpr

- dim : Any

- outputType : - 'nb_math_ts': The result will be an object
of class nb_objectInExpr.

- 'double': The result will be an object
of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► vertcat ↑

```
obj = vertcat(a,b,varargin)
```

Description:

Vertical concatenation ([a;b])

Input:

- a : An object of class nb_objectInExpr

- b : An object of class nb_objectInExpr

- varargin : Optional numbers of objects of class nb_objectInExpr

Output:

- a : An nb_objectInExpr object

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► window ↑

```
obj = window(obj,startDateWin,endDateWin,Pages)
```

Description:

Narrow down window

Input:

- obj : An object of class nb_logicalInExpr

- startDateWin : Any

- endDateWin : Any

- pages : Any

Output:

- obj : An object of class nb_logicalInExpr

Written by Kenneth S. Paulsen

► **x12** ↑

obj = x12(obj,range,varargin)

Description:

Seasonally adjust

Input:

- obj : An object of class nb_objectInExpr.

- range : Any

Optional input (..., 'propertyName', PropertyValue, ...):

Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **x12Census** ↑

obj = x12Census(obj)
[obj,x,outputfile,errorfile,model] = x12Census(obj)
[obj,x,outputfile,errorfile,model] = x12Census(obj,varargin)

Description:

Do x12 Census

Input:

- obj : An object of class nb_objectInExpr.

Optional input (..., 'propertyName', PropertyValue, ...):

Any.

Output:

- obj : An object of class nb_objectInExpr.
- x : An object of class nb_objectInExpr.
- outputfile : ''
- errorfile : {}
- mdl : []

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **nb_x12.x12 ↑**

```
[yData,outData,outp,err,mdl] = x12(data,startdate,dummy,options)
```

Description:

Do x12 Census adjustment to time series using x12awin.exe.

This is a file copied from the IRIS Toolbox an adapted to the NB Toolbox.

x12awin.exe is a program developed by:

U. S. Department of Commerce, U. S. Census Bureau

X-12-ARIMA quarterly seasonal adjustment Method,
Release Version 0.3 Build 192

This method modifies the X-11 variant of Census Method II
by J. Shiskin A.H. Young and J.C. Musgrave of February, 1967.
and the X-11-ARIMA program based on the methodological research
developed by Estela Bee Dagum, Chief of the Seasonal Adjustment
and Time Series Staff of Statistics Canada, September, 1979.

This version of X-12-ARIMA includes an automatic ARIMA model
selection procedure based largely on the procedure of Gomez and
Maravall (1998) as implemented in TRAMO (1996).

Input:

- data : double
- startdate : An nb_date object.

```
- dummy      : double.  
- options    : A structure with options.
```

Output:

```
- yData      : A double with the original data appended backcast  
and forecast.  
- outData    : The adjusted data.  
- outp       : A cellstr array with the output files from  
x12awin.exe  
- err        : A cellstr array with error files from x12awin.exe  
- mdl        : A struct with ARIMA model estimates.
```

◆ **bkfilterls**

```
x = bkfilterls(y,low,high)
```

See also:

[nb_bkfilterls](#)

Written by Kenneth SÃ¶terhagen Paulsen

◆ **createDependentDummy**

```
y = createVarDummy(y,condition)  
y = createVarDummy(y,condition,scalar)
```

Description:

Create dummy series based on time-series stored as double.

Input:

- obj : An double with size nObs x nVars x nPages.
- condition : Name of the added dummy variable.
 - '<' : Less than.
 - '>' : Greater than.
 - '<=' : Less than or equal to.
 - '>=' : Less than or equal to.
 - '==' : Equal to.
 - '~=': Not equal to.
- scalar : A scalar double. Default is 0.

Output:

- obj : An double with size nObs x nVars x nPages.

Examples:

```
y = [1,2;-3,1;-1,3];
y = createDependentDummy(y,'>',0);
```

See also:

[nb_math_ts.createDependentDummy](#)

Written by Kenneth Sæterhagen Paulsen

◆ egrowth

```
dout = egrowth(din,t)
```

Description:

This function uses the standard growth formula as opposed to the log growth economist typically use.

See also:

[growth, iegrowth](#)

Written by Kenneth Sæterhagen Paulsen

◆ epcn

```
dout = epcn(din,t)
```

Description:

This function uses the standard growth formula as opposed to the log growth economist typically use.

See also:

[iepcn](#), [egrowth](#), [iegrowth](#)

Written by Kenneth Sætherhagen Paulsen

◆ **exptrend**

```
trend = exptrend(series)
trend = exptrend(series,weight,numInitialisationAvg)
```

Description:

Exponential smoothing.

Translated from Gauss code originally produced by Anne-Sofie Jore.

Input:

- series : The series to be smoothed (each column is smoothed using the parameter weight). A double with size T x N x P.
- weight : The amount of weight attached to the immediately lagged value or (1-weight) attached to last period's trend value. Default is 0.5.
- numInitialisationAvg : The number of observations to average across at the beginning of the sample

Output:

- trend : The trend. A double with size T x N x P.

See also:

◆ **growth**

```
dout = growth(din,t)
```

See also:

[egrowth](#), [igrowth](#)

Written by Kenneth Sæterhagen Paulsen

◆ **hpfilter**

```
y = hpfilter(x,lamb)
y = hpfilterls(x,lamb,perc,fcstLen)
```

Description:

Hodrick-Prescott filter. Handle nan.

See page 3 of Cornea-Madeira (2016), "The Explicit Formula for the Hodrick-Prescott Filter in Finite Sample".

Input:

- x : A timeseries, as a nobs x 1 x npage double.
- lamb : The lambda of the hp-filter
- perc : Set to true to calculate the gap as (gap/trend)*100.
- fcstLen : The forecast length. Extrapolates the original series using the average of the last 4 periods. Default is 0.

Output:

- y : The cyclical component of the x-series

Examples:

```
y = hpfilter(x,400);
```

Written by Kenneth Sæterhagen Paulsen

◆ **hpfilterls**

```
y = hpfilterls(x,lamb)
y = hpfilterls(x,lamb,perc,fcstLen)
```

Description:

One sided Hodrick-Prescott filter. Handle nan.

Input:

```
- x : A timeseries, as a nobs x nvars x npage double.  
- lamb : The lambda of the hp-filter.  
- perc : Set to true to calculate the gap as (gap/trend)*100.  
- fcstLen : The forecast length. Extrapolates the original series  
using the average of the last 4 periods. Default is 0.
```

Output:

```
- y : The cyclical component of the x-series
```

Examples:

```
y = hpfilter(x,400);
```

See also:

[hpfilter](#)

Written by Kenneth Sæterhagen Paulsen

◆ **iegrowth**

```
dout = iegrowth(DX,X,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of exact growth, i.e. the inverse method of the egrowth method of the double class

Input:

```
- din : A double matrix with dimensions [r,c,p].  
- t : A double matrix with dimensions [r,c,p].  
- periods : The number of periods the din has been growthed over.
```

Output:

```
- dout : A double matrix with dimensions [r,c,p].
```

See also:

[egrowth](#), [igrowth](#)

Written by Kenneth Sæterhagen Paulsen

◆ **iegrowthnan**

- dout = iegrowthnan(din,t,periods)

Description:

- Uses iegrowth, but is robust for trailing and leading NaNs. It also checks whether theres any NaNs in between observations in the double, and returns an error if it is the case.

Input:

- din : A double matrix with dimensions [r,c,p].
- t : A double matrix with dimensions [r,c,p].
- periods : The number of periods the din has been growthed over.

Output:

- dout : A double matrix with dimensions [r,c,p].

Examples:

```
x = rand(3,3,3);  
y = nan(1,3,3);  
t = [y;x;y];  
  
iegrowthnan(t,100)
```

See also:

[egrowth](#), [iegrowth](#), [growth](#)

Written by Tobias Ingebrigtsen

◆ **iepcn**

dout = iepcn(DX,X,periods)

Description:

Construct indicies based on initial values and series which represent the series growth. Inverse of exact percentage growth, i.e. the inverse method of the epcn method of the double class.

Input:

- din : A double matrix with dimensions [r,c,p].
- t : A double matrix with dimensions [r,c,p].
- periods : The number of periods the din has been growthed over.

Output:

- dout : A double matrix with dimensions [r,c,p].

See also:

[egrowth](#), [iegrowth](#)

Written by Kenneth Sætherhagen Paulsen

◆ iepcnnan

- dout = iepcnnan(din,t,periods)

Description:

- Uses iepcn, but is robust for trailing and leading NaNs. It also checks whether theres any NaNs in between observations in the double, and returns an error if it is the case.

Input:

- din : A double matrix with dimensions [r,c,p].
- t : A double matrix with dimensions [r,c,p].
- periods : The number of periods the din has been growthed over.

Output:

- dout : A double matrix with dimensions [r,c,p].

See also:

[epcn](#), [iepcn](#)

Written by Kenneth Sætherhagen Paulsen

◆ igrowth

dout = igrowth(DX,X,periods)

Description:

Construct indicies based on initial values and time-series which represent the series growth. Inverse of log approx. growth, i.e. the inverse method of the growth method of the double class

Input:

- din : A double matrix with dimensions [r,c,p].
- t : A double matrix with dimensions [r,c,p].
- periods : The number of periods the din has been growthed over.

Output:

- dout : A double matrix with dimensions [r,c,p].

See also:

[growth](#), [iegrowth](#)

Written by Kenneth Sæterhagen Paulsen

◆ **igrowthnan**

- dout = igrowthnan(din,t,periods)

Description:

- Uses igrowth, but is robust for trailing and leading NaNs. It also checks whether theres any NaNs in between observations in the double, and returns an error if it is the case.

Input:

- din : A double matrix with dimensions [r,c,p].
- t : A double matrix with dimensions [r,c,p].
- periods : The number of periods the din has been growthed over.

Output:

- dout : A double matrix with dimensions [r,c,p].

Examples:

```
x = rand(3,3,3);
y = nan(1,3,3);
t = [y;x;y];

igrowthnan(t,100)
```

See also:

[egrowth](#), [igrowth](#), [growth](#)

Written by Tobias Ingebrigtsen

◆ ipcn

```
dout = ipcn(DX,X,periods)
```

Description:

Construct indicies based on initial values and series which represent the series growth. Inverse of exact growth, i.e. the inverse method of the pcn method of the double class.

Input:

- din : A double matrix with dimensions [r,c,p].
- t : A double matrix with dimensions [r,c,p].
- periods : The number of periods the din has been growthed over.

Output:

- dout : A double matrix with dimensions [r,c,p].

See also:

[growth](#), [igrowth](#)

Written by Kenneth Sæterhagen Paulsen

◆ ipcnnan

```
- dout = ipcnnan(din,t,periods)
```

Description:

- Uses ipcn, but is robust for trailing and leading NaNs. It also checks whether theres any NaNs in between observations in the double, and returns an error if it is the case.

Input:

- din : A double matrix with dimensions [r,c,p].
- t : A double matrix with dimensions [r,c,p].
- periods : The number of periods the din has been growthed over.

Output:

- dout : A double matrix with dimensions [r,c,p].

See also:

[pcn](#), [ipcn](#)

Written by Kenneth Sætherhagen Paulsen

◆ lag

```
xout = lag(xin,t)
xout = lag(xin,t,d)
```

Input:

- xin : The series to lag, as a nObs x nVar x nPage double.
- t : The number of periods to lag the series.
- d : The number to fill in for the first t periods. Default is nan.

Output:

- xout : The series lagged.

See also:

[lead](#)

Written by Kenneth Sætherhagen Paulsen

◆ lead

```
xout = lead(xin,t)
```

Input:

- xin : The series to lead, as a nObs x nVar x nPage double.
- t : The number of periods to lead the series.

Output:

- xout : The series leaded.

See also:

[lag](#)

Written by Kenneth Sætherhagen Paulsen

◆ nb_addLeads

```
Y = nb_addLeads(X,nLeads,dimExpand,dim)
```

Written by Kenneth Sølnerhagen Paulsen

◆ nb_arRebalance

```
X = nb_arRebalance(X)
```

Description:

Fill in for leading and trailing nan values using a AR(1) with automatic selection of the level of integration of the series.

Input:

- X : A T x 1 double storing the data of the time-series.

Output:

- X : A T x 1 double storing the balanced dataset of the time-series.

See also:

[nb_ts.rebalance](#)

Written by Kenneth Sølnerhagen Paulsen

◆ nb_bkfilter

```
x = nb_bkfilter(y,low,high)
```

Description:

Implements the approximation to the band pass filter found in "The Band Pass Filter" by Lawrence J.Christiano and Terry J. Fitzgerald (1999).

Inputs:

- y : A timeseries, as a nobs x nvars x npage double.
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

```
- x      : double (nobs x 1 x npage) containing filtered data.
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_bkfilter1s

```
x = nb_bkfilter1s(y,low,high)
```

Description:

One sided band-pass filter. For more on the filter see nb_bkfilter.
Handle nan values.

Inputs:

- y : A timeseries, as a nobs x nvars x npage double.
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- x : Double (nobs x 1 x npage) containing filtered data

See also:

[nb_bkfilter](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_breakAdj

```
obj = breakAdj(obj,method,varargin)
```

Description:

The intent of this function is to set observations around break points to nan, and interpolate the observation at these break-points.

Input:

- d : An double with size T x N x P. Interpolation is done along the first dimension.
- method : The wanted interpolation method to use. See the nb_interpolate function.
- indexes : A vector of integers or a logical array of length T for where to set the rows of d to nan.

Output:

- d : An double with size T x N x P.

See also:

[nb_interpolate](#)

Written by Kenneth S. Paulsen

◆ **nb_calculateVariation**

```
[dataLow, dataHigh, dataMAVG, dataMSTD] =...
    nb_calculateVariation(data)
```

Description:

Get some statistical properties of dataseries stored in an nb_ts object.

If number of arguments out is 1, all the statistical properties are stored in one nb_ts object. See the outputs for more.

Input:

- data : An object of class nb_ts

Output:

- dataLow : An object of class nb_ts with the moving average minus the moving standard deviation of the dataseries
- dataHigh : An object of class nb_ts with the moving average plus the moving standard deviation of the dataseries
- dataMAVG : An object of class nb_ts with the 10-year moving average of the dataseries
- dataMSTD : An object of class nb_ts with the 10-year moving standard deviation of the dataseries

Examples:

```
[low, high] = nb_calculateVariation(data);
```

Written by Kenneth S. Paulsen

◆ **nb_closestTo**

```
m = nb_closestTo(X,x,dim,method)
```

Description:

Find the closes path in the multidimension matrix X to the the multidimension matrix x. x must have only dimension 1 in the dimension dim!

Input:

- X : A matrix with dimension less than 4.
- x : A matrix only dimension 1 in the dimension dim. Otherwise have the same dimensions as X.
- dim : The dimension to pick the closest to. An intger between 1 and 4.
- method : Either 'abs' (absolute deviation) or 'square' (square deviation)

Output:

m : The "element" that was closest to x.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_demean**

```
demean = nb_demean(data,dim)
```

Description:

- Demeans data along the dimension you choose.

Input:

- data : A r*c*p double matrix
- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- demean : A r*c*p double matrix.

See also:

[nb_subAvg](#), [nb_subSum](#).

Written by Tobias Ingebrigtsen

◆ nb_denton

```
x = nb_denton(y,z,k,type,d)
```

Description:

The Denton method of transforming a series from low to high frequency.

See Denton (1971), Adjustment of Monthly or Quarterly Series to Annual Totals: An Approach Based on Quadratic Minimization.

Input:

- y : A nobs x nvars x npage double with the main variable to transform.
- z : A nobs*k x nvars x npage double with observations to add judgment.
- k : The number intra low frequency observations. If you have annual data and want out quarterly data use 4.
- type : Either 'sum', 'average', 'first' or 'last'. 'average' is default.
- d : 1 : first differences, 2 : second differences.

Output:

- x : Output series as a nobs*k x nvars x npage double.

See also:

[nb_ts.convert](#), [nb_ts.denton](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_diff

```
dout = nb_diff(din,t)
```

Description:

Difference operator $x(s) - x(s-t)$. dout will append nan at the start to preserve the same size of dout as din.

See also:

[growth](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_double2cell

```
c = nb_double2cell(d,precision)
```

Description:

Convert a double matrix to a cellstr matrix with a given precision.

Input:

- d : A double.
- precision : E.g. '%6.6f' or 4 (number of digits)

Output:

- c : A cell matrix

Written by Kenneth Sæterhagen Paulsen

◆ nb_expandCov

```
C = nb_expandCov(par,n)
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_exponentialDecay

```
out = nb_exponentialDecay(in,lambda)
```

Description:

Exponential decay past observation of a series.

Input:

- in : A nobs x nvar double.
- lambda : A 1 x 1 double between 0 and 1.

Output:

- out : A nobs x nvar double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_exponentialDecayingMean

```
out = nb_exponentialDecayingMean(in, lambda, dim)
```

Description:

Calculate mean using exponential decaying of past observation of a series.

Input:

- in : A nobs x nvar x npage double.
- lambda : A 1 x 1 double between 0 and 1.
- dim : Which dimension to take the mean over. 1, 2 or 3. Default is 1.

Output:

- out : A nobs x nvar x npage double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_exponentialDecayingSum

```
out = nb_exponentialDecayingSum(in, lambda)
```

Description:

Calculate sum using exponential decaying of past observation of a series.

Input:

- in : A nobs x nvar x npage double.
- lambda : A 1 x 1 double between 0 and 1.
- dim : Which dimension to take the mean over. 1, 2 or 3.

Output:

- out : A nobs x nvar x npage double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_findBasis

```
[i,B] = nb_findBasis(A)
```

Description:

Find one basis of the linear system represented by A, and return the location of those equations.

Input:

- A : A NxM double matrix, where N >= M

Output:

- i : The index of the basis of the linear system represented by A.
- B : The basis of the linear system represented by A.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_histcounts**

```
[index,centered] = nb_histcounts(x,interval,centered)
```

Description:

Order the observation (dim1) into bins using the specified interval

Input:

- obj : An object of class double
- interval : A 1 x nBins double
- centered : A 1 x nBins double with the centered bins value.

Output:

- index : Number of counts in each bin. As a 1 x nBins double.
- centered : The centered location of the bins of the elements in index. As a 1 x nBins double.

Examples:

```
obj = nb_data.rand(1,100,4,2);
ind1 = nb_histcounts(obj.data,0.1:0.1:1)
ind2 = nb_histcounts(obj.data,0.1:0.1:1,0.05:0.1:1)
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_hpfILTER**

```
tau = nb_hpfILTER(y,alpha)
```

Description:

Hodrick-Prescott filter. Handle nan.

This is slower than the hpfilter function.

See the "The exact weights of the HP filter" section in Cornea-Madeira (2016), "The Explicit Formula for the Hodrick-Prescott Filter in Finite Sample".

Input:

- x : A time-series, as a nobs x 1 x npage double.
- alpha : The smoothness parameter of the hp-filter.

Output:

- y : The cyclical component of the y-series.

Examples:

```
tau = nb_hpfilter(y, 400);
```

See also:

[hpfilter](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_index

```
d = nb_index(d, ind1, ind2, ind3)
```

Description:**Input:**

- d : A double.
- ind1 : Indices in the first dimension. As a string. E.g. '1:3','1', '1:end' or ':'.
- ind2 : Indices in the second dimension. As a string. E.g. '1:3','1', '1:end' or ':'.
- ind3 : Indices in the third dimension. As a string. E.g. '1:3','1', '1:end' or ':'.

Output:

- d : A double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_interpolate

```
data = nb_interpolate(data)
```

Description:

Interpolate the data given as a double. Will discard leading and trailing nan values.

Input:

- data : A double
- method :
 - > 'nearest' : Nearest neighbor interpolation
 - > 'linear' : Linear interpolation. Default
 - > 'spline' : Piecewise cubic spline interpolation (SPLINE)
 - > 'pchip' : Shape-preserving piecewise cubic interpolation
 - > 'cubic' : Same as 'pchip'
 - > 'v5cubic' : The cubic interpolation from MATLAB 5, which does not extrapolate and uses 'spline' if X is not equally spaced.

Output:

- data : A double

See also:

[interp1](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_isScalarInteger

```
ret = nb_isScalarInteger(x, low, upp)
```

Description:

Test if x is a scalar integer.

Input:

- x : Any type
- low : If x is a number, it will test if $x > \text{low}$ if this input is given.
- upp : If x is a number, it will test if $x < \text{upp}$ if this input is given.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isScalarNumber

```
ret = nb_isScalarNumber(x,low,upp)
```

Description:

Test if x is a scalar number.

Input:

- x : Any type
- low : If x is a number, it will test if $x > \text{low}$ if this input is given.
- upp : If x is a number, it will test if $x < \text{upp}$ if this input is given.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isScalarNumberClosed

```
ret = nb_isScalarNumberClosed(x,low,upp)
```

Description:

Test if x is a scalar number and it is in the closed interval [low,upp].

Input:

- x : Any type
- low : If x is a number, it will test if $x \geq \text{low}$ if this input is given.
- upp : If x is a number, it will test if $x \leq \text{upp}$ if this input is given.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isScalarPositiveNumber

```
ret = nb_isScalarPositiveNumber(x)
```

Description:

Test if x is a scalar positive number.

Input:

- x : Any type

Output:

- ret : true or false.

Written by Kenneth Sætherhagen Paulsen

◆ nb_iswholecolumn

```
ret = nb_iswholecolumn(input)
```

Description:

True for a column of whole numbers

For example,

nb_iswholecolumn([pi NaN 3 -Inf]') is 0.

nb_iswholecolumn([4 2 3 1]') is 1.

Input:

- in : Any

Output:

- ret : an array that contains 1's where
the elements of X are whole numbers and 0's where they are not.

Written by Henrik Halvorsen Hortemo

◆ nb_iswholenumber

```
ret = nb_iswholenumber(input)
```

Description:

True for whole numbers

For example, nb_iswholenumber([pi NaN 3 -Inf]) is [0 0 1 0].

Input:

- in : Any

Output:

- ret : an array that contains 1's where the elements of X are whole numbers and 0's where they are not.

Written by Henrik Halvorsen Hortemo

◆ nb_iswholerow

```
ret = nb_iswholerow(input)
```

Description:

True for a row of whole numbers

For example,

nb_iswholerow([pi NaN 3 -Inf]) is 0.
nb_iswholerow([4 2 3 1]) is 1.

Input:

- in : Any

Output:

- ret : an array that contains 1's where the elements of X are whole numbers and 0's where they are not.

Written by Henrik Halvorsen Hortemo

◆ nb_lagmatrix

Syntax :

```
[output_matrix] = nb_lagmatrix(input_matrix, lags)
```

Description:

For all values in "lags", this function creates the lags of "input_matrix". The result, "output_matrix" contains all lagged values in the order given in lags.

Inputs:

- input_matrix : A matrix

- lags : lags to be computed. Can be a sequence, e.g 0:2, a matrix, e.g. [0, 2, 3], or an integer value.

Outputs:

- `output_matrix` : A matrix containing all the lags of "input_matrix" that are given in "lags".

Example:

```
With lags = 0:2 and input matrix = [1 2; 3 4; 5 6], nb_lagmatrix returns  
  
output_matrix = 1 2 NaN NaN NaN NaN  
                 3 4 1 2 NaN NaN  
                 5 6 3 4 1 1
```

Written by Maximilian Schräder

◆ **nb_linearFilter**

```
y = nb_linearFilter(x)
```

Description:

Linear filter

Input:

- `x` : A double storing timeseries.

Output:

- `y` : The cyclical component of the x-series

Written by Kenneth Sæterhagen Paulsen

◆ **nb_linearFilter1s**

```
y = nb_linearFilter1s(x)
```

Description:

One sided "linear" filter

Input:

- `x` : A double storing timeseries.

Output:

- `y` : The cyclical component of the x-series

Written by Kenneth Sæterhagen Paulsen

◆ nb_linespace

```
l = nb_linespace(x,y,n)
```

Description:

Generates n points between x and y. x and y must be vectors with same size.

Input:

- x : A m x 1 double or a 1 x m double. Must match y.
- y : A m x 1 double or a 1 x m double. Must match x.
- n : Number of generated points. Default is 100.

Output:

- l : A m x n double or a n x m double dependent on the input.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

◆ nb_mavg

```
xout = nb_mavg(xin,backward,forward,flag)
```

Description:

Smooths dataseries. Moving average

Input:

- xin : The data series to smooth. As a double.
- backward : The number of elements backward to include in moving average.
- forward : The number of elements forward to include in moving average.

Examples:

```
newseries = nb_mavg(x,9,0); % 10-element moving average
```

Written by Kenneth S. Paulsen

◆ nb_meanHist

```
meanVector = nb_meanHist(var,periods)
```

Description:

Calculates the mean and return a M X periods vector of the mean value. Where M is the size of the second dimension of the input

Input:

- var : The data series. As a double
- periods : Size of the first dimension of the output double

Output:

- meanVector : An M X periods vector of the mean value. Where M is the size of the second dimension of the input

Examples:

```
meanVector = nb_meanHist(x,10)
```

Written by Kenneth S. Paulsen

◆ nb_mlag

```
xlag = nb_mlag(x,nlag)
```

Description:

Type = 'lagFast':

Creates a matrix of size(x,1) x size(x,2)*nlag. I.e.
[x1(t-1), x1(t-2), ... x1(t-nlag), x2(t-1), ... x2(t-nlag)]

Type = 'varFast':

Creates a matrix of size(x,1) x size(x,2)*nlag. I.e.
[x1(t-1), ... xp(t-1), ... , x1(t-nlag), ... xp(t-nlag)]

Input:

- x : A double
- nlag : The number of lags. Default is 1. Could be a 1 x nvar double.
- type : Either 'lagFast' (default) or 'varFast'

Output:

- xlag : A double

Examples:

```
xlag = nb_mlag(rand(20,2),4)
```

Written by Kenneth S. Paulsen

◆ nb_mlead

```
xout = nb_mlead(xin,nlead)
```

Description:

Type = 'lagFast':

Creates a matrix of size(x,1) x size(x,2)*nlead. I.e.
[x1(t+1), x1(t+2), ... x1(t+nlead), x2(t+1), ... x2(t+nlead)]

Type = 'varFast':

Creates a matrix of size(x,1) x size(x,2)*nlead. I.e.
[x1(t+1), ... xp(t+1), ... , x1(t+nlead), ... xp(t+nlead)]

Input:

- xin : A double

- nlead : The number of lags. Default is 1. Could be a 1 x nvar double.

- type : Either 'lagFast' (default) or 'varFast'

Output:

- xout : A double

Examples:

```
xout = nb_mlead(rand(20,2),4)
```

Written by Kenneth S. Paulsen

◆ nb_msum

```
xout = nb_msum(xin,backward,forward)
```

Description:

Moving sum

Input:

- `xin` : The data series, as a double.
- `backward` : The number of elements backward to include in moving sum.
- `forward` : The number of elements forward to include in moving sum.

Examples:

```
newseries = nb_msum(x, 9, 0); % 10-element moving sum
```

Written by Kenneth S. Paulsen

◆ **nb_nanmavg**

```
xoutnan = nb_nanmavg(xin,backward,forward,flag)
```

Description:

Smooths dataseries. Moving average. Handles leading and trailing nans.

Input:

- `xin` : The data series to smooth. As a double.
- `backward` : The number of elements backward to include in moving average.
- `forward` : The number of elements forward to include in moving average.

Examples:

```
newseries = nb_nanmavg(x, 9, 0); % 10-element moving average
```

Written by Kenneth S. Paulsen

◆ **nb_num2cell**

```
c = nb_num2cell(d)
```

Description:

Convert rows of a double matrix into a cell array.

Input:

- d : A N x Q x M double

Output:

- c : A N x 1 cell array, each element stores a 1 x Q x M double.

Written by Kenneth Sætherhagen Paulsen

◆ nb_num2str

s = nb_num2str(d,precision)

Description:

Convert a scalar double to string. If precision is a string this function do the same as the num2str function by MATLAB, if on the other hand it is a integer it does not collapse big numbers to e^(something). E.g.

```
num2str(6000.354,2) = 6e+03  
nb_num2str(6000.354,2) = 6000.35
```

Input:

- d : Scalar double.

- precision : A char (see num2str) or an integer with the number of decimals to include.

Output:

- s : A char

Written by Kenneth Sætherhagen Paulsen

◆ nb_percentiles

p = nb_percentiles(d,perc,dim)

Description:

Take the percentile over the given dimension of the data of the object.

Uses mid-point interpolation.

Input:

```
- d      : A double with dimension less than or equal to 3.  
- perc  : A double with the wanted percentiles of the data. E.g.  
          50 (median), or [5,15,25,35,50,65,75,85,95]. These values must  
          be integers!  
- dim   : The dimension to calculate the percentiles over. Default is 1.
```

Output:

```
- p      : A double with the percentiles.
```

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_reduceCov**

```
par = nb_reduceCov(C)
```

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_rlag**

```
xout = nb_rlag(xin,t,len)
```

Description:

Rolling lag operator

Input:

```
- xin  : A double  
- t    : The number of lags  
- len  : The number of periods of the output
```

Output:

```
- xout : A double
```

Examples:

```
xout = nb_rlag([1;2;1;2],4,12)
```

Written by Kenneth S. Paulsen

◆ **nb_rrref**

```
A = nb_rrref(X)
```

Description:

This method produces the row echelon form of a matrix A.

Input:

- A : A NxM double matrix.

Output:

- A : A NxM double matrix.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_seasonalDummy**

```
dummy = nb_seasonalDummy(T,frequency,type)
```

Description:

Create seasonal dummies

Input:

- T : Number of periods. As an integer.
- frequency : Either 4 (quarterly) or 12 (monthly)
- type : 'uncentered' or 'centered'

Output:

- dummy : The dummy variables as T x frequency-1

Written by Kenneth Sæterhagen Paulsen

◆ **nb_sgrowth**

```
out = nb_sgrowth(data,horizon)
```

Description:

Calculates smoothed 12 or 6 months growth.

$$\begin{aligned}x(*) &= ((x_{13}+x_{14}+x_{15})/(x_1+x_2+x_3)-1)*100 \\x(*) &= ((x_7+x_8+x_9)/(x_1+x_2+x_3)-1)*100\end{aligned}$$

Note: Works only for monthly data.

Based on Anne Sofie Jores data transformation code.

Input:

- data : As a double r*c*p matrix with monthly observations.
- horizon : Either 1 or 2, depending on the frequency you want your growth to be calculated over. 1 is annual and 2 is semi-annual.

Output:

- out : A r*c*p double matrix.

See also:

[nb_ts.sgrowth](#)

Written by Tobias Ingebrigtsen

◆ **nb_slag**

xlag = nb_slag(xin, lags)

Description:

Creates a matrix of nObs x total number of lags. I.e.
[x1(t-1), x1(t-2), ... x1(t-max([lags{1}]), x2(t-1), ...,
x2(t-max([lags{1}]))]

Input:

- xin : A nObs x nVar double.
- lags : A 1 x nVar cell array. Each element must be a vector of integers with the lags to be made for the corresponding column of xin.

Output:

- xlag : A nObs x total number of lags double.

Examples:

```
xin = rand(20,2);
xlag = nb_slag(xin,{1,[1,2]})
```

Written by Kenneth S. Paulsen

◆ **nb_spline**

X = nb_spline(X)

Description:

Fill in for in-sample missing values of a time-series using cubic spline.

Input:

- X : A T x 1 double storing the data of the time-series.

Output:

- X : A T x 1 double storing the balanced dataset of the time-series.

See also:

[nb_ts.rebalance](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_splitSample**

splitted = nb_splitSample(data,nSteps)

Description:

Split a sample into a matrix with size nSteps x nvar x nobs. Will append nan values for the last observations.

Input:

- data : A nobs x nvar double.
- nSteps : The number of period of the splitted data.

Output:

- splitted : A nSteps x nvar x nobs double.

Examples:

splitted = nb_splitSample(rand(20,2),4)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_subAvg**

xout = nb_subAvg(xin,k)
xout = nb_subAvg(xin,k,w)

Description:

- Will for the last k periods (including the present) calculate the cumulative (weighted) sum and then divide by the amount of periods, which gives you the (weighted) average over those periods.

Input:

- xin : A double of size r*s*p.
- k : Lets you choose what frequency you want to calculate the cumulative average over. As a double. E.g. 4 if you have quarterly data and want to calculate the average over the last 4 quarters.
- w : Weights applies to the k periods to sum over. Default is equal weights! As a double vector with length k.

Output:

- xout : A double.

Examples:

```
xin = rand(10,1);
xout = nb_subAvg(xin,4)
xout = nb_subAvg(xin,4,[0.1,0.4,0.4,0.1])
```

See also:

[nb_subSum](#)

Written by Tobias Ingebrigtsen

◆ nb_subSum

```
xout = nb_subSum(xin,k)
xout = nb_subSum(xin,k,w)
```

Description:

- Calculates the cumulative sum over the last k periods (including the present period).

Input:

- xin : A double of size r*s*p
- k : Lets you choose what frequency you want to calculate the cumulative sum over. As a double. E.g. 4 if you have quarterly data and want to calculate the sum over the last 4 quarters.
- w : Weights applies to the k periods to sum over. Default is equal weights! As a double vector with length k.

Output:

- xout : A double.

Examples:

```
xin = ones(10,1);
xout = nb_subSum(xin,4)
xout = nb_subSum(xin,4,[0.1,0.4,0.4,0.1])
```

See also:

[nb_subAvg](#)

Written by Tobias Ingebrigtsen

◆ **nb_trimr**

```
z = nb_trimr(x,n1,n2)
```

Description:

Strip the rows before and included n1 and the rows after and included n2 of a matrix x.

Note: Modeled after Gauss trimr function

Input:

- x : A double matrix.
- n1 : See above. A scalar.
- n2 : See above. A scalar.

Output:

- z : The stripped matrix as a double.

Written by Kenneth S. Paulsen

◆ **nb_undiff**

```
dout = nb_undiff(DX,initialValues,periods)
```

Description:

Inverse of the diff function

Input:

```
- DX : A double with the differenced data

- initialValues : A scalar or a double with the initial
    values of the indicies. Must be of the same
    size as the number of variables of the
    DX input. And size(initialValues,1) == periods

- periods : The number of periods the initial series
    has been taken diff over.
```

Output:

```
- dout : A double
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_undiffnan**

```
dout = nb_undiffnan(din,t,periods)
```

Description:

Inverse of the diff function, but is robust for trailing and leading NaNs. It also checks whether theres any NaNs in between observations in the double, and returns an error if it is the case.

Input:

```
- din : A double matrix with dimensions [r,c,p].
- t : A double matrix with dimensions [r,c,p].
- periods : The number of periods the din has been growthed over.
```

Output:

```
- dout : A double matrix with dimensions [r,c,p].
```

Examples:

```
x = rand(3,3,3);
y = nan(1,3,3);
t = [y;x;y];

nb_undiffnan(t,100)
```

See also:

[nb_undiff](#), [nb_diff](#), [growth](#), [igrowth](#), [igrowthnan](#)

◆ **pcn**

```
dout = pcn(din,t)
```

See also:

[growth](#), [growth](#), [ipcn](#)

Written by Kenneth S. Paulsen

◆ **q2y**

```
xout = q2y(xin)
```

Description:

Transform quarterly to annual, using sum over the last 4 periods.

See also:

[growth](#)

Written by Kenneth Sæterhagen Paulsen

◆ **steady_state**

```
x = steady_state(x)
```

Description:

Return the same as in. Used by nb_dsgen when checking the steady-state of a model.

See also:

[nb_dsgen.checkSteadyState](#)

Written by Kenneth Sæterhagen Paulsen

◆ **steady_state_first**

```
x = steady_state_first(x)
```

Description:

Return the same as in. Used by nb_dsgen when checking the steady-state of a model.

25.10 IO functions

- nb_any2File
 - nb_copyfile
 - nb_joinPath
 - nb_loadFromUserpath
 - nb_makeWritable
 - nb_parseOneOptional
 - nb_pasteFromClipboard
 - nb_save2Userpath
 - nb_userpath
 - nb_writeError
 - nb_copyToClipboard
 - nb_error
 - nb_load
 - nb_loadWithName
 - nb_parseInputs
 - nb_parseOneOptionalSingle
 - nb_pathCorrect
 - nb_syncFolders
 - nb_wrapped
-

◆ nb_any2File

```
nb_any2File(filename, input)
nb_any2File(filename, input, nestedLevel, numPrecision)
```

Description:

Write a NBTOOLBOX objects to file.

Input:

- filename : Either a string with the name of the output file or file identifier.
- input : A variable (not the name of the variable)
- nestedLevel : Level of nesting of cell arrays and struct.

Output:

- code : A cellstr with the code.

Written by Kenneth Sæterhagen Paulsen

◆ nb_copyToClipboard

```
nb_copyToClipboard(x)
nb_copyToClipboard(x, dec, hSep, vSep)
```

Description:

This function puts a string, cell array, or numerical array into the clipboard.

Input:

- x : One of:
 - > A char array.
 - > A numerical array.
 - > A cell array of the above.Limited to 2-dimensional arrays.
- dec : A character that indicates the decimal separator. Default is the period ('.') .
- hSep : A character that indicates how to split horizontal elements in a given row vector. Default is char(9)
- vSep : A character that indicates how to split horizontal elements in a given row vector. Default char(10)

Examples:

```
nb_copyToClipboard('Test')
nb_copyToClipboard(char('Test','2'))
nb_copyToClipboard(rand(3,3))
```

See also:

[nb_pasteFromClipboard](#)

Written by Kenneth Sætherhagen Paulsen

◆ nb_copyfile

`nb_copyfile(from,to,format)`

Description:

Copy a file to a new location

Input:

- from : The full path name of the copied file. As a string.
- to : The full path name of the new location of the file.
(Including the file name). As a string.
- format : > 'text' : A normal file is copied.
> otherwise : A .mat file is copied.

Examples:

```
nb_copyfile('C:\docs\test.txt', 'C:\newfile.txt', 'text')
```

Written by Kenneth S. Paulsen

◆ nb_error

```
nb_error(message,Err)
```

Description:

Add extra message to a Matlab MException object.

Input:

- message : A string
- Err : Matlab MException object

Written by Kenneth Sæterhagen Paulsen

◆ nb_joinPath

```
out = nb_joinPath(p,f,e)
```

Description:

- Appends a backslash, \, to the end of a cellstring with the path name and then concatenates all the file components into a single cellstring.

Input:

- p,f,e : The different file parts. As cellstrings.

Output:

- out : A single cellstring with all the filepart concatenated.

Examples:

```
p = 'Matlab\B\test'  
f = 'fcsttest'  
e = 'xlsx'  
  
nb_joinPath(p,f,e)  
  
ans = 'Matlab\B\test\fcsttest.xlsx'
```

See also:

Written by Kenneth Sæterhagen Paulsen

◆ nb_load

```
l = nb_load(filename)
l = nb_load(filename,index)
```

Description:

Load .mat file using the MATLAB function load, then select the index of the variable to load. Default is 1.

Input:

- filename : Name of file to load. See the MATLAB load function.
- index : The load function return a struct, where the fields are the separate variables that are stored to the .mat file. The index input refer to the index value of the variable you want to sign the output. Default is 1.

Output:

- l : The loaded variable from the .mat file.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_loadFromUserpath**

```
variable      = nb_loadFromUserpath(filename)
[variable,err] = nb_loadFromUserpath(filename)
```

Description:

Save a variable to the subfolder nb_GUI of the userpath folder.

Input:

- filename : Name of the created file.

Output:

- variable : The variable load from the file.
- err : If nargout > 1 this give an non-empty char if an error occurred.

See also:

[nb_save2Userpath](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_loadWithName**

```
nb_loadWithName(fileName,givenName,workSpace)
```

Description:

Load one (first) MATLAB variable from a .mat file with the same name as the filename or the givenName.

Input:

- fileName : Name of the .mat file to load the MATLAB variable from.
- givenName : If you want to assign the loaded MATLAB variable with another name then the fileName input this option may be used.
- workSpace : Which workspace to load the variable into. Either 'base' (default) or 'caller'.

Output:

- A MATLAB variable stored in the base workspace with the wanted name.

Written by Kenneth SÃ¶therhagen Paulsen

◆ nb_makeWritable

```
c = nb_makeWritable(c)
```

Description:

Make a cellstr or char ready to be written to a file.

Input:

- c : Either a n x 1 cellstr or a n x m char.

Output:

- c : A n x 1 cellstr.

See also:

[nb_cellstr2file](#)

Written by Kenneth SÃ¶therhagen Paulsen

◆ nb_parseInputs

```
[inputs,message,index] = nb_parseInputs(varargin)
```

Description:

Parse inputs.

Input:

- mfile : The name of the function that calls the parser.

- default : A cell with the following:

```
{'inputName1', inputValue1, @isnumeric;...
  'inputName2', inputValue2, {@isa,'nb_ts'},...
  'inputName2', inputValue2, {@isnumeric,'&&',@isscalar}}
```

Can also be a cell array with 4 columns. In the 4th column you can include a function_handle that will be called when the corresponding property is being set. If the element is anything else than a function_handle, it will not be done anything. The function_handle need to take 2 inputs. The input name and the input value (In that order).

- varargin : The input name, input value pairs from the user.

Output:

- inputs : A struct with the parsed options.

- message : Error message. If empty, there where no problems

- index : An index of the inputs that are set by the varargin input. A logical vector with size size(default,1), where the matching element in default is true if set.

Written by Kenneth Sætherhagen Paulsen

◆ nb_parseOneOptional

```
[value,rest] = nb_parseOneOptional(name,default,varargin)
```

Description:

Parse one optional input at the time.

Input:

- name : Name of the optional input as a string.

- default : The default value of the optional input.

- varargin : All the optional inputs.

Output:

- value : Either the found or default value.
- rest : Rest of the optional inputs.

Written by Kenneth Sætherhagen Paulsen

◆ nb_parseOneOptionalSingle

```
[value,rest] = nb_parseOneOptionalSingle(name,ifNotGiven,ifGiven,varargin)
```

Description:

Parse one optional input at the time.

Input:

- name : Name of the optional input as a string.
- ifNotGiven : The value return if name is not found in varargin.
- ifGiven : The value return if name is found in varargin.
- varargin : All the optional inputs.

Output:

- value : Either ifNotGiven or ifGiven.
- rest : Rest of the optional inputs.

Written by Kenneth Sætherhagen Paulsen

◆ nb_pasteFromClipboard

```
x = nb_pasteFromClipboard
x = nb_pasteFromClipboard(dec,hSep,vSep,convert)
```

Description

Does the inverse operation of nb_copyToClipboard, but it can also interpret copied ranges from a excel spreadsheet.

If it cannot figure out the input, a one line char will be returned.

Input:

- dec : A character that indicates the decimal separator. Default is the period ('.') .
- hSep : A character that indicates how to split horizontal elements in a given row vector. Default is char(9)

- vSep : A character that indicates how to split horizontal elements in a given row vector. Default char(10)
- convert : Try to convert to numerical or not. true or false. Default is true. If all elements are numbers a double matrix is returned, otherwise a cell array.

Output :

x : A char, cell or double depending on the input.

Examples:

```
nb_copyToClipboard(char('Test','2'));
p1 = nb_pasteFromClipboard

nb_copyToClipboard(rand(3,3));
p2 = nb_pasteFromClipboard

nb_copyToClipboard('Test');
p3 = nb_pasteFromClipboard

c = {'Var1','Var2';2,2};
nb_copyToClipboard(c);
p4 = nb_pasteFromClipboard
```

See also:

[nb_copyToClipboard](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_pathCorrect**

path = nb_pathCorrect (path)

Description:

Replace \ with \\ in path name.

Inputs:

- path : A 1xN char or cellstr.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_save2Userpath**

nb_save2Userpath(filename,variable)

Description:

Save a variable to the subfolder nb_GUI of the userpath folder.

Input:

- filename : Name of the created file.
- variable : The variable to save to the file.

See also:

[nb_loadFromUserpath](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_syncFolders

`nb_syncFolders(folder1, folder2)`

Description:

Delete the folders and files in folder folder2, which are not in the folder folder1

Input:

- folder1 : A string with the path of the folder.
- folder2 : A string with the path of the folder.

Output:

- deleted : A cellstr with the deleted files and folders

Written by Kenneth Sæterhagen Paulsen

◆ nb_userpath

`uPath = nb_userpath(type)`

Description:

Get userpath. If the path return by the MATLAB function userpath is empty the pwd is used instead.

Input:

- type : A string with either
 - > 'normal' : userpath or pwd (without semicolon at the end). (default)
 - > 'gui' : Same as normal but added \nb_GUI at the end

Output:

- uPath : A string. For more see inputs

Written by Kenneth SÃ¶therhagen Paulsen

◆ nb_wrapped

```
wrapped = nb_wrapped(string,max)
```

Description:

Wrap line at spaces, where each line of the wrapped text is a maximum number of chars.

Input:

- string : A one line char.
- max : Max number of char in one line.

Output:

- wrapped : A cellstr.

Examples:

```
s = 'This is a line that must be wrapped. Can you help me?'  
c = nb_wrapped(s, 40)
```

Written by Tobias Ingebrigtsen

◆ nb_writeError

```
nb_writeError(Err,fileToWrite,extra)
```

Description:

Write error message to file.

Input:

- Err : A MException object.
- fileToWrite : Either a file identifier or the name of the file to write the error message to. As a string.
- extra : A N x M char with extra information on the error. Will be added first in the report written to the file.

Written by Kenneth SÃ¶therhagen Paulsen

■ nb_struct

Go to: [Properties](#) | [Methods](#)

A handle representation of a MATLAB structure (struct).

All the function that works on a struct will also work on a nb_struct.

Differences are:

- Initializing with two inputs, see below.
- Assign a multivalued struct (e.g. with size 1 x 4) with a cell;

```
s = nb_struct(4,{'t'})  
s.t = {'t','d','e','f'};  
s.t  
  
ans = {'t','d','e','f'}  
  
s(4).t = {{'g'}};
```

- Caution: Don't set the fields of this type of struct to other structs, as it is not supported to assign thoose struct. Use instead a normal MATLAB struct!

Superclasses:

`matlab.mixin.Copyable, handle`

Constructor:

`nb_struct(varargin)`

Input:

- Same input as for a MATLAB struct with one exception:

If the first input is a integer and the second is a cellstr, it will create a nb_struct with size varargin{1} and with fields given by the cellstr varargin{2}.

Output:

- `obj` : A nb_struct object.

Examples:

```
st1 = nb_struct();
```

```
st2 = nb_struct('test',{},'test2',{});  
st3 = nb_struct([]) % Empty
```

See also:

[struct](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

• [s](#)

- [s](#) ↑

A normal MATLAB struct.

Methods:

► **arrayfun** ↑

```
obj = arrayfun(obj,field)
```

Description:

This method is not supported by this class.

Written by Kenneth Sætherhagen Paulsen

► **fieldnames** ↑

```
fNames = fieldnames(obj)
```

Description:

Get fieldnames of the nb_struct object.

Input:

- obj : An object of class nb_struct.

Output:

- Same output(s) as the fieldnames function of a normal MATLAB struct.

Written by Kenneth Sætherhagen Paulsen

► getfield ↑

```
value = getfield(obj,varargin)
```

Description:

Get a field from the nb_struct object.

Input:

- obj : An object of class nb_struct.
- Otherwise the same inputs(s) as the getfield function of a normal MATLAB struct.

Output:

- Same output(s) as the getfield function of a normal MATLAB struct.

Written by Kenneth Sætherhagen Paulsen

► horzcat ↑

```
obj = horzcat(obj,varargin)
```

Description:

Horizontal concatenation of nb_struct objects. [obj,a]

Input:

- obj : An object of class nb_struct.

Optional inputs:

- varargin : Object of class nb_struct.

Output:

- obj : An object of class nb_struct.

See also:

[nb_struct.vertcat](#)

Written by Kenneth Sæterhagen Paulsen

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Check if the nb_struct object is empty.

Input:

- obj : An object of class nb_struct.

Output:

- Same output as the isempty function of a normal MATLAB struct.

Written by Kenneth Sæterhagen Paulsen

► **isfield** ↑

```
value = isfield(obj,varargin)
```

Description:

Is the field name a field of the nb_struct object.

Input:

- obj : An object of class nb_struct.

- Otherwise the same inputs(s) as the isfield function of a normal MATLAB struct.

Output:

- Same output(s) as the isfield function of a normal MATLAB struct.

Written by Kenneth Sæterhagen Paulsen

► **isstruct** ↑

```
value = isstruct(obj)
```

Description:

Is the nb_struct object a struct.

Input:

- obj : An object of class nb_struct.

Output:

- value : true

Written by Kenneth Sæterhagen Paulsen

► **nb_addFields** ↑

```
s = nb_addFields(obj, fields)
```

Description:

Add empty fields to a nb_struct.

Input:

- obj : An object of class nb_struct.
- Otherwise the same inputs(s) as the nb_addFields function of a normal MATLAB struct.

Output:

- Same output(s) as the nb_addFields function of a normal MATLAB struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_defaultField** ↑

```
obj = nb_defaultField(obj,field,default)
```

Description:

Add field with default value if not found found to be a field of an existing nb_struct obj.

Input:

- obj : An object of class nb_struct.
- field : Name of field. As a 1xN char.
- default : Default value assign to field if not found.

Output:

- obj : An object of class nb_struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_isfield** ↑

```
TF = nb_isfield(obj, varargin)
```

Description:

Recursive expansion of isfield.

Input:

- obj : An object of class nb_struct.

Output:

- TF : true if the fieldnames provided are recursive fields of the nb_struct.

Examples:

```
s.fieldLevelOne.fieldLevelTwo = 'valueLevelTwo';
TF = nb_isfield(s, 'fieldLevelOne', 'fieldLevelTwo');
```

See also:

[nb_struct.isfield](#)

Written by Henrik Hortemo Halvorsen

► **nb_keepFields** ↑

```
s = nb_keepFields(obj, fields)
```

Description:

Keep selected fields of nb_struct.

Input:

- obj : A nb_struct object.
- fields : A cellstr.

Output:

- obj : A nb_struct object.

Written by Henrik Hortemo Halvorsen

► **nb_rmffield** ↑

obj = nb_rmffield(obj,field)

Description:

Same as rmfield, but also handle the case where field is not a field of obj.

Input:

- s : A nb_struct object.
- field : A char or cellstr.

Output:

- obj : A nb_struct object.

See also:

[nb_struct.rmfield](#)

Written by Kenneth Sæterhagen Paulsen

► **orderfields** ↑

varargout = orderfields(obj,varargin)

Description:

Order the fields of the nb_struct object.

Input:

- obj : An object of class nb_struct.
- Otherwise the same inputs(s) as the orderfields function of a normal MATLAB struct.

Output:

- Same output(s) as the orderfields function of a normal MATLAB struct. Just that the struct is switched to a nb_struct. Remember that nb_struct object is of a handle class.

Written by Kenneth SÃ¶terhagen Paulsen

► **rmfield** ↑

```
obj = rmfield(obj,field)
```

Description:

Remova a field from the nb_struct object.

Input:

- obj : An object of class nb_struct.
- Otherwise the same inputs(s) as the rmfield function of a normal MATLAB struct.

Output:

obj : An object of class nb_struct.

Written by Kenneth SÃ¶terhagen Paulsen

► **size** ↑

```
varargout = size(obj,varargin)
```

Description:

Get the size of the nb_struct object.

Input:

- obj : An object of class nb_struct.
- Otherwise the same inputs(s) as the size function of a normal MATLAB struct.

Output:

- Same output(s) as the size function of a normal MATLAB struct.

Written by Kenneth Sæterhagen Paulsen

► **struct2cell** ↑

```
value = struct2cell(obj,varargin)
```

Description:

Convert a nb_struct object into a cell.

Input:

- obj : An object of class nb_struct.

Output:

- Same output(s) as the struct2cell function of a normal MATLAB struct.

Written by Kenneth Sæterhagen Paulsen

► **struct2table** ↑

```
t = struct2table(obj,varargin)
```

Description:

Convert the nb_struct object into a table.

Input:

- obj : An object of class nb_struct.
- Otherwise the same inputs(s) as the struct2table function of a normal MATLAB struct.

Output:

- Same output(s) as the struct2table function of a normal MATLAB struct.

Written by Kenneth Sæterhagen Paulsen

► **structfun** ↑

```
varargout = structfun(obj,varargin)
```

Description:

Evaluate a function on the nb_struct object. For more see the structfun method of a MATLAB struct,

Input:

- obj : An object of class nb_struct.
- Otherwise the same inputs(s) as the structfun function of a normal MATLAB struct.

Output:

- Same output(s) as the structfun function of a normal MATLAB struct.

Written by Kenneth Sætherhagen Paulsen

► **vertcat** ↑

```
obj = vertcat(obj,varargin)
```

Description:

Vertical concatenation of nb_struct objects. [obj;a]

Input:

- obj : An object of class nb_struct.

Optional inputs:

- varargin : Object of class nb_struct.

Output:

- obj : An object of class nb_struct.

See also:

[nb_struct.horzcat](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_addFields**

```
s = nb_addFields(s, fields)
```

Description:

Add empty fields to a struct.

Input:

- s : A struct.
- fields : A cellstr.

Output:

- s : A struct.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_collapseStruct**

```
cs = nb_collapseStruct(s)
```

Description:

Collapse a 1 x N or N x 1 struct into a 1 x 1. If a field differs across N the field will be stored as a 1 x N array of same type as the original field. One exception is if a field is a double and not a scalar, then it will be a double with size N in the dimension of the double + 1.

Caution : This function assumes that a field has the same size and is of the same type in the array dimension of the struct.

Caution : The extra fields N and collapse are added to store original size and collapsing of fields.

Input:

- s : A 1 x N or N x 1 struct.

Output:

- cs : A 1 x 1 struct.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_defaultField**

```
s = nb_defaultField(s,field,default)
```

Description:

Add field with default value if not found found to be a field of an existing struct s.

Input:

- s : A struct.
- field : Name of field. As a 1xN char.
- default : Default value assign to field if not found.

Output:

- s : A struct.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_isfield**

TF = nb_isfield(s, varargin)

Description:

Recursive expansion of isfield.

Input:

- s : A struct.

Output:

- TF : true if the fieldnames provided are recursive fields of the struct.

Examples:

```
s.fieldLevelOne.fieldLevelTwo = 'valueLevelTwo';
TF = nb_isfield(s, 'fieldLevelOne', 'fieldLevelTwo');
```

See also:

[isfield](#)

Written by Henrik Hortemo Halvorsen

◆ **nb_keepFields**

s = nb_keepFields(s, fields)

Description:

Keep selected fields of struct.

Input:

- s : A struct.
- fields : A cellstr.

Output:

- s : A struct.

Written by Henrik Hortemo Halvorsen

◆ **nb_rmffield**

t = nb_rmffield(s,field)

Description:

Same as rmfield, but also handle the case where field is not a field of s.

Input:

- s : A Struct
- field : A char or cellstr.

Output:

- t : A struct.

See also:

[rmfield](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_struct2cellarray**

c = nb_struct2cellarray(s,type)

Description:

Convert struct to cell.

Input:

```
- s : A struct.  
  
- type : > 'array' (default):  
  
    Convert a struct to a cell array. I.e.  
    {'fieldName1',field1,'fieldName2',field2,...}  
  
> 'matrix':  
  
    Convert a struct to a cell array. I.e.  
    {'fieldName1',field1;'fieldName2',field2;...}
```

Output:

```
- c : A cell array
```

See also:

[struct2cell](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_structEqual**

```
ret = nb_structEqual(s1,s2)
```

Description:

Test for equality of two structs.

Input:

```
- t      : A struct or a nb_struct  
  
- r      : A struct or a nb_struct
```

Output:

```
- ret : true or false. They are false if they have different fields  
      and the same fields contains different values. Cell arrays  
      are not tested, and if a field of the struct is a cell false is  
      returned.
```

See also:

[struct](#), [nb_struct](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_structStrcat**

```
[coeff_out] = nb_structStrcat(coeff_in, what, where)
```

Description:

Use this function to add letters in front or at the end of the fieldnames of a struct. It adds 'coeff' at the front as default.

Input:

- coeff_in : The struct in question.
- what : The letters to add. Default is to add 'coeff'.
- where : Where to add the letters: 'front' or 'back'. Default is 'front'.

Output:

coeff_out : A struct with the updated names.

Example:

```
coeff_out = nb_structStrcat(coeff_in,'letters','back')
```

Written by Erling Motzfeldt Kravik

◆ **nb_structStrrep**

```
[coeff_out] = nb_structStrrep(coeff_in, old, new)
```

Description:

Use this function to remove certain letters in the fieldnames of a struct. It removes 'coeff' as default.

Input:

- coeff_in : The struct in question.
- old : The letters to remove. Default is 'coeff'.
- new : The letters to add. Default is ''.

Output:

coeff_out : A struct with the updated names.

Example:

```
coeff_out = nb_structStrcat(coeff_in,'LAMBDA','rho')
```

Written by Erling M. Kravik

◆ nb_structcat

```
s = nb_structcat(t,r)
```

Description:

Concatenated structs. If they have conflicting fields with same fieldname it will give an error (if type is not set to 'first' or 'last').

Input:

- t : A struct or a nb_struct
- r : A struct or a nb_struct
- type : Set to 'first' to use the conflicting fields of the first input, and set to 'last' to use the second input.

Output:

- s : A struct or a nb_struct. If one of the inputs is a nb_struct the the output will be a nb_struct.

See also:

[struct](#), [nb_struct](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_structdepcat

```
s = nb_structdepcat(t,r)
```

Description:

Generalize the [] operator for structs to handle struct with different fields.

```
s1 = struct('test',1,'test2',2);
s2 = struct('test',2);
s = [s1,s2];
```

Will fail, but not

```
s = nb_structdepcat(s1,s2);
```

Input:

- t : A struct or a nb_struct
- r : A struct or a nb_struct

Output:

- s : A struct or a nb_struct. If one of the inputs is a nb_struct the the output will be a nb_struct.

See also:

[struct](#), [nb_struct](#)

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_uncollapsStruct**

cs = nb_uncollapsStruct(s)

Description:

Reverse the operation of nb_collapsStruct.

Input:

- s : A 1 x 1 struct.

Output:

- cs : A 1 x N or N x 1 struct.

Written by Kenneth SÃ¶terhagen Paulsen

■ **nb_List**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_List()
```

Description:

This is a class for storing objects. Using a list structure

Constructor:

```
obj = nb_List()
```

The empty constructor of the nb_List class

See also:

nb_Node

Written by Kenneth Sæterhagen Paulsen

Properties:

- first
- ids
- last

- **first** ↑

The first nb_Node object of the list

- **ids** ↑

A cellstr with the identifiers of the stored objects.

- **last** ↑

The last nb_Node object of the list

Methods:

- add
- get
- getFirst
- getLast
- getNumberOfStoredObjects
- remove
- reset

► **add** ↑

obj = add(obj,aObj,id)

Description:

Add object to the nb_list object

Input:

- obj : An object of class nb_List
- aObj : All inputs are supported
- id : The identifier of the given input. As a string.

Caution : If not given it will be stored with a string with the number of existing objects stored in the object + 1. I.e. if it is stored 2 object in the list, the identifier for the added object will be '3'.

Output:

- obj : An object of class nb_List, where the input aObj are added to the list of stored objects.

Examples:

```
obj.add(aObj);
obj.add(aObj, 'unique identifier');
```

Written by Kenneth S. Paulsen

► **get ↑**

```
storedObj = get(obj,id)
```

Description:

Get a stored object from a list.

Input:

- obj : An object of class nb_List
- id : The identifier of the stored object. As a string.

Output:

- storedObj : The stored object. Could be of any type.

Examples:

```
obj.get('unique identifier');
```

Written by Kenneth S. Paulsen

► **getFirst ↑**

```
firstNode = getFirst(obj)
```

Description:

Get the first node

Input:

- obj : An object of class nb_List

Output:

- firstNode : The first node, as an nb_Node object.

Examples:

```
firstNode = obj.getFirst()
```

Written by Kenneth S. Paulsen

► **getLast** ↑

```
lastNode = getLast(obj)
```

Description:

Get the last node

Input:

- obj : An object of class nb_List

Output:

- lastNode : The last node, as an nb_node object

Examples:

```
lastNode = obj.getLast()
```

Written by Kenneth S. Paulsen

► **getNumberOfStoredObjects** ↑

```
number = getNumberOfStoredObjects(obj)
```

Description:

Get the number of objects stored in the list

Input:

- obj : An object of class nb_List

Output:

- number : The number of stored objects as an integer (double).

Examples:

```
n = obj.getNumberOfStoredObjects()
```

Written by Kenneth S. Paulsen

► **remove** ↑

```
obj = remove(obj,id)
```

Description:

Remove an object from the nb_List object

Input:

- obj : An object of class nb_List
- id : A unique identifier as a string.

Output:

- obj : The nb_List object without the object with the given identifier.

Examples:

```
obj = obj.remove('unique identifier')
```

Written by Kenneth S. Paulsen

► **reset** ↑

```
obj = reset(obj,aObj,id)
```

Description:

Reset an object of the nb_List object

Input:

- obj : An object of class nb_List
- aObj : All inputs are supported
- id : A unique identifier as a string.

Output:

- obj : The nb_List object with the object with the given identifier reset.

Examples:

```
obj = reset(obj,nb_ts(),'data')
```

Written by Kenneth S. Paulsen

■ nb_Node

Go to: [Properties](#) | [Methods](#)

```
obj = nb_Node(element,id)
```

Superclasses:

handle

Description:

A class for storing any type and include it in a list (nb_list object)

Constructor:

```
obj = nb_Node(element,id)
```

Input:

- element : Any type
- id : A string with an identifier.

Output:

- obj : An object of class nb_Node

Examples:

```
obj = nb_Node(2,'A number with value 2');
```

See also:

[nb_list](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- element • id • next • prev
- **element** ↑

The element stored by the node. Can be of any class.

- **id** ↑

The identifier associated with the stored object

- **next** ↑

The next object (when stored in a nb_List object)

- **prev** ↑

The previous object (when stored in a nb_List object)

Methods:

- [getElement](#)
 - [getID](#)
 - [getNext](#)
 - [getPrev](#)
 - [hasNext](#)
 - [isempty](#)
 - [setElement](#)
 - [setNext](#)
 - [setPrev](#)
-

► **getElement** ↑

```
elem = getElement(obj)
```

Description:

Get the elements of an nb_Node object

Input:

- obj : An object of class nb_Node

Output:

- obj : The element of the nb_Node object. Can be of any MATLAB types (objects).

Examples:

```
elem = obj.getElement();
```

Written by Kenneth S. Paulsen

► **getID** ↑

```
id = getID(obj)
```

Description:

Get the id of the object

Input:

- obj : An object of class nb_Node

Output:

- id : The id of the object. As a string.

Examples:

```
obj = obj.getID();
```

Written by Kenneth S. Paulsen

► **getNext ↑**

```
nextObj = getNext(obj)
```

Description:

Get the next object stored in an nb_List object.

Input:

- obj : An object of class nb_Node

Output:

- nextObj : An object of class nb_Node or an empty double [].

Examples:

```
obj = obj.getNext();
```

Written by Kenneth S. Paulsen

► **getPrev ↑**

```
prevObj = getPrev(obj)
```

Description:

Get the previous node stored in an nb_List object

Input:

- obj : An object of class nb_Node

Output:

- prevObj : An object of class nb_Node or an empty double [].

Examples:

```
obj = obj.getPrev();
```

Written by Kenneth S. Paulsen

► **hasNext ↑**

```
obj = setNext(obj,nextObj)
```

Description:

Test for the existence of a next object (when stored in an nb_List object)

Input:

- obj : An object of class nb_Node

Output:

- ret : true (1) if the next object is not empty, otherwise false (0).

Examples:

```
ret = obj.hasNext();
```

Written by Kenneth S. Paulsen

► **isempty ↑**

```
ret = isempty(obj)
```

Description:

A test if the object is empty, returns true if empty

Input:

- obj : An object of class nb_Node

Output:

- ret : true (1) if the object is empty, else false (0)

Examples:

```
ret = objisempty();
```

Written by Kenneth S. Paulsen

► **setElement** ↑

```
obj = setElement(obj,newElement)
```

Description:

Set the element of an object of class nb_Node

Input:

- obj : An object of class nb_Node

- newElement : The new element. Can be of any MATLAB type
(object)

Output:

- obj : An object of class nb_Node with the new element stored

Examples:

```
obj = obj.setElement(newElement);
```

Written by Kenneth S. Paulsen

► **setNext** ↑

```
obj = setNext(obj,nextObj)
```

Description:

Sets the next node (in a list)

Input:

- obj : An object of class nb_Node
- nextObj : The next object (class nb_Node) in an nb_List object

Output:

- obj : An object of class nb_Node with the next property set

Examples:

```
obj = obj.setNext(aObj);
```

Written by Kenneth S. Paulsen

► **setPrev ↑**

```
obj = setPrev(obj,nextObj)
```

Description:

Sets the previous node (in a list)

Input:

- obj : An object of class nb_Node
- nextObj : The previous object (class nb_Node) in an nb_List object

Output:

- obj : An object of class nb_Node with the prev property set

Examples:

```
obj = obj.setPrev(aObj);
```

Written by Kenneth S. Paulsen

◆ **findjobj**

findjobj Find java objects contained within a specified java container or Matlab GUI handle

Syntax:

```
[handles, levels, parentIds, listing] = findobj(container, 'PropertyName', PropValue(s), ...)
```

Input parameters:

container - optional handle to java container uipanel or figure. If unsupplied then current figure is used.
'PropertyName', PropValue - optional list of property pairs (case insensitive). PropName may also be a string containing a regular expression.
'position' - filter results based on those elements that contain the specified X,Y position.
Note: specify a Matlab position (X,Y = pixels from bottom left corner),
'size' - filter results based on those elements that have the specified W,H (in pixels)
'class' - filter results based on those elements that contain the substring (or regular expression).
Note1: filtering is case insensitive and relies on regexp, so you can pass anything.
Note2: '-class' is an undocumented findobj PropName, but only works on Java components.
'property' - filter results based on those elements that possess the specified case-insensitive property.
Note1: passing a property value is possible if the argument following 'property' is in the format of {'propName','propValue'}. Example: FINDOBJ(...,'property','Text','click me')
Note2: partial property names (e.g. 'Tex') are accepted, as long as they are unique.
'depth' - filter results based on specified depth. 0=top-level, Inf=all levels (all components)
'flat' - same as specifying: 'depth',0
'not' - negates the following filter: 'not','class','c' returns all elements EXCEPT those matching the class.
'persist' - persist figure components information, allowing much faster results for repeated calls.
'nomenu' - skip menu processing, for "lean" list of handles & much faster processing.
This option is the default for HG containers but not for figure, Java and uicontrol components.
'print' - display all java elements in a hierarchical list, indented appropriately.
Note1: optional PropValue of element index or handle to java container
Note2: normally this option would be placed last, after all filtering is done.
Note3: output is to the Matlab command window unless the 'listing' (4th) argument is supplied.
'list' - same as 'print'
'debug' - list found component positions in the Command Window

Output parameters:

handles - list of handles to java elements
levels - list of corresponding hierarchy level of the java elements (top=0)
parentIds - list of indexes (in unfiltered handles) of the parent container of the corresponding handles
listing - results of 'print'/'list' options (empty if these options were not specified)

Note: If no output parameter is specified, then an interactive window will be displayed which shows a tree view of all container components, their properties and callbacks.

Examples:

```
findobj;                                % display list of all javaelements of currrent figure in an interactive window
handles = findobj;                        % get list of all java elements of current figure (inc. menu bars)
findobj('print');                         % list all java elements in current figure
findobj('print',6);                       % list all java elements in current figure, contained within 6 levels
handles = findobj(hButton);                % hButton is a matlab button
handles = findobj(gcf,'position',getpixelposition(hButton,1)); % same as above but also includes menu bars
handles = findobj(hButton,'persist');       % same as above, persists between calls
handles = findobj('class','pushbutton');    % get all pushbuttons in current figure
handles = findobj('class','pushbutton','position',123,456); % get all pushbuttons at position 123,456
handles = findobj(gcf,'class','pushbutton','size',23,15);   % get all pushbuttons with size 23x15
handles = findobj('property','Text','not','class','button'); % get all non-button elements
handles = findobj('-property',{'Text','click me'});          % get all elements with Text property
```

Sample usage:

```
hButton = uicontrol('string','click me');
jButton = findobj(hButton,'nomenu');
% or: jButton = findobj('property',{'Text','click me'});
jButton.setFlyOverAppearance(1);
```

```
jButton.setCursor(java.awt.Cursor.getPredefinedCursor(java.awt.Cursor.HAND_CURSOR));
set(jButton,'FocusGainedCallback',@myMatlabFunction); % some 30 callback points available
jButton.get; % list all changeable properties...
```

```
hEditbox = uicontrol('style','edit');
jEditbox = findobj(hEditbox,'nomenu');
jEditbox.setCaretColor(java.awt.Color.red);
jEditbox.KeyTypedCallback = @myCallbackFunc; % many more callbacks where this came from
jEdit.requestFocus;
```

Technical explanation & details:

<http://undocumentedmatlab.com/blog/findobj/>
<http://undocumentedmatlab.com/blog/findobj-gui-display-container-hierarchy/>

Known issues/limitations:

- Cannot currently process multiple container objects - just one at a time
- Initial processing is a bit slow when the figure is laden with many UI components (so be patient)
- Passing a simple container Matlab handle is currently filtered by its position+size: skip
- Matlab uipanels are not implemented as simple java panels, and so they can't be found via findobj
- Labels have a write-only text property in java, so they can't be found using the 'property'

Warning:

This code heavily relies on undocumented and unsupported Matlab functionality.
It works on Matlab 7+, but use at your own risk!

Bugs and suggestions:

Please send to Yair Altman (altmany at gmail dot com)

Change log:

2015-01-12: Differentiate between overlapping controls (for example in different tabs); fixed a few bugs
2014-10-20: Additional fixes for R2014a, R2014b
2014-10-13: Fixes for R2014b
2014-01-04: Minor fix for R2014a; check for newer FEX version up to twice a day only
2013-12-29: Only check for newer FEX version in non-deployed mode; handled case of invisible scroll-panes
2013-10-08: Fixed minor edge case (retrieving multiple scroll-panes)
2013-06-30: Additional fixes for the upcoming HG2
2013-05-15: Fix for the upcoming HG2
2013-02-21: Fixed HG-Java warnings
2013-01-23: Fixed callbacks table grouping & editing bugs; added hidden properties to the table
2013-01-13: Improved callbacks table; fixed tree refresh failure; fixed: tree node-select bug
2012-07-25: Fixes for R2012a as well as some older Matlab releases
2011-12-07: Fixed 'File is empty' messages in compiled apps
2011-11-22: Fix suggested by Ward
2011-02-01: Fixes for R2011a
2010-06-13: Fixes for R2010b; fixed download (m-file => zip-file)
2010-04-21: Minor fix to support combo-boxes (aka drop-down, popup-menu) on Windows
2010-03-17: Important release: Fixes for R2010a, debug listing, objects not found, component
2010-02-04: Forced an EDT redraw before processing; warned if requested handle is invisible
2010-01-18: Found a way to display label text next to the relevant node name
2009-10-28: Fixed uitreenode warning
2009-10-27: Fixed auto-collapse of invisible container nodes; added dynamic tree tooltips
2009-09-30: Fix for Matlab 7.0 as suggested by Oliver W; minor GUI fix (classname font)
2009-08-07: Fixed edge-case of missing JIDE tables
2009-05-24: Added support for future Matlab versions that will not support JavaFrame
2009-05-15: Added sanity checks for axes items
2009-04-28: Added 'debug' input arg; increased size tolerance 1px => 2px
2009-04-23: Fixed location of popupmenus (always 20px high despite what's reported by Matlab)
2009-04-09: Automatic 'nomenu' for uicontrol inputs; significant performance improvement
2009-03-31: Fixed position of some Java components; fixed properties tooltip; fixed node

2009-02-26: Indicated components visibility (& auto-collapse non-visible containers); auto
2009-02-24: Fixed update check; added dedicated labels icon
2009-02-18: Fixed compatibility with old Matlab versions
2009-02-08: Callbacks table fixes; use uiinspect if available; fix update check according
2008-12-17: R2008b compatibility
2008-09-10: Fixed minor bug as per Johnny Smith
2007-11-14: Fixed edge case problem with class properties tooltip; used existing object i
2007-08-15: Fixed object naming relative property priorities; added sanity check for ille
2007-08-03: Fixed minor tagging problems with a few Java sub-classes; displayed UI Class ID
2007-06-15: Fixed problems finding HG components found by J. Wagberg
2007-05-22: Added 'nomenu' option for improved performance; fixed 'export handles' bug; f
2007-04-23: HTMLized classname tooltip; returned top-level figure Frame handle for figure
2007-04-19: Fixed edge case of missing figure; displayed tree hierarchy in interactive GU
2007-04-04: Improved performance; returned full listing results in 4th output arg; enable
2007-03-20: First version posted on the MathWorks file exchange: <a href="http://www.math

Written by Yair M. Altman

◆ **getundoc**

undocumentedProps = getundoc(arg, skipStandardProps)

Written by Yair Altman

◆ **nb_any2code**

code = nb_any2code(input, varName)

Description:

Convert a MATLAB object to .m code.

Input:

- input : A variable (not the name of the variable)
- varName : Name of the assign variable.
- nestedLevel : Level of nesting of cell arrays and struct.

Output:

- code : A cellstr with the code.

Examples:

See also:

◆ nb_callMethod

```
result = nb_callMethod(obj,meth,classConst,varargin)
```

Description:

Call method meth on the matrix of objects obj.

Input:

- obj : A N x M object of any class.
- meth : The method to call.
- classConst : Class constructor as a function_handle.

Optional input:

- varargin : Given to the method specified by meth.

Output:

- result : A N x M object of class cl.

Written by Kenneth Sæterhagen Paulsen

◆ nb_callMethodWaitbar

```
result = nb_callMethodWaitbar(obj,meth,classConst,waitbar,varargin)
```

Description:

Call method meth on the matrix of objects obj using a waitbar.

Input:

- obj : A N x M object of any class.
- meth : The method to call.
- classConst : Class constructor as a function_handle.
- waitbar : A nb_waitbar5 object.

Optional input:

- varargin : Given to the method specified by meth.

Output:

- result : A N x M object of class cl.

Written by Kenneth Sæterhagen Paulsen

◆ nb_checkForErrors

str = nb_checkForErrors(expression,macro)

Description:

Check for basic errors in an expression to be interpreted by the shunting yard algorithm.

Input:

- expression : A char with the expression to be interpreted.
- macro : Set to true to also handle the NB Toolbox macro processing language as well. Default is false.

Output:

- str : If a non-empty char is returned, the expression cannot be interpreted by the shunting yard algorithm.

See also:

[nb_shuntingYardAlgorithm](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_clearall

nb_clearall()
nb_clearall(false)

Description:

Clear all variables, close all figures and clear command window.

Written by Kenneth Sæterhagen Paulsen

◆ nb_clock

t = nb_clock

Description:

Get the current time on the given format.

Input:

- format : A string with the format:

```
> 'vintagemilliseconds' : 'yyyymmddhhnnssqqq'  
> 'vintagelong' : 'yyyymmddhhnnss'  
> 'vintage' : 'yyyymmddhhnn'  
> 'vintageshort' : 'yyyymmdd'  
> 'gui' : 'Date: dd/mm/yyyy Time: hh:nn'
```

Output:

t : A string.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_colVector**

c = nb_colVector(in)

Description:

Secure a column vector.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_combine**

```
vc = nb_combine(v,n)  
vc = nb_combine(v,n,n2)
```

Description:

Pick n elements from the vector v in all possible ways.

Inspired by a function of Matt Fig.

Reference: <http://mathworld.wolfram.com/BallPicking.html>

Input:

- v : A vector.

- n : The number of picked elements.

- n2 : If 3 inputs is given this function will produce a
nb_countCombine(length(v),n,n2) cell array of all combinations
where n to n2 elements are picked from v.

Output:

- vc : A $n!/k!(n-k)!$ x n matrix, or see input n2.

Written by Kenneth Sæterhagen Paulsen

◆ nb_conditional

```
value = nb_conditional(condition, trueValue, falseValue)
```

Description:

If condition is true return trueValue, or else return falseValue.

Written by Henrik Halvorsen Hortemo and Kenneth Sæterhagen Paulsen

◆ nb_conditionalStatement

```
value = nb_conditional(condition, trueFunc, falseFunc)
```

Description:

If condition is true return output from trueFunc, or else return output from falseFunc.

Written by Henrik Halvorsen Hortemo

◆ nb_copy

```
obj = nb_copy(obj)
```

Description:

Make copy of object. Works on both handle and value objects.

Written by Kenneth Sæterhagen Paulsen

◆ nb_countCombine

```
num = nb_countCombine(nMin, nMax)
```

Description:

This is the number of combinations of N things taken nMin to nMax at a time. I.e. the sum of $n!/k!(n-k)!$ for $k = nMin, \dots, nMax$.

Input:

- n : An integer.
- nMin : An integer.
- nMax : An integer.

Output:

- num : An integer.

See also:

[nchoosek](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_createLinkToClass**

link = nb_createLinkToClass(obj, className)

Description:

Get hyperlink to class doc as a char.

Input:

- obj : Any object.
- className : A one line char.

Output:

- link : A one line char.

Written by Kenneth Sætherhagen Paulsen

◆ **nb_createLinkToClassProperty**

link = nb_createLinkToClassProperty(className, propertyName)

Description:

Get hyperlink to class property or method doc as a char.

Input:

- className : A one line char with the name of the class.
- propertyName : A one line char with the name of the property or method.

Output:

- link : A one line char.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_default**

```
value = nb_default(value, default)
```

Description:

Return default if value is empty.

Input:

- value : Any type.
- default : Any type.

Output:

- value = Either value or default.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_depcat**

```
d = nb_depcat(varargin)
```

Description:

Concatenation of inputs along the 3 dimension.

Input:

- d1 : Any.
- d2 : Any, but same as d1.

Output:

- d : Any, but same type as inputs.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_duplicated**

```
isDup      = nb_duplicated(in)
[isDup,dup] = nb_duplicated(in)
```

Description:

Find the unique duplicated elements of a vector.

Input:

- in : Any vector that are supported by the unique function made by MATLAB.

Output:

- isDup : Return true if any duplicated values are located.
- dup : Return the (unique) located duplicated values.

See also:

[unique](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_evalExpression

```
[out,str] = nb_evalExpression(out,type,nInp)
```

Description:

Evaluate an expression interpreted by the shunting yard algorithm.

Input:

- out : A cell with the out output from nb_shuntingYardAlgorithm interpreted by either nb_getTypes or nb_getTypesC.
- type : A double vector. See the type output from nb_getTypes or nb_getTypesC.
- nInp : A double vector. See the nInp output from the nb_shuntingYardAlgorithm function.

Output:

- out : The evaluated output. Can be of any class (it depend on the out input)
- str : If a non-empty char is returned, the expression cannot be interpreted by the shunting yard algorithm.

See also:

[nb_shuntingYardAlgorithm](#), [nb_getTypes](#), [nb_getTypesC](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_func2Cellstr**

`str = nb_func2Cellstr(func)`

Written by Kenneth Sæterhagen Paulsen

◆ **nb_getCombinations**

`varargout = nb_getCombinations(varargin)`

Description:

Get all possible combinations of the optional inputs. Must be either a cell (1,N) or double (1xN).

Input:

- `nMin` : Min number of elements combined from the first input. If empty 1 is used.
- `nMax` : Max number of elements combined from the first input. If empty `length(varargin{1})` is used
- `varargin{1}` : The main input to max combination of. I.e. the `nMin` and `nMax` is only applicable to this input.
- `varargin{2:end}` : The `varargin{1:ii-1}` are replicated with the size of these inputs to create all combinations.

Output:

- `varargout{1}` = Number of elements of the combinations.
- `varargout(2:end)` = The inputs in all its combinations

Examples:

```
[s,vars,lags] = nb_getCombinations(1,4,{'Var1','Var2','Var3','Var4'},1:10);
[s,vars,lags] = nb_getCombinations(1,3,{'Var1','Var2','Var3','Var4'},1:10);
[s,vars,lags] = nb_getCombinations(1,3,{'Var1','Var2','Var3'},[1,2,3]);
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_getHistPeriodsDuringReporting**

```
value = nb_getHistPeriodsDuringReporting()
value = nb_getHistPeriodsDuringReporting(freq)
```

Description:

Get number of historical observations to use during reporting.

Output:

- value : The number of observations.

Written by Kenneth SÃ¶therhagen Paulsen

◆ **nb_getOpt**

```
opt = nb_getOpt()
```

Description:

Get default options given to fminsearch used by the NBTOOLBOX

Written by Kenneth SÃ¶therhagen Paulsen

◆ **nb_getTypes**

```
[out,type] = nb_getTypes(out,variables,data,macro,nInp)
```

Description:

Fill in data to variables in the output from nb_shuntingYardAlgorithm function.

Input:

- out : A cell with the out output from nb_shuntingYardAlgorithm function.
- variables : Same as the variables input to the nb_shuntingYardAlgorithm function.
- data : The values of the variables. Either as a double or another object that can be indexed by (:,ii,:) , where ii is the variables{ii} value.
- macro : Set to true to also handle the NB Toolbox macro processing language as well. Default is false.
- nInp : Number of inputs to each function in out.

Output:

- out : A cell with same length as the out input, where the the names of the variables has been changed with the data of those variables.
- type : A vector needed to evaluate the expression using nb_evalExpression.

See also:

[nb_shuntingYardAlgorithm](#), [nb_getTypesC](#), [nb_evalExpression](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_getTypesC**

[out,type] = nb_getTypesC(out,variables,data)

Description:

Fill in data to variables in the output from nb_shuntingYardAlgorithm function.

Input:

- out : A cell with the out output from nb_shuntingYardAlgorithm function.
- variables : Same as the variables input to the nb_shuntingYardAlgorithm function.
- data : The values of the variables. A cell vector with same length as variables.

Output:

- out : A cell with same length as the out input, where the the names of the variables has been changed with the data of those variables.
- type : A vector needed to evaluate the expression using nb_evalExpression.

See also:

[nb_shuntingYardAlgorithm](#), [nb_getTypes](#), [nb_evalExpression](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_intersect**

c = nb_intersect(varargin)

Description:

Extension of the MATLAB function intersect, i.e. handles more than two inputs to intersect.

Input:

- varargin : Any type of input you can give to the two first inputs to the intersect function.

Output:

- c : The unique elements found in all inputs.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isLogical

```
ret = nb_isLogical(x)
```

Description:

Test if x is a logical scalar. MATLAB <true> and <false> will both return true. As will 0 or 1 even if given as a double.

Input:

- x : Any type

Output:

- bool : true or false.

Written by Per Bjarne Bye

◆ nb_isScalarLogical

```
ret = nb_isScalarLogical(x)
```

Description:

Test if x is a scalar logical.

Input:

- x : Any type

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

◆ nb_isempty

ret = nb_isempty(in)

Description:

Same as isempty function, but will return true also for structs without fields.

Input:

- in : Any type of inputs.

Output:

- ret : 1 if empty otherwise 0.

See also:

[isempty](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_ismemberi

varargout = nb_ismemberi(varargin)

Description:

Case insensitive ismember

Input:

See ismember

Output:

See ismember

See also:

[ismember](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_parseOptions

```
options = nb_parseOptions(varargin)
```

Description:

Takes structs and key/value-pairs as inputs and returns a struct with lowercase keys

Written by Henrik Halvorsen Hortemo

◆ nb_rowVector

```
c = nb_rowVector(in)
```

Description:

Secure a row vector.

Written by Kenneth Sætherhagen Paulsen

◆ nb_shuntingYardAlgorithm

```
[str,out,nInp,stack,nInpStack,prec] = nb_shuntingYardAlgorithm(...  
    expression,variables,macro)  
[str,out,nInp,stack,nInpStack,prec] = nb_shuntingYardAlgorithm(...  
    expression,variables,macro,out,stack,prec,nInp,nInpStack,last)
```

Description:

MATLAB implementation of the shunting yard algorithm for interpreting a mathematical expression.

Input:

- expression : The expression to interpret. As a 1 x n char.
- variables : The list of variables of the function that the expression consists of.
- macro : Set to true to also handle the NB Toolbox macro processing language as well. Default is false.

The rest of the inputs is used internally in this function.

Output:

- str : If a non-empty char is returned, the expression cannot be interpreted by the shunting yard algorithm.
- out : A cell with the interpretation of the expression.
- nInp : Number of inputs to each function.

See also:

[nb_eval](#), [nb_checkForErrors](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_sizeEqual**

```
ret = sizeEqual(input, shouldBeSize)
```

Description:

Test if the input is of a given size

Input:

- input : Any object
- shouldBeSize : A 1 x n double. Where n must match the potential output size of size(input). If some elements are nan those dimensions are unrestricted.

Output:

- ret : True if the size match shouldBeSize. If the input shouldBeSize does not match the output from size(input) ret is returned as false.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_stateDates**

```
out = nb_stateDates(startYear, endYear, d, freq)
```

Description:

A function to find the release date of variables, given that there is a general rule (day number) which the variable is released. The function controls for Norwegian holidays. If the release date (given by the rule) is on a holiday and/or weekend, it will return the day which is closest.

Input:

- startYear : As an nb_date object or as a string.
- endYear : As an nb_date object or as a string.
- d : The day number where the state variable is published. As a double.
- freq : The frequency of the observations you want. Either 4 or 12. As a double.
- laglead : (Optional) Sets the lag/lead interval of the test.

Output:

- out : A numPeriods*1 nb_day object.

Examples:

```
out = nb_stateDates('2010','2018',10,12)  
out = nb_stateDates('2010','2018',10,4)  
out = nb_stateDates(nb_year('2010'),nb_day('2018M1D10'),10,4)
```

See also:

[nb_easter](#)

Written by Tobias Ingebrigtsen

◆ **nb_union**

c = nb_union(varargin)

Description:

Extension of the MATLAB function union, i.e. handles more than two inputs to union.

Input:

- varargin : Any type of input you can give to the two first inputs to the union function.

Output:

- c : The elements found in some inputs.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_when2Notify**

note = nb_when2Notify(number)

Description:

This function governs how often the waitbars used in the NBTOOLBOX notify the status

Written by Kenneth Sæterhagen Paulsen

◆ vec

```
out = vec(in)
```

Description:

The vector operator. Same as in(:)

Input:

- in : Any array.

Output:

- out : Any array.

Written by Kenneth Sæterhagen Paulsen

25.13 Calendars

- nb_allCalendar
- nb_currentCalendar
- nb_lastCalendar
- nb_manualCalendar
- nb_numDaysCalendar

■ nb_allCalendar

Go to: [Properties](#) | [Methods](#)

An object that will provide the all calendar, i.e. return all runs of a model.

Superclasses:

nb_calendar

Constructor:

```
obj = nb_allCalendar()
```

See also:

[nb_currentCalendar](#), [nb_MPRCalendar](#), [nb_lastCalendar](#)

Written by Kenneth Sæterhagen Paulsen

Properties:**Methods:**

- doOneModel
- getCalendar
- getContextIndex
- getDefaultStart
- getName
- getStartOfCalendar
- getSubClasses
- loadobj
- saveobj
- selectCalendar
- selectRecursiveCalendar
- shrinkCalendar
- struct
- unstruct

► **doOneModel** ↑

```
[index,isMatch] = nb_calendar.doOneModel(model,calendar)
```

Description:

Shrink calendar to a provided window.

Input:

- model : The model of interest. As a nb_model_vintages object.
 - or
 - A cellstr with the contexts of a model. Each element on the format 'yyyymmdd'.
- calendar : Full calendar as a N x 1 double.

Output:

- index : The index for the model that matches the provided calendar, as a 1 x N numerical array, where N is the length of the calendar.
- isMatch : A 1 x N logical array, if false it means that the model doesn't provide a forecast at the given date, where N is the length of the calendar.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getCalendar** ↑

```
calendar = getCalendar(obj,start,finish,modelGroup,doRecursive)
```

Description:

Get calendar.

Input:

- obj : An object of a subclass of the nb_calendar class.
- start : Start date of calendar window, as a nb_day object.
- finish : End date of calendar window, as a nb_day object.
- modelGroup : A vector of objects of class

```
nb_model_forecast_vintages or a cellstr where
each element is on the format 'yyyymmdd' or
'yyyymmddhhnnss'.
```

- doRecursive : If the modelGroup input is a scalar
nb_model_group_vintages object you may want to
get the calender of the children instead of the
object itself. In this case this input must be
set to true. Default is true.
- fromResults : Give true to take the contexts from results
property instead of the forecastOutput property.

This is only supported when modelGroup is an
array of nb_model_vintages objects.

Output:

- calendar : The calendar for the selected window, as a
N x 1 double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getContextIndex** ↑

```
[indC,locC] = nb_calendar.getContextIndex(forecastContexts,calendar)
```

Description:

Get index of the contexts that match a set of calendar dates.

Input:

- forecastContexts : A N x 1 or 1 x N double with the contexts.
- contexts : A 1 x M or M x 1 double with the calendar dates.

Output:

- indC : A 1 x Q index of the contexts that match a set of calendar
dates. Here Q <= M, and is only lower if some of the calendar
dates does not match with any contexts.
- locC : A 1 x M logical. A element is true, if the calendar dates
found a matching context.

See also:

[nb_allCalendar.doOneModel](#), [nb_modelDataSource.update](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getDefaultStart** ↑

```
start = nb_calendar.getDefaultStart(modelGroup, doRecursive, fromResults)
```

Description:

Get default start of calendar if the modelGroup is provide.

Input:

- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- start : The default start date of the calendar. As a nb_day object. Is empty ('') if modelGroup is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getName** ↑

```
name = getName(obj)
```

Description:

Get calendar name as one line char

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getStartOfCalendar** ↑

```
contextsStart = nb_calendar.getStartOfCalendar(modelGroup, doRecursive, ...  
fromResults)
```

Description:

Get first context of a set of nb_model_forecast_vintages, or the children of a scalar nb_model_group_vintages object.

Input:

- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- contextsStart : A cellstr array with same length as the modelGroup input, each element stores the first context of the that particular model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getSubClasses** ↑

```
classes = nb_calendar.getSubClasses()
```

Description:

Get all available subclasses of the nb_calendar for your version of NB Toolbox.

Output:

- classes : A cellstr with the subclasses.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **loadobj** ↑

```
obj = nb_calendar.loadobj(s)
```

Description:

Load object from .mat

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **saveobj** ↑

```
s = saveobj(obj)
```

Description:

Save object to .mat. Called by the save method.

Written by Kenneth S. Paulsen

Inherited from superclass NB_CALENDAR

► **selectCalendar** ↑

```
[index,calendar] = selectCalendar(obj,modelGroup,start,finish,...  
    doRecursive,fromResults)
```

Description:

Select the forecasts that matches the supplied calendar for each model/model group.

Input:

- obj : An object of a subclass of the nb_calendar class.
- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- start : Start date of calendar window, as a nb_day object.
- finish : End date of calendar window, as a nb_day object.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calendar of the children instead of the object itself. In this case this input must be set to true. Default is true.

Output:

- index : The index for each model that matches the provided calendar, as a 1 x nModel cell array. Each element stores a numerical array with the indexes of the forecasts of the given calendar.
- calendar : The calendar used for the given model.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **selectRecursiveCalendar ↑**

[index,calendar] = selectRecursiveCalendar(obj,modelGroup,start,finish,doRecursive)

Description:

Select the forecast that matches the supplied calendar for each model/model group recursively.

Input:

- obj : An object of a subclass of the nb_calendar class.
- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- start : Start date of calendar window, as a nb_day object.
- finish : A 1 x nContext array of nb_day objects. Each element is the end date of each recursive window.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calendar of the children instead of the object itself. In this case this input must be set to true. Default is true.

Output:

- index : The index for each model that matches the provided calendar, as a 1 x nModel cell array, each element consisting of 1 x nRec cell array, where nRec is the number of recursive periods. Each element of these again stores a numerical array with the indexes of the forecasts of the given calendar of a given recursive evaluation period.
- calendar : A 1 x nRec cell array, where nRec is the number of recursive periods. Each element of these again stores a the calendar of each recursive period.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► shrinkCalendar ↑

```
[calendar,ind] = nb_calendar.shrinkCalendar(calendar,start,finish)
```

Description:

Shrink calendar to a provided window.

Input:

- calendar : Full calendar as a N x 1 double.
- start : A nb_day object, or empty.
- finish : A nb_day object, or empty.

Output:

- calendar : The calendar of the provided window.
- ind : A logical of size N x 1. True for each elements kept.

- [struct](#)
- [unstruct](#)

► **doOneModel** ↑

```
[index,isMatch] = nb_calendar.doOneModel(model,calendar)
```

Description:

Shrink calendar to a provided window.

Input:

- model : The model of interest. As a nb_model_vintages object.

or

A cellstr with the contexts of a model. Each element on the format 'yyyymmdd'.

- calendar : Full calendar as a N x 1 double.

Output:

- index : The index for the model that matches the provided calendar, as a 1 x N numerical array, where N is the length of the calendar.
- isMatch : A 1 x N logical array, if false it means that the model doesn't provide a forecast at the given date, where N is the length of the calendar.

Written by Kenneth Sæterhagen Paulsen

► **getCalendar** ↑

```
calendar = getCalendar(obj,start,finish,modelGroup,doRecursive)
```

Description:

Get calendar.

Input:

- obj : An object of a subclass of the nb_calendar class.
- start : Start date of calendar window, as a nb_day object.
- finish : End date of calendar window, as a nb_day object.
- modelGroup : A vector of objects of class nb_model_forecast_vintages or a cellstr where each element is on the format 'yyyymmdd' or 'yyyymmdhhnnss'.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calendar of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- calendar : The calendar for the selected window, as a N x 1 double.

Written by Kenneth Sæterhagen Paulsen

► **getContextIndex** ↑

```
[indC,locC] = nb_calendar.getContextIndex(forecastContexts,calendar)
```

Description:

Get index of the contexts that match a set of calendar dates.

Input:

- forecastContexts : A N x 1 or 1 x N double with the contexts.
- contexts : A 1 x M or M x 1 double with the calendar dates.

Output:

- indC : A 1 x Q index of the contexts that match a set of calendar dates. Here Q <= M, and is only lower if some of the calendar dates does not match with any contexts.
- locC : A 1 x M logical. A element is true, if the calendar dates found a matching context.

Written by Kenneth Sæterhagen Paulsen

► **getDefaultStart** ↑

```
start = nb_calendar.getDefaultStart(modelGroup,doRecursive,fromResults)
```

Description:

Get default start of calendar if the modelGroup is provide.

Input:

- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- start : The default start date of the calendar. As a nb_day object. Is empty ('') if modelGroup is empty.

Written by Kenneth SÃ¶terhagen Paulsen

► getName ↑

```
name = getName(obj)
```

Description:

Get calendar name as one line char

Written by Kenneth SÃ¶terhagen Paulsen

► getStartOfCalendar ↑

```
contextsStart = nb_calendar.getStartOfCalendar(modelGroup, doRecursive, ...  
fromResults)
```

Description:

Get first context of a set of nb_model_forecast_vintages, or the children of a scalar nb_model_group_vintages object.

Input:

- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calendar of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- contextsStart : A cellstr array with same length as the modelGroup input, each element stores the first context of the that particular model.

Written by Kenneth SÃ¶terhagen Paulsen

► **getSubClasses** ↑

```
classes = nb_calendar.getSubClasses()
```

Description:

Get all available subclasses of the nb_calendar for your version of NB Toolbox.

Output:

- classes : A cellstr with the subclasses.

Written by Kenneth Sæterhagen Paulsen

► **loadobj** ↑

```
obj = nb_calendar.loadobj(s)
```

Description:

Load object from .mat

Written by Kenneth Sæterhagen Paulsen

► **saveobj** ↑

```
s = saveobj(obj)
```

Description:

Save object to .mat. Called by the save method.

Written by Kenneth S. Paulsen

► **selectCalendar** ↑

```
[index,calendar] = selectCalendar(obj,modelGroup,start,finish,...  
doRecursive,fromResults)
```

Description:

Select the forecasts that matches the supplied calendar for each model/model group.

Input:

- obj : An object of a subclass of the nb_calendar class.
- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- start : Start date of calendar window, as a nb_day object.
- finish : End date of calendar window, as a nb_day object.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.

Output:

- index : The index for each model that matches the provided calendar, as a 1 x nModel cell array. Each element stores a numerical array with the indexes of the forecasts of the given calendar.
- calendar : The calendar used for the given model.

```
s = struct(obj)
```

Description:

Convert object to a struct.

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

```
obj = nb_calendar.unstruct(s)
```

Description:

Convert struct to a object.

Written by Kenneth Sæterhagen Paulsen

■ **nb_currentCalendar**

Go to: [Properties](#) | [Methods](#)

An object that will provide the current calendar.

Superclasses:

`nb_calendar`

Constructor:

```
obj = nb_currentCalendar(frequency)
```

Input:

- `frequency` : The frequency of the provided kalendar.
 - > 1 : Yearly, i.e. current date each year back in time.
 - > 2 : Semi-annually, i.e. add to each half-year back in time the current number of days since the start of the current half-year implied by todays date.
 - > 4 : Quarterly, i.e. same as for semi-annually, but for quarters instead.
 - > 12: Monthly, i.e. same as for semi-annually, but for months instead.
- Default is yearly (1).

See also:

`nb_MPRCalendar`, `nb_numDaysCalendar`

Written by Kenneth Sæterhagen Paulsen

Properties:

- `frequency`

- **frequency** ↑

The frequency of the current calendar.

Methods:

- `doOneModel`
- `getCalendar`
- `getContextIndex`
- `getDefaultStart`
- `getName`
- `getStartOfCalendar`
- `getSubClasses`
- `loadobj`
- `saveobj`
- `selectCalendar`
- `selectRecursiveCalendar`
- `shrinkCalendar`
- `struct`
- `unstruct`

► **doOneModel** ↑

```
[index, isMatch] = nb_calendar.doOneModel(model, calendar)
```

Description:

Shrink calendar to a provided window.

Input:

- `model` : The model of interest. As a `nb_model_vintages` object.
 - or
 - A cellstr with the contexts of a model. Each element on the format 'yyyymmdd'.
- `calendar` : Full calendar as a $N \times 1$ double.

Output:

- `index` : The index for the model that matches the provided calendar, as a $1 \times N$ numerical array, where N is the length of the calendar.
- `isMatch` : A $1 \times N$ logical array, if false it means that the model doesn't provide a forecast at the given date, where N is the length of the calendar.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_CALENDAR`

► **getCalendar** ↑

```
calendar = getCalendar(obj,start,finish,modelGroup,doRecursive)
```

Description:

Get calendar.

Input:

- `obj` : An object of a subclass of the `nb_calendar` class.
- `start` : Start date of calendar window, as a `nb_day` object.
- `finish` : End date of calendar window, as a `nb_day` object.
- `modelGroup` : A vector of objects of class
 `nb_model_forecast_vintages` or a `cellstr` where
 each element is on the format '`yyyymmdd`' or
 '`yyyymmddhhnnss`'.
- `doRecursive` : If the `modelGroup` input is a scalar
 `nb_model_group_vintages` object you may want to
 get the calendar of the children instead of the
 object itself. In this case this input must be
 set to true. Default is true.
- `fromResults` : Give true to take the contexts from results
 property instead of the `forecastOutput` property.

This is only supported when `modelGroup` is an array of `nb_model_vintages` objects.

Output:

- `calendar` : The calendar for the selected window, as a `N x 1 double`.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_CALENDAR`

► **getContextIndex** ↑

```
[indC,locC] = nb_calendar.getContextIndex(forecastContexts,calendar)
```

Description:

Get index of the contexts that match a set of calendar dates.

Input:

- forecastContexts : A N x 1 or 1 x N double with the contexts.
- contexts : A 1 x M or M x 1 double with the calendar dates.

Output:

- indC : A 1 x Q index of the contexts that match a set of calendar dates. Here Q <= M, and is only lower if some of the calendar dates does not match with any contexts.
- locC : A 1 x M logical. A element is true, if the calendar dates found a matching context.

Inherited from superclass NB_CALENDAR

► getDefaultStart ↑

start = nb_calendar.getDefaultStart(modelGroup, doRecursive, fromResults)

Description:

Get default start of calendar if the modelGroup is provide.

Input:

- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- start : The default start date of the calendar. As a nb_day object. Is empty ('') if modelGroup is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getName** ↑

```
name = getName(obj)
```

Description:

Get calendar name as one line char

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getStartOfCalendar** ↑

```
contextsStart = nb_calendar.getStartOfCalendar(modelGroup, doRecursive, ...  
fromResults)
```

Description:

Get first context of a set of nb_model_forecast_vintages, or the children of a scalar nb_model_group_vintages object.

Input:

- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calendar of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

► **doOneModel** ↑

```
[index,isMatch] = nb_calendar.doOneModel(model,calendar)
```

Description:

Shrink calendar to a provided window.

Input:

- model : The model of interest. As a nb_model_vintages object.
 - or
 - A cellstr with the contexts of a model. Each element on the format 'yyyymmdd'.
- calendar : Full calendar as a N x 1 double.

Output:

- index : The index for the model that matches the provided calendar, as a 1 x N numerical array, where N is the length of the calendar.
- isMatch : A 1 x N logical array, if false it means that the model doesn't provide a forecast at the given date, where N is the length of the calendar.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getCalendar ↑**

```
calendar = getCalendar(obj,start,finish,modelGroup,doRecursive)
```

Description:

Get calendar.

Input:

- obj : An object of a subclass of the nb_calendar class.
- start : Start date of calendar window, as a nb_day object.
- finish : End date of calendar window, as a nb_day object.
- modelGroup : A vector of objects of class nb_model_forecast_vintages or a cellstr where each element is on the format 'yyyymmdd' or 'yyyymmddhhnnss'.

- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.

- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- calendar : The calendar for the selected window, as a N x 1 double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getContextIndex** ↑

```
[indC,locC] = nb_calendar.getContextIndex(forecastContexts,calendar)
```

Description:

Get index of the contexts that match a set of calendar dates.

Input:

- forecastContexts : A N x 1 or 1 x N double with the contexts.

- contexts : A 1 x M or M x 1 double with the calendar dates.

Output:

- indC : A 1 x Q index of the contexts that match a set of calendar dates. Here Q <= M, and is only lower if some of the calendar dates does not match with any contexts.

- locC : A 1 x M logical. A element is true, if the calendar dates found a matching context.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getStartOfCalendar** ↑

```
contextsStart = nb_calendar.getStartOfCalendar(modelGroup, doRecursive, ...  
fromResults)
```

Description:

Get first context of a set of nb_model_forecast_vintages, or the children of a scalar nb_model_group_vintages object.

Input:

- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- contextsStart : A cellstr array with same length as the modelGroup input, each element stores the first context of the that particular model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getSubClasses** ↑

```
classes = nb_calendar.getSubClasses()
```

Description:

Get all available subclasses of the nb_calendar for your version of NB Toolbox.

Output:

- classes : A cellstr with the subclasses.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **loadobj** ↑

```
obj = nb_calendar.loadobj(s)
```

Description:

```
Load object from .mat

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR
```

► **saveobj** ↑

```
s = saveobj(obj)
```

Description:

Save object to .mat. Called by the save method.

Written by Kenneth S. Paulsen

Inherited from superclass NB_CALENDAR

► **selectCalendar** ↑

```
[index,calendar] = selectCalendar(obj,modelGroup,start,finish,...  
    doRecursive,fromResults)
```

Description:

Select the forecasts that matches the supplied calendar for each model/model group.

Input:

- obj : An object of a subclass of the nb_calendar class.
- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- start : Start date of calendar window, as a nb_day object.
- finish : End date of calendar window, as a nb_day object.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calendar of the children instead of the object itself. In this case this input must be set to true. Default is true.

Output:

- index : The index for each model that matches the provided calendar, as a 1 x nModel cell array. Each element stores a numerical array with the indexes of the forecasts of the given calendar.
- calendar : The calendar used for the given model.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **selectRecursiveCalendar ↑**

[index,calendar] = selectRecursiveCalendar(obj,modelGroup,start,finish,doRecursive)

Description:

Select the forecast that matches the supplied calendar for each model/model group recursively.

Input:

- obj : An object of a subclass of the nb_calendar class.
- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- start : Start date of calendar window, as a nb_day object.
- finish : A 1 x nContext array of nb_day objects. Each element is the end date of each recursive window.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calendar of the children instead of the object itself. In this case this input must be set to true. Default is true.

Output:

- index : The index for each model that matches the provided calendar, as a 1 x nModel cell array, each element consisting of 1 x nRec cell array, where nRec is the number of recursive periods. Each element of these again stores a numerical array with the indexes of the forecasts of the given calendar of a given recursive evaluation period.
- calendar : A 1 x nRec cell array, where nRec is the number of recursive periods. Each element of these again stores a the calendar of each recursive period.

Inherited from superclass NB_CALENDAR

► shrinkCalendar ↑

```
[calendar,ind] = nb_calendar.shrinkCalendar(calendar,start,finish)
```

Description:

Shrink calendar to a provided window.

Input:

- calendar : Full calendar as a N x 1 double.
- start : A nb_day object, or empty.
- finish : A nb_day object, or empty.

Output:

- calendar : The calendar of the provided window.
- ind : A logical of size N x 1. True for each elements kept.

Written by Kenneth SÃ¶terhagen Paulsen

obj = nb_calendar.unstruct(s)
```

Description:

Convert struct to a object.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_CALENDAR

■ nb_manualCalendar

Go to: [Properties](#) | [Methods](#)

An object that will provide a manually provided calendar.

Superclasses:

nb_calendar

Constructor:

```
obj = nb_manualCalendar(calendar)
```

Input:

- calendar : The manual calendar provided by the user. Must be a cellstr where all elements are on the format 'yyyymmdd', e.g. {'20120101','20130101'}.

See also:

[nb_currentCalendar](#), [nb_getMPRVintages4](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [calendar](#)

- **calendar** ↑

The calendar provided by the user.

Methods:

- | | | |
|-----------------------------------|---|--------------------------------------|
| • doOneModel | • getCalendar | • getContextIndex |
| • getDefaultStart | • getName | • getStartOfCalendar |
| • getSubClasses | • loadobj | • saveobj |
| • selectCalendar | • selectRecursiveCalendar | • shrinkCalendar |
| • struct | • unstruct | |

► **doOneModel** ↑

```
[index,isMatch] = nb_calendar.doOneModel(model,calendar)
```

Description:

Shrink calendar to a provided window.

Input:

- model : The model of interest. As a nb_model_vintages object.
 - or
 - A cellstr with the contexts of a model. Each element on the format 'yyyymmdd'.
- calendar : Full calendar as a N x 1 double.

Output:

- index : The index for the model that matches the provided calendar, as a 1 x N numerical array, where N is the length of the calendar.
- isMatch : A 1 x N logical array, if false it means that the model doesn't provide a forecast at the given date, where N is the length of the calendar.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► getCalendar ↑

```
calendar = getCalendar(obj,start,finish,modelGroup,doRecursive)
```

Description:

Get calendar.

Input:

- obj : An object of a subclass of the nb_calendar class.
- start : Start date of calendar window, as a nb_day object.
- finish : End date of calendar window, as a nb_day object.
- modelGroup : A vector of objects of class nb_model_forecast_vintages or a cellstr where each element is on the format 'yyyymmdd' or 'yyyymmddhhnnss'.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calendar of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- calendar : The calendar for the selected window, as a N x 1 double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getContextIndex** ↑

```
[indC,locC] = nb_calendar.getContextIndex(forecastContexts,calendar)
```

Description:

Get index of the contexts that match a set of calendar dates.

Input:

- forecastContexts : A N x 1 or 1 x N double with the contexts.
- contexts : A 1 x M or M x 1 double with the calendar dates.

Output:

- indC : A 1 x Q index of the contexts that match a set of calendar dates. Here Q <= M, and is only lower if some of the calendar dates does not match with any contexts.
- locC : A 1 x M logical. A element is true, if the calendar dates found a matching context.

Inherited from superclass NB_CALENDAR

► **getDefaultStart** ↑

```
start = nb_calendar.getDefaultStart(modelGroup,doRecursive,fromResults)
```

Description:

Get default start of calendar if the modelGroup is provide.

Input:

- modelGroup : A vector of objects of class nb_model_forecast_vintages.
- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- start : The default start date of the calendar. As a nb_day object. Is empty ('') if modelGroup is empty.

Written by Kenneth SÃ!terhagen Paulsen

Get calendar name as one line char

Written by Kenneth SÃ!terhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getStartOfCalendar** ↑

contextsStart = nb_calendar.getStartOfCalendar(modelGroup,doRecursive,...
fromResults)

Description:

Get first context of a set of nb_model_forecast_vintages, or the children of a scalar nb_model_group_vintages object.

Input:

```
- modelGroup : A vector of objects of class nb_model_forecast_vintages.  
  
- doRecursive : If the modelGroup input is a scalar  
    nb_model_group_vintages object you may want to  
    get the calender of the children instead of the  
    object itself. In this case this input must be  
    set to true. Default is true.  
  
- fromResults : Give true to take the contexts from results  
    property instead of the forecastOutput property.  
  
    This is only supported when modelGroup is an  
    array of nb_model_vintages objects.
```

Output:

```
- contextsStart : A cellstr array with same length as the modelGroup  
    input, each element stores the first context of the  
    that particular model.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_CALENDAR

■ **nb_numDaysCalendar**

Go to: [Properties](#) | [Methods](#)

An object that will provide the a calendar with X days after the end of each month, quarter, etc. E.g. if numDays is set to 10, and frequency is set to 4, you will get 10.01.2000, 10.04.2000, ...

Superclasses:

[nb_calendar](#)

Constructor:

obj = nb_numDaysCalendar(numDays, frequency)

Input:

- numDays : Number of days into the period. The frequency of the period will decide what is allowed. Default is 1.
- frequency : The frequency of the provided kalendar.
 - > 1 : Yearly, i.e. each year back in time.
 - > 2 : Semi-annually, i.e. each half-year back in time.
 - > 4 : Quarterly, i.e. each quarter back in time.
 - > 12: Monthly, i.e. each month back in time.
 - > 52: Weekly, i.e. each week back in time.Default is yearly (1).

See also:

[nb_currentCalendar](#), [nb_MPRLCalendar](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [frequency](#)
- [numDays](#)
- [frequency](#) ↑

The frequency of the current calendar.

- [numDays](#) ↑

Number of days into the period.

Methods:

- [doOneModel](#)
- [getCalendar](#)
- [getContextIndex](#)
- [getDefaultStart](#)

- [shrinkCalendar](#)
- [struct](#)
- [unstruct](#)

► [doOneModel](#) ↑

```
[index,isMatch] = nb_calendar.doOneModel(model,calendar)
```

Description:

Shrink calendar to a provided window.

Input:

- model : The model of interest. As a nb_model_vintages object.
 - or
 - A cellstr with the contexts of a model. Each element on the format 'yyyymmdd'.
- calendar : Full calendar as a N x 1 double.

Output:

- index : The index for the model that matches the provided calendar, as a 1 x N numerical array, where N is the length of the calendar.
- isMatch : A 1 x N logical array, if false it means that the model doesn't provide a forecast at the given date, where N is the length of the calendar.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getCalendar ↑**

```
calendar = getCalendar(obj,start,finish,modelGroup,doRecursive)
```

Description:

Get calendar.

Input:

- obj : An object of a subclass of the nb_calendar class.
- start : Start date of calendar window, as a nb_day object.
- finish : End date of calendar window, as a nb_day object.
- modelGroup : A vector of objects of class nb_model_forecast_vintages or a cellstr where each element is on the format 'yyyymmdd' or 'yyyymmddhhnnss'.

- doRecursive : If the modelGroup input is a scalar nb_model_group_vintages object you may want to get the calender of the children instead of the object itself. In this case this input must be set to true. Default is true.
- fromResults : Give true to take the contexts from results property instead of the forecastOutput property.

This is only supported when modelGroup is an array of nb_model_vintages objects.

Output:

- calendar : The calendar for the selected window, as a N x 1 double.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_CALENDAR

► **getContextIndex** ↑

[indC,locC] = nb_calendar.getContextIndex(forecastContexts,calendar)

Description:

Get index of the contexts that match a set of calendar dates.

Input:

- forecastContexts : A N x 1 or 1 x N double with the contexts.
- contexts : A 1 x M or M x 1 double with the calendar dates.

Output:

- indC : A 1 x Q index of the contexts that match a set of calendar dates. Here Q <= M, and is only lower if some of the calendar dates does not match with any contexts.
- locC : A 1 x M logical. A element is true, if the calendar dates found a matching context.

■ nb_LMVARTestStatistic

Go to: [Properties](#) | [Methods](#)

A class for doing the LM autocorrelation test on a nb_var object.

See the function nb_LMVARTest for more on this test.

Superclasses:

nb_test_generic

Constructor:

```
obj = nb_LMVARTestStatistic(model,varargin)
```

Input:

- model : An nb_LMVARTestStatistic object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_LMVARTestStatistic object

Written by Kenneth Sæterhagen Paulsen

Properties:

- model
- options
- results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest
- help
- print
- set
- template

► **doTest** ↑

```
obj = doTest(obj)
```

Description:

Do LM test for autocorrelated residuals. Results are stored in the property results.

Input:

- obj : An object of class nb_LMVARTestStatistic.

Output:

- obj : An object of class nb_LMVARTestStatistic.

Written by Kenneth SÃ¶therhagen Paulsen

► **help** ↑

```
help = help(~,option)
```

Description:

A method to give some basic instructions regarding input to nb_LMVARTestStatistic

Input:

- obj : A nb_LMVARTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth SÃ¶therhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_LMVARTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth SÃ¶therhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template** ↑

```
options = nb_LMVARTestStatistic.template()
```

Description:

Construct a struct which must be provided to the nb_LMVARTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ nb_archTestStatistic

Go to: [Properties](#) | [Methods](#)

A class for doing ARCH test on an nb_singleEq object.

Superclasses:

nb_test_generic

Constructor:

obj = nb_archTestStatistic(model,varargin)

Input:

- model : A nb_model_generic object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_archTestStatistic object

Written by Kenneth Sæterhagen Paulsen

Properties:

- model
- options
- results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest
 - help
 - print
 - set
 - template
-

► **doTest** ↑

```
obj = doTest(obj)
```

Description:

Do ARCH-test. Results are stored in the property results.

Input:

- obj : An object of class nb_archTestStatistic.

Output:

- obj : An object of class nb_archTestStatistic.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

```
help = help(~,option)
```

Description:

A method to give some basic instructions regarding input to nb_archTestStatistic

Input:

- obj : A nb_archTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth Sæterhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_archTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template** ↑

```
options = nb_archTestStatistic.template()
```

Description:

Construct a struct which must be provided to the nb_archTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ **nb_autocorrTestStatistic**

Go to: [Properties](#) | [Methods](#)

A class for doing autocorrelation test on a nb_singleEq object.

Superclasses:

nb_test_generic

Constructor:

```
obj = nb_autocorrTestStatistic(model,varargin)
```

Input:

- model : A nb_model_generic object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_autocorrTestStatistic object

Written by Kenneth Sæterhagen Paulsen

Properties:

- model
- options
- results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest
 - help
 - print
 - set
 - template
-

► **doTest** ↑

obj = doTest(obj)

Description:

Do autocorrelation-test. Results are stored in the property results.

Input:

- obj : An object of class nb_autocorrTestStatistic.

Output:

- obj : An object of class nb_autocorrTestStatistic.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

help = help(~,option)

Description:

A method to give some basic instructions regarding input to nb_autocorrTestStatistic

Input:

- obj : A nb_autocorrTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth SÃ¶terhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_autocorrTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth SÃ¶terhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.
Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template ↑**

options = nb_autocorrTestStatistic.template()

Description:

Construct a struct which must be provided to the nb_autocorrTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Återhagen Paulsen

■ **nb_baiPerronTestStatistic**

Go to: [Properties](#) | [Methods](#)

A class for doing Bai and Perron multiple structural break test.

See:

Bai, Jushan and Pierre Perron (1998): "Estimating and Testing Linear Models with Multiple Structural Changes," *Econometrica*, vol 66, 47-78 and

Bai, Jushan and Pierre Perron (2003): "Computation and Analysis of Multiple Structural Change Models," *Journal of Applied Econometrics*, 18, 1-22.

Constructor:

```
obj = nb_baiPerronTestStatistic(data,varargin)
```

Input:

- data : An object of class nb_ts. Can only consist of one page (dataset).

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : A nb_baiPerronTestStatistic object.

See also:

[baiPerron.pbreak](#)

Written by Kenneth Åström Paulsen

Properties:

- data • options • results

- **data** ↑

The test time-series as an nb_ts object.

- **options** ↑

The test options provided to the nb_adf, nb_phillipsPeron or the nb_kpss functions.

- **results** ↑

A struct storing the results of the test.

Methods:

- doTest • help • print • set • template

► **doTest** ↑

```
obj = doTest(obj)
```

Description:

Do the Bai-Perron structural break test. Results are stored in the property results.

Input:

- obj : An object of class nb_baiPerronTestStatistic.

Output:

- obj : An object of class nb_baiPerronTestStatistic.

Written by Kenneth SÃ¶terhagen Paulsen

► **help** ↑

```
helpText = nb_baiPerronTestStatistic.help(option)
```

Description:

Get the help on the different test options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_chowTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

obj = set(obj,varargin)

Description:

Sets the properties or fields of the options property of the nb_baiPerronTestStatistic objects.

Input:

- obj : A vector of nb_baiPerronTestStatistic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the nb_baiPerronTestStatistic.template method.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_baiPerronTestStatistic objects.

Written by Kenneth Sæterhagen Paulsen

► **template** ↑

options = nb_baiPerronTestStatistic.template()

Description:

Construct a struct which must be provided to the nb_baiPerronTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ nb_breuschGodfreyTestStatistic

Go to: [Properties](#) | [Methods](#)

A class for doing Breusch-Godfrey test on a nb_singleEq object.

Superclasses:

nb_test_generic

Constructor:

```
obj = nb_breuschGodfreyTestStatistic(model,varargin)
```

Input:

- model : A nb_model_generic object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_breuschGodfreyTestStatistic object

Written by Kenneth Sæterhagen Paulsen

Properties:

- model
- options
- results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest
 - help
 - print
 - set
 - template
-

► **doTest** ↑

```
obj = doTest(obj)
```

Description:

Do Breusch-Godfrey autocorrelation test. Results are stored in the property results.

Input:

- obj : An object of class nb_breuschGodfreyTestStatistic.

Output:

- obj : An object of class nb_breuschGodfreyTestStatistic.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

```
help = help(~,option)
```

Description:

A method to give some basic instructions regarding input to nb_breuschGodfreyTestStatistic

Input:

- obj : A nb_breuschGodfreyTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth Sæterhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_breuschGodfreyTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth SÃ¶terhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template** ↑

```
options = nb_breuschGodfreyTestStatistic.template()
```

Description:

Construct a struct which must be provided to the nb_breuschGodfreyTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ **nb_breuschPaganTestStatistic**

Go to: [Properties](#) | [Methods](#)

A class for doing the Breusch-Pagan test on an nb_singleEq object.

Superclasses:

nb_test_generic

Constructor:

```
obj = nb_breuschPaganTestStatistic(model,varargin)
```

Input:

- model : A nb_model_generic object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_breuschPaganTestStatistic object

Written by Kenneth Sæterhagen Paulsen

Properties:

- model
- options
- results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest
 - help
 - print
 - set
 - template
-

► **doTest** ↑

obj = doTest(obj)

Description:

Do Breusch-Pagan heteroscedasticity test. Results are stored in the property results.

Input:

- obj : An object of class nb_breuschPaganTestStatistic.

Output:

- obj : An object of class nb_breuschPaganTestStatistic.

Written by Kenneth SÅtterhagen Paulsen

► **help** ↑

help = help(~,option)

Description:

A method to give some basic instructions regarding input to nb_breuschPaganTestStatistic

Input:

- obj : A nb_breuschPaganTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth SÃ¶terhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_breuschPaganTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth SÃ¶terhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.
Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template ↑**

options = nb_breuschPaganTestStatistic.template()

Description:

Construct a struct which must be provided to the nb_breuschPaganTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Återhagen Paulsen

■ **nb_chowTestStatistic**

Go to: [Properties](#) | [Methods](#)

A class for doing chow test on an nb_singleEq object.

Superclasses:

nb_test_generic

Constructor:

```
obj = nb_chowTestStatistic(model,varargin)

Input:

- model : A nb_model_generic object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a
    property of the object or one of the fields of the
    options property. (See the static template method
    for more.)
```

Output:

```
- obj : An nb_chowTestStatistic
```

Written by Kenneth Åström Paulsen

Properties:

- model • options • results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest • help • plot • print • set • template

► **doTest** ↑

```
obj = doTest(obj)
```

Description:

Do Chow-test. Results are stored in the property results.

Input:

```
- obj : An object of class nb_chowTestStatistic.
```

Output:

- obj : An object of class nb_chowTestStatistic.

Written by Kenneth Sæterhagen Paulsen

► help ↑

```
help = help(~,option)
```

Description:

A method to give some basic instructions regarding input to nb_chowTestStatistic

Input:

- obj : A nb_chowTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth Sæterhagen Paulsen

► plot ↑

```
plotter = plot(obj)
```

Description:

Plot recursive chow test p-values

Input:

- obj : An object of class nb_chowTestStatistic.

Output:

- plotter : An object of class nb_graph_ts. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

► print ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_chowTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template** ↑

```
options = nb_chowTestStatistic.template()
```

Description:

Construct a struct which must be provided to the nb_chowTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ **nb_cointTest**

Go to: [Properties](#) | [Methods](#)

A class for cointegration testing of time-series stored in an nb_ts object.

Constructor:

```
obj = nb_cointTest(data,type,varargin)
```

Input:

- data : An object of class nb_ts. Can only consist of one page (dataset).

- type : A string with either:

> 'eg' : Engle-Granger single equation test.
(nb_egcoint)

> 'jo' : Johansen system test. (nb_jcoint)

Optional input:

- Depends on the type input. For information look at the documentation of the function in parentheses above.

Output:

- obj : An nb_cointTest test object.

See also:

[nb_egcoint](#), [nb_jcoint](#), [nb_ts](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- **data**
- **estimationEq**
- **options**
- **results**
- **transformation**
- **type**

- **data** ↑

The test time-series as an nb_ts object.

- **estimationEq** ↑

A 1 x n vector of nb_olsEstimator object storing the estimation results (by OLS).

- **options** ↑

The test options provided to the nb_jcoint or nb_egcoint functions.

- **results** ↑

A struct storing the results of the test. Will depend on the type of test. See the documentation of the functions nb_egcoint and nb_jcoint for more on this structure.

- **transformation** ↑

The transformation of the input data. Either:

```
> 'level'      : Do nothing (default)
> 'firstDiff'  : First difference
> 'secondDiff' : Second difference
```

- **type** ↑

The type of test.

Methods:

- **print**
- **set**

► **print** ↑

```
res = print(obj,precision)
```

Description:

Get the test results as a char.

Input:

- obj : An nb_unitRootTest object.

Output:

- results : A char with the test results.

Written by Kenneth Sæterhagen Paulsen

► set ↑

set(obj,varargin)

Description:

Set the properties of an nb_cointTest object

Input:

- obj : An object of class nb_cointTest
- varargin : ..., 'propertyName', 'propertyValue', ...

Examples:

obj.set('propertyName', 'propertyValue', ...)

Written by Kenneth S. Paulsen

■ nb_durbinWuHausmanStatistic

Go to: [Properties](#) | [Methods](#)

A class for doing the Durbin-Wu-Hausman test for exogeneity on a nb_singleEq object

Superclasses:

nb_test_generic

Constructor:

obj = nb_durbinWuHausmanStatistic(model, varargin)

Input:

- model : A nb_singleEq object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_durbinWuHausmanStatistic

Written by Kenneth Sæterhagen Paulsen

Properties:

- model • options • results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest • help • print • set • template

► **doTest** ↑

obj = doTest(obj)

Description:

Do the Durbin-Wu-Hausman test. Results are stored in the property results.

Input:

- obj : An object of class nb_durbinWuHausmanStatistic. See template for the options of the test.

Output:

- obj : An object of class nb_durbinWuHausmanStatistic.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

```
help = help(~,option)
```

Description:

A method to give some basic instructions regarding input to
nb_durbinWuHausmanStatistic

Input:

- obj : A nb_archTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth Sæterhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_durbinWuHausmanStatistic.

Output:

- res : A string with the test results.

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template ↑**

options = nb_durbinWuHausmanStatistic.template()

Description:

Construct a struct which must be provided to the nb_durbinWuHausmanStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ **nb_fTestStatistic**

Go to: [Properties](#) | [Methods](#)

A class for doing F-test on a nb_singleEq object

Superclasses:

nb_test_generic

Constructor:

obj = nb_fTestStatistic(model, varargin)

Input:

- model : A nb_singleEq object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_fTestStatistic

Written by Kenneth Sæterhagen Paulsen

Properties:

- model • options • results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest • help • print • set • template

► **doTest** ↑

obj = doTest(obj)

Description:

Do f-test. Results are stored in the property results.

Input:

- obj : An object of class nb_fTestStatistics, where the restrictions to test is stored in options.A and options.c. ($A \cdot \beta = c$)

Output:

- obj : An object of class nb_fTestStatistics.

Written by Kenneth SÃ¶terhagen Paulsen

► help ↑

```
help = help(~,option)
```

Description:

A method to give some basic instructions regarding input to nb_fTestStatistic

Input:

- obj : A nb_fTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth SÃ¶terhagen Paulsen

► print ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_fTestStatistics.

Output:

- res : A string with the test results.

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

obj = set(obj,varargin)

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template** ↑

options = nb_fTestStatistic.template()

Description:

Construct a struct which must be provided to the nb_fTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ nb_ljungBoxTestStatistic

Go to: [Properties](#) | [Methods](#)

A class for doing the Ljung-Box test on a nb_var object.

Superclasses:

nb_test_generic

Constructor:

```
obj = nb_ljungBoxTestStatistic(model,varargin)
```

Input:

- model : An nb_ljungBoxTestStatistic object.

Optional input:

- varargin : 'inputName', inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_ljungBoxTestStatistic object

Written by Kenneth Sæterhagen Paulsen

Properties:

- model
- options
- results

- [model ↑](#)

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- [options ↑](#)

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest
 - help
 - print
 - set
 - template
-

► **doTest** ↑

obj = doTest(obj)

Description:

Do Ljung-Box test. Results are stored in the property results.

Input:

- obj : An object of class nb_ljungBoxTestStatistic.

Output:

- obj : An object of class nb_ljungBoxTestStatistic.

Written by Kenneth SÃ¶therhagen Paulsen

► **help** ↑

help = help(~,option)

Description:

A method to give some basic instructions regarding input to nb_ljungBoxTestStatistic

Input:

- obj : A nb_ljungBoxTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth SÃ¶therhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_ljungBoxTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template** ↑

```
options = nb_lljungBoxTestStatistic.template()
```

Description:

Construct a struct which must be provided to the nb_archTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ **nb_sarganHansenTestStatistic**

Go to: [Properties](#) | [Methods](#)

A class for doing the Sargan-Hansen overidentification test.

See documentation of DAG for more on this test.

Superclasses:

nb_test_generic

Constructor:

```
obj = nb_sarganHansenTestStatistic(model,varargin)
```

Input:

- model : An nb_sarganHansenTestStatistic object.

Optional input:

- varargin : 'inputName',inputValue pairs. Will either set a property of the object or one of the fields of the options property. (See the static template method for more.)

Output:

- obj : An nb_sarganHansenTestStatistic object

Written by Kenneth Sæterhagen Paulsen

Properties:

- model • options • results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

Inherited from superclass NB_TEST_GENERIC

- **options** ↑

A struct storing all the options for the test.

Inherited from superclass NB_TEST_GENERIC

- **results** ↑

A struct storing the test results

Inherited from superclass NB_TEST_GENERIC

Methods:

- doTest • help • print • set • template

► **doTest** ↑

obj = doTest(obj)

Description:

Do Sargan-Hansen test. Results are stored in the property results.

Input:

- obj : An object of class nb_sarganHansenTestStatistic.

Output:

- obj : An object of class nb_sarganHansenTestStatistic.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

help = help(~,option)

Description:

A method to give some basic instructions regarding input to
nb_sarganHansenTestStatistic

Input:

- obj : A nb_sarganHansenTestStatistic object
- option : A string with the property to look up.

Output:

- help : A string with the help text.

Written by Kenneth SÃ¶terhagen Paulsen

► **print** ↑

```
res = print(obj)
```

Description:

Print test results.

Input:

- obj : An object of class nb_sarganHansenTestStatistic.

Output:

- res : A string with the test results.

Written by Kenneth SÃ¶terhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TEST_GENERIC

► **template ↑**

options = nb_sarganHansenTestStatistic.template()

Description:

Construct a struct which must be provided to the nb_sarganHansenTestStatistic class constructor.

This structure provided the user the possibility to set different test options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

■ **nb_test_generic**

Go to: [Properties](#) | [Methods](#)

A overhead class to do classical test on a nb_model_generic or a nb_estimator class.

Constructor:

Not possible to initialize an nb_test_generic object. The class is abstract.

Written by Kenneth Sæterhagen Paulsen

Properties:

- model
- options
- results

- **model** ↑

The nb_model_generic or nb_estimator object to be tested.

- **options** ↑

A struct storing all the options for the test.

- **results** ↑

A struct storing the test results

Methods:

- set
-

► **set** ↑

obj = set(obj,varargin)

Description:

Sets the properties of the nb_test_generic objects.

Caution : It will set the fields of the properties of the object.

Input:

- obj : A vector of nb_test_generic objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_test_generic objects.

Written by Kenneth Sæterhagen Paulsen

■ nb_unitRootTest

Go to: [Properties](#) | [Methods](#)

A class for unit root testing of time-series stored in an nb_ts object.

Constructor:

```
obj = nb_unitRootTest(data,type,varargin)
```

Input:

- data : An object of class nb_ts. Can only consist of one page (dataset).
- type : A string with either:
 - > 'adf' : Augmented Dickey-Fuller Test. (nb_adf)
Default.
 - > 'pp' : Phillips-Peron Test. (nb_phillipsPeron)
 - > 'kpss' : Kwiatkowski, Phillips, Schmidt and Shin test. (nb_kpss)

Optional input:

- Depends on the type input. For information look at the documentation of the function in parentheses above.

Output:

- obj : An nb_unitRootTest test object.

See also:

[nb_adf](#), [nb_phillipsPeron](#), [nb_kpss](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- data • estimationEq • options • results • transformation
- type
- **data** ↑

The test time-series as an nb_ts object.

- **estimationEq** ↑

A 1 x numberOfVariables struct storing the estimation results (by OLS).

- **options** ↑

The test options provided to the nb_adf, nb_phillipsPeron or the nb_kpss functions.

- **results** [↑](#)

A struct storing the results of the test. Will depend on the type of test. See the documentation of the functions nb_adf, nb_phillipsPeron and nb_kpss for more on this structure.

Caution : This structure will be of size 1 x
numberOfVariables. I.e. obj.results(1) stores
the test results for variable 1 in the nb_ts
object.

- **transformation** [↑](#)

The transformation of the input data. Either:

```
> 'level'      : Do nothing (default)
> 'firstDiff'  : First difference
> 'secondDiff' : Second difference
```

- **type** [↑](#)

The type of test.

Methods:

- [print](#)
 - [set](#)
-

► **print** [↑](#)

```
res = print(obj,precision)
```

Description:

Get the test results as a char.

Input:

- obj : An nb_unitRootTest object.

Output:

- results : A char with the test results.

Written by Kenneth Sæterhagen Paulsen

► **set** [↑](#)

```
set(obj,varargin)
```

Description:

Set the properties of an nb_unitRootTest object

Input:

- obj : An object of class nb_unitRootTest
- varargin : ..., 'propertyName', 'propertyValue', ...

Examples:

```
obj.set('propertyName', 'propertyValue', ...)
```

Written by Kenneth S. Paulsen

◆ **nb_LMVARTest**

```
[stat,pval] = nb_LMVARTest(residual,X,j)
```

Description:

Test for autocorrelation of residuals of a VAR model using the LM test. See section 4.3.3 of Juselius (2006).

Auxiliary regression:

```
residual(t) = A*X(t) + B*residual_(t-j) + u(t)
```

Input:

- residual : A nobs x neq double with the residuals.
- X : The models regressors, as a nobs x nxvar double. Should not include the constant!
- j : The lag (of the residual) to include in the auxiliary regression.

Output:

- stat : The test-statistics.
- pval : The p-value.

Written by Kenneth Sætherhagen Paulsen

◆ **nb_SERegression**

```
[SERegression,sumOfSqRes] = nb_SERegression(residual,numCoeff)
```

Description:

Calculates the Standard Error of the Regression and the Sum-of-Squared Residuals.

Input:

- residual : The residuals from the ols regression. As a nobs x neqs double.
- numCoeff : The number of estimated coefficients of the model. As a 1 x neqs double.

Output:

- SERegression : Standard Error of the Regression. As a double.

Calculated using the formula:

$$s = \sqrt{\text{residual}' * \text{residual} / (T - \text{numCoeff})}$$

- sumOfSqRes : Sum-of-Squared Residuals

$$S = \text{residual}' * \text{residual}$$

Written by Kenneth Åkerhagen Paulsen

◆ **nb_adf**

```
results = nb_adf(y)
[results,output] = nb_adf(y,varargin)
```

Description:

Augmented Dickey-Fuller tests for unit root. I.e. testing the null hypothesis of a unit root.

Input:

- y : A nb_ts object or a double (nobs x nvars).

Optional input:

- 'nLags' : Sets the number of lags of the estimated model to base the test upon. Default is 0.
- 'maxLags' : Sets the maximum number of lags used by the lag length criteria. Default is 10.
- 'lagLengthCrit' : Lag length selection criterion. Either:

```

> 'aic'    : Akaike information criterion
> 'aicc'   : Corrected Akaike information
               criterion
> 'maic'   : Modified Akaike information
               criterion
> 'sic'    : Schwarz information criterion
> 'msic'   : Modified Schwarz information
               criterion
> 'hqc'    : Hannan-Quinn information criterion
> 'mhqc'   : Modified Hannan-Quinn information
               criterion
> ''       : Manually set lag length.

- 'model'      : Either ('ar' is default):
> 'ar'     :  $y(t) = \beta_1 y(t-1) + \beta_2 (1-L)y(t-1) + \dots + \beta_{p+1} (1-L)y(t-p) + e(t)$ 
> 'ard'    :  $y(t) = \beta_1 + \beta_2 y(t-1) + \beta_3 (1-L)y(t-1) + \dots + \beta_{p+2} (1-L)y(t-p) + e(t)$ 
> 'ts'     :  $y(t) = \beta_1 + \beta_2 t + \beta_3 y(t-1) + \beta_4 (1-L)y(t-1) + \dots + \beta_{p+3} (1-L)y(t-p) + e(t)$ 

- 'method'    : One of;
               > 'standard' : The standard ADF test statistics.
               > 'badf'     : The backward ADF statistic sequence.
               > 'bsadf'   : The backward sup ADF statistic
                  sequence.
               > 'gsadf'   : The generalized sup ADF statistic.
               > 'bgsadf'  : The backward generalized sup ADF
                  statistic sequence.
               > 'sadf'     : The sup ADF statistic.

- 'start'     : The start date of the recursive ADF testing.

- 'draws'     : Number of draws to be used to construct the critical
               values and the p-values when the 'method' input is
               not set to 'standard'.

```

Output:

```

> When 'method' == 'standard':
- results : A struct with the estimation and test results:
> rhoTTest    : T-statisticts of the estimated coefficient
               of the lag.
> rhoPValue   : P-value of the estimated coefficient of the

```

lag. Compared to the critical values for the Dickey-Fuller Test.

```

> rhoCritValue : The rhoTTTest critical values for significance level 0.1, 0.05 and 0.01. A 1 x 3 double. If rhoTTTest > these critical values you can reject the null hypothesis of a unit root at the given significance level.

> Zdf : Dickey-Fuller rho test statistics.

> ZdfPValue : P-value of the Dickey-Fuller rho test statistics. Compared to the critical values for the Dickey-Fuller Test.

> ZdfCritValue : The Zdf critical values for significance level 0.1, 0.05 and 0.01. A 1 x 3 double. If Zdf > these critical values you can reject the null hypothesis of a unit root at the given significance level.

> When 'method' == 'standard':

> test : The wanted test statistics. May be a vector depending on the 'method' input.

> critValue : The critical values of the test for significance level 0.1, 0.05 and 0.01. A N x 3 double.. N may be > 1 depending on the 'method' input.

> pValue : The p-value(s) of the test statistics. May be a vector depending on the 'method' input.

> In both cases:

- ouput : The estimated equation as a struct of size 1 x numberOfVars. Each element consist of two fields; results and options. See the output of nb_olsEstimator.estimate for more on these output.

```

See also:

[nb_unitRootTest](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_archTest**

```
[stat,pval] = nb_archTest(residual, lags)
```

Description:

Arch test of residuals from a regression.

Input:

```
- residual : A nobs x neq double with the residuals.  
- lags      : The number of lags of the test.
```

Output:

```
- stat      : The test-statistics.  
- pval     : The p-value.
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_autocorr

```
acf = nb_autocorr(y, lags)  
[acf, lBound, uBound] = nb_autocorr(y, lags, errorBound, alpha)
```

Description:

Calculate the autocorrelation of a stationary time series.

Input:

```
- y          : A nobs x nvar double matrix with the time-series.  
- lags      : The number of lags to include  
- errorBound : A string. The data must be stationary. Either:  
               > 'asymptotic'      : Using asymptotically derived  
                           formulas.  
               > 'paramBootstrap'   : Calculated by estimating the  
                           data generating process. And  
                           use an ARIMA model to  
                           simulate artifical  
                           time-series. Then the error  
                           bands are constructed by  
                           the wanted percentile.  
               > 'blockBootstrap'   : Calculated by blocking the  
                           observed series and using  
                           these blocks to simulate  
                           artificial time-series. Then  
                           the error bands are  
                           constructed by the wanted  
                           percentile. See nb_blockBootstrap.  
                           The method use is 'random'.  
               > 'copulaBootstrap'  : The observed series is boostraped  
                           based on a copula approach. See  
                           Paulsen (2017).  
- alpha     : Significance level. As a scalar. Default is 0.05.
```

Optional inputs:

- 'constant' : 1 to include constant in the ARIMA model, otherwise 0. Default is 1.
- 'maxAR' : As an integer. See the nb_arima function. Default is 3.
- 'maxMA' : As an integer. See the nb_arima function. Default is 3.
- 'criterion' : As a string. See the nb_arima function. Default is 'aicc'.
- 'method' : As a string. See the nb_arima function. Default is 'hr'.

Output:

- acf : Autocorrelations function. As a lags x nvar double.
- lBound : Lower bound of the error bound of the autocorrelation function. As a lags x nvar double.
- uBound : Upper bound of the error bound of the autocorrelation function. As a lags x nvar double.

Written by Kenneth Sætherhagen Paulsen

◆ **nb_autocorrMat**

```
acf = nb_autocorrMat(y, lags)
acf = nb_autocorrMat(y, lags, demean)
```

Description:

Calculate the autocorrelation matrix of a set of series.

Input:

- y : A nobs x nvar x nPage double.
- lags : A non-negative integer.
- demean : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- acf : A nvar x nvar x lags + 1 x nPage double. The first page being the correlation matrix of the variables.

See also:

[nb_autocov](#), [nb_autocorr](#), [nb_autocovMat](#)

Written by Kenneth Åtterhagen Paulsen

◆ nb_autocorrMat2

```
acf = nb_autocorrMat2(y, lags)
acf = nb_autocorrMat2(y, lags, demean, shrink)
```

Description:

Calculate the autocorrelation matrix of a set of series.

Input:

- y : A nobs x nvar x nPage double.
- lags : A non-negative integer.
- demean : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.
- shrink : Set to true to use the automatic shrinkage parameter of Kwan (2011). false is default

Can also be set to a number bewteen 0 and 1. For more see the lambda input of the nb_covShrinkDiag functin.

Output:

- acf : A nvar x nvar x lags + 1 x nPage double. The first page being the correlation matrix of the variables.

See also:

[nb_autocov](#), [nb_autocorr](#), [nb_autocovMat2](#), [nb_covShrinkDiag](#)

Written by Kenneth Åtterhagen Paulsen

◆ nb_autocorrTest

```
[stat,pval] = nb_autocorrTest(residual, lags)
```

Description:

Test for autocorrelation of residuals from a regression.

Input:

- residual : A nobs x neq double with the residuals.
- lags : The number of lags of the test.

Output:

- stat : The test-statistics.
- pval : The p-value.

Written by Kenneth Sølnerhagen Paulsen

◆ nb_autocov

```
acf = nb_autocov(y, lags)
[acf, lBound, uBound] = nb_autocov(y, lags, errorBound, alpha)
```

Description:

Calculate the autocovariance of a stationary time series.

Input:

- y : A nobs x nvar double matrix with the time-series.
- lags : The number of lags to include
- errorBound : A string. The data must be stationary. Either:
 - > 'asymptotic' : Using asymptotically derived formulas.
 - > 'paramBootstrap' : Calculated by estimating the data generating process. And use an ARIMA model to simulate artificial time-series. Then the error bands are constructed by the wanted percentile.
 - > 'blockBootstrap' : Calculated by blocking the observed series and using these blocks to simulate artificial time-series. Then the error bands are constructed by the wanted percentile. See nb_blockBootstrap. The method use is 'random'.
- alpha : Significance level. As a scalar. Default is 0.05.

Optional inputs:

- 'constant' : 1 to include constant in the ARIMA model, otherwise 0. Default is 1.
- 'maxAR' : As an integer. See the nb_arima function. Default is 3.

- 'maxMA' : As an integer. See the nb_arima function. Default is 3.
- 'criterion' : As a string. See the nb_arima function. Default is 'aicc'.
- 'method' : As a string. See the nb_arima function. Default is 'hr'.

Output:

- acf : Autocovariance function. As a lags x nvar double.
- lBound : Lower bound of the error bound of the autocovariance function. As a lags x nvar double.
- uBound : Upper bound of the error bound of the autocovariance function. As a lags x nvar double.

Written by Kenneth Sølnerhagen Paulsen

◆ nb_autocovMat

```
acf = nb_autocovMat(y, lags)
acf = nb_autocovMat(y, lags, demean)
```

Description:

Calculate the autocovariance matrix of a set of series.

Input:

- y : A nobs x nvar x nPage double.
- lags : A non-negative integer.
- demean : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- acf : A nvar x nvar x lags + 1 x nPage double. The first page being the covariance matrix of the variables.

See also:

[nb_autocov](#), [nb_autocorr](#), [nb_autocorrMat](#)

Written by Kenneth Sølnerhagen Paulsen

◆ nb_autocovMat2

```
acf = nb_autocovMat2(y, lags)
acf = nb_autocovMat2(y, lags, demean, shrink)
```

Description:

Calculate the autocovariance matrix of a set of series.

Input:

- y : A nobs x nvar x nPage double.
- lags : A non-negative integer.
- demean : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.
- shrink : Set to true to use the automatic shrinkage parameter of Kwan (2011). false is default

Can also be set to a number bewteen 0 and 1. For more see the lambda input of the nb_covShrinkDiag functin.

Output:

- acf : A nvar x nvar * (lags + 1) x nPage double. Variables are looped fast, lags slow.

See also:

[nb_autocorrMat2](#), [nb_autocovMat](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_automaticModelSelection**

```
results = nb_automaticModelSelection(y, X, varargin)
```

Description:

Automatic model selection for single-equation models.

References:

- G. Sucarrat and A. Escrivano (2011): "Automated Model Selection in Finance: General-to-Specific Modelling of the Mean and Volatility Specifications"
- D. F. Hendry and H.-M. Krolzig (2005): "The Properties of Automatic Gets Modelling." Economic Journal 115, C32-C61.
- D. F. Hendry and H.-M. Krolzig (2001): "Automatic Econometric Model Selection using PcGets". London: Timberlake Consultants Press.

Input:

- y : A nobs x neqs double. (Dependent variables)
- X : A nobs x nvar double. Regressors.

Optional input:

- 'alpha' : Significance level of the arch, normality and autocorrelation test statistics used for validating models.
- 'constant' : 1 if you want to include constant, else 0. Default is 1.
- 'lags' : A double vector with the lags to test out. E.g. 1:10 or [1,3,4,5-6]
- 'criterion' : Criterion to use to select models from the sample of valid models.
- 'fixed' : The regressors to force to include in the model, and not append, lags.
- 'start' : The index to start the estimation from. Be aware that if you set this to 1 and maxLagLength > 0, then the data will include nan values, so startInd should be at least 1 + max(lags).

Output:

- results : A struct with the model selection results

Original code by Junior Maih (autmatic_model_selection method of the ts class of the RISE toolbox.). Modified by Kenneth Sæterhagen Paulsen

◆ nb_blockBootstrap

```
artificial = nb_blockBootstrap(y, draws, method, blockLength)
```

Description:

Block bootstrap time-series to generate artificial draws from the assumed data generating processes.

The time-series are assumed stationary.

Input:

- y : A nobs x nvar x npage double.
- draws : Number of draws to be made.
- method : The method to use. Either:

```

> 'overlapping'      : Overlapping block bootstrap
> 'nonoverlapping'  : Non-overlapping block bootstrap
> 'random'          : Random length overlapping block
                      bootstrap. Can in some case avoid
                      the bootstrapped sample to be
                      non-stationary.

>

- blockLength : Length of each blocks. Only for the method 'overlapping'
   and 'nonoverlapping'. Default is nobs^(1/3).

```

Output:

- artificial : A nobs x nvar x npage x draws double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_bootstrap

E = nb_bootstrap(resid,replic,method)

Description:

Bootstrap residuals

Input:

```

- resid  : A nobs x nEq double

- replic : The number of bootstrapped residuals. As an integer

- method :

  > 'bootstrap'           : Classical bootstrap by drawing a sample
                             with replacement.

  > 'wildBootstrap'       : Create artificial data by wild
                             bootstrap.

  > 'blockBootstrap'      : Create artificial data by
                             non-overlapping block bootstrap.

  > 'mBlockBootstrap'     : Create artificial data by
                             overlapping block bootstrap.

  > 'rBlockBootstrap'     : Create artificial data by
                             overlapping random block length
                             bootstrap.

  > 'dependentWildBootstrap' : Create artificial data by dependent
                             wild bootstrap.

```

```
> 'wildBlockBootstrap'      : Create artificial data by wild  
                           overlapping random block length  
                           bootstrap.
```

Output:

- E : A nEq x replic x nobs double

Written by Kenneth Sæterhagen Paulsen

◆ **nb_boxPierceQTest**

```
boxQTest = nb_boxPierceQTest(residual,nlag)
```

Description:

Box-Pierce Q-test

Inspired by the vare function of LeSage.

Input:

- residual : A double vector of residuals from an ols estimation.
- nlag : The number of lags. Default is 1. As a scalar.

Output:

- boxQTest : A scalar with the result of the Box-Pierce Q-test.

Written by Kenneth S. Paulsen

◆ **nb_breuschGodfreyTest**

```
[stat,pval] = nb_breuschGodfreyTest(residual,X,lags)
```

Description:

Test for autocorrelation of residuals from a regression using the Breusch-Godfrey test.

Caution: It will test each equation individually.

Input:

- residual : A nobs x neq double with the residuals.
- X : The models regressors, as a nobs x nxvar double. Should not include the constant!
- lags : Number of lags of the residual in the auxiliary regression.

Output:

- stat : The test-statistics.
- pval : The p-value.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_breuschPaganTest**

```
[stat,pval] = nb_breuschPaganTest(residual,X)
```

Description:

Test for heteroscedasticity of residuals from a regression using the Breusch-Pagan test.

This test is corrected for possible non-normality in the residuals based on Koenker(1981) and Koenker and Bassett (1982).

Caution: It will test each equation individually.

Input:

- residual : A nobs x neq double with the residuals.
- X : The models regressors, as a nobs x nxvar double. The constant should not be included.

Output:

- stat : The test-statistics.
- pval : The p-value.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_calcRoots**

```
[realD,imagD,modulus] = nb_calcRoots(model)
```

Description:

Calculates the roots of the companion from of the model.

If the modulus is larger than 1 for any of the roots the model is not stable.

Input:

- A : The transition matrix of the model.

Output:

- realD : The real part of the roots.
- imagD : The imaginary part of the roots.
- modulus : The modulus of the roots.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_cfsTest**

```
test = nb_cfsTest(X,varargin)
```

Description:

This function implements the procedure suggested by Barigozzi and Trapani (2018) to determine the dimension of the common factor space in a large, possibly non-stationary, dataset.

References:

Barigozzi and Trapani (2018), "Determining the dimension of factor structures in non-stationary large datasets", Discussion Papers 18/01, University of Nottingham, Granger Centre for Time Series Econometrics.

Trapani (2018), "A Randomized Sequential Procedure to Determine the Number of Factors", Journal of American Statistical Associations, vol. 113, no. 523, 1341-1349.

Input:

- X : A nobs x nvar double.

Optional input:

- 'alpha' : Significance level of the test. Default is 0.05. Must be in (0,1).
- 'k' : Select the value of the k parameter of the paper. Either '1', 'p' or 'p+1'. Default is '1'.
- 'u' : Select the bound during randomization procedure. Default is sqrt(2). The actual limits will be +- this number.

Output:

```
- test : A struct with fields:  
  
    > 'r'      : Estimated total number of factors.  
  
    > 'r1'     : 1 if the data is estimated to have factors with  
                  linear trends, otherwise 0.  
  
    > 'r2'     : Estimated number of zero-mean I(1) factors;  
                  r2 = rStar - r1.  
  
    > 'r3'     : Estimated number of I(0) factors; r3 = r - rStar.  
  
    > 'rStar'   : Estimated number of non-stationary common factors.
```

Examples:**See also:**

[nb_pca](#), [nb_trapaniNFactorTest](#)

Written by Kenneth Åtterhagen Paulsen

◆ **nb_chowTest**

```
results = nb_chowTest(y,X,constant,timeTrend,breakPoint)
```

Description:

Test for breaks in the estimated coefficients. Null is no breaks.

Input:

- y : A double matrix of size nobs x 1 of the dependent variable of the regression.
- x : A double matrix of size nobs x nxvar of the right hand side variables of the equation of the regression.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second)
- breakpoint : Index of breakpoint. As a numeric scalar.

Output:

```

- results : A struct with the fields:

    > chowTest : Chow test statistic for structural
      break.

    > chowProb : P-value of test statistic.  $F(k, T-2k)$ 
      distributed.

```

nb_ols

Written by Kenneth S. Paulsen

◆ nb_copulaBootstrap

```
artificial = nb_copulaBootstrap(y, draws, method, lags)
```

Description:

Copula bootstrap time-series to generate artificial draws from the assumed data generating processes.

The time-series are assumed stationary.

Input:

```

- y      : A nobs x nvar x npage double.

- draws  : Number of draws to be made.

- method : The method to use. Either:

    > 'autocorr'       : Univariate, autocorrelation robust.

- lags   : Number of lags of the autocorrelation of the series to use.
      Default is min(ceil(nobs^(1/3))), 5.

```

Output:

```
- artificial : A nobs x nvar x npage x draws double.
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_cucconiTest

```
[CT,pValue] = nb_cucconiTest(x,y)
```

Description:

Implements the Cucconi test for equal location and scale of two random samples coming from two different distributions. The H0 is that the distributions are equal. So a p-value < alpha means that you can reject that the distributions are equal.

Input:

- x : A n x 1 double. n > 6.
- y : A m x 1 double. m > 6.

Output:

- CT : The Cucconi test statistics.
- pValue : The p-value of the test.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_durbinWatson**

```
dwtest = nb_durbinWatson(residual)
dwtest = nb_durbinWatson(y,x,beta)
```

Description:

Durbin-Watson Statistic.

Input:

- y : The dependent variable as a double or the residual if only one input is provided. Must be a nobs x neqs double.
- x : The right hand side variables of the regression. Must be a nobs x neqs double.
- beta : Estimated coefficients. As a ncoeff x neqs double.

Output:

- dwtest : Durbin-Watson Statistic. A 1 x neqs double.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_durbinWuHausman**

```
[test,pval] = nb_durbinWuHausman(y,x,z,inst,constant,timeTrend)
```

Description:

Durbin-Wu-Hausman test for regressors exogeneity.

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x nxvar of the exogenous variables of all equations of the regression.
- z : A double matrix of size nobs x nzvar of the endogenous variables of all equations of the regression.
- inst : A 1 x nzvar cell of the instruments for each endogenous variable. Each element must be a double with size nobs x nzivar. nzivar must be greater than 0.
- constant : If a constant is wanted in the estimation.
- timeTrend : If a linear time trend is wanted in the estimation.

Output:

- test : Durbin-Wu-Hausman statistic. A 1 x 1 double.
- pval : P-value of the test statistic. The test statistic is distributed as F(nzvar,nobs - nzvar - nxvar).

Written by Kenneth Sæterhagen Paulsen

◆ **nb_egcoint**

```
results      = nb_egcoint(y)
[results,model] = nb_egcoint(y,varargin)
```

Description:

Engle-Granger cointegration test. Using Dickey-Fuller test for unit root of the residual from the cointegration equation
 $y_1 = X \cdot a + Y_2 \cdot b + e$.

All the variables in the input y will be included in the cointegration test equation.

Input:

- y : An nb_ts object.

Optional input:

```

- 'dependent'      : The variable which are decleared as the
                      left-hand side variable of the cointegration
                      test equation. As a string.

- 'test'           : Either:

> 'adf' : Dickey-Fuller test.

- 'nLags'          : Sets the number of lags of the estimated
                      residual model to base the test upon. Default
                      is 0. ('adf')

- 'maxLags'        : Sets the maximum number of lags used by the
                      lag length criteria. Default is 10. ('adf')

- 'lagLengthCrit' : Lag length selection criterion ('adf').
                     Either:

> 'aic'   : Akaike information criterion

> 'aicc'  : Corrected Akaike information
                     criterion

> 'maic'  : Modified Akaike information
                     criterion

> 'sic'   : Schwarz information criterion

> 'msic'  : Modified Schwarz information
                     criterion

> 'hqc'   : Hannan-Quinn information criterion

> 'mhqc'  : Modified Hannan-Quinn information
                     criterion

> ''      : Manually set lag length.

- 'model'          : y1 = X*a + Y2*b + e ('c' is default):

> 'no'   : No constant or trend in X.

> 'c'    : Constant but no trend in X.

> 'ct'   : Constant and linear trend in X.

> 'ctt'  : Constant, linear trend, and
                     quadratic trend in X.

```

Output:

```

- results : A struct with the estimation and test results:

> rhoTTest       : T-statisticts of the estimated coefficient
                      of the lag. ('adf')

> rhoPValue      : P-value of the estimated coefficient of the
                      lag. Compared to the critical values for the
                      (spurious regression adjusted) Dickey-Fuller

```

```

Test. ('adf')

> rhoCritValue : The rhoTTTest critical values for significance
level 0.1, 0.05 and 0.01. A 1 x 3 double.
If rhoTTTest > these critical values you can
reject the null hypothesis of a unit root (of
the residual) at the given significance
level. ('adf')

> cointVec : The cointegrated vector. Will include the
a as well. I.e. [a,b].

- model : The estimated equation as 1 x 2 struct. See the output
of the nb_olsEstimator function for more on these.

> model(1) : OLS estimation of the cointegration eq.

> model(2) : OLS estimation of the residual unit root
test eq.

```

See also:

[nb_cointTest](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_fTest**

```
[fTest,fProb] = nb_fTest(residual1,residual2,nCoeff1,nCoeff2)
```

Description:

Calculates the F-statistics for beta = 0 restrictions.

```
RSS1 = residual1'*residual1;
RSS2 = residual2'*residual2;
fTest = ((RSS1 - RSS2)/(nCoeff2 - nCoeff1))/(RSS2/(T - nCoeff2));
```

Input:

- residual1 : Residuals from the restricted model.
- residual2 : Residuals from the unrestricted model.
- nCoeff1 : Number of estimated coefficients of the restricted model.
- nCoeff2 : Number of estimated coefficients of the unrestricted model.

Output:

- fTest : F-statistic

- fProb : F-test statistic p-value.

Written by Kenneth Sæterhagen Paulsen

◆ nb_grangerTest

```
[F,FPValue] = nb_grangerTest(x,y,alpha,max_lag)
```

Description:

Granger Causality test. Does Y Granger Cause X?

References:

[1] Granger, C.W.J., 1969. "Investigating causal relations by econometric models and cross-spectral methods". *Econometrica* 37 (3), 424438.

Input:

- x : A nobs x 1 double.
- y : A nobs x 1 double.
- alpha : The significance level of the test.
- max_lag : The maximum number of lags to be considered.
- criterion : Lag length selection criterion. See the nb_lagLengthSelection function for more on this input. Default is 'aic'.

Output:

- F : The value of the F-statistic
- FPValue : The p-value of the F-statistic.

Written by Kenneth Sæterhagen Paulsen

◆ nb_hornParallelAnalysis

```
[sMEV,ciEV,cumE,resL2,nBasis] = nb_hornParallelAnalysis(data,K)
```

Description:

This function simulates a distribution of eigenvalues by resampling a set of random variables of the real data size, and compares the eigenvalues of the real data and the distribution of eigenvalues from simulation; then the number of retained basis factors is decided by keeping those who are bigger than 95% of simulated distribution of eigenvalues. This is to implement the parallel analysis approach proposed by Horn (1965) and developed by Ledesma et al. (2007).

Input:

- data : Standardized real data (subtract mean and divide by std for each variable);
- K : Number of resampling.

Output:

- sMEV : Mean eigenvalues from simulation.
- ciEV : Confidence intervals of eigenvalues from simulation.
- cumE : cumulative energy content / total energy content
- resL2 : L2 norm of residual for each eigenvalue of real data;
- nBasis : Number of retained basis factors.

Written by Lanya T. Cai on June 22 2016.

- Corrected documentation to fit NB toolbox

◆ nb_infoCriterion

```
infoCrit = nb_infoCriterion(type, loglogLikelihood, T, numCoeff)
```

Description:

Calculates the information criterion for a model given the logLikelihood, sample size and number of coefficients.

All input but the first can be given as vectors (of same size).

Input:

- type : Either:
 - > 'aic' : Akaike information criterion.
 - > 'aicc' : Corrected Akaike information criterion.
 - > 'maic' : Modified Akaike information criterion.
 - > 'sic' : Schwarz information criterion.
 - > 'msic' : Modified Schwarz information criterion.
 - > 'hqc' : Hannan and Quinn information criterion.
 - > 'mhqc' : Modified Hannan and Quinn information criterion.
- loglogLikelihood : The models log logLikelihood. As a 1 x neq

```

double.

- T          : Size of estimation sample. As a scalar.

- numCoeff    : The number of estimated coefficients of the
               model. A 1 x neq double.

- kappa       : Modifiying element for the 'maic', 'msic'
               and 'mhqc' criterion. A 1 x neq double.

```

Output:

```
- infoCrit : The calculated information criterion. A 1 x neq
            double.
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_jcoint**

```
results      = nb_jcoint(y)
[results,models] = nb_jcoint(y,varargin)
```

Description:

Johansen cointegration test.

All the variables in the input y vil be included in the cointegration test equation.

There are still some unfinished business here!!!!

Input:

```
- y          : An nb_ts object or a nobs x nVars double.
```

Optional input:

```
- 'model'      : (1-L)y(t) = A*B'*y(t-1) + D*x
                  + B1*(1-L)y(t-1) + ... + Bq*(1-L)y(t-q)
                  + e(t)

                  Form of A*B'*y(t-1) + D*x

> 'H2'   : A*B'*y(t-1). There are no intercepts
            or trends in the cointegrating
            relations and there are no trends
            in the data. This model is only
            appropriate if all series have zero
            mean. Default.

> 'H1*' : A*(B'*y(t-1) + c0). There are
            intercepts in the cointegrating
            relations and there are no trends
            in the data. This model is
```

appropriate for nontrending data
with nonzero mean.

```

> 'H1'   : A*(B'*y(t-1) + c0) + c1. There are
           intercepts in the cointegrating
           relations and there are linear
           trends in the data. This is a model
           of "deterministic cointegration,"
           where the cointegrating relations
           eliminate both stochastic and
           deterministic trends in the data.
           This is the default value.

> 'H*'   : A*(B'*y(t-1) + c0 + d0*t) + c1.
           There are intercepts and linear
           trends in the cointegrating
           relations and there are linear
           trends in the data. This is a model
           of "stochastic cointegration,"
           where the cointegrating relations
           eliminate stochastic but not
           deterministic trends in the data.

> 'H'    : A*(B'*y(t-1) + c0 + d0*t) + c1 + d1*t.
           There are intercepts and linear
           trends in the cointegrating
           relations and there are quadratic
           trends in the data. Unless quadratic
           trends are actually present in the
           data, this model may produce good
           in-sample fits but poor
           out-of-sample forecasts.

'hypo'      : String. Either ('trace' is default):

> 'trace'  : The alternative hypothesis is
           H(num). Statistics are:
           -T*[log(1-lambda(h+1)) + ... +
           log(1-lambda(num))]

> 'maxeig'. The alternative hypothesis is
           H(h+1).

           -T*log(1-lambda(h+1))

- 'nLags'   : Sets the number of lags of the estimated
               model to base the test upon. Default is 0.

- 'maxLags' : Sets the maximum number of lags used by the
               lag length criteria. Default is 10.

- 'lagLengthCrit' : Lag length selection criterion. Either:

> 'aic'    : Akaike information criterion

> 'aicc'   : Corrected Akaike information
               criterion
```

```

> 'maic' : Modified Akaike information
criterion

> 'sic' : Schwarz information criterion

> 'msic' : Modified Schwarz information
criterion

> 'hqc' : Hannan-Quinn information criterion

> 'mhqc' : Modified Hannan-Quinn information
criterion

> ''      : Manually set lag length. Default

- 'mlresults' : Give 1 if you want to report the maximal
likelihood estimates.

```

Output:

```

- results : A struct with the estimation and test results:

    Test results:

        > lambda    : Eigenvalues. 1 x h double.*

        > eigVec    : The corresponding eigenvectors.

        > testStat   : Test-statistic. 1 x h double.*

        > pValue     : P-values. 1 x h double.*

        > critValue : Critical values. 3 x h double.* 1%
                      5% and 10%.

```

*h = Max number of possible cointegrated relations.

```

- models : The estimated equation as 1 x 2 struct. See the results
output of the nb_olsEstimator.estimate function for more
on this output.

    > models(1) : OLS estimation of the differenced eq.

    > models(2) : OLS estimation of the lagged level eq.

```

See also:

[nb_cointTest](#)

Written by Kenneth Åkerhagen Paulsen

◆ **nb_lagLengthSelection**

```

nlags = nb_lagLengthSelection(y,X,constant,time_trend, ...
                               maxLagLength,criterion,method)

```

Description:

Lag length selection algorithm.

Input:

- constant : 1 if constant should be included in the regression, otherwise 0.
- time_trend : 1 if time trend should be included in the regression, otherwise 0.
- maxLagLength : The maximal number of tested lags. As a double.
- criterion : The criterion to use for the selection.
 - > 'aic' : Akaike information criterion
 - > 'maic' : Modified Akaike information criterion
 - > 'sic' : Schwarz information criterion
 - > 'msic' : Modified Schwarz information criterion
 - > 'hqc' : Hannan-Quinn information criterion
 - > 'mhqc' : Modified Hannan-Quinn information criterion
- method : The estimation method to use.
 - > 'ols' : Ordinary least squares. Assumes that the residual are normally distributed.
 - > 'quantile' : Quantile regression. Assumes that the residual are normally distributed. This may be a bad assumption!
- y : Dependent variable. As an nobs x 1 double.
- X : Exogenous regressors. As an nobs x nvar double.
- fixed : Indicate if an exogenous regressor should have fixed lag length. A 1 x nvar logical.
- startInd : The index to start the estimation from. Be aware that if you set this to 1 and maxLagLength > 0, then the data will include nan values, so startInd should be at least 1 + maxLagLength.

Output:

- nlags : Number of (extra) lags selected for the provided model.
- y : Dependent variable(s). Shrunked to the new sample.

- X : Selected regressors. (Without constant and time-trend). Shrunked to the new sample.

Written by Kenneth Sæterhagen Paulsen

◆ nb_ljungBoxTest

```
[stat,pval] = nb_ljungBoxTest(residual,k)
```

Description:

Test for autocorrelation of residuals from a regression using the Ljung-Box test. Only for a VAR model.

Input:

- residual : A nobs x neq double with the residuals.
- k : Number of lags of the VAR, as an integer.

Output:

- stat : The test-statistics.
- pval : The p-value.

Written by Kenneth Sæterhagen Paulsen

◆ nb_normalityTest

```
[stat,pval] = nb_normalityTest(residual)
[stat,pval] = nb_normalityTest(residual,k)
```

Description:

This is the Jarque-Bera test, which test for normality. Null hypothesis of the test is that the series y is normal.

Input:

- residual : A nobs x neq double.
- k : Number of estimated parameters of the model.

Output:

- stat : The test-statistic. As a 1 x neq double.
- pval : The p-values. As a 1 x neq double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_olsConfInt

```
confInt = nb_olsConfInt(beta, stdBeta, nobs)
```

Description:

Confidence intervals of estimated parameters.

Input:

- beta : A nvar x 1 double with the estimated parameters.
- stdBeta : A nvar x 1 double with the std of the estimated parameters.
- nobs : Number of observation of the estimation. As an integer.
- alpha : The critical value. Default is 0.05.

Output:

- confInt : Confidence intervals. A nvar x 2 matrix. With lower and upper limit.

Examples:

See also:

Written by Kenneth Sætherhagen Paulsen

◆ nb_olsLikelihood

```
logLikelihood = nb_olsLikelihood(residual)
logLikelihood = nb_olsLikelihood(residual, method, numCoeff)
```

Description:

Calculate the log likelihood of an ols regression based on the residuals.

Input:

- residual : The residuals from the ols regression. As a nobs x neqs double. The equations must be unrelated or have the same regressors.
- method : Either 'full' (full likelihood of the system) or 'single' (individually likelihood calculations).
 - 'single' : Uses the equation (24.9) in EViews 6 User's Guide 2
 - 'full' : Uses the equation (34.4) in EViews 6 User's Guide 2

Output:

- logLikelihood : The log likelihood of the ols regression.
As a 1 x neqs double.

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_parcorr**

```
pacf = nb_parcorr(y, lags)
[pacf, lBound, uBound] = nb_parcorr(y, lags, errorBound, alpha)
```

Description:

Calculate the partial autocorrelation of a stationary time series.

Input:

- y : A nobs x nvar double matrix with the time-series.
- lags : The number of lags to include
- errorBound : A string. The data must be stationary. Either:
 - > 'asymptotic' : Using asymptotically derived formulas.
 - > 'paramBootstrap' : Calculated by estimating the data generating process. And use an ARIMA model to simulate artificial time-series. Then the error bands are constructed by the wanted percentile.
 - > 'blockBootstrap' : Calculated by blocking the observed series and using these blocks to simulate artificial time-series. Then the error bands are constructed by the wanted percentile. See nb_blockBootstrap. The method use is 'random'.
- alpha : Significance level. As a scalar. Default is 0.05.

Optional inputs:

- 'constant' : 1 to include constant in the ARIMA model, otherwise 0. Default is 1.
- 'maxAR' : As an integer. See the nb_arima function. Default is 3.

- 'maxMA' : As an integer. See the nb_arima function. Default is 3.
- 'criterion' : As a string. See the nb_arima function. Default is 'aicc'.
- 'method' : As a string. See the nb_arima function. Default is 'hr'.

Output:

- pacf : Partial autocorrelations function. As a lags x nvar double.
- lBound : Lower bound of the error bound of the partial autocorrelation function. As a lags x nvar double.
- uBound : Upper bound of the error bound of the partial autocorrelation function. As a lags x nvar double.

Written by Kenneth Å!terhagen Paulsen

◆ **nb_phillipsPerron**

```
results = nb_phillipsPerron(y)
[results,model] = nb_phillipsPerron(y,varargin)
```

Description:

Phillips-Perron tests for unit roots.

Input:

- y : An nb_ts object.

Optional input:

- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use the Newey-West selection criterion.
- 'bandWidthCrit' : Band width selection criterion. Either:
 - > 'nw' : Newey-West selection method.
Default. (Newey West, 1994)
 - > 'a' : Andrews selection method.
(Andrews, 1991)
- 'freqZeroSpectrumEstimator' :
 - Either:
 - > 'bartlett' : Bartlett kernel function.

```

Default.

> 'parzen'      : Parzen kernel function.

> 'quadratic'  : Quadratic Spectral kernel
                  function.

- 'model'        : Either:

> 'ar'   :  $y(t) = \rho y(t-1) + e(t)$  (Default)

> 'ard'  :  $y(t) = \alpha + \rho y(t-1) + e(t)$ 

> 'ts'   :  $y(t) = \alpha + \delta t + \rho y(t-1) + e(t)$ 

```

Output:

- results : A struct with the estimation and test results
(See page 514 in Hamilton):
 - > Zt : Zt test statistics.
 - > ZtPValue : P-value of the Zt test statistics.
 - > ZtCritValue : The Zt critical values for significance level 0.1, 0.05 and 0.01. A 1 x 3 double.
If Zdf > these critical values you can reject the null hypothesis of a unit root at the given significance level.
- model : The estimated equation as a struct with fields results and options. See the nb_olsEstimator.estimate function for more.

◆ nb_quantileWaldTest

```
[wTest,wProb] = nb_quantileWaldTest(A,b,X,beta,residual,q)
```

Description:

Calculates the Wald-statistics for a general linear restriction.

$A * \beta = c$

This will be the null hypotheses, and we can reject it if wProb < alpha, where alpha is the choosen significance level.

Input:

- A : A nrestrictions x ncoeff*nq double with the linear restrictions of the estimated coefficients (beta).
- c : A nrestrictions x 1 double with what the linear restrictions should equal.
- X : The right hand side regressors. As a nobs x ncoeff matrix.
- beta : A ncoeff*nq x 1 double with the estimated coefficients. We allow for beta to include estimated coefficients of different quantiles q (nq>1). We order the coefficients [coeff(q(1));coeff(q(2));...], i.e. in the order of the input q.
- residual : A nobs x nq double with the residual from the regression. NOTE: Not in use at the moment! If we allow for departure IID and the normality approximation we need to use an empirical estimate of the sparsity function based on these residuals!
- q : A 1 x nq double with the quantiles. Must be in [0,1].

Output:

- wTest : Wald-statistic
- wProb : Wald-test statistic p-value.

Written by Kenneth Sæterhagen Paulsen

◆ nb_rSquared

```
[rSquared,adjRSquared] = nb_rSquared(y,x,beta)
```

Description:

Calculate R-Squared and/or adjusted R-Squared of (an) estimated equation(s).

Inspired by the vare function of LeSage.

Input:

- y : A double vector with the dependent variable of the regression. A double matrix nobs x neqs.
- residual : The residual of the regression. A double vector nobs x neqs.
- numCoeff : The number of estimated parameters of the model. As 1 x neqs double.

Output:

```
- rSquared      : As 1 x neqs double.  
- adjRSquared : As 1 x neqs double.
```

Written by Kenneth S. Paulsen

◆ nb_restrictedFTest

```
[fTest,fProb] = nb_restrictedFTest(A,b,X,beta,residual)
```

Description:

Calculates the F-statistics for a general linear restriction.

A*beta = c

This will be the null hypotheses, and we can reject it if fProb < alpha, where alpha is the choosen significance level.

Input:

- A : A nrestrictions x ncoeff double with the linear restrictions of the estimated coefficients (beta).
- c : A nrestrictions x 1 double with what the linear restrictions should equal.
- X : The right hand side regressors. As a nobs x ncoeff matrix.
- beta : A ncoeff x 1 double with the estimated coefficients
- residual : A nobs x 1 double with the residual from the regression.

Output:

- fTest : F-statistic
- fProb : F-test statistic p-value.

Written by Kenneth Sæterhagen Paulsen

◆ nb_sarganHansen

```
[test,pval] = nb_sarganHansen(residual,x,z,inst,overident,constant,...  
                                timeTrend)
```

Description:

Sargan-Hansen test for instruments validity. Only for overidentified models.

For more see the documentation of DAG.

Input:

- residual : A double matrix of size nobs x neq of the residual from the overidentified regression(s).
- x : A double matrix of size nobs x nxvar of the exogenous variables of all equations of the regression.
- inst : A nobs x nivar double of the instruments for all the endogenous variables.
- overident : The number of overidentifying restrictions. I.e. the number of instruments which are included in the "equations" of the endogenous variables, but not in the estimated equation.
- constant : If a constant is wanted in the estimation.
- timeTrend : If a linear time trend is wanted in the estimation.

Output:

- test : Sargan-Hansen statistic. A 1 x 1 double.
- pval : P-value of the test statistic. The test statistic is distributed as F(nzvar,nobs - nzvar - nxvar).

Written by Kenneth Sæterhagen Paulsen

◆ nb_shockDecomp

```
decomp = nb_shockDecomp(model,options,results,startInd,endInd,inputs)
```

Description:

Shock decomposition of a model on the companion form as below.

Caution : For models with unobservables the filter method must be run first.

Caution : This method does not allow parameter uncertainty for filtered models.

Input:

- model : A struct storing the companion form of the model:

$$y_t = A*y_{t-1} + B*x_t + C*e_t$$

Fields:

> A : See the equation above. A nendo x nendo double.

> B : See the equation above. A nendo x nexo

```

double.

> C      : See the equation above. A nendo x nresidual
double.

> endo   : A cellstr with the decleared endogenous
variables.

> exo    : A cellstr with the decleared exogenous
variables.

> res    : A cellstr with the decleared
residuals/shocks.

> vcv    : Variance/covariance matrix of the
residuals/shocks.

- options   : Estimation options. Output from the estimator functions.
E.g. nb_olsEstimator.estimate.

- results   : Estimation results. Output from the estimator functions.
E.g. nb_olsEstimator.estimate.

- startInd : Start index of the shock decomposition.

- endInd   : End index of the shock decomposition.

- inputs    : See nb_model_generic.shock_decomposition.

```

Output:

```

- decomp   : If perc is empty; A nObs x [nShock (1:end-1) + initial
conditions (end-1) + steady-state (end)] x nVar, otherwise;
A nObs x [nShock (1:end-1) + initial conditions (end-1) +
steady-state (end)] x nVar x nPerc + 1, where the closest
model to the median is located at decomp(:,:, :, end)

Caution : Initial conditions are all that is not explained
by the shocks.

Caution : Please have in mind that the percentiles are
the numerically calculated percentiles and will
not sum up the actual series!

```

See also:

◆ **nb_smirnovTest**

[ST,pValue] = nb_smirnovTest(x,y,m,n)

Description:

Implements the Smirnov test for equal distributions of two random samples coming from two different distributions. The H0 is that the distributions are equal. So a p-value < alpha means that you can reject that the distributions are equal.

Caution: It is assumed that the provided CDF are given at the same domain!

Input:

- x : A n x 1 double with the CDF of the first distribution. n > 6.
- y : A m x 1 double with the CDF of the second distribution. m > 6.
- m : Number of observations the estimation of the CDF of the first distribution is based on.
- n : Number of observations the estimation of the CDF of the second distribution is based on.

Output:

- CT : The Smirnov test statistics.
- pValue : The p-value of the test.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_spearmanTest**

```
[tTest,pVal] = nb_spearmanTest(X,beta,resid)
```

Description:

Spearman correlation test for heteroskedacity.

Input:

- X : The right hand side variables of the regression. Must be a nobs x 1 double.
- beta : Estimated coefficients. As a ncoeff x 1 double.
- resid : Residual of regression. Must be a nobs x 1 double

Output:

- tTest : Spearman Statistic. A 1 x 1 double.
- pVal : P value of test.

Written by Kenneth Sæterhagen Paulsen

◆ nb_trapaniNFactorTest

```
r = nb_trapaniNFactorTest(X)
```

Description:

This function implements a test for the number of common components in a large dataset based on the eigenvalues of the matrix $X'X/T$.

References:

Trapani (2018), "A Randomized Sequential Procedure to Determine the Number of Factors", Journal of American Statistical Associations, vol. 113, no. 523, 1341-1349.

Input:

- X : A nobs x nvar double.

Optional input:

- 'alpha' : Significance level of the test. Default is 0.05. Must be in (0,1).
- 'k' : Select the value of the k parameter of the paper. Either '1', 'p' or 'p+1'. Default is '1'.
- 'u' : Select the bound during randomization procedure. Default is $\sqrt{2}$. The actual limits will be \pm this number.

Output:

- 'r' : Estimated total number of factors.

See also:

Written by Kenneth Sæterhagen Paulsen

◆ nb_varFTest

```
[fTest,fProb] = nb_varFTest(y,nlag,x,beta,constant)
```

Description:

Joint F-test

Inspired by the vare function of LeSage.

Input:

```

- y           : A double vector with the dependent variable of the
                regression. A double vector nobs x 1.

- nlag        : The number of lags of the VAR. Default is 1.

                !!! Should be made specific to each endogenous var.

- x           : Dependent or number of inputs:

                - 2 : Taken as the residual of the regression.
                      A double vector nobs - nlag x 1.

                - 3 : Taken as the right hand side matrix of the
                      estimation. A double vector nobs x nxvar.

- beta        : The estimated parameters of the model. As a double
                vector of size nxvar x 1.

```

Output:

```
- boxQTest : A scalar with the result of the Box-Pierce Q-test.
```

Examples:

Written by Kenneth S. Paulsen

◆ **nb_whiteTest**

```
[test,prob] = nb_whiteTest(residual,X)
```

Description:

White (1980) test for heteroscedasticity.

Input:

```
- residual : Residuals from the model. As a nobs x 1 double.

- X         : Regressors from the model. As a nobs x nxvar double. Should
               not include a constant.
```

Output:

```
- test   : Test statistic

- fProb : P-value of test
```

► nb_mcmc.NUTS ↑

```
[theta, alpha_ave, nfevals, logp, grad] = nb_mcmc.NUTS(f, epsilon, ...
theta0, maxTreeDepth, lb, ub, logp0, grad0)
```

Description:

Carries out one iteration of No-U-Turn-Sampler.

Input:

- f : A function_handle that returns the log probability of the target and its gradient.

- epsilon : A scalar double. Step size of leap-frog integrator.
- theta0 : A nVar x 1 double. Current state of a Markov chain and the initial state for the trajectory of Hamiltonian dynamics.
- maxTreeDepth : An integer with the maximum depth of tree.
- lb : A nVar x 1 double with the lower bounds on the parameters. Give -inf for elements that is not bounded. Give [] if no parameters are bounded.
- ub : A nVar x 1 double with the upper bounds on the parameters. Give inf for elements that is not bounded. Give [] if no parameters are bounded.
- logp0 : A nVar x 1 double. The log probability computed at theta0.
- grad0 : A nVar x 1 double. Gradient of the log probability computed at theta0.

Output:

- theta : Next state of the chain, as a nVar x 1 double.
- alpha_ave : Average acceptance probability of the states proposed at the last doubling step of NUTS. It measures of the accuracy of the numerical approximation of Hamiltonian dynamics and is used to find an optimal step size value epsilon.
- nfevals : The number of log likelihood and gradient evaluations one iteration of NUTS required
- logp : Log probability computed at theta, as a scalar double.
- grad : A nVar x 1 double. The gradient computed at theta.

Written by Matthew D. Hoffman

Edited by Kenneth Sæterhagen Paulsen

- Updated the documentation in line with NB Toolbox.
- Removed the global variable nfevals.
- Removed notifications when maximum tree depth where reached.
- Removed the optional inputs.
- Added the lower and upper bounds inputs.

► **[nb_mcmc.adaptiveRandomWalk](#)** ↑

[betaDraw,output] = nb_mcmc.adaptiveRandomWalk(output)

Description:

Draw one candidate during Metropolis-Hastings algorithm using the random walk assumption.

In this case the covariance matrix is updated based on the kept draws from the draws of the parameters. See Haario et al. (2001).

Input:

- output : See the output of the nb_mcmc.mhSampler function.

Output:

- betaDraw : A nVar x 1 double.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_mcmc.adaptiveRandomWalkRecTarget ↑**

[betaDraw,output] = nb_mcmc.adaptiveRandomWalkRecTarget(output)

Description:

Draw one candidate during Metropolis-Hastings algorithm using the random walk assumption.

In this case the covariance matrix is updated based on the draws of the parameters. See Haario et al. (2001).

Also the scaling of the covariance matrix is updated for every X simulation. I.e. each time we check the covariance matrix, it is scaled so to make the acceptance ratio equal to the target.

Input:

- output : See the output of the nb_mcmc.mhSampler function.

Output:

- betaDraw : A nVar x 1 double.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_mcmc.adaptiveRandomWalkTarget](#)** ↑

```
[betaDraw,output] = nb_mcmc.adaptiveRandomWalkTarget(output)
```

Description:

Draw one candidate during Metropolis-Hastings algorithm using the random walk assumption.

In this case the scaling of the covariance matrix is updated for every X simulation. I.e. each time we check the covariance matrix, it is scaled so to make the acceptance ratio equal to the target.

Input:

- output : See the output of the nb_mcmc.mhSampler function.

Output:

- betaDraw : A nVar x 1 double.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_mcmc.dualAveraging](#)** ↑

```
[theta, epsilonbar, epsilon_seq, epsilonbar_seq, logp, grad] = ...
    nb_mcmc.dualAveraging(f, theta0, delta, n_warmup, ...
        maxTreeDepth, lb, ub, n_updates, waitbar)
```

Description:

Adjusts the step-size of NUTS by the dual-averaging (stochastic optimization) algorithm of Hoffman and Gelman (2014).

Input:

- f : A function-handle that returns the log probability of the target and its gradient.
- theta0 : A nVar x 1 double. Initial state for the trajectory of Hamiltonian dynamics.
- delta : A scalar double in the range [0, 1]: the target "acceptance rate" of NUTS.

- n_warmup : A scalar integer with the number of NUTS iterations for the dual-averaging algorithm.
- maxTreeDepth : An integer with the maximum depth of tree.
- lb : A nVar x 1 double with the lower bounds on the parameters. Give -inf for elements that is not bounded. Give [] if no parameters are bounded.
- ub : A nVar x 1 double with the upper bounds on the parameters. Give inf for elements that is not bounded. Give [] if no parameters are bounded.
- n_updates : A scalar integer with the number of periods between updates.
- waitbar : Either a scalar logical or a nb_waitbar object. Default is false.

Output:

- theta : Last state of the chain after the step-size adjustment, which can be used as the initial state for the sampling stage (no need for additional 'burn-in' samples)
- epsilonbar : A scalar double with the step-size corresponding to the target "acceptance rate".
- epsilon_seq : A n_warmup x 1 double with the value of epsilon at each step of the dual averaging algorithm.
- epsilonbar_seq : A n_warmup x 1 double with the value of epsilonbar at each step of the dual averaging algorithm.
- logp : Log probability computed at theta(end), as a scalar double.
- grad : A nVar x 1 double. The gradient computed at theta(end).

Written by Matthew D. Hoffman

Edited by Kenneth Sæterhagen Paulsen

- Added the waitbar option.
- Change the interpretation of the n_updates input.
- Removed some of the optional inputs.
- Added the maxTreeDepth.
- Added the lower and upper bounds inputs.

► [nb_mcmc.gelmanRubin](#) ↑

```
R = nb_mcmc.gelmanRubin(varargin)
```

Description:

Calculates the Gelman–Rubin diagnostic of multiple M–H chains.

Input:

- varargin : Each input must be $2*n \times q$ double with the M–H draws of a set of q variables/parameters and length $2*n$. The test discard the first n draws.

Output:

- R : A $1 \times q$ test statistics. If any element is $>> 1$ run the M–H for a longer period, as it has not converged to the stationary distribution.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_mcmc.gelmanRubinRecursive](#)** ↑

```
R = nb_mcmc.gelmanRubinRecursive(varargin)
```

Description:

Calculates the recursive Gelman–Rubin diagnostic of multiple M–H chains.

Input:

- varargin : Each input must be $2*n \times q$ double with the M–H draws of a set of q variables/parameters and length $2*n$. The test discard the first n draws.

Output:

- R : A $n \times q$ test statistics. If any element is $>> 1$ run the M–H for a longer period, as it has not converged to the stationary distribution.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sæterhagen Paulsen

► nb_mcmc.geweke ↑

```
[z,p] = nb_mcmc.geweke(beta)
```

Description:

Test for convergence of a M-H chain.

Geweke (1992) test. This test split sample into two parts. The first 10% and the last 50%. If the chain is at stationarity, the means of two samples should be equal. The null hypothesis is that the subsamples has the same mean.

Input:

- beta : A draws x numVar double.

Output:

- z : A 1 x numVar double with the difference in mean statistics.

- p : A 1 x numVar double with the p-values of the test statistics.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sæterhagen Paulsen

► nb_mcmc.leapfrog ↑

```
[thetaprime, rprime, gradprime, logpprime] = ...
    nb_mcmc.leapfrog(theta, r, grad, epsilon, f)
```

Description:

Carries out the leapfrog step of the NUTS algorithm.

Input:

- theta : A nVar x 1 double. Current state of a Markov chain and the initial state for the trajectory of Hamiltonian dynamics.

- r : The current state of the momentum. As a nVar x 1 double.

- grad : A nVar x 1 double. Gradient of the log probability computed at theta.

- epsilon : A scalar double. Step size of leap-frog integrator.

- f : A function_handle that returns the log probability of the target and its gradient.

Output:

- thetaprime : Next state of the chain, as a nVar x 1 double.
- rprime : Next state of the momentum, as a nVar x 1 double.
- gradprime : A nVar x 1 double. Gradient of the log probability computed at thetaprime.
- logpprime : The log probability at thetaprime, as a scalar double.

See also:

[nb_mcmc.NUTS](#), [nb_mcmc.dualAveraging](#)

Written by Matthew D. Hoffman

Edited by Kenneth Sætherhagen Paulsen

- Separated out as an own function.
- Added documentation.
- Added the lower and upper bound on the parameters.

► **[nb_mcmc.loadBetaFromOuput](#)** ↑

```
beta = nb_mcmc.loadBetaFromOuput(output,chain)
```

Description:

Load the sampled draws of the parameters from files.

Input:

- output : The output struct on of the samplers of the nb_mcmc package.
- chain : Sepcify the loaded chain. If empty all chains are loaded.

Output:

- beta : The sampled parameters as a nDraws x nPar x nChains double.

See also:

[nb_mcmc.mhSampler](#), [nb_mcmc.nutSampler](#)

Written by Kenneth Sætherhagen Paulsen

► **[nb_mcmc.mhSampler](#)** ↑

```
output = nb_mcmc.mhSampler(objective,beta,sigma,varargin)
```

Description:

Implementation of the Metropolis-Hastings algorithm.

Input:

- objective : A function handle that represents a function that is proportional to the target distribution. Takes one input, and that are the simulated random variables, which has the same type and size as the beta input.
- beta : Initial values of the random variables to draw from. E.g. the mode found under optimization in the case of parameter estimates from a DSGE model. As a $1 \times \text{numVar}$ double.
- sigma : Initial guess on the covariance matrix of the random variables. E.g. the inverted Hessian found during estimation of parameters of a DSGE model. As a $\text{numVar} \times \text{numVar}$ double matrix.

Optional input:

- 'accTarget' : Sets the preferred acceptance ratio when 'adaptive' is set to 'target' or 'recTarget'. Default is 0.5.
 - 'accScale' : The value to re-scale the cholesky factorization of the covariance matrix with when acceptance ratio is less or greater than the target ('accTarget'). I.e. $\exp(\text{accScale} \cdot a)$, where a is incremented by +/- 1 if acceptance ratio is higher/lower than the target.
 - 'adaptive' : Either;
 - > 'recursive' : Calculates the covariance matrix based on the simulated observation from the target function. Uses the approach suggested by Haario et al. (2001). Use the 'weight' input to adjust the weight on the initial covariance matrix.
 - > 'recTarget' : Combining the approaches in 'recursive' and 'target'.
 - > 'target' : Scales the initial covariance matrix with a constant (that changes) to get the wanted acceptance rate. See 'accTarget', 'recursive' is default.
- Caution: Only applies for when the 'qFunction' input is set to 'arw'. For more see the nb_mcmc.adaptiveRandomWalk and nb_mcmc.adaptiveRandomWalkUpdate function.
- 'burn' : The number of burned simulation in the start of the M-H algorithm. Default is 4000.
 - 'chains' : The number of M-H chains to run. Default is 1. If 'parallel' is set to true, this also will be the number of parallel workers.

- 'covrepair' : Give true to secure that the provided covariance matrix is positive semi-definite. If false (default), then an error will be thrown if the covariance matrix is not positive definite.
- 'draws' : The number of draws returned for each chain. As a scalar integer. Default is 10000.
- 'lb' : Lower bound on the variables. As a 1 x numVar double. Default is [], i.e. no lower bound on any variable.
- 'log' : Give true if the objective function is in log. Default is false.
- 'minIter' : A user defined threshold value that can be used by the function given by the 'qFunction' input.
 - If 'qFunction' is set to
 - > 'arw' : An 'adaptive' is set to 'recursive' this options sets how many past burning simulation that must be done before the calculation of the covariance matrix used by the 'phi' input does not use the burn in simulations.

Default is 20.
- 'parallel' : Set to true to run M-H in parallel using parfor.
- 'phi' : A function handle that simulates eps from the wanted distribution, i.e. the distribution to draw from when simulating the jump in the random variables at a iteration of the Metropolis - Hastings algorithm. Default is @(x)nb_mcmc.mvnRandChol(x).
- Caution : The x input is the same struct that is given by the output.
- 'qFuncPDF' : The PDF of the suggested conditional distribution that is assign to the 'qFunction' input. Only needed if 'qFunction' is not symmetric. If provided it must be a function handle that takes the output struct as its only input.

This function must provide 2 outputs. The first is the value of qFunction(betaDraw,betaLast), and the second is the value of qFunction(betaLast,betaDraw).
- 'qFunction' : A string or a function handle with how to draw the candidate distribution conditional on past draw. Either:
 - > 'rw' : Random-walk. $\beta(i+1) = \beta(i) + \text{eps}$, where $\text{eps} \sim \phi(0, \sigma)$.
 - > 'arw' : Adaptive random-walk. $\beta(i+1) = \beta(i) + \text{eps}$, where $\text{eps} \sim \phi(0, \sigma(i))$. In this case $\sigma(i)$ is an estimate of the covariance matrix of the sampled values of β .
 - > handle : A function handle taking 1 input. The input is on the same format as the output of this function.

Default is to use 'rw'.

This function must return 2 outputs; the candidate draw of the random variables with same size as the beta input, and it must return the input given to this function, as you may have alter it when constructing the candidate draw. For examples see; nb_mcmc.randomWalk or nb_mcmc.adaptiveRandomWalk.

- 'storeAt' : The number of simulations before the draws are stored to a file during the M-H algorithm. Default is 1000000.

Caution: In this case the names of the files that the draws are in can be found in the field files, while the beta output will be empty.
- 'storeFile' : Prefix of the names of the .mat files stored with the posterior draws. Include path if wanted. Caution: should not end with \. Defualt is 'mh_sampler'.
- 'thin' : The number of simulations before a draw is kept during the M-H algorithm. Default is 10.
- 'ub' : Upper bound on the variables. As a 1 x numVar double. Default is [], i.e. no lower bound on any variable.
- 'waitbar' : Give true to include waitbar.
- 'weight' : The weight put on the initial covariance matrix when 'qFunction' is set to 'arw' and 'adaptive' is set to 'recursive'. Default is 0.05 (the smalles possible value).

Output:

- output : A 1 x number of chains struct array with the following fields
 - > beta : A draws x numVar double. Empty if 'storeAt' is so small that the sampler start storing to files.
 - > files : The names of the files for where the draws are saved in the case tha the 'storeAt' limit is reached.

► **nb_mcmc.mvnRand** ↑

betaDraw = nb_mcmc.mvnRand(output)

Description:

A function that may be assign to the 'phi' input to the nb_mcmc.mhSampler function.

Input:

- output : See documentation of the output from the nb_mcmc.mhSampler function.

Output:

- betaDraw : A nVar x 1 double.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_mcmc.mvnRandChol** ↑

betaDraw = nb_mcmc.mvnRandChol(output)

Description:

Default function assign to the 'phi' input to the nb_mcmc.mhSampler.

Input:

- output : See documentation of the output from the nb_mcmc.mhSampler function.

Output:

- betaDraw : A nVar x 1 double.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_mcmc.nutSampler** ↑

output = nb_mcmc.nutSampler(objective,beta,sigma,varargin)

Description:

Implementation of the No U-turn (NUT) sampler algorithm.

This uses the functions nb_mcmc.NUTS and nb_mcmc.dualAveraging made by Matthew D. Hoffman.

Input:

- objective : A function handle that represents a function that is proportional to the target distribution. Takes one input, and that are the simulated random variables, which has the same type and size as the beta input.

Caution : This function may also return the gradient of the objective. It must have size numVar x 1.
- beta : Initial values of the random variables to draw from. E.g. the mode found under optimization in the case of parameter estimates from a DSGE model. As a 1 x numVar double.
- sigma : Not used. Only to make it generic to other samplers...

Optional input:

- 'accTarget' : Sets the preferred acceptance ratio when 'adaptive' is set to 'target' or 'recTarget'. Default is 0.8.
- 'burn' : The number of burned simulation in the start of the M-H algorithm. Default is 4000.
- 'chains' : The number of M-H chains to run. Default is 1. If 'parallel' is set to true, this also will be the number of parallel workers.
- 'draws' : The number of draws returned for each chain. As a scalar integer. Default is 10000.
- 'lb' : Lower bound on the variables. As a 1 x numVar double. Default is [], i.e. no lower bound on any variable.
- 'log' : Give true if the objective function is in log. Default is false.
- 'parallel' : Set to true to run M-H in parallel using parfor.
- 'thin' : The number of simulations between storing a draw during the NUT algorithm. Default is 10.
- 'ub' : Upper bound on the variables. As a 1 x numVar double. Default is [], i.e. no upper bound on any variable.
- 'waitbar' : Give true to include waitbar.

Output:

- output : A 1 x number of chains struct array with the following fields
> beta : A draws x numVar double.

[nb_mcmc.NUTS](#), [nb_mcmc.dualAveraging](#), [nb_mcmc.mhSampler](#), [nb_waitbar](#)

Written by Kenneth Sætherhagen Paulsen

► **nb_mcmc.optimset** ↑

```
opt = nb_mcmc.optimset(varargin)
```

Description:

Default setting of the `nb_mcmc.mhSampler` and `nb_mcmc.nutsampler`. See these function for help on the different fields (i.e. the optional inputs).

Optional input:

- `varargin` : Field name, field value pairs. These can be used to correct the default values to your prefered choice.

Output:

- `opt` : a struct with the default options of the sampler

See also:

[nb_mcmc.mhSampler](#), [nb_mcmc.nutsampler](#)

Written by Kenneth Sætherhagen Paulsen

► **nb_mcmc.randomWalk** ↑

```
[betaDraw,output] = nb_mcmc.randomWalk(output)
```

Description:

Draw one candidate during Metropolis-Hastings algorithm using the random walk assumption.

Input:

- `output` : See the output of the `nb_mcmc.mhSampler` function.

Output:

- `betaDraw` : A `nVar x 1` double.

See also:

[nb_mcmc.mhSampler](#)

Written by Kenneth Sætherhagen Paulsen

■ nb_copula

Go to: [Properties](#) | [Methods](#)

A class for constructing a multivariate distribution given marginal distributions of the separate variables and a correlation matrix using a gaussian copula.

Caution: Some of the methods utilizes the MATLAB statistics package.

Superclasses:

handle

Constructor:

```
obj = nb_copula(distr,varargin)
```

Input:

- distr : A 1xN vector of nb_distribution objects. N > 1.
- varargin : Property name and property value pair arguments. See the set method for an example. Type properties(obj) in the command line to get a list of supported properties, and type help nb_distribution.<propertyName> to get help on a specific property.

Output:

- obj : An object of class nb_copula

Examples:

```
distr = nb_distribution.initialize('type',{'normal','gamma'},...  
                                'parameters',{{6,2},{2,2}});  
obj = nb_copula(distr);
```

Written by Kenneth Sætherhagen Paulsen

Properties:

- distributions • numberOfDistributions • sigma • transformedSigma • type

- **distributions** ↑

The marginal distributions of the separate variables as a 1xN vector of nb_distribution objects.

- **numberOfDistributions** ↑

The number of distributions in the copula. As a scalar double.

- **sigma** ↑

The linear correlation matrix. As a NxN double with ones along the diagonal. Must be reordered accordingly to the property distributions. Default is uncorrelated marginals.

- **transformedSigma** ↑

nb_copula/transformedSigma is a property.

- **type** ↑

Set the transformation method to use to transform the rank correlation coefficients to the linear correlation coefficients.

- 'none' : If the correlation in the data is calculated based on the linear correlation coefficients. Default.
- 'spearman' : Uses the formula $\rho = 2 \cdot \sin(\sigma \cdot \pi / 6)$. Can be used if the rank correlation coefficients are calculated based on the data series. Using the `corr(X, 'type', 'spearman')` function.
- 'kendall' : Uses the formula $\rho = \sin(\sigma \cdot \pi / 2)$. Can be used if the rank correlation coefficients are calculated based on the data series. Using the `corr(X, 'type', 'kendall')` function.

The rank correlation coefficients are approximately invariant to the choice of marginal distribution used to transform the draws from the copula to the draws of the different marginals.

Methods:

- `cdf`
- `domain`
- `get`
- `kurtosis`
- `mean`
- `median`
- `mode`
- `pdf`
- `plot`
- `random`
- `set`
- `skewness`
- `std`
- `variance`

► **cdf** ↑

`f = cdf(obj, x, type)`

Description:

Evaluate the cdf of the given distribution at the value(s) `x`.

The value is only an approximation!

Input:

- obj : An object of class nb_copula
- x : A double size TxN, where N is the dimension of the multivariate distribution.
- type : See output f.

Output:

- f : Dependent on the type input:
 - > 'full' : A Tx1 double with the multivariate cumulative probabilities at the wanted points of the multivariate domain. Default.
 - > 'marginals' : A TxN double with the marginal cumulative probabilities at the wanted points of the multivariate domain.
 - > 'conditional' : Calculate the conditional probability for the multivariate probabilities at the wanted points of the multivariate domain. The variables to condition on are identified by the the distribution which the conditionalValue property is set to a number.

Written by Kenneth Sæterhagen Paulsen

► domain ↑

d = domain(obj)

Description:

Returns the full domain of the marginal distributions combined by the copula.

Input:

- obj : An object of class nb_copula
- out :
 - 0 : Returns the lower and upper bound of the distribution, if truncated does limits are returned. Default.
 - 1 : Returns the lower and upper bound of the distribution, if truncated does limits are not returned.
 - 2 : Returns the lower and upper bound of the distribution, if truncated it will only return the lower truncation limit.
 - 3 : Returns the lower and upper bound of the distribution,

if truncated it will only return the upper truncation limit.

Output:

- domain : A Nx2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property value of a nb_copula object.

Type properties(obj) in the command line to get a list of supported properties, and type help nb_copula.<propertyName> to get help on a specific property.

Input:

- obj : An object of class nb_copula
- propertyName : A string with the property name

Output:

- propertyValue : The return value of the wanted property.

Examples:

```
propertyValue = get(obj,'type');
```

Written by Kenneth S. Paulsen

► **kurtosis** ↑

```
x = kurtosis(obj)
```

Description:

Evaluate the kurtosis of the marginal distributions combined by the copula.

The kurtosis will be adjusted for bias. See the function kurtosis made by MATLAB inc.

Input:

- obj : An object of class nb_copula

Output:

- x : A double with size 1xN, where N is the number of marginal distributions combined with the copula.

Written by Kenneth SÃ¶terhagen Paulsen

► mean ↑

x = mean(obj)

Description:

Evaluate the mean of the marginal distributions combined by the copula.

Input:

- obj : An object of class nb_copula

Output:

- x : A double with size 1xN, where N is the number of marginal distributions combined with the copula.

Written by Kenneth SÃ¶terhagen Paulsen

► median ↑

x = median(obj)

Description:

Evaluate the median of the marginal distributions combined by the copula.

Input:

- obj : An object of class nb_copula

Output:

- x : A double with size 1xN, where N is the number of marginal distributions combined with the copula.

Written by Kenneth SÃ¶terhagen Paulsen

► **mode** ↑

```
x = mode(obj)
```

Description:

Evaluate the mode of the marginal distributions combined by the copula.

Input:

- obj : An object of class nb_copula

Output:

- x : A double with size 1xN, where N is the number of marginal distributions combined with the copula.

Written by Kenneth Sæterhagen Paulsen

► **pdf** ↑

```
f = pdf(obj,x,type)
```

Description:

Evaluate the pdf of the given distribution at the value(s) x.

To condition on a value for a given marginal distribution, see the conditionalValue property of nb_distribution.

Input:

- obj : An object of class nb_copula

- x : A double size TxN, where N is the dimension of the multivariate distribution.

Caution : If 'type' is set to 'conditional' N is equal to the number of multivariate distribution not conditioned on.

- type : See output f.

Output:

- f : Dependent on the type input:

> 'full' : A Tx1 double with the multivariate

```

probabilities at the wanted points of the
multivariate domain. Default.

> 'marginals'    : A TxN double with the marginal probabilities at
                     the wanted points of the multivariate domain.

> 'conditional' : Calculate the conditional probability for the
                     multivariate probabilities at the wanted points
                     of the multivariate domain. The variables
                     to condition on are identified by the
                     the distribution which the conditionalValue
                     property is set to a number.

> 'log'          : Log of the likelihood.

```

Written by Kenneth Sæterhagen Paulsen

► **plot** ↑

```
plotter = plot(obj,type)
```

Description:

Graph either the PDF or CDF of one of the marginal distribution

Input:

- obj : A nb_distribution object.
- x : The values to evaluate the distribution. x must be a Nx1 double.
If not provided or empty the full domain of the distribution(s) will be used
- type : A string with either 'pdf' (default) or 'cdf'
- index : The index of the marginal distribution to plot. Default is 1.

Output:

- plotter : A nb_graph_data object. If nargout is 0 the graph will be plotted automatically, otherwise you need to call the graph method on the plotter object.

Examples:

```
obj = nb_distribution
plot(obj)
```

Written by Kenneth Sæterhagen Paulsen

► random ↑

```
D = random(obj,nrow,npage)
```

Description:

Draw random numbers from the multivariate distribution represented by the nb_copula object. I.e. uses a gaussian copula to draw correlated draws from each marginal distribution.

Caution: If numel(obj) > 1 the number of marginal distribution of each copula must be the same.

Caution: If some of the marginal distributions objects has set the conditonalValue property to some number, the random numbers are generated conditional on this value(s).

Input:

- obj : An object of class nb_copula
- nrow : The number of rows of the draws output
- npage : The number of pages of the draws output

Output:

- D : A nrow x N x npage x nobj1 x nobj2 double with the draws from the multivariate distribution, where N is the number of marginal distributions.

Examples:

```
distr = nb_distribution.initialize('type',{'normal','gamma'},...  
                                    'parameters',{{6,2},{2,2}});  
obj   = nb_copula(distr,'type','kendall','sigma',[1,0.5;0.5,1]);  
D     = random(obj,100);
```

Written by Kenneth Sæterhagen Paulsen

► set ↑

```
set(obj,varargin)
```

Description:

Sets the properties of the nb_copula object.

Type properties(obj) in the command line to get a list of supported properties, and type help nb_copula.<propertyName> to get help on a specific property.

Input:

- obj : An object of class nb_copula
- varargin : 'propertyName',PropertyValue,...

Output:

- obj : The input object with the updated properties.

Examples:

```
set(obj,'propertyName',PropertyValue);
obj.set('propertyName',PropertyValue,...)
obj = obj.set('type','kendall');
```

Written by Kenneth S. Paulsen

► **skewness** ↑

```
x = skewness(obj)
```

Description:

Evaluate the skewness of the marginal distributions combined by the copula.

The skewness will be adjusted for bias. See the function skewness made by MATLAB inc.

Input:

- obj : An object of class nb_copula

Output:

- x : A double with size 1xN, where N is the number of marginal distributions combined with the copula.

Written by Kenneth Sæterhagen Paulsen

► **std** ↑

```
x = std(obj)
```

Description:

Evaluate the standard deviation of the marginal distributions combined by the copula.

The variance is normalized with T-1

Input:

- obj : An object of class nb_copula

Output:

- x : A double with size 1xN, where N is the number of marginal distributions combined with the copula.

Written by Kenneth Sæterhagen Paulsen

► **variance ↑**

x = variance(obj)

Description:

Evaluate the variance of the marginal distributions combined by the copula.

The variance is normalized with T-1

Input:

- obj : An object of class nb_copula

Output:

- x : A double with size 1xN, where N is the number of marginal distributions combined with the copula.

Written by Kenneth Sæterhagen Paulsen

■ **nb_distribution**

Go to: [Properties](#) | [Methods](#)

A class for evaluate the pdf, cdf, icdf etc of a known distribution as well as for a estimated distribution (using kernel density estimates)

Caution: Some of the methods utilizes the MATLAB statistics package.

Superclasses:

handle

Constructor:

```
obj = nb_distribution(varargin)
```

Input:

- varargin : Property name and property value pair arguments. See the set method for a example. Type properties(obj) in the command line to get a list of supported properties, and type help nb_distribution.<propertyName> to get help on a specific property.

Caution : When the property type is set, the parameters property will be set to its default value given the type of distribution. See the paramters for more on this.

Output:

- obj : An object of class nb_distribution

Examples:

```
obj = nb_distribution('type','gamma');
```

Written by Kenneth Sætherhagen Paulsen

Properties:

- conditionalValue • lowerBound • meanShift • name • parameters
- type • upperBound • userData

- **conditionalValue** ↑

The value to condition on when included in a nb_copula object and the 'conditional' type is used by the pdf, cdf and random methods, otherwise it has no effect.

- **lowerBound** ↑

Lower bound of truncated distribution. Use the set method to truncate the distribution.

- **meanShift** ↑

Shift mean. As a double. If the distribution is truncated this will only shift the untruncated distributions mean with this magnitude. Default is empty, i.e. no mean shift.

- **name** ↑

The name of the distribution. It is possible to set this property by the set method. If not set it will be given a default name that will depend on the distribution and its parametrization.

- **parameters** ↑

The parameters of the wanted distribution. This property will depend on the distribution type;

Caution : When the property type is set, the parameters property will be set to its default value given the type of distribution.

- 'ast' : The parameters property must be set to a 1x5 cell. {location,scale,skewness,lefthead,righttail}, where location is any double, scale > 0, skewness is between 0 and 1, lefthead > 0 and righttail > 0. Default is {0,1,0,1000,1000} ~ N(0,1).
- 'beta' : The parameters property must be set to a 1x2 cell. {param1,param2}, where both must be set to a 1x1 double greater than 0. Default is {2,2}. The mean will be given by param1/(param1 + param2).
- 'cauchy' : The parameters property must be set to a 1x2 cell. {location,scale}, where location must be set to a 1x1 double, and scale must be set to a 1x1 double greater than 0. Default is {0,2}.
- 'chis' : The parameters property must be set to a 1x1 cell. {param1}, where param1 must be set to a 1x1 double greater than 0. Default is {2}.
- 'constant' : The parameters property must be set to a 1x1 cell. {constant}, where constant must be set to a 1x1 double. Default is {0}.
- 'empirical' : The parameters property must be set to a 1 x 2 cell. First element must be the domain (1 x N double) and the second element must be the probability density (1 x N double).
- 'exp' : The parameters property must be set to a 1x1 cell. {param1}, where param1 must be set to a 1x1 double greater than 0. Default is {2}.
- 'f' : The parameters property must be set to a 1x1 cell. {param1,parma2}, where both must be set to a 1x1 double greater than 0. Default is {10,10}.
- 'fgamma' : The parameters property must be set to a 1x2 cell. {shape,scale}, where shape and scale must both be a 1x1 double greater than 0. Default is {2,2}. The mean will be given by shape*scale.
- 'finvgamma' : The parameters property must be set to a 1x2 cell. {shape,scale}, where shape and scale must both be a 1x1 double greater than 0. Default is {4,2}. The mean will be given by scale/(shape - 1) for shape > 1.
- 'gamma' : The parameters property must be set to a 1x2 cell. {shape,scale}, where shape and scale must both be a 1x1 double greater than 0. Default is {2,2}. The mean will be given by shape*scale.

- 'hist' : The paramters property must be set to a 1x1 cell. {data}, where data must be a Nx1 double. Default is {randn(100,1)}.
 - 'invgamma' : The paramters property must be set to a 1x2 cell. {shape,scale}, where shape and scale must both be a 1x1 double greater than 0. Default is {4,2}. The mean will be given by scale/(shape - 1) for shape > 1.
 - 'kernel' : The parameters property must be set to a 1 x 2 cell. First element must be the domain (1 x N double) and the second element must be the probability density (1 x N double).
 - 'laplace' : The paramters property must be set to a 1x2 cell. {location,scale}, where location must be a 1x1 double and scale must be 1x1 double greater than 0. Default is {0,1}.
 - 'logistic' : The paramters property must be set to a 1x2 cell. {location,scale}, where location must be set to a 1x1 double, and scale must be set to a 1x1 double greater than 0. Default is {0,2}.
 - 'lognormal' : The paramters property must be set to a 1x2 cell. {param1,param2}, where both must be set to a 1x1 double greater than 0. Default is {1,1}.
 - 'normal' : The paramters property must be set to a 1x2 cell. {mean,std}, where mean must be a 1x1 double and std must be 1x1 double greater than 0. Default is {0,1}.
 - 'skewedt' : The paramters property must be set to a 1x4 cell. {mean,std,skewness,kurtosis}. Default is {0,1,2.910,0,2.5}, i.e. same as student-t with 5 degrees of freedom.
 - 'skt' : The paramters property must be set to a 1x4 cell. {location,scale,shape,dof}. Default is {0,1,0,inf}, i.e. same as the normal distribution. dof is the degree of freedom, and must be set to a 1x1 double greater than 0. shape must be in (-1,1). scale > 0. No restrictions on location.
 - 't' : The paramters property must be set to a 1x1 cell. {dof}, where dof must be set to a 1x1 double greater than 0. Default is {5}.
- You can also use the Non-standardized student-t distribution by setting this property to a 1x3 cell, where the two additional inputs are location and scale. location must be set to a 1x1 double and scale must be set to a 1x1 double greater than 0.
- 'tri' : The paramters property must be set to a 1x3 cell.

- {low,high,mode}, where low, high and mode must be set to a 1x1 double. Default is {0,1,0.5}.
- 'uniform' : The paramters property must be set to a 1x2 cell. {lower,upper}, where bust must be a 1x1 double. Default is {0,1}.
 - 'wald' : The paramters property must be set to a 1x2 cell. {mean,shape}, where mean must be a 1x1 double greater than 0 and shape must be 1x1 double greater than 0. Default is {1,1}.
- type ↑**
- The type of distributions. The following are supported;
- 'ast' : Asymetric student-t distribution. See Zhu and Galbraith (2009)
 - 'beta' : Beta distribution
 - 'cauchy' : Cauchy distribution
 - 'chis' : Chi-squared distribution
 - 'constant' : A constant. I.e. the distribution of a non-random variable.
 - 'empirical' : Empirical (Kaplan-Meier) cumulative distribution function.
 - 'f' : F-distribution
 - 'fgamma' : Flipped gamma distribution
 - 'finvgamma' : Flipped inverse gamma distribution
 - 'gamma' : Gamma distribution
 - 'hist' : Create a histogram. This to make it easy to compare the estimated distribution against a histogram. For the moments operators the empirical counterparts are returned!
 - 'invgamma' : Inverse gamma distribution
 - 'kernel' : Kernel density estimation. Please see the method estimate on how to estimate a kernel distribution.
 - 'laplace' : Laplace distribution.
 - 'lognormal' : Lognormal distribution.
 - 'logistic' : Logistic distribution.
 - 'normal' : Normal distribution. Default
 - 'skewedt' : Skewed t-distribution. [https://en.wikipedia.org/...](https://en.wikipedia.org/)

wiki/Skewed_generalized_t_distribution

- 'skt' : Azzalini skewed t-distribution. Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution.
J.Roy.Statist.Soc. B 65, 367–389. May not be available in public version.
- 't' : Student-t distribution
- 'tri' : Triangular distribution
- 'uniform' : Uniform distribution
- 'wald' : Wald distribution

- **upperBound** ↑

Upper bound of truncated distribution. Use the set method to truncate the distribution.

- **userData** ↑

User data stored to the object. Can be of any type

► **asData** ↑

```
data = asData(obj,x,type)
```

Description:

Create an nb_data object from either the PDF or CDF of the distribution

Input:

- obj : A nb_distribution object.
- x : The values to evaluate the distribution. x must be a Nx1 double.
If not provided or empty the full domain of the distribution(s) will be used
- type : A string with either 'pdf' (default) or 'cdf'

Output:

- data : A nb_data object.

Examples:

```
obj = nb_distribution  
asData(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **assignParameters ↑**

```
assignParameters(obj,param)
```

Description:

Assign parameters to a scalar distribution object.

Input:

- obj : A nb_distribution object.
- param : The parameters to assign the object, as 1 x nParam double.

Written by Kenneth Sæterhagen Paulsen

► **ast_cdf ↑**

```
f = nb_distribution.ast_cdf(x,a,b,c,d,e)
```

Description:

CDF of the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- x : The point to evaluate the cdf, as a double.
- a : The location parameter.
- b : The scale parameter (>0).
- c : The skewness parameter (1>c>0).
- d : The left parameter (>0).
- e : The right parameter (>0).

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.ast_pdf](#), [nb_distribution.ast_rand](#)
[nb_distribution.ast_icdf](#), [nb_mci](#)

Written by Kenneth Sæterhagen Paulsen

► **ast_domain** ↑

f = nb_distribution.ast_domain

Description:

Get the domain of the asymmetric t-distribution of Zhu and Galbraith (2009).

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **ast_icdf** ↑

x = nb_distribution.ast_icdf(p,a,b,c,d,e)

Description:

Returns the inverse of the cdf at p of the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- p : A vector of probabilities
- a : The location parameter.
- b : The scale parameter (>0).
- c : The skewness parameter (1>c>0).
- d : The left parameter (>0).
- e : The right parameter (>0).

Output:

- x : A double with the quantile at each element of p of the gamma(m,k) distribution

See also:

[nb_distribution.ast_cdf](#), [nb_distribution.ast_rand](#)
[nb_distribution.ast_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **ast_kurtosis ↑**

x = nb_distribution.ast_kurtosis(a,b,c,d,e)

Description:

Kurtosis of the asymmetric t-distribution of Zhu and Galbraith (2009).

Caution : Simulation based (seed is set) !

Input:

- a : The location parameter.
- b : The scale parameter (>0).
- c : The skewness parameter (1>c>0).
- d : The left parameter (>0).
- e : The right parameter (>0).

Output:

- x : The kurtosis of the distribution

See also:

[nb_distribution.ast_median](#), [nb_distribution.ast_mean](#)
[nb_distribution.ast_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **ast_mean ↑**

x = nb_distribution.ast_mean(a,b,c,d,e)

Description:

Mean of the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- a : The location parameter.
- b : The scale parameter (>0).
- c : The skewness parameter ($1 > c > 0$).
- d : The left parameter (>0).
- e : The right parameter (>0).

Output:

- x : The mean of the distribution

See also:

[nb_distribution.ast_mode](#), [nb_distribution.ast_median](#)
[nb_distribution.ast_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **ast_median ↑**

x = nb_distribution.ast_median(a,b,c,d,e)

Description:

Median of the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- a : The location parameter.
- b : The scale parameter.
- c : The skewness parameter.
- d : The left parameter (>0).
- e : The right parameter (>0).

Output:

- x : The median of the distribution

See also:

[nb_distribution.ast_mode](#), [nb_distribution.ast_mean](#)
[nb_distribution.ast_variance](#)

Written by Kenneth Å!terhagen Paulsen

► **ast_mode** ↑

```
x = nb_distribution.ast_mode(a,b,c,d,e)
```

Description:

Mode of the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- a : The location parameter.
- b : The scale parameter (>0).
- c : The skewness parameter ($1 > c > 0$).
- d : The left parameter (>0).
- e : The right parameter (>0).

Output:

- x : The mode of the distribution

See also:

[nb_distribution.ast_median](#), [nb_distribution.ast_mean](#)
[nb_distribution.ast_variance](#)

Written by Kenneth Å!terhagen Paulsen

► **ast_pdf** ↑

```
f = nb_distribution.ast_pdf(x,a,b,c,d,e)
```

Description:

PDF of the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- `x` : The point to evaluate the pdf, as a double
- `a` : The location parameter.
- `b` : The scale parameter (>0).
- `c` : The skewness parameter ($1>c>0$).
- `d` : The left parameter (>0).
- `e` : The right parameter (>0).

Output:

- `f` : The PDF at the evaluated points, same size as `x`.

See also:

[nb_distribution.ast_cdf](#), [nb_distribution.ast_rand](#)
[nb_distribution.ast_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **ast_rand** ↑

```
draws = nb_distribution.ast_rand(nrow, ncol, a, b, c, d, e)
```

Description:

Draw random numbers from the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- `nrow` : Number of rows of the matrix drawn from the distribution
- `ncol` : Number of columns of the matrix drawn from the distribution
- `a` : The location parameter.
- `b` : The scale parameter (>0).
- `c` : The skewness parameter ($1>c>0$).
- `d` : The left parameter (>0).
- `e` : The right parameter (>0).

Output:

- `draws` : A `nrow` x `ncol` matrix of random numbers from the distribution

See also:

[nb_distribution.ast_pdf](#), [nb_distribution.ast_cdf](#)

Modified by Kenneth S. Paulsen

► **ast_skewness ↑**

`x = nb_distribution.ast_skewness(a,b,c,d,e)`

Description:

Skewness of the asymmetric t-distribution of Zhu and Galbraith (2009).

Caution : Simulation based (seed is set) !

Input:

- `a` : The location parameter.
- `b` : The scale parameter (>0).
- `c` : The skewness parameter ($1>c>0$).
- `d` : The left parameter (>0).
- `e` : The right parameter (>0).

Output:

- `x` : The skewness of the distribution

See also:

[nb_distribution.ast_median](#), [nb_distribution.ast_mean](#)
[nb_distribution.ast_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **ast_std ↑**

`x = nb_distribution.ast_std(a,b,c,d,e)`

Description:

Standard deviation of the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- a : The location parameter.
- b : The scale parameter (>0).
- c : The skewness parameter ($1>c>0$).
- d : The left parameter (>0).
- e : The right parameter (>0).

Output:

- x : The standard deviation of the distribution

See also:

[nb_distribution.ast_mode](#), [nb_distribution.ast_median](#)
[nb_distribution.ast_mean](#), [nb_distribution.ast_variance](#)

Written by Kenneth Sæterhagen Paulsen

► [ast_variance ↑](#)

`x = nb_distribution.ast_variance(a,b,c,d,e)`

Description:

Variance of the asymmetric t-distribution of Zhu and Galbraith (2009).

Input:

- a : The location parameter.
- b : The scale parameter (>0).
- c : The skewness parameter ($1>c>0$).
- d : The left parameter (>0).
- e : The right parameter (>0).

Output:

- x : The variance of the distribution

See also:

[nb_distribution.ast_mode](#), [nb_distribution.ast_median](#)
[nb_distribution.ast_mean](#)

► **beta_cdf** ↑

```
f = nb_distribution.beta_cdf(x,m,k)
```

Description:

CDF of the beta distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.beta_pdf](#), [nb_distribution.beta_rand](#)
[nb_distribution.beta_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **beta_domain** ↑

```
f = nb_distribution.beta_domain
```

Description:

Get the domain of the beta distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **beta_icdf** ↑

```
x = nb_distribution.beta_icdf(p,m,k)
```

Description:

Returns the inverse of the cdf at p of the beta(m,k) distribution

Input:

- p : A vector of probabilities
- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- x : A double with the quantile at each element of p of the beta(m,k) distribution

See also:

[nb_distribution.beta_cdf](#), [nb_distribution.beta_rand](#)
[nb_distribution.beta_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **beta_kurtosis ↑**

```
x = nb_distribution.beta_kurtosis(m,k)
```

Description:

Kurtosis of the beta distribution

Input:

- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- x : The kurtosis of the beta distribution

See also:

[nb_distribution.beta_median](#), [nb_distribution.beta_mean](#)
[nb_distribution.beta_variance](#)

► **beta_mean** ↑

```
x = nb_distribution.beta_mean(m,k)
```

Description:

Mean of the beta distribution

Input:

- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- x : The mean of the beta distribution

See also:

[nb_distribution.beta_mode](#), [nb_distribution.beta_median](#)
[nb_distribution.beta_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **beta_median** ↑

```
x = nb_distribution.beta_median(m,k)
```

Description:

Median of the beta distribution

Input:

- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- x : The median of the beta distribution

See also:

[nb_distribution.beta_mode](#), [nb_distribution.beta_mean](#)
[nb_distribution.beta_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **beta_mode** ↑

```
x = nb_distribution.beta_mode(m, k)
```

Description:

Mode of the beta distribution. When the $m, k \leq 1$ the distribution get bimodal, so mode can be either 0 or 1, so nan is returned

Input:

- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- x : The mode of the beta distribution

See also:

[nb_distribution.beta_median](#), [nb_distribution.beta_mean](#)
[nb_distribution.beta_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **beta_pdf** ↑

```
f = nb_distribution.beta_pdf(x, m, k)
```

Description:

PDF of the beta distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.beta_cdf](#), [nb_distribution.beta_rand](#)
[nb_distribution.beta_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **beta_rand** ↑

```
draws = nb_distribution.beta_rand(nrow, ncol, m, k)
```

Description:

Draw random numbers from the beta distribution

Input:

- nrow : Number of rows of the matrix drawn from the beta distribution
- ncol : Number of columns of the matrix drawn from the beta distribution
- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- draws : A nrow x ncol matrix of random numbers from the beta distribution

See also:

[nb_distribution.beta_pdf](#), [nb_distribution.beta_cdf](#)

Written by Kenneth S. Paulsen

► **beta_skewness** ↑

```
x = nb_distribution.beta_skewness(m, k)
```

Description:

Skewness of the beta distribution

Input:

- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- x : The skewness of the beta distribution

See also:

[nb_distribution.beta_median](#), [nb_distribution.beta_mean](#)
[nb_distribution.beta_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **beta_std ↑**

x = nb_distribution.beta_std(m, k)

Description:

Standard deviation of the beta distribution

Input:

- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- x : The standard deviation of the beta distribution

See also:

[nb_distribution.beta_mode](#), [nb_distribution.beta_median](#)
[nb_distribution.beta_mean](#), [nb_distribution.beta_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **beta_variance ↑**

```
x = nb_distribution.beta_variance(m,k)
```

Description:

Variance of the beta distribution

Input:

- m : First shape parameter of the beta distribution. The mean will be given by $m/(m + k)$
- k : Second shape parameter of the beta distribution

Output:

- x : The variance of the beta distribution

See also:

[nb_distribution.beta_mode](#), [nb_distribution.beta_median](#)
[nb_distribution.beta_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_cdf** ↑

```
f = nb_distribution.cauchy_cdf(x,m)
```

Description:

CDF of the cauchy distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.cauchy_pdf](#), [nb_distribution.cauchy_rand](#)
[nb_distribution.cauchy_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_domain** ↑

```
f = nb_distribution.cauchy_domain
```

Description:

Get the domain of the cauchy distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **cauchy_icdf** ↑

```
x = nb_distribution.cauchy_icdf(p,m,k)
```

Description:

Returns the inverse of the cdf at p of the cauchy distribution

Input:

- p : A vector of probabilities
- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : A double with the quantile at each element of p of the cauchy(m,k) distribution

See also:

[nb_distribution.cauchy_cdf](#), [nb_distribution.cauchy_rand](#)
[nb_distribution.cauchy_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_kurtosis** ↑

```
x = nb_distribution.cauchy_kurtosis(m,k)
```

Description:

Kurtosis of the cauchy distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The kurtosis of the cauchy distribution

See also:

[nb_distribution.cauchy_median](#), [nb_distribution.cauchy_mean](#)
[nb_distribution.cauchy_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_mean** ↑

x = nb_distribution.cauchy_mean(m, k)

Description:

Mean of the cauchy distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The mean of the cauchy distribution

See also:

[nb_distribution.cauchy_mode](#), [nb_distribution.cauchy_median](#)
[nb_distribution.cauchy_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_median** ↑

```
x = nb_distribution.cauchy_median(m, k)
```

Description:

Median of the cauchy distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The median of the cauchy distribution

See also:

[nb_distribution.cauchy_mode](#), [nb_distribution.cauchy_mean](#)
[nb_distribution.cauchy_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_mode** ↑

```
x = nb_distribution.cauchy_mode(m, k)
```

Description:

Mode of the cauchy distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The mode of the cauchy distribution

See also:

[nb_distribution.cauchy_median](#), [nb_distribution.cauchy_mean](#)
[nb_distribution.cauchy_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_pdf** ↑

```
f = nb_distribution.cauchy_pdf(x,m,k)
```

Description:

PDF of the cauchy distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.cauchy_cdf](#), [nb_distribution.cauchy_rand](#)
[nb_distribution.cauchy_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_rand** ↑

```
draws = nb_distribution.cauchy_rand(nrow,ncol,m,k)
```

Description:

Draw random numbers from the cauchy distribution

Input:

- nrow : Number of rows of the matrix drawn from the cauchy distribution
- ncol : Number of columns of the matrix drawn from the cauchy distribution
- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

```
- draws : A nrow x ncol matrix of random numbers from the cauchy distribution
```

See also:

[nb_distribution.cauchy_pdf](#), [nb_distribution.cauchy_cdf](#)

Modified by Kenneth S. Paulsen

► **cauchy_skewness ↑**

```
x = nb_distribution.cauchy_skewness(m, k)
```

Description:

Skewness of the cauchy distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The skewness of the cauchy distribution

See also:

[nb_distribution.cauchy_median](#), [nb_distribution.cauchy_mean](#)
[nb_distribution.cauchy_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **cauchy_std ↑**

```
x = nb_distribution.cauchy_std(m, k)
```

Description:

Standard deviation of the cauchy distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The standard deviation of the cauchy distribution

See also:

`nb_distribution.cauchy_mode`, `nb_distribution.cauchy_median`
`nb_distribution.cauchy_mean`, `nb_distribution.cauchy_variance`

Written by Kenneth Sæterhagen Paulsen

► **cauchy_variance ↑**

`x = nb_distribution.cauchy_variance(m, k)`

Description:

Variance of the cauchy distribution

Input:

- m : The location parameter. Mode = m. Must be a number.

- k : Scale parameter. Must be a positive number.

Output:

- x : The variance of the cauchy distribution

See also:

`nb_distribution.cauchy_mode`, `nb_distribution.cauchy_median`
`nb_distribution.cauchy_mean`

Written by Kenneth Sæterhagen Paulsen

► **cdf ↑**

`f = cdf(obj, x)`

Description:

Evaluate the cdf of the given distribution at the value(s) x.

Input:

- `obj` : An object of class `nb_distribution`
- `x` : A double with any size if `numel(obj) == 1`, otherwise it must be a `Tx1` double.

Output:

- `f` : `numel(obj) == 1` : A double with the same size as `x`
otherwise : A double with size `T x nobj`

Written by Kenneth Sæterhagen Paulsen

► **chis_cdf** ↑

```
f = nb_distribution.chis_cdf(x,m)
```

Description:

CDF of the chi squared distribution

Input:

- `x` : The point to evaluate the cdf, as a double
- `m` : A parameter such that the mean is `m`

Output:

- `f` : The CDF at the evaluated points, same size as `x`.

See also:

`nb_distribution.chis_pdf`, `nb_distribution.chis_rand`
`nb_distribution.chis_icdf`

Written by Kenneth Sæterhagen Paulsen

► **chis_domain** ↑

```
f = nb_distribution.chis_domain
```

Description:

Get the domain of the chis distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **chis_icdf** ↑

```
x = nb_distribution.chis_icdf(p,m)
```

Description:

Returns the inverse of the cdf at p of the chi squared distribution

Input:

- p : A vector of probabilities
- m : A parameter such that the mean is m

Output:

- x : A double with the quantile at each element of p of the chis(m,k) distribution

See also:

[nb_distribution.chis_cdf](#), [nb_distribution.chis_rand](#)
[nb_distribution.chis_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **chis_kurtosis** ↑

```
x = nb_distribution.chis_kurtosis(m)
```

Description:

Kurtosis of the chi squared distribution

Input:

- m : A parameter such that the mean is m

Output:

- x : The kurtosis of the chi squared distribution

See also:

`nb_distribution.chis_median`, `nb_distribution.chis_mean`
`nb_distribution.chis_variance`

Written by Kenneth Sæterhagen Paulsen

► **chis_mean** ↑

`x = nb_distribution.chis_mean(m)`

Description:

Mean of the chi squared distribution

Input:

- `m` : A parameter such that the mean is `m`

Output:

- `x` : The mean of the chi squared distribution

See also:

`nb_distribution.chis_mode`, `nb_distribution.chis_median`
`nb_distribution.chis_variance`

Written by Kenneth Sæterhagen Paulsen

► **chis_median** ↑

`x = nb_distribution.chis_median(m)`

Description:

Median of the chi squared distribution

Input:

- `m` : A parameter such that the mean is `m`

Output:

- `x` : The median of the chi squared distribution

See also:

`nb_distribution.chis_mode`, `nb_distribution.chis_mean`

[nb_distribution.chis_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **chis_mode** ↑

`x = nb_distribution.chis_mode(m)`

Description:

Mode of the chi squared distribution

Input:

- `m` : A parameter such that the mean is `m`

Output:

- `x` : The mode of the chi squared distribution

See also:

[nb_distribution.chis_median](#), [nb_distribution.chis_mean](#)
[nb_distribution.chis_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **chis_pdf** ↑

`f = nb_distribution.chis_pdf(x,m)`

Description:

PDF of the chi squared distribution

Input:

- `x` : The point to evaluate the pdf, as a double

- `m` : A parameter such that the mean is `m`

Output:

- `f` : The PDF at the evaluated points, same size as `x`.

See also:

`nb_distribution.chis_cdf`, `nb_distribution.chis_rand`
`nb_distribution.chis_icdf`

Written by Kenneth SÃ¶terhagen Paulsen

► **chis_rand** ↑

`draws = nb_distribution.chis_rand(nrow, ncol, m)`

Description:

Draw random numbers from the chis distribution

Input:

- `nrow` : Number of rows of the matrix drawn from the chis distribution
- `ncol` : Number of columns of the matrix drawn from the chis distribution
- `m` : A parameter such that the mean is `m`

Output:

- `draws` : A `nrow x ncol` matrix of random numbers from the chis distribution

See also:

`nb_distribution.chis_pdf`, `nb_distribution.chis_cdf`

Modified by Kenneth S. Paulsen

► **chis_skewness** ↑

`x = nb_distribution.chis_skewness(m)`

Description:

Skewness of the chi squared distribution

Input:

- `m` : A parameter such that the mean is `m`

Output:

- x : The skewness of the chi squared distribution

See also:

[nb_distribution.chis_median](#), [nb_distribution.chis_mean](#)
[nb_distribution.chis_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **chis_std** ↑

x = nb_distribution.chis_std(m)

Description:

Standard deviation of the chi squares distribution

Input:

- m : A parameter such that the mean is m

Output:

- x : The standard deviation of the chi squared distribution

See also:

[nb_distribution.chis_mode](#), [nb_distribution.chis_median](#)
[nb_distribution.chis_mean](#), [nb_distribution.chis_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **chis_variance** ↑

x = nb_distribution.chis_variance(m)

Description:

Variance of the chi squared distribution

Input:

- m : A parameter such that the mean is m

Output:

- x : The variance of the chi squared distribution

See also:

[nb_distribution.chis_mode](#), [nb_distribution.chis_median](#)
[nb_distribution.chis_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **confidenceInterval** ↑

```
ci = confidenceInterval(distribution, alpha)
```

Description:

Calculate confidence/probability interval

Input:

- distribution : A nb_distribution object
- alpha : Significance value. Default is 0.05;

Output:

- ci : A nobj x 2 double storing the confidence/probability intervals.

See also:

[nb_distribution.icdf](#)

Written by Henrik Halvorsen Hortemo

► **constant_cdf** ↑

```
f = nb_distribution.constant_cdf(x,m)
```

Description:

CDF of a constant.

Input:

- x : The point to evaluate the cdf, as a double
- m : The constant

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.constant_pdf](#), [nb_distribution.constant_rand](#)
[nb_distribution.constant_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **constant_domain** ↑

```
f = nb_distribution.constant_domain
```

Description:

Get the domain of a constant.

Input:

- m : The constant

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **constant_icdf** ↑

```
x = nb_distribution.constant_icdf(p,m)
```

Description:

Returns the inverse of the cdf at p of a constant

Input:

- p : A vector of probabilities
- m : The constant

Output:

- x : A double with the quantile at each element of p of the constant(m,k) distribution

See also:

[nb_distribution.constant_cdf](#), [nb_distribution.constant_rand](#)
[nb_distribution.constant_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **constant_kurtosis** ↑

`x = nb_distribution.constant_kurtosis(m)`

Description:

Kurtosis of a constant

Input:

- `m` : The constant

Output:

- `x` : 0

See also:

[nb_distribution.constant_median](#), [nb_distribution.constant_mean](#)
[nb_distribution.constant_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **constant_mean** ↑

`x = nb_distribution.constant_mean(m)`

Description:

Mean of a constant

Input:

- `m` : The constant

Output:

- `x` : The mean; `m`

See also:

`nb_distribution.constant_mode`, `nb_distribution.constant_median`
`nb_distribution.constant_variance`

Written by Kenneth Sæterhagen Paulsen

► **constant_median** ↑

`x = nb_distribution.constant_median(m)`

Description:

Median of a constant

Input:

- `m` : The constant

Output:

- `x` : The median; `m`

See also:

`nb_distribution.constant_mode`, `nb_distribution.constant_mean`
`nb_distribution.constant_variance`

Written by Kenneth Sæterhagen Paulsen

► **constant_mode** ↑

`x = nb_distribution.constant_mode(m)`

Description:

Mode of a constant

Input:

- `m` : The constant

Output:

- `x` : The mode; `m`

See also:

`nb_distribution.constant_median`, `nb_distribution.constant_mean`

`nb_distribution.constant_variance`

Written by Kenneth Sæterhagen Paulsen

► `constant_pdf` ↑

```
f = nb_distribution.constant_pdf(x,m)
```

Description:

PDF of a constant

Input:

- `x` : The point to evaluate the pdf, as a double
- `m` : The constant

Output:

- `f` : The PDF at the evaluated points, same size as `x`.

See also:

`nb_distribution.constant_cdf`, `nb_distribution.constant_rand`
`nb_distribution.constant_icdf`

Written by Kenneth Sæterhagen Paulsen

► `constant_rand` ↑

```
draws = nb_distribution.constant_rand(nrow,ncol,m)
```

Description:

"Draw" random numbers from distribution which always return the same number `m`. Same as `repmat(m,nrow,ncol)`.

Input:

- `nrow` : Number of rows of the matrix of the constant
- `ncol` : Number of columns of the matrix of the constant
- `m` : The constant

Output:

- draws : A nrow x ncol matrix of the number m

See also:

[nb_distribution.constant_pdf](#), [nb_distribution.constant_cdf](#)

Modified by Kenneth S. Paulsen

► **constant_skewness ↑**

x = nb_distribution.constant_skewness(m)

Description:

Skewness of a constant

Input:

- m : The constant

Output:

- x : 0

See also:

[nb_distribution.constant_median](#), [nb_distribution.constant_mean](#)
[nb_distribution.constant_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **constant_std ↑**

x = nb_distribution.constant_std(m)

Description:

Standard deviation of a constant

Input:

- m : The constant

Output:

- x : 0

See also:

[nb_distribution.constant_mode](#), [nb_distribution.constant_median](#)
[nb_distribution.constant_mean](#), [nb_distribution.constant_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **constant_variance** ↑

`x = nb_distribution.constant_variance(m)`

Description:

Variance of a constant

Input:

- `m` : The constant

Output:

- `x` : 0

See also:

[nb_distribution.constant_mode](#), [nb_distribution.constant_median](#)
[nb_distribution.constant_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **convert** ↑

`convert(obj)`

Description:

Convert a distribution to type 'kernel'

Input:

- `obj` : A matrix of nb_distributions objects

Output:

- `obj` : A matrix of nb_distributions objects with type set to 'kernel'

Written by Kenneth Sæterhagen Paulsen

► **defaultParameters** ↑

```
parameters = defaultParameters(type)
```

Description:

Get default parameters of a given distribution type.

Input:

- type : The type of distribution.

Output:

- parameters : A cell with the default parameters.

Written by Kenneth Sæterhagen Paulsen

► **domain** ↑

```
d = domain(obj)
```

Description:

Returns the full domain of the distribution represented by a nb_distribution object.

Input:

- obj : An object of class nb_distribution
- out : - 0 : Returns the lower and upper bound of the distribution, if truncated those limits are returned. Default.
- 1 : Returns the lower and upper bound of the distribution, if truncated those limits are not returned.
- 2 : Returns the lower and upper bound of the distribution, if truncated it will only return the lower truncation limit.
- 3 : Returns the lower and upper bound of the distribution, if truncated it will only return the upper truncation limit.

Output:

- domain : A nobjx2 double with the lower and upper limits of the domain.

Examples:

See also:

[nb_distribution.getEndOfDomain](#), [nb_distribution.getStartOfDomain](#)

Written by Kenneth Sæterhagen Paulsen

► **double2Dist** ↑

```
obj = nb_distribution.double2Dist(d)
```

Description:

Convert a double to a nb_distribution object representing a non-random variable, i.e. a constant.

Input:

- d : A double matrix. dim < 3

Output:

- obj : An object of class nb_distribution matching the size of d.

Examples:

```
obj = nb_distribution.double2Dist(rand(2,2))
```

Written by Kenneth Sæterhagen Paulsen

► **double2NormalDist** ↑

```
obj = nb_distribution.double2NormalDist(d,sigma)
```

Description:

Convert a double to a nb_distribution object representing a random univariate normal variable.

Input:

- d : A double matrix representing the mean. dim < 3

- sigma : A double matrix with same size as d representing the std.

Output:

```
- obj : An object of class nb_distribution matching the size of d.
```

Examples:

```
obj = nb_distribution.double2Dist(rand(2,2))
```

Written by Kenneth Sæterhagen Paulsen

► **empirical_cdf ↑**

```
f = nb_distribution.empirical_cdf(x,domain,density)
```

Description:

CDF of the (Kaplan-Meier) cumulative distribution function. To get the CDF of a point in between two points of the domain, a linear interpolation method is used.

Input:

```
- x : The points to evaluate the cdf, as a double (max dim is 3)  
- domain : The domain of the CDF.  
- CDF : The empirical cumulative density function.
```

Output:

```
- f : The CDF at the evaluated points, same size as x.
```

See also:

[nb_distribution.empirical_pdf](#), [nb_distribution.empirical_rand](#)
[nb_distribution.empirical_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **empirical_domain ↑**

```
f = nb_distribution.empirical_domain(domain)
```

Description:

Get the domain of the distribution

Input:

- domain : The domain of the distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **empirical_icdf** ↑

```
x = nb_distribution.empirical_icdf(p, domain, CDF)
```

Description:

Inverse CDF of the estimated empirical distribution. Uses the mean of the two closest points in the domain.

Input:

- p : A vector of probabilities
- domain : The domain of the distribution
- CDF : The cumulative density function

Output:

- x : The inverse CDF at the evaluated probabilities, same size as p.

See also:

[nb_distribution.empirical_pdf](#), [nb_distribution.empirical_rand](#)
[nb_distribution.empirical_cdf](#)

Written by Kenneth Sæterhagen Paulsen

► **empirical_mean** ↑

```
x = nb_distribution.empirical_mean(domain, density)
```

Description:

Mean of the estimated empirical density. This will use the [nb_distribution.empirical_rand](#) to make 1000 draws from the distribution, and then calculate the mean based on these draws.

Input:

- domain : The domain of the distribution
- CDF : The empirical CDF

Output:

- x : The mean of the estimated empirical density

See also:

[nb_distribution.empirical_median](#), [nb_distribution.empirical_mean](#)
[nb_distribution.empirical_variance](#), [nb_distribution.empirical_rand](#)

Written by Kenneth Sæterhagen Paulsen

► [**empirical_median**](#) ↑

x = nb_distribution.empirical_median(domain,density)

Description:

Median of the estimated empirical CDF. This will use the nb_distribution.empirical_icdf method to estimate the median.

Input:

- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The median of the estimated kernel density

See also:

[nb_distribution.kernel_mode](#), [nb_distribution.kernel_mean](#)
[nb_distribution.kernel_variance](#), [nb_distribution.kernel_rand](#)

Written by Kenneth Sæterhagen Paulsen

► [**empirical_mode**](#) ↑

x = nb_distribution.empirical_mode(domain,density)

Description:

The mode is found by finding the max point of the estimated PDF of the empirical CDF, and return the matching point in its domain.

Input:

- domain : The domain of the distribution.
- density : The cumulative density function of the distribution.

Output:

- x : The kurtosis of the estimated PDF of the empirical CDF density

See also:

[nb_distribution.empirical_median](#), [nb_distribution.empirical_mean](#)
[nb_distribution.empirical_variance](#), [nb_distribution.empirical_rand](#)

Written by Tobias Ingebrigtsen

► [empirical_pdf ↑](#)

```
f = nb_distribution.empirical_pdf(x,domain,CDF)
```

Description:

PDF of the estimated empirical density. To get the PDF of a point in between two points of the domain, a linear interpolation method is used.

Input:

- x : The points to evaluate the pdf, as a double.
- domain : The domain of the distribution.
- density : The empirical CDF.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.empirical_cdf](#), [nb_distribution.empirical_rand](#)
[nb_distribution.empirical_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► [empirical_rand ↑](#)

```
draws = nb_distribution.empirical_rand(nrow,ncol,domain,CDF)
```

Description:

Draw random numbers from an estimated empirical density.

Input:

- nrow : Number of rows of the matrix drawn from the normal distribution.
- ncol : Number of columns of the matrix drawn from the normal distribution.
- domain : The domain of the distribution.
- CDF : The empirical CDF.

Output:

- draws : A nrow x ncol matrix of random numbers from the estimated empirical density.

See also:

[nb_distribution.empirical_pdf](#), [nb_distribution.empirical_cdf](#)

Written by Kenneth S. Paulsen

► **empirical_skewness ↑**

```
x = nb_distribution.empirical_skewness(domain,density)
```

Description:

Skewness of the estimated empirical density. This will use the `nb_distribution.empirical_rand` to make 1000 draws from the distribution, and then calculate the skewness based on these draws.

It will adjust the skewness for bias. See the `skewness` method by MATLAB for more on this

Input:

- domain : The domain of the distribution.
- density : The empirical CDF.

Output:

- x : The skewness of the estimated empirical density

See also:

`nb_distribution.empirical_median`, `nb_distribution.empirical_mean`
`nb_distribution.empirical_variance`, `nb_distribution.empirical_rand`

Written by Kenneth Sæterhagen Paulsen

► **`empirical_std`** ↑

`x = nb_distribution.empirical_std(domain, density)`

Description:

Standard deviation of the estimated empirical density. This will use the `nb_distribution.empirical_rand` to make 1000 draws from the distribution, and then calculate the standard deviation based on those draws.

It will adjust the standard deviation by T-1.

Input:

- `domain` : The domain of the distribution.
- `CDF` : The empirical CDF.

Output:

- `x` : The standard deviation of the estimated empirical density.

See also:

`nb_distribution.empirical_median`, `nb_distribution.empirical_mean`
`nb_distribution.empirical_variance`, `nb_distribution.empirical_rand`

Written by Kenneth Sæterhagen Paulsen

► **`empirical_variance`** ↑

`x = nb_distribution.empirical_variance(domain, CDF)`

Description:

Variance of the empirical density. This will use the `nb_distribution.empirical_rand` to make 1000 draws from the distribution, and then calculate the variance based on those draws.

It will adjust the variance by T-1.

Input:

- domain : The domain of the distribution.
- density : The empirical CDF.

Output:

- x : The variance of the estimated empirical density.

See also:

[nb_distribution.empirical_median](#), [nb_distribution.empirical_mean](#)
[nb_distribution.empirical_std](#), [nb_distribution.empirical_rand](#)

Written by Kenneth Sæterhagen Paulsen

► estimate ↑

```
obj = nb_distribution.estimate(x,xi,varargin)
```

Description:

Estimate a distribution using kernel density estimation.

Input:

- x : The assumed random observations of the distribution. As a nobs x 1 double.
- xi : The points where the distribution should be evaluated, i.e. the domain of the distribution. As a nobs x 1 double.
If not provided or given as empty the method `nb_distribution.estimateDomain` will be used.
- varargin : Optional input given to the `nb_ksdensity` function. Please see help for that function.

Output:

- obj : A `nb_distribution` object. See the property `domain` for the distributions `domain`, and `density` to see its PDF.

Examples:

```
x = randn(100,1);
obj = nb_distribution.estimate(x);
```

See also:

nb_distribution.estimateDomain

Written by Kenneth Sæterhagen Paulsen

► **estimateDomain** ↑

```
xi = nb_distribution.estimateDomain(x)
xi = nb_distribution.estimateDomain(x,numberOfStd,numDomain)
```

Description:

Estimate the domain of a distribution. Calculated as;

```
xi = min(x) - std(x):incr:max(x) + std(x)
```

Where;

```
incr = (xi(end) - xi(1))/999
```

Caution: The estimated domain will be estimated separately for each variable.

Input:

- x : The assumed random observation of the distribution.
As a nobs x nvars double.
- numberOfStd : Number of added space in the tails. In terms of the standard deviation. Default is 1.
- numDomain : Number of points of the returned domain. Default is 1000.

Output:

- xi : The domain of the distribution, as 1000 x nvars double

Written by Kenneth Sæterhagen Paulsen

► **exp_cdf** ↑

```
f = nb_distribution.exp_cdf(x,m)
```

Description:

CDF of the exponential distribution

Input:

- `x` : The point to evaluate the cdf, as a double
- `m` : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- `f` : The CDF at the evaluated points, same size as `x`.

See also:

[nb_distribution.exp_pdf](#), [nb_distribution.exp_rand](#)
[nb_distribution.exp_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► [exp_domain ↑](#)

`f = nb_distribution.exp_domain`

Description:

Get the domain of the exponential distribution

Output:

- `domain` : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► [exp_icdf ↑](#)

`x = nb_distribution.exp_icdf(p,m)`

Description:

Returns the inverse of the cdf at `p` of the exponential distribution

Input:

- `p` : A vector of probabilities
- `m` : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- `x` : A double with the quantile at each element of `p` of the $F(m, k)$ distribution

See also:

[nb_distribution.exp_cdf](#), [nb_distribution.exp_rand](#)
[nb_distribution.exp_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **exp_kurtosis** ↑

`x = nb_distribution.exp_kurtosis(m)`

Description:

Kurtosis of the exponential distribution.

Input:

- `m` : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- `x` : The kurtosis of the exponential distribution

See also:

[nb_distribution.exp_median](#), [nb_distribution.exp_mean](#)
[nb_distribution.exp_variance](#), [nb_distribution.exp_skewness](#)

Written by Kenneth Sæterhagen Paulsen

► **exp_mean** ↑

`x = nb_distribution.exp_mean(m)`

Description:

Mean of the exponential distribution.

Input:

- `m` : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- x : The mean of the exponential distribution

See also:

[nb_distribution.exp_mode](#), [nb_distribution.exp_mean](#)
[nb_distribution.exp_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **exp_median** ↑

x = nb_distribution.exp_median(m)

Description:

Median of the exponential distribution

Input:

- m : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- x : The median of the exponential distribution

See also:

[nb_distribution.exp_mode](#), [nb_distribution.exp_mean](#)
[nb_distribution.exp_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **exp_mode** ↑

x = nb_distribution.exp_mode(m)

Description:

Mode of the exponential distribution.

Input:

- m : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- `x` : The mode of the exponential distribution

See also:

`nb_distribution.exp_median`, `nb_distribution.exp_mean`
`nb_distribution.exp_variance`

Written by Kenneth Sæterhagen Paulsen

► **`exp_pdf`** ↑

```
f = nb_distribution.exp_pdf(x,m)
```

Description:

PDF of the exponential distribution

Input:

- `x` : The point to evaluate the pdf, as a double

- `m` : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- `f` : The PDF at the evaluated points, same size as `x`.

See also:

`nb_distribution.exp_cdf`, `nb_distribution.exp_rand`
`nb_distribution.exp_icdf`

Written by Kenneth Sæterhagen Paulsen

► **`exp_rand`** ↑

```
draws = nb_distribution.exp_rand(nrow,ncol,m)
```

Description:

Draw random numbers from the exponential distribution

Input:

- nrow : Number of rows of the matrix drawn from the exponential distribution
- ncol : Number of columns of the matrix drawn from the exponential distribution
- m : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- draws : A nrow x ncol matrix of random numbers from the exponential distribution

See also:

[nb_distribution.exp_pdf](#), [nb_distribution.exp_cdf](#)

Modified by Kenneth S. Paulsen

► [**exp_skewness ↑**](#)

`x = nb_distribution.exp_skewness(m)`

Description:

Skewness of the exponential distribution.

Input:

- m : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- x : The skewness of the exponential distribution

See also:

[nb_distribution.exp_median](#), [nb_distribution.exp_mean](#)
[nb_distribution.exp_variance](#)

Written by Kenneth Sæterhagen Paulsen

► [**exp_std ↑**](#)

`x = nb_distribution.exp_std(m)`

Description:

Standard deviation of the exponential distribution.

Input:

- m : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- x : The standard deviation of the exponential distribution

See also:

[nb_distribution.exp_mode](#), [nb_distribution.exp_median](#)
[nb_distribution.exp_mean](#), [nb_distribution.exp_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **exp_variance ↑**

x = nb_distribution.exp_variance(m)

Description:

Variance of the exponential distribution.

Input:

- m : The rate parameter of the distribution. Must be positive 1x1 double.

Output:

- x : The variance of the exponential distribution

See also:

[nb_distribution.exp_mode](#), [nb_distribution.exp_median](#)
[nb_distribution.exp_mean](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **f_cdf ↑**

f = nb_distribution.f_cdf(x,m,k)

Description:

CDF of the F(m, k) distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- f : The CDF at the evaluated points, same size as x .

See also:

[nb_distribution.f_pdf](#), [nb_distribution.f_rand](#)
[nb_distribution.f_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► [f_domain ↑](#)

`f = nb_distribution.f_domain`

Description:

Get the domain of the F-distribution

Output:

- $domain$: A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► [f_icdf ↑](#)

`x = nb_distribution.f_icdf(p, m, k)`

Description:

Returns the inverse of the cdf at p of the F(m, k) distribution

Input:

- p : A vector of probabilities
- m : First parameter of the distribution. Must be positive.
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- x : A double with the quantile at each element of p of the $F(m, k)$ distribution

See also:

[nb_distribution.f_cdf](#), [nb_distribution.f_rand](#)
[nb_distribution.f_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► f_kurtosis ↑

`x = nb_distribution.f_kurtosis(m, k)`

Description:

Kurtosis of the $F(m, k)$ distribution. Only defined for $k > 8$, otherwise not defined (will return nan).

Input:

- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- x : The kurtosis of the $F(m, k)$ distribution

See also:

[nb_distribution.f_median](#), [nb_distribution.f_mean](#)
[nb_distribution.f_variance](#), [nb_distribution.f_skewness](#)

Written by Kenneth Sæterhagen Paulsen

► **f_mean** ↑

```
x = nb_distribution.f_mean(m, k)
```

Description:

Mean of the $F(m, k)$ distribution. Only defined for $k > 2$, otherwise not defined (will return nan).

Input:

- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- x : The mean of the $F(m, k)$ distribution

See also:

[nb_distribution.f_mode](#), [nb_distribution.f_median](#)
[nb_distribution.f_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **f_median** ↑

```
x = nb_distribution.f_median(m, k)
```

Description:

Median of the $F(m, k)$ distribution

Input:

- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- x : The median of the $F(m, k)$ distribution

See also:

[nb_distribution.f_mode](#), [nb_distribution.f_mean](#)
[nb_distribution.f_variance](#)

Written by Kenneth Å!terhagen Paulsen

► **f_mode** ↑

`x = nb_distribution.f_mode(m, k)`

Description:

Mode of the $F(m, k)$ distribution. Only defined for $m > 2$, otherwise not defined (will return nan).

Input:

- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- x : The mode of the $F(m, k)$ distribution

See also:

[nb_distribution.f_median](#), [nb_distribution.f_mean](#)
[nb_distribution.f_variance](#)

Written by Kenneth Å!terhagen Paulsen

► **f_pdf** ↑

`f = nb_distribution.f_pdf(x, m, k)`

Description:

PDF of the $F(m, k)$ distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : First parameter of the distribution. Must be positive.
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- f : The PDF at the evaluated points, same size as x .

See also:

[nb_distribution.f_cdf](#), [nb_distribution.f_rand](#)
[nb_distribution.f_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **f_rand** ↑

```
draws = nb_distribution.f_rand(nrow, ncol, m, k)
```

Description:

Draw random numbers from the $F(m, k)$ distribution

Input:

- $nrow$: Number of rows of the matrix drawn from the $F(m, k)$ distribution
- $ncol$: Number of columns of the matrix drawn from the $F(m, k)$ distribution
- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- $draws$: A $nrow \times ncol$ matrix of random numbers from the $F(m, k)$ distribution

See also:

[nb_distribution.f_pdf](#), [nb_distribution.f_cdf](#)

Modified by Kenneth S. Paulsen

► **f_skewness** ↑

```
x = nb_distribution.f_skewness(m,k)
```

Description:

Skewness of the $F(m, k)$ distribution. Only defined for $k > 6$. Will return nan otherwise.

Input:

- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- x : The skewness of the $F(m, k)$ distribution

See also:

[nb_distribution.f_median](#), [nb_distribution.f_mean](#)
[nb_distribution.f_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **f_std** ↑

```
x = nb_distribution.f_std(m,k)
```

Description:

Standard deviation of the $F(m, k)$ distribution. Only defined for $k > 4$. Will return nan otherwise.

Input:

- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- x : The standard deviation of the $F(m, k)$ distribution

See also:

[nb_distribution.f_mode](#), [nb_distribution.f_median](#)
[nb_distribution.f_mean](#), [nb_distribution.f_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **f_variance ↑**

```
x = nb_distribution.f_variance(m,k)
```

Description:

Variance of the F(m, k) distribution. Only defined for $k > 4$. Will return nan otherwise.

Input:

- m : First parameter of the distribution. Must be positive
- k : Second parameter of the distribution. A parameter such that the mean of the F-distribution is equal to $k/(k-2)$ for $k > 2$. Must be positive.

Output:

- x : The variance of the F(m, k) distribution

See also:

[nb_distribution.f_mode](#), [nb_distribution.f_median](#)
[nb_distribution.f_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **fgamma_cdf ↑**

```
f = nb_distribution.fgamma_cdf(x,m,k)
```

Description:

CDF of the flipped gamma distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : A parameter such that the mean of the flipped gamma = $-m*k$
- k : A parameter such that the variance of the flipped gamma = $m*(k^2)$

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.fgamma_pdf](#), [nb_distribution.fgamma_rand](#)
[nb_distribution.fgamma_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► [fgamma_domain](#) ↑

f = nb_distribution.fgamma_domain

Description:

Get the domain of the flipped gamma distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► [fgamma_icdf](#) ↑

x = nb_distribution.fgamma_icdf(p,m,k)

Description:

Returns the inverse of the cdf at p of the flipped gamma(m,k) distribution.

Input:

- p : A vector of probabilities

- m : A parameter such that the mean of the flipped gamma = -m*k

- k : A parameter such that the variance of the flipped gamma = m*(k^2)

Output:

- x : A double with the quantile at each element of p of the flipped gamma(m,k) distribution

See also:

[nb_distribution.fgamma_cdf](#), [nb_distribution.fgamma_rand](#)
[nb_distribution.fgamma_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **fgamma_kurtosis** ↑

`x = nb_distribution.fgamma_kurtosis(m,k)`

Description:

Kurtosis of the flipped gamma distribution

Input:

- `m` : A parameter such that the mean of the flipped gamma = $-m*k$
- `k` : A parameter such that the variance of the flipped gamma = $m*(k^2)$

Output:

- `x` : The kurtosis of the flipped gamma distribution

See also:

[nb_distribution.fgamma_median](#), [nb_distribution.fgamma_mean](#)
[nb_distribution.fgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **fgamma_mean** ↑

`x = nb_distribution.fgamma_mean(m,k)`

Description:

Mean of the flipped gamma distribution

Input:

- `m` : A parameter such that the mean of the flipped gamma = $-m*k$
- `k` : A parameter such that the variance of the flipped gamma = $m*(k^2)$

Output:

- `x` : The mean of the flipped gamma distribution

See also:

`nb_distribution.fgamma_mode`, `nb_distribution.fgamma_median`
`nb_distribution.fgamma_variance`

Written by Kenneth SÃ¶terhagen Paulsen

► **`fgamma_median`** ↑

`x = nb_distribution.fgamma_median(m, k)`

Description:

Median of the flipped gamma distribution

Input:

- `m` : A parameter such that the mean of the flipped gamma = $-m*k$
- `k` : A parameter such that the variance of the flipped gamma = $m*(k^2)$

Output:

- `x` : The median of the flipped gamma distribution

See also:

`nb_distribution.fgamma_mode`, `nb_distribution.fgamma_mean`
`nb_distribution.fgamma_variance`

Written by Kenneth SÃ¶terhagen Paulsen

► **`fgamma_mode`** ↑

`x = nb_distribution.fgamma_mode(m, k)`

Description:

Mode of the flipped gamma distribution

Input:

- `m` : A parameter such that the mean of the flipped gamma = $-m*k$
- `k` : A parameter such that the variance of the flipped gamma = $m*(k^2)$

Output:

- x : The mode of the flipped gamma distribution

See also:

[nb_distribution.fgamma_median](#), [nb_distribution.fgamma_mean](#)
[nb_distribution.fgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► [fgamma_pdf](#) ↑

f = nb_distribution.fgamma_pdf(x,m,k)

Description:

PDF of the flipped gamma distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : A parameter such that the mean of the flipped gamma = -m*k
- k : A parameter such that the variance of the flipped gamma = m*(k^2)

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.fgamma_cdf](#), [nb_distribution.fgamma_rand](#)
[nb_distribution.fgamma_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► [fgamma_rand](#) ↑

draws = nb_distribution.fgamma_rand(nrow,ncol,m,k)

Description:

Draw random numbers from the flipped gamma distribution

Input:

```
- nrow : Number of rows of the matrix drawn from the gamma distribution  
- ncol : Number of columns of the matrix drawn from the gamma distribution  
- m : A parameter such that the mean of the flipped gamma = -m*k  
- k : A parameter such that the variance of the flipped gamma = m*(k^2)
```

Output:

```
- draws : A nrow x ncol matrix of random numbers from the flipped gamma distribution
```

See also:

[nb_distribution.fgamma_pdf](#), [nb_distribution.fgamma_cdf](#)

Modified by Kenneth S. Paulsen

► **fgamma_skewness ↑**

```
x = nb_distribution.fgamma_skewness(m, k)
```

Description:

Skewness of the flipped gamma distribution

Input:

```
- m : A parameter such that the mean of the flipped gamma = -m*k  
- k : A parameter such that the variance of the flipped gamma = m*(k^2)
```

Output:

```
- x : The skewness of the flipped gamma distribution
```

See also:

[nb_distribution.fgamma_median](#), [nb_distribution.fgamma_mean](#)
[nb_distribution.fgamma_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **fgamma_std ↑**

```
x = nb_distribution.fgamma_std(m, k)
```

Description:

Standard deviation of the flipped gamma distribution

Input:

- m : A parameter such that the mean of the flipped gamma = -m*k
- k : A parameter such that the variance of the flipped gamma = m*(k^2)

Output:

- x : The standard deviation of the flipped gamma distribution

See also:

[nb_distribution.fgamma_mode](#), [nb_distribution.fgamma_median](#)
[nb_distribution.fgamma_mean](#), [nb_distribution.fgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **fgamma_variance ↑**

```
x = nb_distribution.fgamma_variance(m, k)
```

Description:

Variance of the flipped gamma distribution

Input:

- m : A parameter such that the mean of the flipped gamma = -m*k
- k : A parameter such that the variance of the flipped gamma = m*(k^2)

Output:

- x : The variance of the flipped gamma distribution

See also:

[nb_distribution.fgamma_mode](#), [nb_distribution.fgamma_median](#)
[nb_distribution.fgamma_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **[finvgamma_cdf](#)** ↑

```
f = nb_distribution.finvgamma_cdf(x,m,k)
```

Description:

CDF of the flipped invgamma distribution

Input:

- *x* : The point to evaluate the cdf, as a double
- *m* : The shape parameter, as a double >0.
- *k* : The scale parameter, as a double >0.

Output:

- *f* : The CDF at the evaluated points, same size as *x*.

See also:

[nb_distribution.finvgamma_pdf](#), [nb_distribution.finvgamma_rand](#)
[nb_distribution.finvgamma_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **[finvgamma_domain](#)** ↑

```
f = nb_distribution.finvgamma_domain
```

Description:

Get the domain of the flipped invgamma distribution

Output:

- *domain* : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **[finvgamma_icdf](#)** ↑

```
x = nb_distribution.finvgamma_icdf(p,m,k)
```

Description:

Returns the inverse of the cdf at p of the flipped invgamma(m,k) distribution

Input:

- p : A vector of probabilities
- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : A double with the quantile at each element of p of the flipped invgamma(m,k) distribution

See also:

[nb_distribution.finvgamma_cdf](#), [nb_distribution.finvgamma_rand](#)
[nb_distribution.finvgamma_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **finvgamma_kurtosis ↑**

x = nb_distribution.finvgamma_kurtosis(m,k)

Description:

Kurtosis of the flipped invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The kurtosis of the flipped invgamma distribution

See also:

[nb_distribution.finvgamma_median](#), [nb_distribution.finvgamma_mean](#)
[nb_distribution.finvgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **finvgamma_mean** ↑

```
x = nb_distribution.finvgamma_mean(m,k)
```

Description:

Mean of the flipped invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The mean of the flipped invgamma distribution

See also:

[nb_distribution.finvgamma_mode](#), [nb_distribution.finvgamma_median](#)
[nb_distribution.finvgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **finvgamma_median** ↑

```
x = nb_distribution.finvgamma_median(m,k)
```

Description:

Median of the flipped invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The median of the flipped invgamma distribution

See also:

[nb_distribution.finvgamma_mode](#), [nb_distribution.finvgamma_mean](#)
[nb_distribution.finvgamma_variance](#)

► **finvgamma_mode** ↑

```
x = nb_distribution.finvgamma_mode(m,k)
```

Description:

Mode of the flipped invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The mode of the flipped invgamma distribution

See also:

[nb_distribution.finvgamma_median](#), [nb_distribution.finvgamma_mean](#)
[nb_distribution.finvgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **finvgamma_pdf** ↑

```
f = nb_distribution.finvgamma_pdf(x,m,k)
```

Description:

PDF of the flipped invgamma distribution

Input:

- x : The point to evaluate the pdf, as a double

Written by Kenneth Sæterhagen Paulsen

► **finvgamma_rand** ↑

```
draws = nb_distribution.finvgamma_rand(nrow, ncol, m, k)
```

Description:

Draw random numbers from the flipped invgamma distribution

Input:

- nrow : Number of rows of the matrix drawn from the invgamma distribution
- ncol : Number of columns of the matrix drawn from the invgamma distribution
- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- draws : A nrow x ncol matrix of random numbers from the flipped invgamma distribution

See also:

[nb_distribution.finvgamma_pdf](#), [nb_distribution.finvgamma_cdf](#)

Modified by Kenneth S. Paulsen

► **finvgamma_skewness** ↑

```
x = nb_distribution.finvgamma_skewness(m, k)
```

Description:

Skewness of the flipped invgamma distribution

Input:

- m : The shape parameter, as a double >0.

- k : The scale parameter, as a double >0.

Output:

- x : The skewness of the flipped invgamma distribution

See also:

[nb_distribution.finvgamma_median](#), [nb_distribution.finvgamma_mean](#)
[nb_distribution.finvgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **finvgamma_std ↑**

x = nb_distribution.finvgamma_std(m, k)

Description:

Standard deviation of the flipped invgamma distribution

Input:

- m : The shape parameter, as a double >0.

- k : The scale parameter, as a double >0.

Output:

- x : The standard deviation of the flipped invgamma distribution

See also:

[nb_distribution.finvgamma_mode](#), [nb_distribution.finvgamma_median](#)
[nb_distribution.finvgamma_mean](#), [nb_distribution.finvgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **finvgamma_variance ↑**

x = nb_distribution.finvgamma_variance(m, k)

Description:

Variance of the flipped invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The variance of the flipped invgamma distribution

See also:

[nb_distribution.finvgamma_mode](#), [nb_distribution.finvgamma_median](#)
[nb_distribution.finvgamma_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **gamma_cdf** ↑

f = nb_distribution.gamma_cdf(x, m, k)

Description:

CDF of the gamma distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : A parameter such that the mean of the gamma = m*k
- k : A parameter such that the variance of the gamma = m*(k^2)

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.gamma_pdf](#), [nb_distribution.gamma_rand](#)
[nb_distribution.gamma_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **gamma_domain** ↑

f = nb_distribution.gamma_domain

Description:

Get the domain of the gamma distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth SÃ¶terhagen Paulsen

► **gamma_icdf** ↑

```
x = nb_distribution.gamma_icdf(p,m,k)
```

Description:

Returns the inverse of the cdf at p of the gamma(m,k) distribution

Input:

- p : A vector of probabilities
- m : A parameter such that the mean of the gamma = m*k
- k : A parameter such that the variance of the gamma = m*(k^2)

Output:

- x : A double with the quantile at each element of p of the gamma(m,k) distribution

See also:

[nb_distribution.gamma_cdf](#), [nb_distribution.gamma_rand](#)
[nb_distribution.gamma_pdf](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **gamma_kurtosis** ↑

```
x = nb_distribution.gamma_kurtosis(m,k)
```

Description:

Kurtosis of the gamma distribution

Input:

- m : A parameter such that the mean of the gamma = $m \cdot k$
- k : A parameter such that the variance of the gamma = $m \cdot (k^2)$

Output:

- x : The kurtosis of the gamma distribution

See also:

[nb_distribution.gamma_median](#), [nb_distribution.gamma_mean](#)
[nb_distribution.gamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **gamma_mean** ↑

x = nb_distribution.gamma_mean(m, k)

Description:

Mean of the gamma distribution

Input:

- m : A parameter such that the mean of the gamma = $m \cdot k$
- k : A parameter such that the variance of the gamma = $m \cdot (k^2)$

Output:

- x : The mean of the gamma distribution

See also:

[nb_distribution.gamma_mode](#), [nb_distribution.gamma_median](#)
[nb_distribution.gamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **gamma_median** ↑

x = nb_distribution.gamma_median(m, k)

Description:

Median of the gamma distribution

Input:

- m : A parameter such that the mean of the gamma = m*k
- k : A parameter such that the variance of the gamma = m*(k^2)

Output:

- x : The median of the gamma distribution

See also:

[nb_distribution.gamma_mode](#), [nb_distribution.gamma_mean](#)
[nb_distribution.gamma_variance](#)

Written by Kenneth SÃ¶derhagen Paulsen

► **gamma_mode** ↑

x = nb_distribution.gamma_mode(m,k)

Description:

Mode of the gamma distribution

Input:

- m : A parameter such that the mean of the gamma = m*k
- k : A parameter such that the variance of the gamma = m*(k^2)

Output:

- x : The mode of the gamma distribution

See also:

[nb_distribution.gamma_median](#), [nb_distribution.gamma_mean](#)
[nb_distribution.gamma_variance](#)

Written by Kenneth SÃ¶derhagen Paulsen

► **gamma_pdf** ↑

f = nb_distribution.gamma_pdf(x,m,k)

Description:

PDF of the gamma distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : A parameter such that the mean of the gamma = $m \cdot k$
- k : A parameter such that the variance of the gamma = $m \cdot (k^2)$

Output:

- f : The PDF at the evaluated points, same size as x .

See also:

[nb_distribution.gamma_cdf](#), [nb_distribution.gamma_rand](#)
[nb_distribution.gamma_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **gamma_rand** ↑

draws = nb_distribution.gamma_rand(nrow, ncol, m, k)

Description:

Draw random numbers from the Gamma distribution

Input:

- $nrow$: Number of rows of the matrix drawn from the gamma distribution
- $ncol$: Number of columns of the matrix drawn from the gamma distribution
- m : A parameter such that the mean of the gamma = $m \cdot k$
- k : A parameter such that the variance of the gamma = $m \cdot (k^2)$

Output:

- $draws$: A $nrow \times ncol$ matrix of random numbers from the gamma distribution

See also:

[nb_distribution.gamma_pdf](#), [nb_distribution.gamma_cdf](#)

Modified by Kenneth S. Paulsen

► **gamma_skewness** ↑

```
x = nb_distribution.gamma_skewness(m,k)
```

Description:

Skewness of the gamma distribution

Input:

- m : A parameter such that the mean of the gamma = $m \cdot k$
- k : A parameter such that the variance of the gamma = $m \cdot (k^2)$

Output:

- x : The skewness of the gamma distribution

See also:

[nb_distribution.gamma_median](#), [nb_distribution.gamma_mean](#)
[nb_distribution.gamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **gamma_std** ↑

```
x = nb_distribution.gamma_std(m,k)
```

Description:

Standard deviation of the gamma distribution

Input:

- m : A parameter such that the mean of the gamma = $m \cdot k$
- k : A parameter such that the variance of the gamma = $m \cdot (k^2)$

Output:

- x : The standard deviation of the gamma distribution

See also:

[nb_distribution.gamma_mode](#), [nb_distribution.gamma_median](#)
[nb_distribution.gamma_mean](#), [nb_distribution.gamma_variance](#)

► **gamma_variance** ↑

```
x = nb_distribution.gamma_variance(m,k)
```

Description:

Variance of the gamma distribution

Input:

- m : A parameter such that the mean of the gamma = m*k
- k : A parameter such that the variance of the gamma = m*(k^2)

Output:

- x : The variance of the gamma distribution

See also:

[nb_distribution.gamma_mode](#), [nb_distribution.gamma_median](#)
[nb_distribution.gamma_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property value of a nb_distribution object.

Type properties(obj) in the command line to get a list of supported properties, and type help nb_distribution.<propertyName> to get help on a specific property.

Input:

- obj : An object of class nb_distribution
- propertyName : A string with the property name

Output:

- `propertyValue` : The return value of the wanted property.

Examples:

```
propertyValue = get(obj,'type');
```

Written by Kenneth S. Paulsen

► **getEndOfDomain** ↑

```
start = getEndOfDomain(obj)
```

Description:

Get the approximate end point of the domain of all the distributions.
Uses the 99th percentile.

Input:

- `obj` : A vector of `nb_distribution` objects

Output:

- `finish` : The start point of the distribution, as `1x1 double`

See also:

[nb_distribution.domain](#)

Written by Kenneth Sæterhagen Paulsen

► **getNumberOfParameters** ↑

```
value = getNumberOfParameters(obj)
```

Description:

Get the number of parameters of the distribution.

Output:

- `value` : The number of parameters of the object.

Written by Kenneth Sæterhagen Paulsen

► **getParameters** ↑

```
value = getParameters(obj)
```

Description:

Get the parameter values.

Output:

- value : The parameters of the object, as 1 x nParam double.

Written by Kenneth Sæterhagen Paulsen

► **getStartOfDomain** ↑

```
start = getStartOfDomain(obj)
```

Description:

Get the approximate start point of the domain of all the distributions.
Uses the 1st percentile.

Input:

- obj : A vector of nb_distribution objects

Output:

- start : The start point of the distribution, as 1x1 double

See also:

[nb_distribution.domain](#)

Written by Kenneth Sæterhagen Paulsen

► **getTheoreticalHistCounts** ↑

```
hist = getTheoreticalHistCounts(obj,intervals)
```

Description:

Get the theoretical hist counts of the distribution. The output is per observation, so you need to multiply it by the number of observation to get the final histogram counts.

Input:

- obj : A nb_distribution object.
- intervals : A 1 x N double with upper bound of the intervals of the return histogram. intervals(end), should be the upper bound of the domain of the distribution.

Output:

- hist : A 1 x N double with the theoretical count of each interval.

Written by Kenneth Sæterhagen Paulsen

► hist_cdf ↑

```
f = nb_distribution.hist_cdf(x,a,b,c,d,e)
```

Description:

"CDF" type histogram.

Input:

- x : The bin points of the histogram, as a vector double.
- a : The data points, as a nobs x 1 double.

Output:

- f : The "CDF" at the evaluated bins, same size as x.

See also:

[nb_distribution.hist_pdf](#), [nb_distribution.hist_rand](#)
[nb_distribution.hist_icdf](#), [nb_mci](#)

Written by Kenneth Sæterhagen Paulsen

► hist_domain ↑

```
f = nb_distribution.hist_domain(a)
```

Description:

Get the domain of the histogram, i.e. min and max of the empirical data.

Input:

- a : The data points.

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **hist_icdf** ↑

```
x = nb_distribution.hist_icdf(p,a,b,c,d,e)
```

Description:

Inverse "CDF" type histogram.

Input:

- p : A vector of probabilities
- a : The data points, as a nobs x 1 double.

Output:

- x : A double with the quantile at each element of p of the gamma(m,k) distribution

See also:

[nb_distribution.hist_cdf](#), [nb_distribution.hist_rand](#)
[nb_distribution.hist_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **hist_kurtosis** ↑

```
x = nb_distribution.hist_kurtosis(a,b,c,d,e)
```

Description:

Empirical kurtosis.

Input:

- a : The data points, as a nobs x 1 double.

Output:

- x : The kurtosis of the data.

See also:

[nb_distribution.hist_median](#), [nb_distribution.hist_mean](#)
[nb_distribution.hist_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **hist_mean** ↑

```
x = nb_distribution.hist_mean(a)
```

Description:

Empirical mean.

Input:

- a : The data points, as a nobs x 1 double.

Output:

- x : The mean of the data.

See also:

[nb_distribution.hist_mode](#), [nb_distribution.hist_median](#)
[nb_distribution.hist_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **hist_median** ↑

```
x = nb_distribution.hist_median(a)
```

Description:

Empirical median.

Input:

- a : The data points, as a nobs x 1 double.

Output:

- x : The median of the data.

See also:

[nb_distribution.hist_mode](#), [nb_distribution.hist_mean](#)
[nb_distribution.hist_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **hist_mode** ↑

x = nb_distribution.hist_mode(a)

Description:

Empirical mode. Calculated using a kernel method.

Input:

- a : The data points, as a nobs x 1 double.

Output:

- x : The mode of the data.

See also:

[nb_distribution.hist_median](#), [nb_distribution.hist_mean](#)
[nb_distribution.hist_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **hist_pdf** ↑

f = nb_distribution.hist_pdf(x,a)

Description:

"PDF" type histogram.

Input:

- x : The bin points of the histogram, as a vector double

- a : The data points, as a nobs x 1 double.

Output:

- f : The "PDF" at the evaluated points, same size as x.

See also:

[nb_distribution.hist_cdf](#), [nb_distribution.hist_rand](#)
[nb_distribution.hist_icdf](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **hist_rand** ↑

draws = nb_distribution.hist_rand(nrow, ncol, a)

Description:

This function is not supported!

Input:

- nrow : Number of rows of the matrix drawn from the distribution
- ncol : Number of columns of the matrix drawn from the distribution
- a : The data points, as a nobs x 1 double.

Output:

- draws : No output returned.

See also:

[nb_distribution.hist_pdf](#), [nb_distribution.hist_cdf](#)

Modified by Kenneth S. Paulsen

► **hist_skewness** ↑

x = nb_distribution.hist_skewness(a)

Description:

Empirical skewness.

Input:

- a : The data points, as a nobs x 1 double.

Output:

- x : The skewness of the data.

See also:

[nb_distribution.hist_median](#), [nb_distribution.hist_mean](#)
[nb_distribution.hist_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **hist_std** ↑

x = nb_distribution.hist_std(a)

Description:

Empirical standard deviation.

Input:

- a : The data points, as a nobs x 1 double.

Output:

- x : The standard deviation of the data.

See also:

[nb_distribution.hist_mode](#), [nb_distribution.hist_median](#)
[nb_distribution.hist_mean](#), [nb_distribution.hist_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **hist_variance** ↑

x = nb_distribution.hist_variance(a)

Description:

Empirical variance.

Input:

- a : The data points, as a nobs x 1 double.

Output:

- `x` : The variance of the data.

See also:

`nb_distribution.hist_mode`, `nb_distribution.hist_median`
`nb_distribution.hist_mean`

Written by Kenneth Sæterhagen Paulsen

► **horzcat** ↑

`obj = horzcat(varargin)`

Description:

Horizontal concatenation

Input:

- `varargin` : Either an object of class `nb_distribution` or an object of class `double`

Output:

- `obj` : An object of class `nb_distribution`

Written by Kenneth Sæterhagen Paulsen

► **icdf** ↑

`f = icdf(obj,x)`

Description:

Evaluate the inverse cdf of the given distribution at the value(s) `x`.

Input:

- `obj` : An object of class `nb_distribution`

- `x` : A double with any size if `numel(obj) == 1`, otherwise it must be a `Tx1` double.

Output:

- `f` : `numel(obj) == 1` : A double with the same size as `x`
otherwise : A double with size `T x nobj`

Written by Kenneth Sæterhagen Paulsen

► **increment** ↑

```
increment(obj,type,index,value,smoothing)
```

Description:

Increment the probability density at a selected point with a given value. Please note that the underlying object must be of type 'kernel'.

Input:

- obj : An object of class nb_distribution.
- typeOfDensity : Either 'pdf' or 'cdf'.
- index : The point in the domain of the distribution to increment. See the property parameters.
- value : The value to increment the selected point in the domain. Must be lower than a certain value, as the density at any point cannot be higher than 1.
- smoothing :> An integer : The number of elements to smmoth out in the neighbourhood of the selected point.
 - > 'kernel' : Using a kernel smoother on the random draws produced by the incremented distribution. This will not reproduce the selected points density, as much of its density will be smoothed out to the neighbourhood.
 - > [] : No smoothing.

See also:

[nb_distribution.decrement](#), [nb_distribution.convert](#)

Written by Kenneth SÅ!terhagen Paulsen

► **initialize** ↑

```
obj = nb_distribution.initialize(varargin)
```

Description:

Intialize a vector of nb_distribution objects with 'propertyName', 'propertyValue' pairs. The propertyValue part must be a cell with same size for all properties set, i.e. with the same size as the number of created distributions.

This is a static method

Input:

- varargin : See the description of the method

Output:

- obj : A vector of nb_distribution objects

Examples:

```
obj = nb_distribution.initialize('type',{'normal','gamma'},...
    'parameters',{{6,2},{2,2}});
plot(obj,2:0.1:16,'pdf')
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **invgamma_cdf** ↑

```
f = nb_distribution.invgamma_cdf(x,m,k)
```

Description:

CDF of the invgamma distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.invgamma_pdf](#), [nb_distribution.invgamma_rand](#)
[nb_distribution.invgamma_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **invgamma_domain** ↑

```
f = nb_distribution.invgamma_domain
```

Description:

Get the domain of the invgamma distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth SÃ¶terhagen Paulsen

► **invgamma_icdf ↑**

```
x = nb_distribution.invgamma_icdf(p,m,k)
```

Description:

Returns the inverse of the cdf at p of the invgamma(m,k) distribution

Input:

- p : A vector of probabilities
- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : A double with the quantile at each element of p of the invgamma(m,k) distribution

See also:

[nb_distribution.invgamma_cdf](#), [nb_distribution.invgamma_rand](#)
[nb_distribution.invgamma_pdf](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **invgamma_kurtosis ↑**

```
x = nb_distribution.invgamma_kurtosis(m,k)
```

Description:

Kurtosis of the invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The kurtosis of the invgamma distribution

See also:

[nb_distribution.invgamma_median](#), [nb_distribution.invgamma_mean](#)
[nb_distribution.invgamma_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► [invgamma_mean ↑](#)

x = nb_distribution.invgamma_mean(m, k)

Description:

Mean of the invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The mean of the invgamma distribution

See also:

[nb_distribution.invgamma_mode](#), [nb_distribution.invgamma_median](#)
[nb_distribution.invgamma_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► [invgamma_median ↑](#)

x = nb_distribution.invgamma_median(m, k)

Description:

Median of the invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The median of the invgamma distribution

See also:

[nb_distribution.invgamma_mode](#), [nb_distribution.invgamma_mean](#)
[nb_distribution.invgamma_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► [invgamma_mode](#) ↑

x = nb_distribution.invgamma_mode(m, k)

Description:

Mode of the invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The mode of the invgamma distribution

See also:

[nb_distribution.invgamma_median](#), [nb_distribution.invgamma_mean](#)
[nb_distribution.invgamma_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► [invgamma_pdf](#) ↑

f = nb_distribution.invgamma_pdf(x, m, k)

Description:

PDF of the invgamma distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : The shape parameter, as a double >0 .
- k : The scale parameter, as a double >0 .

Output:

- f : The PDF at the evaluated points, same size as x .

See also:

[nb_distribution.invgamma_cdf](#), [nb_distribution.invgamma_rand](#)
[nb_distribution.invgamma_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► [invgamma_rand](#) ↑

```
draws = nb_distribution.invgamma_rand(nrow, ncol, m, k)
```

Description:

Draw random numbers from the invgamma distribution

Input:

- $nrow$: Number of rows of the matrix drawn from the invgamma distribution
- $ncol$: Number of columns of the matrix drawn from the invgamma distribution
- m : The shape parameter, as a double >0 .
- k : The scale parameter, as a double >0 .

Output:

- $draws$: A $nrow \times ncol$ matrix of random numbers from the invgamma distribution

See also:

[nb_distribution.invgamma_pdf](#), [nb_distribution.invgamma_cdf](#)

► **invgamma_skewness** ↑

```
x = nb_distribution.invgamma_skewness(m,k)
```

Description:

Skewness of the invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The skewness of the invgamma distribution

See also:

[nb_distribution.invgamma_median](#), [nb_distribution.invgamma_mean](#)
[nb_distribution.invgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **invgamma_std** ↑

```
x = nb_distribution.invgamma_std(m,k)
```

Description:

Standard deviation of the invgamma distribution

Input:

- m : The shape parameter, as a double >0.
- k : The scale parameter, as a double >0.

Output:

- x : The standard deviation of the invgamma distribution

See also:

`nb_distribution.invgamma_mode`, `nb_distribution.invgamma_median`
`nb_distribution.invgamma_mean`, `nb_distribution.invgamma_variance`

Written by Kenneth Sæterhagen Paulsen

► **invgamma_variance** ↑

```
x = nb_distribution.invgamma_variance(m,k)
```

Description:

Variance of the invgamma distribution

Input:

- `m` : The shape parameter, as a double >0.
- `k` : The scale parameter, as a double >0.

Output:

- `x` : The variance of the invgamma distribution

See also:

`nb_distribution.invgamma_mode`, `nb_distribution.invgamma_median`
`nb_distribution.invgamma_mean`

Written by Kenneth Sæterhagen Paulsen

► **invwish_rand** ↑

```
A = invwish_rand(h,n)
A = invwish_rand(h,n,type)
```

Description:

Draws an $m \times m$ matrix from a inverse wishart distribution with scale matrix `h` and degrees of freedom `nu = n`. This procedure uses Bartlett's decomposition.

Note: Parameterized so that mean is `h/n`

Input:

- `h` : $m \times m$ scale matrix.
- `n` : scalar degrees of freedom.
- `type` : 'cov' or 'covrepair'. See `nb_chol`

Output:

- A : m x m matrix draw from the inverse wishart distribution.

Written by Kenneth Sæterhagen Paulsen

► isnan ↑

Description:

Input:**Output:****Examples:****See also:**

Written by Kenneth Sæterhagen Paulsen

► kernel_cdf ↑

```
f = nb_distribution.kernel_cdf(x,domain,density)
```

Description:

CDF of the estimated kernel density. To get the CDF of a point in between two points of the domain, a linear interpolation method is used.

Input:

- x : The points to evaluate the cdf, as a double (max dim is 3)
- domain : The domain of the distribution
- density : The density of the distribution

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.kernel_pdf](#), [nb_distribution.kernel_rand](#)
[nb_distribution.kernel_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **kernel_domain** ↑

```
f = nb_distribution.kernel_domain(domain)
```

Description:

Get the domain of the distribution

Input:

- domain : The domain of the distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **kernel_icdf** ↑

```
x = nb_distribution.kernel_icdf(p, domain, density)
```

Description:

Inverse CDF of the estimated kernel distribution. Uses the mean of the two closest points in the domain.

Input:

- p : A vector of probabilities
- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The inverse CDF at the evaluated probabilities, same size as p.

See also:

[nb_distribution.kernel_pdf](#), [nb_distribution.kernel_rand](#)
[nb_distribution.kernel_cdf](#)

Written by Kenneth Sæterhagen Paulsen

► **kernel_kurtosis** ↑

```
x = nb_distribution.kernel_kurtosis(domain,density)
```

Description:

Kurtosis of the estimated kernel density. This will use the nb_distribution.kernel_rand make 1000 draws from the distribution, and then calculate the kurtois based on these draws.

It will adjust the kurtosis for bias. See the kurtosis method by MATLAB for more on this

Input:

- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The kurtosis of the estimated kernel density

See also:

[nb_distribution.normal_median](#), [nb_distribution.normal_mean](#)
[nb_distribution.normal_variance](#), [nb_distribution.kernel_rand](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **kernel_mean** ↑

```
x = nb_distribution.kernel_mean(domain,density)
```

Description:

Mean of the estimated kernel density. This will use the nb_distribution.kernel_rand to make 1000 draws from the distribution, and then calculate the mean based on these draws.

Input:

- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The mean of the estimated kernel density

See also:

[nb_distribution.kernel_median](#), [nb_distribution.kernel_mean](#)
[nb_distribution.kernel_variance](#), [nb_distribution.kernel_rand](#)

Written by Kenneth Sæterhagen Paulsen

► [kernel_median ↑](#)

x = nb_distribution.kernel_median(domain,density)

Description:

Median of the estimated kernel density. This will use the nb_distribution.kernel_icdf method to estimate the median.

Input:

- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The median of the estimated kernel density

See also:

[nb_distribution.kernel_mode](#), [nb_distribution.kernel_mean](#)
[nb_distribution.kernel_variance](#), [nb_distribution.kernel_rand](#)

Written by Kenneth Sæterhagen Paulsen

► [kernel_mode ↑](#)

x = nb_distribution.kernel_mode(domain,density)

Description:

The mode is found by finding the max point of the estimated kernel density, and return the matching point in its domain.

Input:

- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The kurtosis of the estimated kernel density

See also:

[nb_distribution.kernel_median](#), [nb_distribution.kernel_mean](#)
[nb_distribution.kernel_variance](#), [nb_distribution.kernel_rand](#)

Written by Kenneth Sæterhagen Paulsen

► **kernel_pdf** ↑

```
f = nb_distribution.kernel_pdf(x,domain,density)
```

Description:

PDF of the estimated kernel density. To get the PDF of a point in between two points of the domain, a linear interpolation method is used.

Input:

- x : The points to evaluate the pdf, as a double
- domain : The domain of the distribution
- density : The density of the distribution

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.kernel_cdf](#), [nb_distribution.kernel_rand](#)
[nb_distribution.kernel_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **kernel_rand** ↑

```
draws = nb_distribution.kernel_rand(nrow,ncol,domain,density)
```

Description:

Draw random numbers from an estimated kernel density.

Input:

- nrow : Number of rows of the matrix drawn from the normal distribution
- ncol : Number of columns of the matrix drawn from the normal distribution
- domain : The domain of the distribution
- density : The density of the distribution

Output:

- draws : A nrow x ncol matrix of random numbers from the estimated kernel density

See also:

[nb_distribution.kernel_pdf](#), [nb_distribution.kernel_cdf](#)

Written by Kenneth S. Paulsen

► **kernel_skewness ↑**

`x = nb_distribution.kernel_skewness(domain,density)`

Description:

Skewness of the estimated kernel density. This will use the `nb_distribution.kernel_rand` to make 1000 draws from the distribution, and then calculate the skewness based on these draws.

It will adjust the skewness for bias. See the `skewness` method by MATLAB for more on this

Input:

- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The skewness of the estimated kernel density

See also:

```
nb_distribution.kernel_median, nb_distribution.kernel_mean  
nb_distribution.kernel_variance, nb_distribution.kernel_rand
```

Written by Kenneth SÃ¶terhagen Paulsen

► **kernel_std** ↑

```
x = nb_distribution.kernel_std(domain,density)
```

Description:

Standard deviation of the estimated kernel density. This will use the nb_distribution.kernel_rand to make 1000 draws from the distribution, and then calculate the standard deviation based on those draws.

It will adjust the standard deviation by T-1.

Input:

- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The standard deviation of the estimated kernel density

See also:

```
nb_distribution.kernel_median, nb_distribution.kernel_mean  
nb_distribution.kernel_variance, nb_distribution.kernel_rand
```

Written by Kenneth SÃ¶terhagen Paulsen

► **kernel_variance** ↑

```
x = nb_distribution.kernel_variance(domain,density)
```

Description:

Variance of the estimated kernel density. This will use the nb_distribution.kernel_rand to make 1000 draws from the distribution, and then calculate the variance based on those draws.

It will adjust the variance by T-1.

Input:

- domain : The domain of the distribution
- density : The density of the distribution

Output:

- x : The variance of the estimated kernel density

See also:

[nb_distribution.kernel_median](#), [nb_distribution.kernel_mean](#)
[nb_distribution.kernel_std](#), [nb_distribution.kernel_rand](#)

Written by Kenneth Sæterhagen Paulsen

► **kurtosis** ↑

x = kurtosis(obj)

Description:

Evaluate the kurtosis of the given distribution.

The kurtosis will be adjusted for bias. See the function kurtosis made by MATLAB inc.

Input:

- obj : An object of class nb_distribution

Output:

- x : numel(obj) == 1 : A double with size as 1 x 1
- otherwise : A double with size 1 x nobj

Written by Kenneth Sæterhagen Paulsen

► **laplace_cdf** ↑

f = nb_distribution.laplace_cdf(x,m)

Description:

CDF of the laplace distribution

Input:

- `x` : The point to evaluate the cdf, as a double
- `m` : The location parameter. Median = `m`. Must be a number.
- `k` : Scale parameter. Must be a positive number.

Output:

- `f` : The CDF at the evaluated points, same size as `x`.

See also:

[nb_distribution.laplace_pdf](#), [nb_distribution.laplace_rand](#)
[nb_distribution.laplace_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **laplace_domain** ↑

`f = nb_distribution.laplace_domain`

Description:

Get the domain of the laplace distribution

Output:

- `domain` : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **laplace_icdf** ↑

`x = nb_distribution.laplace_icdf(p,m,k)`

Description:

Returns the inverse of the cdf at `p` of the laplace distribution

Input:

- `p` : A vector of probabilities
- `m` : The location parameter. Median = `m`. Must be a number.
- `k` : Scale parameter. Must be a positive number.

Output:

- `x` : A double with the quantile at each element of `p` of the `laplace(m,k)` distribution

See also:

[nb_distribution.laplace_cdf](#), [nb_distribution.laplace_rand](#)
[nb_distribution.laplace_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► laplace_kurtosis ↑

`x = nb_distribution.laplace_kurtosis(m,k)`

Description:

Kurtosis of the laplace distribution

Input:

- `m` : The location parameter. Median = `m`. Must be a number.
- `k` : Scale parameter. Must be a positive number.

Output:

- `x` : The kurtosis of the laplace distribution

See also:

[nb_distribution.laplace_median](#), [nb_distribution.laplace_mean](#)
[nb_distribution.laplace_variance](#)

Written by Kenneth Sæterhagen Paulsen

► laplace_mean ↑

`x = nb_distribution.laplace_mean(m,k)`

Description:

Mean of the laplace distribution

Input:

- m : The location parameter. Median = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The mean of the laplace distribution

See also:

[nb_distribution.laplace_mode](#), [nb_distribution.laplace_median](#)
[nb_distribution.laplace_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **laplace_median** ↑

x = nb_distribution.laplace_median(m, k)

Description:

Median of the laplace distribution

Input:

- m : The location parameter. Median = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The median of the laplace distribution

See also:

[nb_distribution.laplace_mode](#), [nb_distribution.laplace_mean](#)
[nb_distribution.laplace_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **laplace_mode** ↑

x = nb_distribution.laplace_mode(m, k)

Description:

Mode of the laplace distribution

Input:

- m : The location parameter. Median = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The mode of the laplace distribution

See also:

[nb_distribution.laplace_median](#), [nb_distribution.laplace_mean](#)
[nb_distribution.laplace_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **laplace_pdf** ↑

```
f = nb_distribution.laplace_pdf(x,m,k)
```

Description:

PDF of the laplace distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : The location parameter. Median = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.laplace_cdf](#), [nb_distribution.laplace_rand](#)
[nb_distribution.laplace_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **laplace_rand** ↑

```
draws = nb_distribution.laplace_rand(nrow,ncol,m,k)
```

Description:

Draw random numbers from the laplace distribution

Input:

- nrow : Number of rows of the matrix drawn from the laplace distribution
- ncol : Number of columns of the matrix drawn from the laplace distribution
- m : The location parameter. Median = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- draws : A nrow x ncol matrix of random numbers from the laplace distribution

See also:

[nb_distribution.laplace_pdf](#), [nb_distribution.laplace_cdf](#)

Modified by Kenneth S. Paulsen

► **laplace_skewness ↑**

`x = nb_distribution.laplace_skewness(m, k)`

Description:

Skewness of the laplace distribution

Input:

- m : The location parameter. Median = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The skewness of the laplace distribution

See also:

[nb_distribution.laplace_median](#), [nb_distribution.laplace_mean](#)
[nb_distribution.laplace_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **laplace_std** ↑

```
x = nb_distribution.laplace_std(m, k)
```

Description:

Standard deviation of the laplace distribution

Input:

- m : The location paramter. Mode = m. Must be a number.
- k : Scale paramter. Must be a positive number.

Output:

- x : The standard deviation of the laplace distribution

See also:

[nb_distribution.laplace_mode](#), [nb_distribution.laplace_median](#)
[nb_distribution.laplace_mean](#), [nb_distribution.laplace_variance](#)

Written by Kenneth Sætherhagen Paulsen

► **laplace_variance** ↑

```
x = nb_distribution.laplace_variance(m, k)
```

Description:

Variance of the laplace distribution

Input:

- m : The location paramter. Median = m. Must be a number.
- k : Scale paramter. Must be a positive number.

Output:

- x : The variance of the laplace distribution

See also:

[nb_distribution.laplace_mode](#), [nb_distribution.laplace_median](#)
[nb_distribution.laplace_mean](#)

Written by Kenneth Sæterhagen Paulsen

► logistic_cdf ↑

```
f = nb_distribution.logistic_cdf(x,m)
```

Description:

CDF of the logistic distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.logistic_pdf](#), [nb_distribution.logistic_rand](#)
[nb_distribution.logistic_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► logistic_domain ↑

```
f = nb_distribution.logistic_domain
```

Description:

Get the domain of the logistic distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► logistic_icdf ↑

```
x = nb_distribution.logistic_icdf(p,m,k)
```

Description:

Returns the inverse of the cdf at p of the logistic distribution

Input:

- p : A vector of probabilities
- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : A double with the quantile at each element of p of the logistic(m,k) distribution

See also:

[nb_distribution.logistic_cdf](#), [nb_distribution.logistic_rand](#)
[nb_distribution.logistic_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **logistic_kurtosis ↑**

```
x = nb_distribution.logistic_kurtosis(m,k)
```

Description:

Kurtosis of the logistic distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The kurtosis of the logistic distribution

See also:

[nb_distribution.logistic_median](#), [nb_distribution.logistic_mean](#)
[nb_distribution.logistic_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **[logistic_mean](#)** ↑

```
x = nb_distribution.logistic_mean(m, k)
```

Description:

Mean of the logistic distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The mean of the logistic distribution

See also:

[nb_distribution.logistic_mode](#), [nb_distribution.logistic_median](#)
[nb_distribution.logistic_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **[logistic_median](#)** ↑

```
x = nb_distribution.logistic_median(m, k)
```

Description:

Median of the logistic distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The median of the logistic distribution

See also:

[nb_distribution.logistic_mode](#), [nb_distribution.logistic_mean](#)
[nb_distribution.logistic_variance](#)

► **logistic_mode** ↑

```
x = nb_distribution.logistic_mode(m,k)
```

Description:

Mode of the logistic distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The mode of the logistic distribution

See also:

[nb_distribution.logistic_median](#), [nb_distribution.logistic_mean](#)
[nb_distribution.logistic_variance](#)

► **logistic_pdf** ↑

```
f = nb_distribution.logistic_pdf(x,m,k)
```

Description:

PDF of the logistic distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.logistic_cdf](#), [nb_distribution.logistic_rand](#)
[nb_distribution.logistic_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **logistic_rand** ↑

```
draws = nb_distribution.logistic_rand(nrow, ncol, m, k)
```

Description:

Draw random numbers from the logistic distribution

Input:

- nrow : Number of rows of the matrix drawn from the logistic distribution
- ncol : Number of columns of the matrix drawn from the logistic distribution
- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- draws : A nrow x ncol matrix of random numbers from the logistic distribution

See also:

[nb_distribution.logistic_pdf](#), [nb_distribution.logistic_cdf](#)

Modified by Kenneth S. Paulsen

► **logistic_skewness** ↑

```
x = nb_distribution.logistic_skewness(m, k)
```

Description:

Skewness of the logistic distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The skewness of the logistic distribution

See also:

[nb_distribution.logistic_median](#), [nb_distribution.logistic_mean](#)
[nb_distribution.logistic_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **logistic_std ↑**

x = nb_distribution.logistic_std(m, k)

Description:

Standard deviation of the logistic distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The standard deviation of the logistic distribution

See also:

[nb_distribution.logistic_mode](#), [nb_distribution.logistic_median](#)
[nb_distribution.logistic_mean](#), [nb_distribution.logistic_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **logistic_variance ↑**

x = nb_distribution.logistic_variance(m, k)

Description:

Variance of the logistic distribution

Input:

- m : The location parameter. Mode = m. Must be a number.
- k : Scale parameter. Must be a positive number.

Output:

- x : The variance of the logistic distribution

See also:

[nb_distribution.logistic_mode](#), [nb_distribution.logistic_median](#)
[nb_distribution.logistic_mean](#)

Written by Kenneth Sæterhagen Paulsen

► [lognormal_cdf ↑](#)

f = nb_distribution.lognormal_cdf(x, m, k)

Description:

CDF of the lognormal distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.lognormal_pdf](#), [nb_distribution.lognormal_rand](#)
[nb_distribution.lognormal_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► [lognormal_domain ↑](#)

f = nb_distribution.lognormal_domain

Description:

Get the domain of the lognormal distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth SÃ¶terhagen Paulsen

► lognormal_icdf ↑

```
x = nb_distribution.lognormal_icdf(p,m,k)
```

Description:

Inverse CDF of the lognormal density

Input:

- p : A vector of probabilities
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- x : The inverse CDF at the evaluated probabilities, same size as p.

See also:

[nb_distribution.lognormal_pdf](#), [nb_distribution.lognormal_rand](#)
[nb_distribution.lognormal_cdf](#)

Written by Kenneth SÃ¶terhagen Paulsen

► lognormal_kurtosis ↑

```
x = nb_distribution.lognormal_kurtosis(m,k)
```

Description:

Kurtosis of the lognormal distribution

Input:

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- x : The kurtosis of the lognormal distribution

See also:

[nb_distribution.lognormal_median](#), [nb_distribution.lognormal_mean](#)
[nb_distribution.lognormal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **lognormal_mean** ↑

x = nb_distribution.lognormal_mean(m, k)

Description:

Mean of the lognormal distribution

Input:

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- x : The mean of the lognormal distribution

See also:

[nb_distribution.lognormal_mode](#), [nb_distribution.lognormal_median](#)
[nb_distribution.lognormal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **lognormal_median** ↑

x = nb_distribution.lognormal_median(m, k)

Description:

Median of the lognormal distribution

Input:

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$

Output:

- x : The median of the lognormal distribution

See also:

[nb_distribution.lognormal_mode](#), [nb_distribution.lognormal_mean](#)
[nb_distribution.lognormal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **lognormal_mode** ↑

x = nb_distribution.lognormal_mode(m, k)

Description:

Mode of the lognormal distribution

Input:

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$

Output:

- x : The mode of the lognormal distribution

See also:

[nb_distribution.lognormal_median](#), [nb_distribution.lognormal_mean](#)
[nb_distribution.lognormal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **lognormal_pdf** ↑

f = nb_distribution.lognormal_pdf(x, m, k)

Description:

PDF of the lognormal distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- f : The PDF at the evaluated points, same size as x .

See also:

[nb_distribution.lognormal_cdf](#), [nb_distribution.lognormal_rand](#)
[nb_distribution.lognormal_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **lognormal_rand** ↑

draws = nb_distribution.lognormal_rand(nrow, ncol, m, k)

Description:

Draw random numbers from the lognormal distribution

Input:

- $nrow$: Number of rows of the matrix drawn from the lognormal distribution
- $ncol$: Number of columns of the matrix drawn from the lognormal distribution
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- $draws$: A $nrow \times ncol$ matrix of random numbers from the lognormal distribution

See also:

[nb_distribution.lognormal_pdf](#), [nb_distribution.lognormal_cdf](#)

► **lognormal_skewness** ↑

```
x = nb_distribution.lognormal_skewness(m,k)
```

Description:

Skewness of the lognormal distribution

Input:

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- x : The skewness of the lognormal distribution

See also:

[nb_distribution.lognormal_median](#), [nb_distribution.lognormal_mean](#)
[nb_distribution.lognormal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **lognormal_std** ↑

```
x = nb_distribution.lognormal_std(m,k)
```

Description:

Standard deviation of the lognormal distribution

Input:

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- x : The standard deviation of the lognormal distribution

See also:

[nb_distribution.lognormal_mode](#), [nb_distribution.lognormal_median](#)
[nb_distribution.lognormal_mean](#), [nb_distribution.lognormal_std](#)

Written by Kenneth Sæterhagen Paulsen

► **lognormal_variance ↑**

```
x = nb_distribution.lognormal_variance(m, k)
```

Description:

Variance of the lognormal distribution

Input:

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- x : The variance of the lognormal distribution

See also:

[nb_distribution.lognormal_mode](#), [nb_distribution.lognormal_median](#)
[nb_distribution.lognormal_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **mean ↑**

```
x = mean(obj)
```

Description:

Evaluate the mean of the given distribution.

Input:

- obj : An object of class nb_distribution

Output:

- x : $\text{numel}(\text{obj}) == 1$: A double with size as 1 x 1
- otherwise : A double with size nobj1 x nobj2

Written by Kenneth Sæterhagen Paulsen

► **meanshift_cdf** ↑

```
f = nb_distribution.meanshift_cdf(x,dist,param,lb,ub,ms)
```

Description:

CDF of the mean shifted possibly truncated distribution.

Input:

- `x` : The point to evaluate the cdf, as a double
- `dist` : The name of the underlying distribution as a string. Must be supported by the `nb_distribution` class.
- `param` : A cell with the parameters of the selected distribution.
- `lb` : Lower bound of the truncated distribution.
- `ub` : Upper bound of the truncated distribution.
- `ms` : Mean shift parameter.

Output:

- `f` : The CDF at the evaluated points, same size as `x`.

See also:

[nb_distribution.meanshift_pdf](#), [nb_distribution.meanshift_rand](#)
[nb_distribution.meanshift_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **meanshift_domain** ↑

```
f = nb_distribution.meanshift_domain(dist,param,lb,ub,ms)
```

Description:

Get the domain of the mean shifted possibly truncated distribution.

Inputs:

- `dist` : The name of the underlying distribution as a string. Must be supported by the `nb_distribution` class.
- `param` : A cell with the parameters of the selected distribution.
- `lb` : Lower bound of the truncated distribution.

- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **meanshift_icdf** ↑

```
x = nb_distribution.meanshift_icdf(p,dist,param,lb,ub,ms)
```

Description:

Returns the inverse of the CDF of the mean shifted possibly truncated distribution.

Input:

- p : A vector of probabilities
- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- x : A double with the quantile at each element of p of the truncated distribution

See also:

[nb_distribution.meanshift_cdf](#), [nb_distribution.meanshift_rand](#)
[nb_distribution.meanshift_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **meanshift_kurtosis** ↑

```
x = nb_distribution.meanshift_kurtosis(dist,param,lb,ub,ms)
```

Description:

Kurtosis of the mean shifted and possibly truncated distribution. The calculation may be simulation based and may vary (if the distribution is truncated). Set seed to prevent this, or see the kurtosis method of the nb_distribution class.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- x : The kurtosis of the truncated distribution

See also:

[nb_distribution.meanshift_median](#), [nb_distribution.meanshift_mean](#)
[nb_distribution.meanshift_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **meanshift_mean** ↑

```
x = nb_distribution.meanshift_mean(dist,param,lb,ub,ms)
```

Description:

Mean of the mean shifted and possibly truncated distribution. The calculation may be simulation based and may vary (if the distribution is truncated). Set seed to prevent this, or see the mean method of the nb_distribution class.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.

- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- x : The mean of the mean shifted and possibly truncated distribution.

See also:

[nb_distribution.meanshift_mode](#), [nb_distribution.meanshift_median](#)
[nb_distribution.meanshift_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **meanshift_median ↑**

x = nb_distribution.meanshift_median(dist,param,lb,ub,ms)

Description:

Median of the mean shifted and possibly truncated distribution.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- x : The median of the mean shifted and possibly truncated distribution.

See also:

[nb_distribution.meanshift_mode](#), [nb_distribution.meanshift_mean](#)
[nb_distribution.meanshift_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **meanshift_mode ↑**

```
x = nb_distribution.meanshift_mode(dist,param,lb,ub,ms)
```

Description:

Mode of the mean shifted and possibly truncated distribution.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- x : The mode of the mean shifted and possibly truncated distribution.

See also:

[nb_distribution.meanshift_median](#), [nb_distribution.meanshift_mean](#)
[nb_distribution.meanshift_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **meanshift_pdf ↑**

```
f = nb_distribution.meanshift_pdf(x,dist,param,lb,ub,ms)
```

Description:

PDF of the mean shifted possibly truncated distribution.

Input:

- x : The point to evaluate the pdf, as a double
- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.meanshift_cdf](#), [nb_distribution.meanshift_rand](#)
[nb_distribution.meanshift_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **meanshift_rand** ↑

```
draws = nb_distribution.meanshift_rand(nrow,ncol,dist,param,lb,ub,ms)
```

Description:

Draw random number from a mean shifted possibly truncated distribution.

Input:

- nrow : Number of rows of the matrix drawn from the student-t distribution
- ncol : Number of columns of the matrix drawn from the student-t distribution
- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- draws : A nrow x ncol matrix of random numbers from the mean shifted possibly truncated distribution.

Written by Kenneth Sæterhagen Paulsen

► **meanshift_skewness** ↑

```
x = nb_distribution.meanshift_skewness(dist,param,lb,ub,ms)
```

Description:

Skewness of the mean shifted and possibly truncated distribution. The calculation may be simulation based and may vary (if the distribution is truncated). Set seed to prevent this, or see the skewness method of the nb_distribution class.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- x : The skewness of the mean shifted and possibly truncated distribution.

See also:

[nb_distribution.meanshift_median](#), [nb_distribution.meanshift_mean](#)
[nb_distribution.meanshift_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **meanshift_std ↑**

`x = nb_distribution.meanshift_std(dist,param,lb,ub,ms)`

Description:

Standard deviation of the mean shifted and possibly truncated distribution.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.
- ms : Mean shift parameter.

Output:

- `x` : The standard deviation of the mean shifted and possibly truncated distribution.

See also:

[nb_distribution.meanshift_mode](#), [nb_distribution.meanshift_median](#)
[nb_distribution.meanshift_mean](#), [nb_distribution.meanshift_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **meanshift_variance** ↑

`x = nb_distribution.meanshift_variance(dist,param,lb,ub,ms)`

Description:

Variance of the mean shifted and possibly truncated distribution.
The calculation may be simulation based and may vary (if the distribution is truncated). Set `seed` to prevent this, or see the `variance` method of the `nb_distribution` class.

Input:

- `dist` : The name of the underlying distribution as a string. Must be supported by the `nb_distribution` class.
- `param` : A cell with the parameters of the selected distribution.
- `lb` : Lower bound of the truncated distribution.
- `ub` : Upper bound of the truncated distribution.
- `ms` : Mean shift parameter.

Output:

- `x` : The variance of the mean shifted and possibly truncated distribution.

See also:

[nb_distribution.meanshift_mode](#), [nb_distribution.meanshift_median](#)
[nb_distribution.meanshift_mean](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **median** ↑

```
x = median(obj)
```

Description:

Evaluate the median of the given distribution.

Input:

- obj : An object of class nb_distribution

Output:

- x : numel(obj) == 1 : A double with size as 1 x 1
- otherwise : A double with size 1 x nobj

Written by Kenneth Sæterhagen Paulsen

► **mle** ↑

```
obj = nb_distribution.mle(x,distribution)
```

Description:

Estimate a distribution using maximum likelihood estimator.

Input:

- x : The assumed random observation of the distribution. As a nobs x nvars double.
- dist : A string with the distribution to match to the data.

The supported distributions are:

```
> 'ast'  
> 'beta'  
> 'chis'  
> 'constant'  
> 'exp'  
> 'f'  
> 'gamma'  
> 'invgamma'  
> 'laplace'  
> 'logistic'  
> 'lognormal'  
> 'normal'  
> 't'  
> 'uniform'  
> 'wald'
```

Type <help nb_distribution.type> to get a description of the of the different distributions.

Output:

- obj : A 1 x nvars nb_distribution object array.

Examples:

```
x = randn(100,1);
obj = nb_distribution.mle(x,'normal');
```

See also:

[nb_distribution.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► [mme](#) ↑

```
[obj,params] = nb_distribution.mme(x,dist,lb,ub)
```

Description:

Estimate a distribution using metods of moment estimator.

Input:

- x : The assumed random observation of the distribution. As a nobs x 1 double.

- dist : A string with the distribution to match to the data.

The supported distributions are:

```
> 'beta'
> 'chis'
> 'constant'
> 'exp'
> 'f'
> 'gamma'
> 'invgamma'
> 'laplace'
> 'logistic'
> 'lognormal'
> 'normal'
> 'skt'
> 't'
> 'tri'
> 'uniform'
> 'wald'
```

Type `<help nb_distribution.type>` to get a description of the of the different distributions.

Output:

```
- obj      : A nb_distribution object.  
- params : The hyperparameters as a cell array
```

Examples:

```
x = randn(100,1);  
obj = nb_distribution.mme(x,'normal');
```

See also:

[nb_distribution.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **mode** ↑

```
x = mode(obj)
```

Description:

Evaluate the mode of the given distribution.

Input:

```
- obj : An object of class nb_distribution
```

Output:

```
- x   : numel(obj) == 1 : A double with size as 1 x 1  
       otherwise        : A double with size 1 x nobj
```

Written by Kenneth Sæterhagen Paulsen

► **normal_cdf** ↑

```
f = nb_distribution.normal_cdf(x,m,k)
```

Description:

CDF of the normal distribution

Input:

```
- x : The point to evaluate the cdf, as a double  
- m : The mean of the distribution  
- k : The std of the distribution
```

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.normal_pdf](#), [nb_distribution.normal_rand](#)
[nb_distribution.normal_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **normal_domain** ↑

f = nb_distribution.normal_domain

Description:

Get the domain of the normal distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **normal_icdf** ↑

x = nb_distribution.normal_icdf(p,m,k)

Description:

Inverse CDF of the normal density

Input:

- p : A vector of probabilities
- m : The mean of the distribution
- k : The std of the distribution

Output:

- x : The inverse CDF at the evaluated probabilities, same size as p.

See also:

[nb_distribution.normal_pdf](#), [nb_distribution.normal_rand](#)

`nb_distribution.normal_cdf`

Written by Kenneth Sæterhagen Paulsen

► **normal_kurtosis ↑**

`x = nb_distribution.normal_kurtosis(m,k)`

Description:

Kurtosis of the normal distribution

Input:

- `m` : A parameter such that the mean of the normal is `m`
- `k` : A parameter such that the std of the normal is `k`

Output:

- `x` : The kurtosis of the normal distribution

See also:

`nb_distribution.normal_median`, `nb_distribution.normal_mean`
`nb_distribution.normal_variance`

Written by Kenneth Sæterhagen Paulsen

► **normal_mean ↑**

`x = nb_distribution.normal_mean(m,k)`

Description:

Mean of the normal distribution

Input:

- `m` : A parameter such that the mean of the normal is `m`
- `k` : A parameter such that the std of the normal is `k`

Output:

- `x` : The mean of the normal distribution

See also:

[nb_distribution.normal_mode](#), [nb_distribution.normal_median](#)
[nb_distribution.normal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► [normal_median ↑](#)

`x = nb_distribution.normal_median(m, k)`

Description:

Median of the normal distribution

Input:

- `m` : A parameter such that the mean of the normal is `m`
- `k` : A parameter such that the std of the normal is `k`

Output:

- `x` : The median of the normal distribution

See also:

[nb_distribution.normal_mode](#), [nb_distribution.normal_mean](#)
[nb_distribution.normal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► [normal_mode ↑](#)

`x = nb_distribution.normal_mode(m, k)`

Description:

Mode of the normal distribution

Input:

- `m` : A parameter such that the mean of the normal is `m`
- `k` : A parameter such that the std of the normal is `k`

Output:

- `x` : The mode of the normal distribution

See also:

[nb_distribution.normal_median](#), [nb_distribution.normal_mean](#)
[nb_distribution.normal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **normal_pdf ↑**

`f = nb_distribution.normal_pdf(x,m,k)`

Description:

PDF of the normal distribution

Input:

- `x` : The point to evaluate the cdf, as a double
- `m` : The mean of the distribution
- `k` : The std of the distribution

Output:

- `f` : The PDF at the evaluated points, same size as `x`.

See also:

[nb_distribution.normal_cdf](#), [nb_distribution.normal_rand](#)
[nb_distribution.normal_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **normal_rand ↑**

`draws = nb_distribution.normal_rand(nrow,ncol,m,k)`

Description:

Draw random numbers from the normal distribution

Input:

```
- nrow : Number of rows of the matrix drawn from the normal distribution  
- ncol : Number of columns of the matrix drawn from the normal distribution  
- m : The mean of the distribution  
- k : The std of the distribution
```

Output:

```
- draws : A nrow x ncol matrix of random numbers from the normal distribution
```

See also:

[nb_distribution.normal_pdf](#), [nb_distribution.normal_cdf](#)

Written by Kenneth S. Paulsen

► **normal_skewness ↑**

```
x = nb_distribution.normal_skewness(m,k)
```

Description:

Skewness of the normal distribution

Input:

```
- m : A parameter such that the mean of the normal is m  
- k : A parameter such that the std of the normal is k
```

Output:

```
- x : The skewness of the normal distribution
```

See also:

[nb_distribution.normal_median](#), [nb_distribution.normal_mean](#)
[nb_distribution.normal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **normal_std ↑**

```
x = nb_distribution.normal_std(m,k)
```

Description:

Standard deviation of the normal distribution

Input:

- m : A parameter such that the mean of the normal is m
- k : A parameter such that the std of the normal is k

Output:

- x : The standard deviation of the normal distribution

See also:

[nb_distribution.normal_mode](#), [nb_distribution.normal_median](#)
[nb_distribution.normal_mean](#), [nb_distribution.normal_std](#)

Written by Kenneth Sæterhagen Paulsen

► **normal_variance ↑**

x = nb_distribution.normal_variance(m, k)

Description:

Variance of the normal distribution

Input:

- m : A parameter such that the mean of the normal = m
- k : A parameter such that the std of the normal = k

Output:

- x : The variance of the normal distribution

See also:

[nb_distribution.normal_mean](#), [nb_distribution.normal_std](#)

Written by Kenneth Sæterhagen Paulsen

► **parameterization ↑**

```
obj = nb_distribution.parameterization(m,v,dist)
obj = nb_distribution.parameterization(m,v,dist,lb,ub)
obj = nb_distribution.parameterization(m,v,dist,lb,ub,s,k,mo)
```

Description:

Back out the hyperparameters given some moments.

Supported distribution:

```
> Mean only: 'chis', 'constant', 'exp'
> Variance only: 't' (1 parameter family)
> Mean and variance only: 'beta', 'f', 'gamma', 'invgamma', 'laplace',
  'logistic', 'lognormal', 'normal', 'uniform', 'wald'
> Mean, variance and kurtosis: 't' (3 parameter family)
> Mean, variance, skewness and kurtosis: 'skt'
> Mean, mode and variance: 'tri'
> Mode and variance (Set mean (me input) to []): 'gamma'
```

Input:

- me : Mean of the distribution.
- v : Variance of the distribution.
- dist : A string with the distribution to match to the data.

See description for the supported distributions.

- lb : Lower bound of the distribution. Default is no lower bound.
- ub : Upper bound of the distribution. Default is no upper bound.
- s : Skewness of the distribution.
- k : Kurtosis of the distribution.
- mo : Mode of the distribution.

Output:

- obj : A nb_distribution object.
- params : The hyperparameters as a cell array

Examples:

```
x          = randn(100,1);
obj        = nb_distribution.parameterization(x,'normal');
[~, params] = nb_distribution.parameterization(x,'normal');
```

See also:

[nb_distribution.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **parametrization** ↑

```
obj = nb_distribution.parametrization(m,v,distribution)
obj = nb_distribution.parametrization(m,v,distribution,lb,ub)
obj = nb_distribution.parametrization(m,v,distribution,lb,ub,s,k,mo)
```

Description:

Deprecated method. See `nb_distribution.parameterization` instead.

See also:

[nb_distribution.parameterization](#)

Written by Kenneth Sæterhagen Paulsen

► **pdf** ↑

```
f = pdf(obj,x)
```

Description:

Evaluate the pdf of the given distribution at the value(s) `x`.

Input:

- `obj` : An object of class `nb_distribution`
- `x` : A double with any size if `numel(obj) == 1`, otherwise it must be a `Tx1` double.

Output:

- `f` : `numel(obj) == 1` : A double with the same size as `x`
otherwise : A double with size `T x nobj`

Written by Kenneth Sæterhagen Paulsen

► **perc2Dist** ↑

```
obj = nb_distribution.perc2Dist(perc,values,nDraws,gridpoints,iter, ...
                                varargin)
```

Description:

This method makes draws from the percentiles, and do a kernel density estimation based on those draws.

Be aware that there is no unique solution to this problem, as the estimated kernel density is only one of possible many distribution with the wanted percentiles!

Input:

- perc : The percentiles to fit. Must at least provide 3 percentiles. E.g. [10,30,50,70,90]
- values : The values of the distribution at the given percentiles.
- nDraws : Number of draws.
- gridpoints : The number of grid points of the domain. Default is 1000.
- iter : The number of iteration of the algorithm. Default is 1.
- varargin : Optional input given to the nb_ksdensity function. Please see help for that function.

Output:

- obj : An object of class nb_distribution

Examples:

```
obj = nb_distribution.perc2Dist([10,30,50,70,90],[1,4,6,7,8],1000);
plot(obj)
```

See also:

[nb_distribution.perc2DistCDF](#)

Written by Kenneth Sæterhagen Paulsen

► **perc2DistCDF** ↑

```
obj = nb_distribution.perc2DistCDF(perc,values,startD,endD, ...
gridpoints,nDraws,varargin)
```

Description:

This method makes draws from the percentiles, and do a kernel density estimation based on those draws.

Be aware that there is no unique solution to this problem, as the estimated kernel density is only one of possible many distribution with the wanted percentiles!

Input:

- perc : The percentiles to fit. Must at least provide 3 percentiles. E.g. [10,30,50,70,90]
- values : The values of the distribution at the given percentiles.
- startD : Start value of the domain. Will be the "0" percentile.
- endD : End value of the domain. Will be the "100" percentile.
- gridpoints : The number of grid points of the domain. Default is 1000.
- nDraws : The number of draws from the interpolated cdf to base the kernel density estimation on. Default is 1000.
- varargin : Optional input given to the nb_ksdensity function. Please see help for that function.

Output:

- obj : An object of class nb_distribution

Examples:

```
obj = nb_distribution.perc2DistCDF([10,30,50,70,90],[1,4,6,7,8],-1,14);
plot(obj)
```

See also:

[nb_distribution.perc2Dist](#)

Written by Kenneth Sæterhagen Paulsen

► perc2ParamDist ↑

```
[obj,err] = nb_distribution.perc2ParamDist(dist,perc,values,varargin)
```

Description:

This method estimate the parameters of the wanted distribution based on a set of percentiles. It will minimize the distance between the parameterized distribution and the provided percentiles.

Input:

- dist : A string with the distribution to match to the percentiles.
See help on the nb_distribution.type property for the supported distributions.
- perc : The percentiles to fit. Must at least provide as many

percentiles as there are parameters of the distribution.
E.g. [10,30,50,70,90]

- values : The values of the distribution at the given percentiles.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : An object of class nb_distribution
- err : Ask for this output if you want to return a potential error instead of it being thrown by this method. If an error occurs this output is non-empty, while obj is.

Examples:

```
orig = nb_distribution('type','normal','parameters',{0,2});
perc = [10,30,50,70,90];
values = percentile(orig,perc);
obj = nb_distribution.perc2ParamDist('normal',perc,values);
plot([orig,obj])
```

See also:

[nb_distribution.perc2Dist](#), [nb_callOptimizer](#)

Written by Kenneth Sæterhagen Paulsen

► **percentile ↑**

x = percentile(obj,perc)

Description:

Get the wanted percentiles of the distribution(s). Same as icdf.

Input:

- obj : A vector of nb_distribution objects
- perc : 1 x nPerc double with the wanted percentiles. E.g. [10,90]

Output:

```
- x      : A nPerc x nobj double
```

Examples:

```
obj(2) = nb_distribution('type','normal','parameters',{0,2})  
x      = percentile(obj,[10,90])
```

See also:

[nb_distribution.icdf](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **plot** ↑

```
plotter = plot(obj,type)
```

Description:

Graph either the PDF or CDF of the distribution

Input:

- obj : A nb_distribution object.
- x : The values to evaluate the distribution. x must be a Nx1 double.
If not provided or empty the full domain of the distribution(s) will be used
- type : A string with either 'pdf' (default) or 'cdf'

Output:

- plotter : A nb_graph_data object. If nargout is 0 the graph will be plotted automatically, otherwise you need to call the graph method on the plotter object.

Examples:

```
obj = nb_distribution  
plot(obj)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **plot3d** ↑

```
plotter = plot(obj,type)
```

Description:

Graph either the PDF or CDF of the distribution

Input:

- obj : A vector of nb_distribution objects.
- x : The values to evaluate the distribution. x must be a Nx1 double.
If not provided or empty the full domain of the distribution(s) will be used
- type : A string with either 'pdf' (default) or 'cdf'
- plot : To set plottype. Either 'surf' (default) or 'mesh'. Either as a string or a function handle.

Output:

- plotter : A nb_graph_data object. If nargout is 0 the graph will be plotted automatically, otherwise you need to call the graph method on the plotter object.

Examples:

Written by Kenneth Sæterhagen Paulsen

► qestimation ↑

```
dist = nb_distribution.qestimation(type, quantiles, values)
```

Description:

Estimate a distribution given known quantiles.

Caution : Only for the distribution family with two parameters, except for 'ast'.

Caution : This function minimizes the absolute deviation between the quantiles provided and the quantiles of the (parameterized) distribution.

Input:

- type : The type of distribution to estimate.
See the nb_distribution class for the supported distributions.
- quantiles : The 1xN quantiles. Should be between 0 and 1. N must be greater than or equal to the number of parameters (K) of

the distribution to estimate. If the distribution does not match perfectly a sum(abs(qDist-quantiles)) measure will be minimized. Here qDist is the quantiles produced by the provided distribution.

- values : The 1xN known values at the quantiles.

Optional input:

- 'optimizer' : 'lsqnonlin', 'fminsearch' or 'fmincon'.
- 'optimset' : A struct. See optimset function. If not given the default settings are used.
- 'init' : Initial values for the parameters. Depends on the type input:
 - > 'skt' : 1 x 4 double. See help on 4 last input to nb_distribution.skt_icdf
 - > 'ast' : 1 x 5 double. See help on 5 last input to nb_distribution.ast_icdf
 - > otherwise : 1 x 2 double. See help on 2 last input to nb_distribution.XXX_icdf, where XX needs to be substituted by type (name of distribution).

Output:

- dist : The found distribution as an nb_distribution object.

Examples:

```
dist1 = nb_distribution.qestimation('normal',[0.5,0.7],[0,0.5])
dist2 = nb_distribution.qestimation('normal',[0.5,0.7,0.9],[0,0.5,0.8])
dist3 = nb_distribution.qestimation('ast',[0.1,0.3,0.5,0.7],...
[0,0.5,0.7,0.9])
```

Written by Kenneth Sæterhagen Paulsen

► **random ↑**

```
draws = random(obj,nrow,ncol)
```

Description:

Draw random numbers from the distribution represented by the nb_distribution object.

Input:

- obj : An object of class nb_distribution
- nrow : The number of rows of the draws output
- ncol : The number of columns of the draws output

Output:

```
- draws : numel(obj) == 1 : A nrow x ncol double with the draws from the
                           distribution
otherwise           : A nrow x ncol x nobj1 x nobj2 double with the
                           draws from the distributions
```

Examples:

```
obj = nb_distribution;
d   = random(obj,10,1);
```

Written by Kenneth Sæterhagen Paulsen

► set ↑

```
set(obj,varargin)
```

Description:

Sets the properties of the nb_distribution object.

Type properties(obj) in the command line to get a list of supported properties, and type help nb_distribution.<propertyName> to get help on a specific property.

Caution : When the property type is set, the paramters property will be set to its default value given the type of the distribution. See the paramters for more on this.

Caution : When the property type is set, the name property will be set to its default value given the type and parameterization of the distribution.

Input:

```
- obj      : An object of class nb_distribution
- varargin : 'propertyName',propertyValue,...
```

Output:

```
- obj      : The input object with the updated properties.
```

Examples:

```
set(obj,'propertyName',propertyValue);
obj.set('propertyName',propertyValue,...)
obj = obj.set('type','gamma');
```

Written by Kenneth S. Paulsen

► **sim2KernelDist** ↑

```
dist = nb_distribution.sim2KernelDist(y)
dist = nb_distribution.sim2KernelDist(y,lb,ub,varargin)
```

Description:

Convert a simulated data to a nb_distribution object.

Input:

- y : A nHor x nVar x nDraws double matrix.
- lb : A nHor x nVar double matrix with the lower bounds. Set to empty if no bounds on any elements (default). Set to -inf to not bound a given element.
- ub : A nHor x nVar double matrix with the upper bounds. Set to empty if no bounds on any elements (default). Set to inf to not bound a given element.

Optional input:

- varargin : See varargin in nb_distribution.estimate. 'support' is not supported. See the lb and ub inputs instead.

Output:

- obj : An nHor x nVar object of class nb_distribution.

Examples:

```
obj = nb_distribution.sim2KernelDist(rand(2,2,1000))
```

See also:

[nb_distribution.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **skewedt_cdf** ↑

```
f = nb_distribution.skewedt_cdf(x,a,b,c,d)
```

Description:

CDF of the generalized skewed t-distribution.

Caution : Calculated using monte carlo integration. This may induce numerical problems with calculating the CDF of this distribution.

Input:

- *x* : The point to evaluate the cdf, as a double.
- *a* : The location parameter (mean).
- *b* : The scale parameter.
- *c* : The skewness parameter.
- *d* : The kurtosis parameter.

Output:

- *f* : The CDF at the evaluated points, same size as *x*.

See also:

[nb_distribution.skewedt_pdf](#), [nb_distribution.skewedt_rand](#)
[nb_distribution.skewedt_icdf](#), [nb_mci](#)

Written by Kenneth Sæterhagen Paulsen

► [skewedt_domain](#) ↑

f = `nb_distribution.skewedt_domain`

Description:

Get the domain of the generalized skewed t-distribution

Output:

- *domain* : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► [skewedt_icdf](#) ↑

x = `nb_distribution.skewedt_icdf(p,a,b,c,d)`

Description:

Returns the inverse of the cdf at *p* of the generalized skewed t-distribution.

Caution : There are may be some numerical problems with calculating the CDF of this distribution, so the results in the tails may wrong.

Input:

- p : A vector of probabilities
- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- x : A double with the quantile at each element of p of the gamma(m,k) distribution

See also:

[nb_distribution.skewedt_cdf](#), [nb_distribution.skewedt_rand](#)
[nb_distribution.skewedt_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **skewedt_kurtosis ↑**

x = nb_distribution.skewedt_kurtosis(a,b,c,d)

Description:

Kurtosis of the generalized skewed t-distribution.

Input:

- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- x : The kurtosis of the distribution

See also:

[nb_distribution.skewedt_median](#), [nb_distribution.skewedt_mean](#)
[nb_distribution.skewedt_variance](#)

► **skewedt_mean** ↑

```
x = nb_distribution.skewedt_mean(a,b,c,d)
```

Description:

Mean of the generalized skewed t-distribution.

Input:

- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- x : The mean of the distribution

See also:

[nb_distribution.skewedt_mode](#), [nb_distribution.skewedt_median](#)
[nb_distribution.skewedt_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **skewedt_median** ↑

```
x = nb_distribution.skewedt_median(a,b,c,d)
```

Description:

Median of the generalized skewed t-distribution.

Input:

- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- x : The median of the distribution

See also:

[nb_distribution.skewedt_mode](#), [nb_distribution.skewedt_mean](#)
[nb_distribution.skewedt_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **skewedt_mode** ↑

`x = nb_distribution.skewedt_mode(a,b,c,d)`

Description:

Mode of the generalized skewed t-distribution.

Input:

- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- x : The mode of the distribution

See also:

[nb_distribution.skewedt_median](#), [nb_distribution.skewedt_mean](#)
[nb_distribution.skewedt_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **skewedt_pdf** ↑

`f = nb_distribution.skewedt_pdf(x,a,b,c,d)`

Description:

PDF of the generalized skewed t-distribution.

Input:

- x : The point to evaluate the pdf, as a double
- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.skewedt_cdf](#), [nb_distribution.skewedt_rand](#)
[nb_distribution.skewedt_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► [skewedt_rand](#) ↑

```
draws = nb_distribution.skewedt_rand(nrow, ncol, a, b, c, d)
```

Description:

Draw random numbers from the generalized skewed t-distribution.

Caution : This method use the inverse cdf function to produce draws.
As the CDF is calculated by MCI it is prone to errors, this
may also result in draws that are wrong!

Input:

- nrow : Number of rows of the matrix drawn from the distribution
- ncol : Number of columns of the matrix drawn from the distribution
- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- draws : A nrow x ncol matrix of random numbers from the distribution

See also:

[nb_distribution.skewedt_pdf](#), [nb_distribution.skewedt_cdf](#)

Modified by Kenneth S. Paulsen

► **skewedt_skewness ↑**

`x = nb_distribution.skewedt_skewness(a,b,c,d)`

Description:

Skewness of the generalized skewed t-distribution.

Input:

- `a` : The location parameter (mean).
- `b` : The scale parameter.
- `c` : The skewness parameter.
- `d` : The kurtosis parameter.

Output:

- `x` : The skewness of the distribution

See also:

[nb_distribution.skewedt_median](#), [nb_distribution.skewedt_mean](#)
[nb_distribution.skewedt_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **skewedt_std ↑**

`x = nb_distribution.skewedt_std(a,b,c,d)`

Description:

Standard deviation of the generalized skewed t-distribution.

Input:

- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- x : The standard deviation of the distribution

See also:

[nb_distribution.skewedt_mode](#), [nb_distribution.skewedt_median](#)
[nb_distribution.skewedt_mean](#), [nb_distribution.skewedt_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **skewedt_variance** ↑

x = nb_distribution.skewedt_variance(a,b,c,d)

Description:

Variance of the generalized skewed t-distribution.

Input:

- a : The location parameter (mean).
- b : The scale parameter.
- c : The skewness parameter.
- d : The kurtosis parameter.

Output:

- x : The variance of the distribution

See also:

[nb_distribution.skewedt_mode](#), [nb_distribution.skewedt_median](#)
[nb_distribution.skewedt_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **skewness** ↑

```
x = skewness(obj)
```

Description:

Evaluate the skewness of the given distribution.

The skewness will be adjusted for bias. See the function skewness made by MATLAB inc.

Input:

- obj : An object of class nb_distribution
- type : Type of skewness measure
 - > 'normal' : $E[(X - \text{mean}(X))^3] / \text{var}(X)^{2/3}$
 - > 'pearson1' : $(\text{mean}(X) - \text{mode}(X)) / \sqrt{\text{var}(X)}$
 - > 'pearson2' : $3 * (\text{mean}(X) - \text{median}(X)) / \sqrt{\text{var}(X)}$
 - > 'bowley' : Set u to 3/4 in the max problem below.
 - > 'quantile' : $\max [icdf(u) + icdf(1-u) - 2\text{median}(X) / \dots$
 $icdf(u) + icdf(1-u)]$
 - > 'paulsen' : $\text{cdf}(\text{mean}(X)) - (1 - \text{cdf}(\text{mean}(X)))$

Output:

- x : $\text{numel}(\text{obj}) == 1$: A double with size as 1 x 1
otherwise : A double with size 1 x nobj

Written by Kenneth Sæterhagen Paulsen

► **skt_cdf ↑**

```
f = nb_distribution.skt_cdf(x,a,b,c,d)
```

Description:

CDF of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. J.Roy.Statist.Soc. B 65, 367-389.

Input:

- x : The point to evaluate the cdf, as a double.
- a : The location parameter.
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

`nb_distribution.skt_pdf`, `nb_distribution.skt_rand`
`nb_distribution.skt_icdf`, `nb_mci`

Written by Kenneth Sæterhagen Paulsen

► **`skt_domain`** ↑

`f = nb_distribution.skt_domain`

Description:

Get the domain of the Azzalini skewed t-distribution

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. *J.Roy.Statist.Soc. B* 65, 367-389.

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **`skt_icdf`** ↑

`x = nb_distribution.skt_icdf(p,a,b,c,d)`

Description:

Returns the inverse of the cdf at p of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. *J.Roy.Statist.Soc. B* 65, 367-389.

Input:

- p : A vector of probabilities
- a : The location parameter (mean).
- b : The scale parameter.

- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- x : A double with the quantile at each element of p of the gamma(m,k) distribution

See also:

[nb_distribution.skt_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **skt_kurtosis ↑**

x = nb_distribution.skt_kurtosis(a,b,c,d)

Description:

Kurtosis of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. J.Roy.Statist.Soc. B 65, 367-389.

Input:

- a : The location parameter.
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- x : The kurtosis of the distribution

See also:

[nb_distribution.skt_median](#), [nb_distribution.skt_mean](#)
[nb_distribution.skt_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **skt_mean** ↑

```
x = nb_distribution.skt_mean(a,b,c,d)
```

Description:

Mean of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. J.Roy.Statist.Soc. B 65, 367–389.

Input:

- a : The location parameter (mean).
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- x : The mean of the distribution

See also:

[nb_distribution.skt_mode](#), [nb_distribution.skt_median](#)
[nb_distribution.skt_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **skt_median** ↑

```
x = nb_distribution.skt_median(a,b,c,d)
```

Description:

Median of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. J.Roy.Statist.Soc. B 65, 367–389.

Input:

- a : The location parameter.
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- x : The median of the distribution

See also:

[nb_distribution.sklt_mode](#), [nb_distribution.sklt_mean](#)
[nb_distribution.sklt_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **skt_mode ↑**

```
x = nb_distribution.sklt_mode(a,b,c,d)
```

Description:

Mode of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. J.Roy.Statist.Soc. B 65, 367-389.

Input:

- a : The location parameter.
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- x : The mode of the distribution

See also:

[nb_distribution.sklt_median](#), [nb_distribution.sklt_mean](#)
[nb_distribution.sklt_variance](#)

► **skt_pdf** ↑

```
f = nb_distribution.skt_pdf(x,a,b,c,d)
```

Description:

PDF of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. J.Roy.Statist.Soc. B 65, 367-389.

Input:

- x : The point to evaluate the pdf, as a double
- a : The location parameter.
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.skt_cdf](#), [nb_distribution.skt_rand](#)
[nb_distribution.skt_icdf](#)

Written by Kenneth Sætherhagen Paulsen

► **skt_rand** ↑

```
draws = nb_distribution.skt_rand(nrow,ncol,a,b,c,d)
```

Description:

Draw random numbers from the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. J.Roy.Statist.Soc. B 65, 367-389.

Input:

- nrow : Number of rows of the matrix drawn from the distribution
- ncol : Number of columns of the matrix drawn from the distribution
- a : The location parameter.
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- draws : A nrow x ncol matrix of random numbers from the distribution

See also:

[nb_distribution.skt_pdf](#), [nb_distribution.skt_cdf](#)

Modified by Kenneth S. Paulsen

► skt_skewness ↑

`x = nb_distribution.skt_skewness(a,b,c,d)`

Description:

Skewness of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t-distribution. J.Roy.Statist.Soc. B 65, 367-389.

Input:

- a : The location parameter.
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- x : The skewness of the distribution

See also:

[nb_distribution.skt_median](#), [nb_distribution.skt_mean](#)
[nb_distribution.skt_variance](#)

Written by Kenneth Åström Paulsen

► **skt_std ↑**

`x = nb_distribution.skt_std(a,b,c,d)`

Description:

Standard deviation of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. *J.Roy.Statist.Soc. B* 65, 367–389.

Input:

- `a` : The location parameter.
- `b` : The scale parameter.
- `c` : The shape parameter.
- `d` : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- `x` : The standard deviation of the distribution

See also:

[nb_distribution.skt_mode](#), [nb_distribution.skt_median](#)
[nb_distribution.skt_mean](#), [nb_distribution.skt_variance](#)

Written by Kenneth Åström Paulsen

► **skt_variance ↑**

`x = nb_distribution.skt_variance(a,b,c,d)`

Description:

Variance of the Azzalini skewed t-distribution.

Azzalini, A. and Capitanio,A. (2003). Distributions generated by perturbation of symmetry with emphasis on a multivariate skew-t distribution. J.Roy.Statist.Soc. B 65, 367-389.

Input:

- a : The location parameter.
- b : The scale parameter.
- c : The shape parameter.
- d : Degrees of freedom (default is positive infinity which corresponds to the skew normal distribution)

Output:

- x : The variance of the distribution

See also:

[nb_distribution.skt_mode](#), [nb_distribution.skt_median](#)
[nb_distribution.skt_mean](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **smoothDensity ↑**

`smoothDensity(obj,smoothing,varargin)`

Description:

Smooth out a distribution of type kernel.

This method should be used with care, as the many of the properties of the original distribution may be changed.

Input:

- obj : A scalar nb_distribution object
- smoothing : > A 1x2 cell : First element is the number of elements to smooth out in the neighbourhood of the selected point, while the second input is the index of selected point.
 - > 'kernel' : Using a kernel smoother on the random draws to smooth out distribution.

Optional input:

```
- varargin : Optional input given to the nb_ksdensity function. Please  
see help for that function.
```

Examples:

```
est = nb_distribution.perc2DistCDF([10,30,50,70,90],[1,4,6,7,8],-1,14);  
s = copy(est);  
smoothDensity(s,'kernel');  
plot([est,s])
```

Written by Kenneth Sæterhagen Paulsen

► **std** ↑

```
x = std(obj)
```

Description:

Evaluate the standard deviation of the given distribution.

The variance is normalized with T-1

Input:

```
- obj : An object of class nb_distribution
```

Output:

```
- x : numel(obj) == 1 : A double with size as 1 x 1  
otherwise : A double with size 1 x nobj
```

Written by Kenneth Sæterhagen Paulsen

► **t_cdf** ↑

```
f = nb_distribution.t_cdf(x,m)  
f = nb_distribution.t_cdf(x,m,a,b)
```

Description:

CDF of the student-t distribution.

Input:

- `x` : The point to evaluate the cdf, as a double
- `m` : The number of degrees of freedom. Must be positive.
- `a` : The location parameter. Optional. Default is 0.
- `b` : The scale parameter. Must be > 0 . Optional. Default is 1.

Output:

- `f` : The CDF at the evaluated points, same size as `x`.

See also:

[nb_distribution.t_pdf](#), [nb_distribution.t_rand](#)
[nb_distribution.t_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **t_domain** ↑

```
f = nb_distribution.t_domain
```

Description:

Get the domain of the student's t-distribution

Output:

- `domain` : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **t_icdf** ↑

```
x = nb_distribution.t_icdf(p,m)
x = nb_distribution.t_icdf(p,m,a,b)
```

Description:

Returns the inverse of the cdf at `p` of the student-t distribution

Input:

- `p` : A vector of probabilities
- `m` : The number of degrees of freedom. Must be positive.
- `a` : The location parameter. Optional. Default is 0.
- `b` : The scale parameter. Must be > 0 . Optional. Default is 1.

Output:

- x : A double with the quantile at each element of p of the student-t distribution

See also:

[nb_distribution.t_cdf](#), [nb_distribution.t_rand](#)
[nb_distribution.t_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► t_kurtosis ↑

```
x = nb_distribution.t_kurtosis(m)
x = nb_distribution.t_kurtosis(m,a,b)
```

Description:

Kurtosis of the student-t distribution. Only defined for $m > 2$, otherwise not defined (will return nan).

Input:

- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0 . Optional. Default is 1.

Output:

- x : The kurtosis of the student-t distribution

See also:

[nb_distribution.f_median](#), [nb_distribution.f_mean](#)
[nb_distribution.f_variance](#), [nb_distribution.f_skewness](#)

Written by Kenneth Sæterhagen Paulsen

► t_mean ↑

```
x = nb_distribution.t_mean(m)
x = nb_distribution.t_mean(m,a,b)
```

Description:

Mean of the student-t distribution. Only defined for $m > 1$, otherwise not defined (will return nan).

Input:

- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0 . Optional. Default is 1.

Output:

- x : The mean of the student-t distribution

See also:

[nb_distribution.t_mode](#), [nb_distribution.t_median](#)
[nb_distribution.t_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **t_median** ↑

```
x = nb_distribution.t_median(m)
x = nb_distribution.t_median(m,a,b)
```

Description:

Median of the student-t distribution

Input:

- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0 . Optional. Default is 1.

Output:

- x : The median of the student-t distribution

See also:

[nb_distribution.t_mode](#), [nb_distribution.t_mean](#)
[nb_distribution.t_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **t_mode** ↑

```
x = nb_distribution.t_mode(m)
x = nb_distribution.t_mode(m, a, b)
```

Description:

Mode of the student-t distribution.

Input:

- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0. Optional. Default is 1.

Output:

- x : The mode of the student-t distribution

See also:

[nb_distribution.t_median](#), [nb_distribution.t_mean](#)
[nb_distribution.t_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **t_pdf** ↑

```
f = nb_distribution.t_pdf(x, m)
f = nb_distribution.t_pdf(x, m, a, b)
```

Description:

PDF of the student-t distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0. Optional. Default is 1.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.t_cdf](#), [nb_distribution.t_rand](#)
[nb_distribution.t_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **t_rand** ↑

```
draws = nb_distribution.t_rand(nrow, ncol, m)
draws = nb_distribution.t_rand(nrow, ncol, m, a, b)
```

Description:

Draw random numbers from the student-t distribution

Input:

- nrow : Number of rows of the matrix drawn from the student-t distribution
- ncol : Number of columns of the matrix drawn from the student-t distribution
- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0. Optional. Default is 1.

Output:

- draws : A nrow x ncol matrix of random numbers from the student-t distribution

See also:

[nb_distribution.t_pdf](#), [nb_distribution.t_cdf](#)

Written by Kenneth S. Paulsen

► **t_skewness** ↑

```
x = nb_distribution.t_skewness(m)
x = nb_distribution.t_skewness(m, a, b)
```

Description:

Skewness of the student-t distribution. Only defined for $m > 3$. Will return nan otherwise.

Input:

- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0 . Optional. Default is 1.

Output:

- x : The skewness of the student-t distribution

See also:

[nb_distribution.t_median](#), [nb_distribution.t_mean](#)
[nb_distribution.t_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **t_std ↑**

```
x = nb_distribution.t_std(m)
x = nb_distribution.t_std(m,a,b)
```

Description:

Standard deviation of the student-t distribution. Only defined for $m > 2$. Will return nan otherwise.

Input:

- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0 . Optional. Default is 1.

Output:

- x : The standard deviation of the student-t distribution

See also:

[nb_distribution.t_mode](#), [nb_distribution.t_median](#)
[nb_distribution.t_mean](#), [nb_distribution.t_variance](#)

► **t_variance ↑**

```
x = nb_distribution.t_variance(m)
x = nb_distribution.t_variance(m,a,b)
```

Description:

Variance of the student-t distribution. Only defined for $m > 1$. Will return nan otherwise.

Input:

- m : The number of degrees of freedom. Must be positive.
- a : The location parameter. Optional. Default is 0.
- b : The scale parameter. Must be > 0 . Optional. Default is 1.

Output:

- x : The variance of the student-t distribution

See also:

[nb_distribution.t_mode](#), [nb_distribution.t_median](#)
[nb_distribution.t_mean](#)

► **tri_cdf ↑**

```
f = nb_distribution.tri_cdf(x,m,k,d)
```

Description:

CDF of the triangular distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.tri_pdf](#), [nb_distribution.tri_rand](#)
[nb_distribution.tri_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **tri_domain** ↑

f = nb_distribution.tri_domain(m,k,d)

Description:

Get the domain of the triangular distribution

Inputs:

- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **tri_icdf** ↑

x = nb_distribution.tri_icdf(p,m,k,d)

Description:

Returns the inverse of the cdf at p of the triangular distribution

Input:

- p : A vector of probabilities
- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- `x` : A double with the quantile at each element of `p` of the triangular distribution

See also:

[nb_distribution.tri_cdf](#), [nb_distribution.tri_rand](#)
[nb_distribution.tri_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **tri_kurtosis** ↑

`x = nb_distribution.tri_kurtosis(m, k, d)`

Description:

Kurtosis of the triangular distribution

Input:

- `m` : Lower bound of the triangular distribution.
- `k` : Upper bound of the triangular distribution.
- `d` : Mode of the triangular distribution.

Output:

- `x` : The kurtosis of the triangular distribution

See also:

[nb_distribution.tri_median](#), [nb_distribution.tri_mean](#)
[nb_distribution.tri_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **tri_mean** ↑

`x = nb_distribution.tri_mean(m, k, d)`

Description:

Mean of the triangular distribution

Input:

- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- x : The mean of the triangular distribution

See also:

[nb_distribution.tri_mode](#), [nb_distribution.tri_median](#)
[nb_distribution.tri_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **tri_median** ↑

```
x = nb_distribution.tri_median(m, k, d)
```

Description:

Median of the triangular distribution

Input:

- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- x : The median of the triangular distribution

See also:

[nb_distribution.tri_mode](#), [nb_distribution.tri_mean](#)
[nb_distribution.tri_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **tri_mode** ↑

```
x = nb_distribution.tri_mode(m, k, d)
```

Description:

Mode of the triangular distribution.

Input:

- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- x : The mode of the triangular distribution

See also:

[nb_distribution.tri_median](#), [nb_distribution.tri_mean](#)
[nb_distribution.tri_variance](#)

Written by Kenneth Sæterhagen Paulsen

► [tri_pdf ↑](#)

```
f = nb_distribution.tri_pdf(x, m, k, d)
```

Description:

PDF of the triangular distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.tri_cdf](#), [nb_distribution.tri_rand](#)

[nb_distribution.tri_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **tri_rand** ↑

```
draws = nb_distribution.tri_rand(nrow,ncol,m,k,d)
```

Description:

Draw random numbers from the triangular distribution

Input:

- nrow : Number of rows of the matrix drawn from the triangular distribution
- ncol : Number of columns of the matrix drawn from the triangular distribution
- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- draws : A nrow x ncol matrix of random numbers from the triangular distribution

See also:

[nb_distribution.tri_pdf](#), [nb_distribution.tri_cdf](#)

Written by Kenneth S. Paulsen

► **tri_skewness** ↑

```
x = nb_distribution.tri_skewness(m,k,d)
```

Description:

Skewness of the triangular distribution

Input:

- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- x : The skewness of the triangular distribution

See also:

[nb_distribution.tri_median](#), [nb_distribution.tri_mean](#)
[nb_distribution.tri_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **tri_std ↑**

x = nb_distribution.tri_std(m,k,d)

Description:

Standard deviation of the triangular distribution

Input:

- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- x : The standard deviation of the triangular distribution

See also:

[nb_distribution.tri_mode](#), [nb_distribution.tri_median](#)
[nb_distribution.tri_mean](#), [nb_distribution.tri_variance](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **tri_variance ↑**

x = nb_distribution.tri_variance(m,k,d)

Description:

Variance of the triangular distribution

Input:

- m : Lower bound of the triangular distribution.
- k : Upper bound of the triangular distribution.
- d : Mode of the triangular distribution.

Output:

- x : The variance of the triangular distribution

See also:

[nb_distribution.tri_mode](#), [nb_distribution.tri_median](#)
[nb_distribution.tri_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **truncated_cdf ↑**

f = nb_distribution.truncated_cdf(x,dist,param,lb,ub)

Description:

CDF of the truncated distribution

Input:

- x : The point to evaluate the cdf, as a double
- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.

Output:

- f : The CDF at the evaluated points, same size as x.

See also:

[nb_distribution.truncated_pdf](#), [nb_distribution.truncated_rand](#)

`nb_distribution.truncated_icdf`

Written by Kenneth Sæterhagen Paulsen

► **truncated_domain** ↑

```
f = nb_distribution.truncated_domain(dist,param,lb,ub)
```

Description:

Get the domain of the truncated distribution

Inputs:

- `dist` : The name of the underlying distribution as a string. Must be supported by the `nb_distribution` class.
- `param` : A cell with the parameters of the selected distribution.
- `lb` : Lower bound of the truncated distribution.
- `ub` : Upper bound of the truncated distribution.

Output:

- `domain` : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **truncated_icdf** ↑

```
x = nb_distribution.truncated_icdf(p,dist,param,lb,ub)
```

Description:

Returns the inverse of the cdf at `p` of the truncated distribution

Input:

- `p` : A vector of probabilities
- `dist` : The name of the underlying distribution as a string. Must be supported by the `nb_distribution` class.
- `param` : A cell with the parameters of the selected distribution.
- `lb` : Lower bound of the truncated distribution.
- `ub` : Upper bound of the truncated distribution.

Output:

- `x` : A double with the quantile at each element of `p` of the truncated distribution

See also:

[nb_distribution.truncated_cdf](#), [nb_distribution.truncated_rand](#)
[nb_distribution.truncated_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **truncated_kurtosis** ↑

`x = nb_distribution.truncated_kurtosis(dist,param,lb,ub)`

Description:

Kurtosis of the truncated distribution. The calculation is simulation based and may vary. Set seed to prevent this, or see the kurtosis method of the `nb_distribution` class.

Input:

- `dist` : The name of the underlying distribution as a string. Must be supported by the `nb_distribution` class.
- `param` : A cell with the parameters of the selected distribution.
- `lb` : Lower bound of the truncated distribution.
- `ub` : Upper bound of the truncated distribution.

Output:

- `x` : The kurtosis of the truncated distribution

See also:

[nb_distribution.truncated_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **truncated_mean** ↑

`x = nb_distribution.truncated_mean(dist,param,lb,ub)`

Description:

Mean of the truncated distribution. The calculation is simulation based and may vary, except for truncated normal. Set seed to prevent this, or see the mean method of the nb_distribution class.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.

Output:

- x : The mean of the truncated distribution

See also:

[nb_distribution.truncated_mode](#), [nb_distribution.truncated_median](#)
[nb_distribution.truncated_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **truncated_median ↑**

x = nb_distribution.truncated_median(dist,param,lb,ub)

Description:

Median of the truncated distribution.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.

Output:

- x : The median of the truncated distribution

See also:

[nb_distribution.truncated_mode](#), [nb_distribution.truncated_mean](#)
[nb_distribution.truncated_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **truncated_mode** ↑

```
x = nb_distribution.truncated_mode(dist,param,lb,ub)
```

Description:

Mode of the truncated distribution.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.

Output:

- x : The mode of the truncated distribution

See also:

[nb_distribution.truncated_median](#), [nb_distribution.truncated_mean](#)
[nb_distribution.truncated_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **truncated_pdf** ↑

```
f = nb_distribution.truncated_pdf(x,dist,param,lb,ub)
```

Description:

PDF of the truncated distribution

Input:

```
- x      : The point to evaluate the pdf, as a double
- dist   : The name of the underlying distribution as a string. Must be
           supported by the nb_distribution class.
- param  : A cell with the parameters of the selected distribution.
- lb     : Lower bound of the truncated distribution.
- ub     : Upper bound of the truncated distribution.
```

Output:

```
- f : The PDF at the evaluated points, same size as x.
```

See also:

[nb_distribution.truncated_cdf](#), [nb_distribution.truncated_rand](#)
[nb_distribution.truncated_icdf](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **truncated_rand** ↑

```
draws = nb_distribution.truncated_rand(nrow, ncol, dist, param, lb, ub)
```

Description:

Draw random number from a truncated distribution.

Input:

```
- nrow  : Number of rows of the matrix drawn from the student-t
          distribution
- ncol  : Number of columns of the matrix drawn from the student-t
          distribution
- dist   : The name of the underlying distribution as a string. Must be
           supported by the nb_distribution class.
- param  : A cell with the parameters of the selected distribution.
- lb     : Lower bound of the truncated distribution.
- ub     : Upper bound of the truncated distribution.
```

Output:

```
- draws : A nrow x ncol matrix of random numbers from the truncated
          distribution
```

Written by Kenneth SÃ¶terhagen Paulsen

► **truncated_skewness** ↑

```
x = nb_distribution.truncated_skewness(dist,param,lb,ub)
```

Description:

Skewness of the truncated distribution. The calculation is simulation based and may vary. Set seed to prevent this, or see the skewness method of the nb_distribution class.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.

Output:

- x : The skewness of the truncated distribution

See also:

[nb_distribution.truncated_median](#), [nb_distribution.truncated_mean](#)
[nb_distribution.truncated_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **truncated_std** ↑

```
x = nb_distribution.truncated_std(dist,param,lb,ub)
```

Description:

Standard deviation of the truncated distribution

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.

Output:

- x : The standard deviation of the truncated distribution

See also:

[nb_distribution.truncated_mode](#), [nb_distribution.truncated_median](#)
[nb_distribution.truncated_mean](#), [nb_distribution.truncated_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **truncated_variance ↑**

```
x = nb_distribution.truncated_variance(dist,param,lb,ub)
```

Description:

Variance of the truncated distribution. The calculation is simulation based and may vary, except for truncated normal. Set seed to prevent this, or see the variance method of the nb_distribution class.

Input:

- dist : The name of the underlying distribution as a string. Must be supported by the nb_distribution class.
- param : A cell with the parameters of the selected distribution.
- lb : Lower bound of the truncated distribution.
- ub : Upper bound of the truncated distribution.

Output:

- x : The variance of the truncated distribution

See also:

[nb_distribution.truncated_mode](#), [nb_distribution.truncated_median](#)
[nb_distribution.truncated_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **truncgamma_mean ↑**

```
x = nb_distribution.truncgamma_mean(m,k,lb,ub)
```

Description:

Mean of the truncated gamma distribution

Input:

- m : A parameter such that the mean of the gamma = $m*k$
- k : A parameter such that the variance of the gamma = $m*(k^2)$
- lb : Lower bound
- ub : Upper bound

Output:

- x : The mean of the truncated gamma distribution

See also:

[nb_distribution.truncgamma_variance](#)

Written by Kenneth Sæterhagen Paulsen

► [truncgamma_variance ↑](#)

x = nb_distribution.truncgamma_variance(m, k)

Description:

Variance of the truncated gamma distribution

Input:

- m : A parameter such that the mean of the gamma = $m*k$
- k : A parameter such that the variance of the gamma = $m*(k^2)$

Output:

- x : The variance of the truncated gamma distribution

See also:

[nb_distribution.truncgamma_mean](#)

Written by Kenneth Sæterhagen Paulsen

► [truncnormal_mean ↑](#)

```
x = nb_distribution.truncnormal_mean(m, k, lb, ub)
```

Description:

Mean of the truncated normal distribution

Input:

- m : A parameter such that the mean of the normal is m
- k : A parameter such that the std of the normal is k
- lb : Lower bound
- ub : Upper bound

Output:

- x : The mean of the truncated normal distribution

See also:

[nb_distribution.truncnormal_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **truncnormal_variance ↑**

```
x = nb_distribution.truncnormal_variance(m, k, lb, ub)
```

Description:

Variance of the truncated normal distribution

Input:

- m : A parameter such that the mean of the normal = m
- k : A parameter such that the std of the normal = k

Output:

- x : The variance of the truncated normal distribution

See also:

[nb_distribution.truncnormal_mean](#)

Written by Kenneth Sæterhagen Paulsen

► **uniform_cdf** ↑

```
f = nb_distribution.uniform_cdf(x,m,k)
```

Description:

CDF of the uniform distribution

Input:

- *x* : The point to evaluate the cdf, as a double
- *m* : Lower limit of the support.
- *k* : Upper limit of the support.

Output:

- *f* : The CDF at the evaluated points, same size as *x*.

See also:

[nb_distribution.uniform_pdf](#), [nb_distribution.uniform_rand](#)
[nb_distribution.uniform_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **uniform_domain** ↑

```
f = nb_distribution.uniform_domain
```

Description:

Get the domain of the uniform distribution

Inputs:

- *m* : Lower limit of the support.
- *k* : Upper limit of the support.

Output:

- *domain* : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **uniform_icdf** ↑

```
x = nb_distribution.uniform_icdf(p,m,k)
```

Description:

Returns the inverse of the cdf at p of the uniform(m,k) distribution

Input:

- p : A vector of probabilities
- m : Lower limit of the support.
- k : Upper limit of the support.

Output:

- x : A double with the quantile at each element of p of the uniform(m,k) distribution

See also:

[nb_distribution.uniform_cdf](#), [nb_distribution.uniform_rand](#)
[nb_distribution.uniform_pdf](#)

Written by Kenneth Sæterhagen Paulsen

► **uniform_kurtosis** ↑

```
x = nb_distribution.uniform_kurtosis(m,k)
```

Description:

Kurtosis of the uniform distribution

Input:

- m : Lower limit of the support.
- k : Upper limit of the support.

Output:

- x : The kurtosis of the uniform distribution

See also:

[nb_distribution.uniform_median](#), [nb_distribution.uniform_mean](#)
[nb_distribution.uniform_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **uniform_mean** ↑

`x = nb_distribution.uniform_mean(m, k)`

Description:

Mean of the uniform distribution

Input:

- `m` : Lower limit of the support.
- `k` : Upper limit of the support.

Output:

- `x` : The mean of the uniform distribution

See also:

[nb_distribution.uniform_mode](#), [nb_distribution.uniform_median](#)
[nb_distribution.uniform_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **uniform_median** ↑

`x = nb_distribution.uniform_median(m, k)`

Description:

Median of the uniform distribution

Input:

- `m` : Lower limit of the support.
- `k` : Upper limit of the support.

Output:

- `x` : The median of the uniform distribution

See also:

[nb_distribution.uniform_mode](#), [nb_distribution.uniform_mean](#)
[nb_distribution.uniform_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **uniform_mode** ↑

`x = nb_distribution.uniform_mode(m, k)`

Description:

Mode of the uniform distribution. Any point between m and k . Return the mid point (mean).

Input:

- m : Lower limit of the support.
- k : Upper limit of the support.

Output:

- x : The mode of the uniform distribution

See also:

[nb_distribution.uniform_median](#), [nb_distribution.uniform_mean](#)
[nb_distribution.uniform_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **uniform_pdf** ↑

`f = nb_distribution.uniform_pdf(x, m, k)`

Description:

PDF of the uniform distribution

Input:

- x : The point to evaluate the pdf, as a double
- m : Lower limit of the support.
- k : Upper limit of the support.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.uniform_cdf](#), [nb_distribution.uniform_rand](#)
[nb_distribution.uniform_icdf](#)

Written by Kenneth Sætherhagen Paulsen

► **uniform_rand** ↑

```
draws = nb_distribution.uniform_rand(nrow, ncol, m, k)
```

Description:

Draw random numbers from the uniform distribution

Input:

- nrow : Number of rows of the matrix drawn from the uniform distribution.
- ncol : Number of columns of the matrix drawn from the uniform distribution.
- m : Lower limit of the support.
- k : Upper limit of the support.

Output:

- draws : A nrow x ncol matrix of random numbers from the uniform distribution

See also:

[nb_distribution.uniform_pdf](#), [nb_distribution.uniform_cdf](#)

Written by Kenneth S. Paulsen

► **uniform_skewness** ↑

```
x = nb_distribution.uniform_skewness(m, k)
```

Description:

Skewness of the uniform distribution

Input:

- m : Lower limit of the support.
- k : Upper limit of the support.

Output:

- x : The skewness of the uniform distribution

See also:

[nb_distribution.uniform_median](#), [nb_distribution.uniform_mean](#)
[nb_distribution.uniform_variance](#)

Written by Kenneth SÃ¶therhagen Paulsen

► **uniform_std** ↑

x = nb_distribution.uniform_std(m, k)

Description:

Standard deviation of the uniform distribution

Input:

- m : Lower limit of the support.
- k : Upper limit of the support.

Output:

- x : The standard deviation of the uniform distribution

See also:

[nb_distribution.uniform_mode](#), [nb_distribution.uniform_median](#)
[nb_distribution.uniform_mean](#), [nb_distribution.uniform_variance](#)

Written by Kenneth SÃ¶therhagen Paulsen

► **uniform_variance** ↑

x = nb_distribution.uniform_variance(m, k)

Description:

Variance of the uniform distribution

Input:

- m : Lower limit of the support.
- k : Upper limit of the support.

Output:

- x : The variance of the uniform distribution

See also:

[nb_distribution.uniform_mode](#), [nb_distribution.uniform_median](#)
[nb_distribution.uniform_mean](#)

Written by Kenneth Sæterhagen Paulsen

► var ↑

x = var(obj)

Description:

Re-directs to the variance method.

Written by Kenneth Sæterhagen Paulsen

► variance ↑

x = variance(obj)

Description:

Evaluate the variance of the given distribution.

The variance is normalized with T-1

Input:

- obj : An object of class nb_distribution

Output:

```
- x      : numel(obj) == 1 : A double with size as 1 x 1
           otherwise       : A double with size 1 x nobj
```

Written by Kenneth SÃ¶terhagen Paulsen

► **vertcat** ↑

```
obj = vertcat(varargin)
```

Description:

Vertical concatenation

Input:

```
- varargin : Either an object of class nb_distribution or an object of
            class double
```

Output:

```
- obj      : An object of class nb_distribution
```

Written by Kenneth SÃ¶terhagen Paulsen

► **wald_cdf** ↑

```
f = nb_distribution.wald_cdf(x,m,k)
```

Description:

CDF of the wald distribution

Input:

```
- x : The point to evaluate the cdf, as a double
- m : The first parameter of the wald distribution. Must be a 1x1 double
      greater than 0. E[X] = m.
- k : The second parameter of the wald distribution. Must be a 1x1 double
      greater than 0.
```

Output:

```
- f : The CDF at the evaluated points, same size as x.
```

See also:

[nb_distribution.wald_pdf](#), [nb_distribution.wald_rand](#)
[nb_distribution.wald_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **wald_domain** ↑

f = nb_distribution.wald_domain

Description:

Get the domain of the wald distribution

Output:

- domain : A 1x2 double with the lower and upper limits of the domain.

Written by Kenneth Sæterhagen Paulsen

► **wald_icdf** ↑

x = nb_distribution.wald_icdf(p,m,k)

Description:

Inverse CDF of the wald density

Input:

- p : A vector of probabilities

- m : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.

- k : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- x : The inverse CDF at the evaluated probabilities, same size as p.

See also:

[nb_distribution.wald_pdf](#), [nb_distribution.wald_rand](#)
[nb_distribution.wald_cdf](#)

Written by Kenneth Sæterhagen Paulsen

► **wald_kurtosis** ↑

```
x = nb_distribution.wald_kurtosis(m,k)
```

Description:

Kurtosis of the wald distribution

Input:

- m : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- k : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- x : The kurtosis of the wald distribution

See also:

[nb_distribution.wald_median](#), [nb_distribution.wald_mean](#)
[nb_distribution.wald_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **wald_mean** ↑

```
x = nb_distribution.wald_mean(m,k)
```

Description:

Mean of the wald distribution

Input:

- m : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- k : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- x : The mean of the wald distribution

See also:

`nb_distribution.wald_mode`, `nb_distribution.wald_median`
`nb_distribution.wald_variance`

Written by Kenneth Sæterhagen Paulsen

► **wald_median** ↑

`x = nb_distribution.wald_median(m, k)`

Description:

Median of the wald distribution

Input:

- `m` : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- `k` : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- `x` : The median of the wald distribution

See also:

`nb_distribution.wald_mode`, `nb_distribution.wald_mean`
`nb_distribution.wald_variance`

Written by Kenneth Sæterhagen Paulsen

► **wald_mode** ↑

`x = nb_distribution.wald_mode(m, k)`

Description:

Mode of the wald distribution

Input:

- `m` : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- `k` : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- x : The mode of the wald distribution

See also:

[nb_distribution.wald_median](#), [nb_distribution.wald_mean](#)
[nb_distribution.wald_variance](#)

Written by Kenneth Sæterhagen Paulsen

► **wald_pdf** ↑

f = nb_distribution.wald_pdf(x,m,k)

Description:

PDF of the wald distribution

Input:

- x : The point to evaluate the cdf, as a double
- m : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- k : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- f : The PDF at the evaluated points, same size as x.

See also:

[nb_distribution.wald_cdf](#), [nb_distribution.wald_rand](#)
[nb_distribution.wald_icdf](#)

Written by Kenneth Sæterhagen Paulsen

► **wald_rand** ↑

draws = nb_distribution.wald_rand(nrow,ncol,m,k)

Description:

Draw random numbers from the wald distribution

Input:

- nrow : Number of rows of the matrix drawn from the wald distribution
- ncol : Number of columns of the matrix drawn from the wald distribution
- m : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- k : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- draws : A nrow x ncol matrix of random numbers from the wald distribution

See also:

[nb_distribution.wald_pdf](#), [nb_distribution.wald_cdf](#)

Written by Kenneth S. Paulsen

► **wald_skewness ↑**

`x = nb_distribution.wald_skewness(m, k)`

Description:

Skewness of the wald distribution

Input:

- m : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- k : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- x : The skewness of the wald distribution

See also:

[nb_distribution.wald_median](#), [nb_distribution.wald_mean](#)
[nb_distribution.wald_variance](#)

Written by Kenneth Sætherhagen Paulsen

► **wald_std** ↑

```
x = nb_distribution.wald_std(m,k)
```

Description:

Standard deviation of the wald distribution

Input:

- m : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- k : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- x : The standard deviation of the wald distribution

See also:

[nb_distribution.wald_mode](#), [nb_distribution.wald_median](#)
[nb_distribution.wald_mean](#), [nb_distribution.wald_std](#)

Written by Kenneth Sæterhagen Paulsen

► **wald_variance** ↑

```
x = nb_distribution.wald_variance(m,k)
```

Description:

Variance of the wald distribution

Input:

- m : The first parameter of the wald distribution. Must be a 1x1 double greater than 0. $E[X] = m$.
- k : The second parameter of the wald distribution. Must be a 1x1 double greater than 0.

Output:

- x : The variance of the wald distribution

See also:

```
nb_distribution.wald_mode, nb_distribution.wald_median  
nb_distribution.wald_mean
```

Written by Kenneth SÃ¶terhagen Paulsen

► **wish_rand** ↑

```
A = wish_rand(h,n)
```

Description:

Draws an $m \times m$ matrix from a wishart distribution with scale matrix h and degrees of freedom $\nu = n$. This procedure uses Bartlett's decomposition.

Note: Parameterized so that mean is $n \cdot h$

Input:

- h : $m \times m$ scale matrix.
- n : scalar degrees of freedom.

Output:

- A : $m \times m$ matrix draw from the wishart distribution.

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_ast_b**

```
f = nb_ast_b(x)
```

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_ast_cstar**

```
cstar = nb_ast_cstar(c,d,e)
```

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_ast_k**

```
f = nb_ast_k(x)
```

Written by Kenneth SÃ¶terhagen Paulsen

◆ nb_chol

```
C = nb_chol(A,type)
```

Description:

Cholesky decomposition. If type is given as 'cov' it will do a eigenvalue decomposition such that $C \cdot C' = A$. In the last case the matrix A must be positive semi-definite.

Input:

- A : A symmetric positive (semi-)definite matrix
- type : Give 'cov' to use eigenvalue decomposition if cholesky decomposition fails. C is not necessary symmetric in this case!
Give 'covrepair' to reset all eigenvalue that are negative to 0.

Output:

- C : A matrix such that $C \cdot C' = A$

Written by Kenneth Sæterhagen Paulsen

◆ nb_copulacondrnd

```
U = nb_copulacondrnd(M,P,sigma,indC,a,type)
```

Description:

Generate random variables from the conditional gaussian copula.

Input:

- M : The number of simulated observations of each variables.
- P : The number of simulated observations of each variables. (Added as a page)
- sigma : The correlation matrix. As a $N \times N$ double, with ones along the diagonal.
- indC : Index for the variables to condition on. As a $1 \times N$ or $N \times 1$ logical. sum(indC) must equal Q.
- a : The values to condition on. As $Q \times 1$ double.
- type : Set the transformation method to use to transform the rank correlation coefficients to the linear correlation coefficients.

- 'none' : If the correlation in the data is calculated based on the linear correlation coefficients. Default.
- 'spearman' : Uses the formula $\rho = 2 \cdot \sin(\sigma \cdot \pi / 6)$. Can be used if the rank correlation coefficients are calculated based on the data series. Using the `corr(X,'type','spearman')` function.
- 'kendall' : Uses the formula $\rho = \sin(\sigma \cdot \pi / 2)$. Can be used if the rank correlation coefficients are calculated based on the data series. Using the `corr(X,'type','kendall')` function.

The rank correlation coefficients are approximately invariant to the choice of marginal distribution used to transform the draws from the copula to the draws of the different marginals.

Output:

- U : A M x N-Q x P matrix.

Examples:

```
U = nb_copularnd([1,0.5;0.5,1],'spearman');
```

See also:

[nb_copula](#)

Written by Kenneth Sølnerhagen Paulsen

◆ [nb_copularnd](#)

```
U = nb_copularnd(M,P,sigma,type)
```

Description:

Generate random variables from the gaussian copula.

Input:

- M : The number of simulated observations of each variables.
- P : The number of simulated observations of each variables. (Added as a page)
- sigma : The correlation matrix. As a N x N double, with ones along the diagonal.
- type : Set the transformation method to use to transform the rank correlation coefficients to the linear correlation coefficients.

- 'none' : If the correlation in the data is calculated based on the linear correlation coefficients. Default.
- 'spearman' : Uses the formula $\rho = 2 \cdot \sin(\sigma \cdot \pi / 6)$. Can be used if the rank correlation coefficients are calculated based on the data series. Using the `corr(X,'type','spearman')` function.
- 'kendall' : Uses the formula $\rho = \sin(\sigma \cdot \pi / 2)$. Can be used if the rank correlation coefficients are calculated based on the data series. Using the `corr(X,'type','kendall')` function.

The rank correlation coefficients are approximately invariant to the choice of marginal distribution used to transform the draws from the copula to the draws of the different marginals.

Output:

- U : A M x N x P matrix.

Examples:

```
U = nb_copularnd([1,0.5;0.5,1],'spearman');
```

See also:

[nb_copula](#)

Written by Kenneth Åkerhagen Paulsen

◆ nb_covShrinkDiag

```
[C,lambda]= nb_covShrinkDiag(x,lambda)
```

Description:

Let X be a data matrix with size T x N. This function estimate the covariance matrix of the data X using a shrinkage against the diagonal matrix of the variances of the data in X.

```
C = lambda*D + (1-lambda)*S
```

where D is the diagonal matrix and S is the normal estimate of the covariance matrix $((X'*X)/(T-1))$

References:

Kwan (2011), "An Introduction to Shrinkage Estimation of the Covariance Matrix: A Pedagogic Illustration"

Input:

- X : A T x N double where T is the number of observations and N is the number of variables.
- lambda : Give this input, if you want to set the shrinkage parameter based on judgment. Must in this case be a number between 0 and 1. Default is to estimate lambda as in Kwan (2011). 0 means no shrinkage.

Output:

- C : The estimate covariance matrix.
- lambda : The calculated shrinkage parameter.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

◆ nb_covrepair

C = nb_covrepair(A,type)

Description:

Convert a non (semi-)definite matrix to (semi-)definite matrix.

Input:

- A : A symmetric matrix.
- type : true or false. Give true to find the closest semi-definite matrix. Default is false, i.e. to find the closest definite matrix.

Output:

- C : A symmetric matrix with same size as A.

Written by Kenneth Sæterhagen Paulsen

◆ nb_drawCov

C = nb_drawCov(N,P)

Description:

Draw random correlation matrices of size N x N.

Input:

- N : The size of the correlation matrix.
- draws : Number of draws. Added as separate pages.

Output:

- C : A N x N x draws double.

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_fStatPValue**

p = nb_fStatPValue(x, m, k)

Description:

P-value of F-statistics.

Input:

- x : The point to evaluate the t-statistics at, as a double.
- m : Numerator degree of freedom. Must be positive.
- k : Denominator degree of freedom. Must be positive.

Output:

- p : P-value of F-statistics, same size as x.

See also:

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_invppsi**

y = nb_invppsi(x, err)

Description:

Inverse of psi function using a newton algorithm.

Input:

```
- x : A double.  
- err : The stopping criterion for the newton algorithm.
```

Output:

```
- y : A double.
```

See also:

[psi](#)

Kenneth Sæterhagen Paulsen

◆ nb_ksdensity

```
[f,x,u] = nb_ksdensity(yData,varargin)  
[f,x,u] = nb_ksdensity(yData,domain,varargin)
```

Description:

Kernel density estimation.

Input:

```
- yData : A numVar x numSim double.  
- domain : Same as the 'domain' input.
```

Optional input:

```
- 'domain' : Either a 1 x numDomain or a numVar x numDomain double  
with the point for where to evaluate the function f.  
Can be empty, and in this case it will be estimated.  
  
- 'bandWidth' : Sets the bandwidth to use during kernel density  
estimation. If given as a number less than or equal to  
0, the default value is used; sigma*(4/(3*N))^(1/5),  
where sigma is the standard deviation of the xi input  
calculated using mean absolute deviation and N is the  
size(yData,2). The default value is found for each  
function separately (numVar).  
  
- 'numDomain' : This option will set the number of values for where the  
function f are to be evaluated if domain is not provided.  
Default is 1000.
```

Output:

```
- f : A numVar x numDomain double with the estimated density function.  
- x : A numVar x numDomain double with the domain of the density  
function f.  
- u : A numVar x 1 double with the selected band widths.
```

Written by Kenneth Sæterhagen Paulsen

◆ **nb_lognormal_deriv**

```
x = nb_lognormal_deriv(x,m,k)
```

Description:

Derivate of the log normal distribution.

Input:

- x : The point to evaluate the derivative of the log normal PDF, as a double.
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$
- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$

Output:

- x : The derivatives of the log normal PDF at the evaluated points, same size as x.

See also:

[nb_distribution](#), [nb_distribution.lognormal_pdf](#)
[nb_distribution.lognormal_cdf](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_mci**

```
x = nb_mci(func,a,b,draws,dist)
```

Description:

Integrate a univariate function from a to b using a monte carlo method.

Input:

- func : A function handle.
- a : Lower limit, as a scalar double. Can be -inf.
- b : Upper limit, as a scalar double. Can be inf.

- draws : Number of draws. As a number grater than or equal to 1000. Default is 10000.
- dist : The distribution to use to do the montecarlo integration. As a nb_distribution object. Default is to use the uniform(a,b) distribution. This distribution will be truncated in the interval [a,b], so this means that the domain of the given distribution must contain the interval [a,b].

Caution : If a == -inf and/or b == inf. The truncated normal distribution is used as the default distribution.

Output:

- x : The value of the integral.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_mode**

```
m = nb_mode(x,dim,method,varargin)
```

Description:

Find the mode of the empirical distribution of the number in x along the wanted dimension.

Input:

- x : A 3D double matrix.
- dim : Either 1, 2 or 3. 1 is default.
- method : A string:
 - > 'kernel' : Using kernel density estimation and finds the mode of the estimated distribution. (Default)

To decrease the std in the mode estimate the 'width' input can be used. The default is

```
sig = median(abs(x-median(x))) / 0.6745;
w    = 2 * sig * (4/(3*N))^(1/5);
```
- varargin : Extra inputs to the differen mode estimators
 - > 'kernel' :

Optional input given to the nb_ksdensity function. Please see help for that function.
 - > The rest of the methods have no optional inputs.

Output:

- m : The mode with size matching the inputs x and dim.

Examples:

```
m = nb_mode(randn(1000,1),1,'kernel')
```

See also:

[mode](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_mvExpNorm**

```
x = nb_mvExpNorm(n,sigma)
```

Description:

Calculates the expectation of the 2-norm of a multivariate normal distribution with diagonal covariance matrix and where all the diagonal elements has the same value; sigma.

It is also assumed that the distribution has mean zero for all elements.

Input:

- n : The number of variables. As a positive integer.
- sigma : The standard deviation of all the variables. As a positive double.

Output:

- x : The expected 2-norm of the distribution. As a scalar double.

Written by Kenneth Sætherhagen Paulsen

◆ **nb_mvncdf**

```
p = nb_mvncdf(x,mu,sigma)
```

Description:

Evaluate multivariate normal cdf

This code uses the qsimvn made by;

Alan Genz, WSU Math, PO Box 643113, Pullman, WA 99164-3113

Input:

```
- x      : A nPoints x nVar double with the points to evaluate.  
- mu    : A 1 x nVar double with the mean of the different variables of the  
          distribution.  
- sigma : A nVar x nVar double with the correlation matrix.
```

Output:

p : A nPoints x 1 double with the evaluated probabilities.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_mvnrnd**

U = nb_mvnrnd(M,P,mu,sigma,tol)

Description:

Draw random variables from the multivariate normal distribution.

Input:

```
- M      : The number of simulate observation of each variables.  
- P      : The number of simulate observation of each variables. (Added  
          as a page)  
- mu    : The mean of the variables. As a 1 x N double.  
- sigma : The covariance matrix. As a N x N double. Must be symmetric.
```

Caution: Notice that this function compared to mvnrnd made by MATLAB tries to repair the covariance matrix if it is not positive semi-definite. This it does by setting all eigenvalues of the sigma matrix that are negative to zero.

- tol : The tolerance when checking for symmetry of sigma.

Output:

- U : A M x N x P matrix.

See also:

[nb_chol](#), [nb_mvtnrand](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_mvnrndChol**

```
U = nb_mvnrndChol(M,P,mu,T)
```

Description:

Draw random variables from the multivariate normal distribution.

Input:

- M : The number of simulate observation of each variables.
- P : The number of simulate observation of each variables. (Added as a page)
- mu : The mean of the variables. As a 1 x N double.
- T : The cholesky factorized correlation matrix. As a N x N double.

Output:

- U : A M x N x P matrix.

See also:

[nb_mvnrnd](#), [nb_chol](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_mvtncondrand**

```
U = nb_mvtncondrand(M,P,mu,sigma,l,u,indC,a,tol)
```

Description:

Draw random variables from the conditional multivariate truncated normal distribution.

Input:

- M : The number of simulate observation of each variables.
- P : The number of simulate observation of each variables. (Added as a page)
- mu : The mean of the variables. As a N x 1 double.
- sigma : The covariance matrix. As a N x N double. Must be symmetric.
- l : Lower bound of the truncated distribution. As a 1 x N double.
May include -inf.
- u : Upper bound of the truncated distribution. As a 1 x N double.
May include inf.

- `indC` : Index for the variables to condition on. As a $1 \times N$ or $N \times 1$ logical. `sum(indC)` must equal Q .
- `a` : The values to condition on. As $Q \times 1$ double.
- `tol` : The tolerance when checking for symmetry of σ .

Output:

- `U` : A $M \times N \times P$ matrix.

See also:

[nb_chol](#), [nb_mvtnrand](#), [nb_mvnrand](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_mvtnrand**

`U = nb_mvtnrand(M,P,mu,sigma,l,u,tol)`

Description:

Draw random variables from the multivariate truncated normal distribution.

This function is based on the `trandn` function written by Zdravko Botev. Available here "https://se.mathworks.com/matlabcentral/fileexchange/53180-truncated-normal-generator?s_tid=prof_contriblnk". Main modifications:

1. Generalized to the non-standardized truncated normal distribution using the Geweke, Hajivassiliou and Keane algorithm.
https://en.wikipedia.org/wiki/GHK_algorithm
2. Allow for simulations of multiple draws from the variables of the distribution.

Reference:

Botev, Z. I. (2016). "The normal law under linear restrictions: simulation and estimation via minimax tilting". Journal of the Royal Statistical Society: Series B (Statistical Methodology). doi:10.1111/rssb.12162

Input:

- `M` : The number of simulate observation of each variables.
- `P` : The number of simulate observation of each variables. (Added as a page)
- `mu` : The mean of the variables. As a $N \times 1$ double.
- `sigma` : The covariance matrix. As a $N \times N$ double. Must be symmetric.
- `l` : Lower bound of the truncated distribution. As a $N \times 1$ double.

May include -inf.

- u : Upper bound of the truncated distribution. As a N x 1 double.
May include inf.
- tol : The tolerance when checking for symmetry of sigma.

Output:

- U : A M x N x P matrix.

See also:

[nb_chol](#), [nb_mvnrnd](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_normal_deriv**

`x = nb_normal_deriv(x,m,k)`

Description:

Derivative of the normal distribution.

Input:

- x : The point to evaluate the derivative of the normal PDF, as a double.
- m : The mean of the distribution.
- k : The std of the distribution.

Output:

- x : The derivatives of the normal PDF at the evaluated points, same size as x.

See also:

[nb_distribution](#), [nb_distribution.normal_pdf](#)
[nb_distribution.normal_cdf](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_tAbsMoment**

`f = nb_tAbsMoment(x,r)`

Description:

Absolute moment of the Student-t distribution.

See Zhu and Galbraith (2009).

Input:

- x : The number of degrees of freedom.
- r : The absolute moment order to calculate.

Output:

- f : The rth order absolute moment

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_tStatPValue**

p = nb_tStatPValue(x, m)

Description:

P-value of t-statistics.

Input:

- x : The point to evaluate the t-statistics at, as a double.
- m : The number of degrees of freedom. Must be positive.

Output:

- p : P-value of t-statistics, same size as x.

See also:

[nb_distribution.t_pdf](#), [nb_distribution.t_rand](#)
[nb_distribution.t_icdf](#), [nb_distribution.t_cdf](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **qsimvn**

[p,e] = qsimvn(m,r,a,b)

Description:

This function uses a randomized quasi-random rule with m points to estimate an MVN probability for positive definite covariance matrix r , with lower integration limits a and upper integration limits b . Probability p is output with error estimate e .

This function uses an algorithm given in the paper
"Numerical Computation of Multivariate Normal Probabilities", in
J. of Computational and Graphical Stat., 1(1992), pp. 141-149, by
Alan Genz, WSU Math, PO Box 643113, Pullman, WA 99164-3113
Email : AlanGenz@wsu.edu

The primary references for the numerical integration are
"On a Number-Theoretical Integration Method"
H. Niederreiter, Aequationes Mathematicae, 8(1972), pp. 304-11, and
"Randomization of Number Theoretic Methods for Multiple Integration"
R. Cranley and T.N.L. Patterson, SIAM J Numer Anal, 13(1976), pp.
904-14.

Examples:

```
r      = [4 3 2 1;3 5 -1 1;2 -1 4 2;1 1 2 5];
a      = -inf*[1 1 1 1]'; b = [ 1 2 3 4 ]';
[p, e] = qsimvn( 5000, r, a, b ); disp([ p e ])
```

Written by Kenneth Sætherhagen Paulsen

► **[nb_lasso.optimset](#)** ↑

```
options = nb_lasso.optimset(varargin)
```

Description:

Get optimization settings or help for use by the nb_lasso function.

Optional input:

- Run without inputs to get defaults.
- Run with 'list' as the first input to get a cellstr with the supported options.
- Run with 'help' to get a char with help on each option.
- Run with 'optionName' to get help on a particular option, i.e. only one input.
- Use 'optionName', optionValue pairs to set options of the returned struct.

Output:

- Depends on the input.

See also:

[nb_lasso](#)

Written by Kenneth Sæterhagen Paulsen

► nb_arimaEstimator.bootstrapModel ↑

```
[betaDraws,sigmaDraws,estOpt] = nb_arimaEstimator.bootstrapModel(...  
    model,options,results,method,draws,iter)
```

Description:

Bootstrap model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► nb_arimaEstimator.drawParameters ↑

```
[betaDraws,sigmaDraws] = nb_arimaEstimator.drawParameters(results,...  
    options,draws,iter)
```

Description:

Draw parameters using asymptotic normality assumption and numerically calculated Hessian from ML estimation. Do not draw from the distribution of the std of the residual.

Written by Kenneth Sæterhagen Paulsen

► nb_arimaEstimator.estimate ↑

```
[results,options] = nb_arimaEstimator.estimate(options)
```

Description:

Estimate a ARIMA model with a selected algorithm.

Input:

- options : A struct on the format given by nb_arimaEstimator.template.
See also nb_arimaEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options.

See also:

```
nb_arimaEstimator.print, nb_arimaEstimator.help  
nb_arimaEstimator.template
```

Written by Kenneth Sæterhagen Paulsen

► **nb_arimaEstimator.getCoeff** ↑

```
[coeff,numCoeff] = nb_arimaEstimator.getCoeff(options)
```

Description:

Get names of arima coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_arimaEstimator.getDependent** ↑

```
residual = nb_arimaEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_arimaEstimator.getMeasurementEqRes** ↑

```
u = nb_arimaEstimator.getMeasurementEqRes(options,sq,sp,beta,y,z,x)
```

Description:

Get residual from the measurement equation.

Written by Kenneth Sæterhagen Paulsen

► **nb_arimaEstimator.getPredicted** ↑

```
residual = nb_arimaEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_arimaEstimator.getResidual ↑**

```
residual = nb_arimaEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_arimaEstimator.help ↑**

```
helpText = nb_arimaEstimator.help
helpText = nb_arimaEstimator.help(option)
helpText = nb_arimaEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_arimaEstimator.makeArtificial ↑**

```
[YDRAW,start,finish,indY] = nb_arimaEstimator.makeArtificial(model, ...
options,results,method,draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► nb_arimaEstimator.print ↑

```
res = nb_arimaEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_arimaEstimator.estimate function.
- options : A struct with the estimation options from the nb_arimaEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► nb_arimaEstimator.template ↑

```
options = nb_arimaEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_arimaEstimator class constructor.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_bVarEstimator.CCCMSampler** ↑

```
[PAI,lambda,tau] = nb_bVarEstimator.CCCMSampler(Y,X,N,K,~,A_,sqrt_ht,  
PAI,lambda,tau)
```

Description:

Performs a draw from the conditional posterior of the VAR conditional mean coefficients by using the triangular algorithm. The triangularization achieves computation gains of order N^2 where N is the number of variables in the VAR. Algorithm developed in Carriero, Chan, Clark, and Marcellino (2021), Corrigendum to "Large Vector Autoregressions with stochastic volatility and non-conjugate priors."

The model is:

```
Y(t) = Pai(L)Y(t-1) + v(t); Y(t) is Nx1; t=1,...,T, L=1,...,p.  
v(t) = inv(A)*(LAMBDA(t)^0.5)*e(t); e(t) ~ N(0,I);
```

$$A = \begin{pmatrix} - & 1 & 0 & 0 & \dots & 0 \\ | & A(2,1) & 1 & 0 & \dots & 0 \\ | & A(3,1) & A(3,2) & 1 & \dots & 0 \\ | & \dots & \dots & \dots & \dots & \dots \\ | & A(N,1) & \dots & \dots & A(N,N-1) & 1 \end{pmatrix}$$

```
Lambda(t)^0.5 = diag[sqrt_h(1,t) , ..., sqrt_h(N,t)];
```

Input:

- Y : (TxN) matrix of data appearing on the LHS of the VAR
- X : (TxK) matrix of data appearing on the RHS of the VAR. The matrix needs to be ordered as: [1, y(t-1), y(t-2), ..., y(t-p)]
- N : scalar, #of variables in VAR
- K : scalar, #of regressors (=N*p+1)
- T : scalar, #of observations
- invA_ : (NxN) inverse of lower triangular covariance matrix A
- sqrt_ht : (TxN) time series of diagonal elements of volatility matrix. For a homoskedastic system, with Sigma the error variance, one can perform the LDL decomposition (command [L,D] =LDL(Sigma)) and set inv_A=L and sqrt_ht = repmat(sqrt(diag(D)'),T,1).

Output:

- One draw from (PAI|A,Lambda,data). PAI=[Pai(0), Pai(1), ..., Pai(p)].

[betaD,sigmaD,XX,posterior,options,fVal,pY] = ...  
    nb_bVarEstimator.doEmpiricalBayesian(options,h,nLags,restrictions,...  
        y,X,yFull,XFull,func)
```

Description:

Estimate B-VAR model with optimizing hyperparameters of the priors. See Giannone, Lenza and Primiceri (2014), "Prior selection for vector autoregressions"

Caution: We do not use MCMC methods to sample from the posterior of the hyperparameters even if options.hyperprior is set to true.

Written by Kenneth Sæterhagen Paulsen

► nb_bVarEstimator.doEmpiricalBayesianMF ↑

```
[betaD,sigmaD,R,ys,XX,posterior,options,fVal,pY] = ...
nb_bVarEstimator.doEmpiricalBayesian(options,h,nLags,restrictions, ...
y,X,freq,H,mixing,func)
```

Description:

Estimate B-VAR model with optimizing hyperparameters of the priors. See Giannone, Lenza and Primiceri (2014), "Prior selection for vector autoregressions"

Caution: We do not use MCMC methods to sample from the posterior of the hyperparameters even if options.hyperprior is set to true.

We do the optimization step over a balanced dataset, and then use the hyperparameters from this step to estimate the model on the full dataset.

Caution: Only missing observations at the end of the example is supported!

Written by Kenneth Sæterhagen Paulsen

► nb_bVarEstimator.dsge ↑

```
beta = nb_bVarEstimator.dsge(draws,y,x,nLags, ...
constant,timeTrend,prior,restrictions,waitbar)

[beta,sigma,X,posterior,pY] = nb_bVarEstimator.dsge(draws,y,x,nLags, ...
constant,timeTrend,prior,restrictions,waitbar)
```

Description:

Estimate VAR model using dsge-prior, as in Del Negro and Schorfheide (2004), "Priors from General Equilibrium Models for VARS".

Input:

```

- y : A double matrix of size nobs x neq of the dependent
      variable of the regression(s).

- x : A double matrix of size nobs x h + neq*nlags. Where h
      is the exogenous variables of the model.

- nLags : Number of lags of the VAR. As an integer

- constant : If a constant is wanted in the estimation. Will be
      added first in the right hand side variables.

- timeTrend : If a linear time trend is wanted in the estimation.
      Will be added first/second in the right hand side
      variables. (First if constant is not given, else
      second)

- prior : A struct with the prior options. See
      nb_var.priorTemplate for more on this input

- restrictions : Index of parameters that are restricted to zero.

- waitbar : true, false or an object of class nb_waitbar5.

```

Output:

```

- beta : A (extra + neq*nlags + h) x neq x draws matrix with the
      posterior draws of the estimated coefficients.

      Caution : If nargout == 1, this output is the marginal
      likelihood.

- sigma : A neq x neq x draws matrix with the posterior variance of
      the estimated coefficients.

- X : Regressors including constant and time-trend.

- posterior : A struct with all the needed information to do posterior
      draws.

- pY : Log marginal likelihood.

```

See also

`nb_bVarEstimator.estimate`, `nb_var`, `nb_bVarEstimator.logMarginalLikelihood`

Written by Kenneth S. Paulsen

► **`nb_bVarEstimator.dummyNormalizationConstant` ↑**

```
norm = nb_bVarEstimator.dummyNormalizationConstant(yd, xd, d, priorBeta, ...
                                                     PSI, Omega)
```

Description:

Calculate the normalization constant due dummy observation prior.

Input:

- T : Number of observation.
- n : Number of dependent variables of the VAR.
- p : Number of lags in the VAR.
- d : Number of degrees of freedom of the prior on Sigma.
- xx : Calculated as $x'x$, where x is the regressors of the VAR.
- PSI : Prior of Sigma.
- Omega : Scale matrix of the prior of beta.

Output:

- norm : Normalization constant.

Written by Kenneth Sæterhagen Paulsen

► nb_bVarEstimator.estimate ↑

```
[results,options] = nb_bVarEstimator.estimate(options)
```

Description:

This code is based on code from a paper by Koop and Korobilis (2010), Bayesian Multivariate Time Series Methods for Empirical Macroeconomics.

Estimate a model with bayesian methods. The following priors are supported (Can be set by the prior field of the options struct):

- 'jeffrey' : Diffuse (M-C Integration)
- 'minnesota' : Minnesota (M-C Integration) or (Gibbs sampler)
- 'nwishart' : Normal-Wishart (M-C Integration)
- 'inwishart' : Independent Normal-Wishart (Gibbs sampler)
- 'glp' : This is the prior used in the paper by Giannone, Lenza and Primiceri (2014), which is of the Normal-Wishart type prior. (Gibbs sampler)
- 'dsge' : Normal-Wishart type prior with dummy observations from another model (often dsge, therefor the name).

The code is also extended to handle missing observations and mixed-frequency VAR models. Then the following priors are supported:

- 'minnesotaMF' : Minnesota (Gibbs sampler)
- 'nwishartMF' : Normal-Wishart (Gibbs sampler)
- 'inwishartMF' : Independent Normal-Wishart (Gibbs sampler)
- 'glpMF' : This is the prior used in the paper by Giannone, Lenza and Primiceri (2014), which is of

the Normal-Wishart type prior. (Gibbs sampler)

A Kalman smoother is ran to get the posterior distribution of the missing observations.

Input:

- options : A struct on the format given by nb_bVarEstimator.template.
See also nb_bVarEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example using the 'modelSelection' options.

```

Description:

Go from draws from the posterior to state-space representation of the model. Used by the Kalman filter iteration when dealing with missing observations or mixed frequency VARs.

Written by Kenneth Sæterhagen Paulsen

► **nb_bVarEstimator.glp** ↑

```
beta = nb_bVarEstimator.glp(draws,y,x,nLags,...  
    constant,constantAR,timeTrend,prior,restrictions,waitbar)  
  
[beta,sigma,X,posterior,pY] = nb_bVarEstimator.glp(draws,y,x,nLags,...  
    constant,constantAR,timeTrend,prior,restrictions,waitbar)
```

Description:

Estimate VAR model using prior used in the paper by Giannone, Lenza and Primiceri (2014), "Prior selection for vector autoregressions" and Giannone, Lenza and Primiceri (2017), "Priors for the long run".

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x h + neq*nlags. Where h is the exogenous variables of the model.
- nLags : Number of lags of the VAR. As an integer
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- constantAR : Include constant in AR models that is used to set up the prior for sigma.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second)
- prior : A struct with the prior options. See nb_var.priorTemplate for more on this input

- restrictions : Index of parameters that are restricted to zero.
- waitbar : true, false or an object of class nb_waitbar5.

Output:

- beta : A (extra + neq*nlags + h) x neq x draws matrix with the posterior draws of the estimated coefficients.
Caution : If nargout == 1, this output is the marginal likelihood.
- sigma : A neq x neq x draws matrix with the posterior variance of the estimated coefficients.
- X : Regressors including constant and time-trend.
- posterior : A struct with all the needed information to do posterior draws.
- pY : Log marginal likelihood.

nb_bVarEstimator.estimate, **nb_var**, **nb_bVarEstimator.logMarginalLikelihood**

Written by Kenneth S. Paulsen

► **nb_bVarEstimator.glpMF ↑**

```
[beta,sigma,R,yM,X,posterior,prior] = nb_bVarEstimator.glpMF(draws,y,x, ...
    nLags,constant,constantAR,timeTrend,prior,restrictions,waitbar, ...
    freq,H,mixing)
```

Description:

Estimate VAR model using prior used in the paper by Giannone, Lenza and Primiceri (2014), "Prior selection for vector autoregressions" and Giannone, Lenza and Primiceri (2017), "Priors for the long run". In contrast to the **nb_bVarEstimator.glp** prior this prior also handle missing observations (but not mixed frequency VARs!).

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x h + neq*nlags. Where h is the exogenous variables of the model.
- nLags : Number of lags of the VAR. As an integer
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.

```

- timeTrend : If a linear time trend is wanted in the estimation.
    Will be added first/second in the right hand side
    variables. (First if constant is not given, else
    second)

- prior : A struct with the prior options. See
    nb_var.priorTemplate for more on this input

- restrictions : Index of parameters that are restricted to zero.

- waitbar : true, false or an object of class nb_waitbar5.

- empirical : A struct with the options on how to do the empirical
    bayesian. Default is empty, i.e. do not do empirical
    bayesian.

- freq : A 1 x nDep int with the frequencies of the variables
    of the MF-VAR. Is empty if VAR with missing
    observations.

- H : Mapping of the measurement equation of the state-space
    representation of the missing observation VAR or MF-VAR
    model.

- mixing : A struct with the information on the variables that
    are observed with different frequencies.

    If empty, it is assumed that no variable is measured
    with more than one frequency.

```

Output:

```

- beta : A (extra + neq*nlags + h) x neq x draws matrix with the
    posterior draws of the estimated coefficients.

- sigma : A neq x neq x draws matrix with the posterior variance of
    the estimated coefficients.

- R : A nobs x nobs double matrix with the measurement error
    covariance matrix.

- X : Regressors including constant and time-trend.

- yM : Observations on the dependent variables. Mean estimates
    of the unobserved values are returned. Including lags.

- posterior : A struct with all the needed information to do posterior
    draws.

- fVal : Initial log posterior on the full balanced sample.

- prior : Updated prior structure. I.e. the optimized
    hyperparameters will be reset if empirical bayesian is
    done.

```

► nb_bVarEstimator.help ↑

```
helpText = nb_bVarEstimator.help  
helpText = nb_bVarEstimator.help(option)  
helpText = nb_bVarEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sætherhagen Paulsen

► nb_bVarEstimator.horseshoe ↑

```
[beta,sigma,X,posterior] = nb_bVarEstimator.inwishart(draws,y,x,...  
constant,timeTrend,prior,restrictions,waitbar)
```

Description:

Estimate VAR model using horseshoe prior.

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x neq*nlags + h. Where h is the exogenous variables of the model.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else

```

        second)

- prior      : A struct with the prior options. See
               nb_bVarEstimator.priorTemplate for more on this input

- restrictions : Index of parameters that are restricted to zero.

- waitbar     : true, false or an object of class nb_waitbar5.
```

Output:

```

- beta       : A (extra + neq*nlags + h) x neq x draws matrix with the
               posterior draws of the estimated coefficients.

- sigma      : A neq x neq x draws matrix with the posterior variance of
               the estimated coefficients.

- X          : Regressors including constant and time-trend.

- posterior  : A struct with all the needed information to do posterior
               draws.
```

```
[beta,sigma] = nb_bVarEstimator.inwishartGibbs(draws,y,X,initBeta, ...
initSigma,a_prior,S_prior,v_post, ...
restrictions,thin,burn,waitbar)
```

Description:

Gibbs sampler draws of B-VAR with horseshoe prior.

Input:

See nb_bVarEstimator.inwishart

Output:

See nb_bVarEstimator.inwishart

Written by Maximilian Schröder

► **nb_bVarEstimator.horseshoePrior** ↑

```
[Beta,lambda,tau,sigma_sq] = nb_bVarEstimator.horseshoePrior(y,X,XX,...  
lambda,tau,sigma_sq,type)
```

Description:

Function to implement Horseshoe shrinkage prior (<http://faculty.chicagobooth.edu/nicholas.polson/research/papers/Horse.pdf>) in Bayesian Linear Regression.

```
Model: y=X\beta+\epsilon, \epsilon \sim N(0,\sigma^2)  
\beta_j \sim N(0,\sigma^2 \lambda_j^2 \tau^2)  
\lambda_j \sim Half-Cauchy(0,1), \tau \sim Half-Cauchy (0,1)  
\pi(\sigma^2) \sim 1/\sigma^2
```

This function employs the algorithm proposed in "Fast Sampling with Gaussian Scale-Mixture priors in High-Dimensional Regression" by Bhattacharya et. al. (2015). The global local scale parameters are updated via a Slice sampling scheme given in the online supplement of "The Bayesian Bridge" by Polson et. al. (2011). Two different algorithms are used to compute posterior samples of the $p \times 1$ vector of regression coefficients β . Type=1 corresponds to the proposed method in Bhattacharya et. al. and Type=2 corresponds to an algorithm provided% in Rue (2001). We recommend our algorithm when $p > n$.

Input:

- y : Response, a $n \times 1$ vector
- X : Matrix of covariates, dimension $n \times p$
- type : > 1 if sampling from posterior of beta is done by Proposed Method
> 2 if sampling is done by Rue's algorithm

Output:

- pMean : Posterior mean of Beta, a $p \times 1$ vector
- pMedian : Posterior median of Beta, a $p \times 1$ vector
- pLambda : Posterior mean of local scale parameters, a $p \times 1$ vector
- pSigma : Posterior mean of Error variance
- betaout : Posterior samples of beta

► **nb_bVarEstimator.inwishart** ↑

```
[beta,sigma,X,posterior] = nb_bVarEstimator.inwishart(draws,y,x,...  
constant,timeTrend,prior,restrictions,waitbar)
```

Description:

Estimate VAR model using independent Normal-Wishart prior.

This code is based on the paper by Koop and Korobilis (2009),
Bayesian Multivariate Time Series Methods for Empirical Macroeconomics.
See page 12-13.

See also the DAG.pdf documentation.

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x neq*nlags + h. Where h is the exogenous variables of the model.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second)
- prior : A struct with the prior options. See nb_bVarEstimator.priorTemplate for more on this input
- restrictions : Index of parameters that are restricted to zero.
- waitbar : true, false or an object of class nb_waitbar5.

Output:

```
- beta      : A (extra + neq*nlags + h) x neq x draws matrix with the
              posterior draws of the estimated coefficients.

- sigma     : A neq x neq x draws matrix with the posterior variance of
              the estimated coefficients.

- X         : Regressors including constant and time-trend.

Written by Kenneth Sætherhagen Paulsen

► **`nb_bVarEstimator.inwishartMF`** ↑

```
beta,sigma,R,yM,X,posterior] = nb_bVarEstimator.inwishartMF(draws,y,x, ...
                                                               nLags,constant,timeTrend,prior,restrictions, ...
                                                               waitbar,H,mixing)
```

Description:

This method extends nb_bVarEstimator.inwishart so it also handle missing observations and mixed frequency VAR models.

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x h. Where h is the exogenous variables of the model.
- nLags : Number of lags of the VAR. As an integer
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second)
- prior : A struct with the prior options. See nb_bVarEstimator.priorTemplate for more on this input
- restrictions : Index of parameters that are restricted to zero.
- waitbar : true, false or an object of class nb_waitbar5.
- H : Mapping of the measurement equation of the state-space representation of the missing observation VAR or MF-VAR model.
- mixing : A struct with the information on the variables that are observed with different frequencies.
If empty, it is assumed that no variable is measured with more than one frequency.

Output:

- beta : A (extra + neq*nlags + h) x neq x draws matrix with the posterior draws of the estimated coefficients.
- sigma : A neq x neq x draws matrix with the posterior variance of the estimated coefficients.
- R : A nobs x nobs double matrix with the measurement error covariance matrix.
- yM : Observations on the dependent variables. Mean estimates of the unobserved values are returned. Including lags.
- X : Regressors including constant and time-trend. The mean of the unobserved values is returned.
- posterior : A struct with all the needed information to do posterior draws.

► **nb_bVarEstimator.laplace** ↑

```
[beta,sigma,x] = nb_bVarEstimator.laplace(draws,y,x,constant,...  
timeTrend,prior,restrictions,waitbar)
```

Description:

Estimate VAR model using laplace prior.

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x neq*nlags + h. Where h is the exogenous variables of the model.
- draws : Number of draws.
- recDraws : Number of draws to discard in the beginning.
- Xt1 : Value of predictors at time T+1.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second)
- restrictions : Index of parameters that are restricted to zero.
- waitbar : true, false or an object of class nb_waitbar5.
- prior : Struct with prior options. See nb_var.priorTemplate.

Output:

- beta : A (extra + neq*nlags + h) x neq x draws matrix with the posterior draws of the estimated coefficients.
- sigma : A neq x neq x draws matrix with the posterior variance of the estimated coefficients.
- X : Regressors including constant and time-trend.
- posterior : A struct with all the needed information to do posterior draws.

```
pY = nb_bVarEstimator.logMarginalLikelihood(T,n,d,xx,A_prior,A_post,...  
PSI,Omega,eps)
```

Description:

Calculate the marginal likelihood of a B-VAR model with a normal-whishart prior. See Appendix A of Giannone, Lenza and Primiceri (2014), "Prior selection for vector autoregressions".

Input:

- T : Number of observation.
- n : Number of dependent variables of the VAR.
- d : Number of degrees of freedom of the prior on Sigma.
- A_prior : Prior coefficients.
- A_post : Posterior coefficients.
- xx : Calculated as $x'x$, where x is the regressors of the VAR.
- PSI : Prior of Sigma.
- Omega : Scale matrix of the prior of beta.
- eps : Residuals at posterior

Output:

- pY : Log marginal likelihood.

Written by Kenneth Sæterhagen Paulsen

► **nb_bVarEstimator.minnesota** ↑

```
[beta,sigma,X] = nb_bVarEstimator.minnesota(draws,y,x,nLags,constant,...  
constantAR,timeTrend,prior,restrictions,waitbar)
```

Description:

Estimate VAR model using minnesota prior.

This code is based on the paper by Koop and Korobilis (2009),
Bayesian Multivariate Time Series Methods for Empirical Macroeconomics.
See page 7 of Koop and Korobilis (2009).

See also the documentation DAG.pdf.

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x h + neq*nlags. Where h is the exogenous variables of the model.
- nLags : Number of lags of the VAR. As an integer
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- constantAR : Include constant in AR models that is used to set up the prior for sigma.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second)
- prior : A struct with the prior options. See nb_bVarEstimator.priorTemplate for more on this input
- restrictions : Index of parameters that are restricted to zero.
- waitbar : true, false or an object of class nb_waitbar5.

Output:

- beta : A (extra + neq*nlags + h) x neq x draws matrix with the posterior draws of the estimated coefficients.
- sigma : A neq x neq x draws matrix with the posterior variance of the estimated coefficients.
- X : Regressors including constant and time-trend.
- posterior : A struct with all the needed information to do posterior draws.

    nLags,constant,timeTrend,prior,restrictions, ...
    waitbar,freq,H,mixing)
```

Description:

Estimate mixed frequency or missing observations B-VAR model using minnesota type prior. This method extends `nb_bVarEstimator.minnesota`.

Input:

- `y` : A double matrix of size `nobs` x `neq` of the dependent variable of the regression(s).
- `x` : A double matrix of size `nobs` x `h`. Where `h` is the exogenous variables of the model.
- `nLags` : Number of lags of the VAR. As an integer
- `constant` : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- `timeTrend` : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second)
- `prior` : A struct with the prior options. See `nb_bVarEstimator.priorTemplate` for more on this input
- `restrictions` : Index of parameters that are restricted to zero.
- `waitbar` : `true`, `false` or an object of class `nb_waitbar5`.
- `freq` : A `1` x `nDep` int with the frequencies of the variables of the MF-VAR. Is empty if VAR with missing observations.
- `H` : Mapping of the measurement equation of the state-space representation of the missing observation VAR or MF-VAR model.
- `mixing` : A struct with the information on the variables that are observed with different frequencies.
If empty, it is assumed that no variable is measured with more than one frequency.

Output:

- `beta` : A `(extra + neq*nlags + h) x neq x draws` matrix with the posterior draws of the estimated coefficients.
- `sigma` : A `neq x neq x draws` matrix with the posterior variance of the estimated coefficients.
- `R` : A `nobs x nobs` double matrix with the measurement error

covariance matrix.

- yM : Observations on the dependent variables. Mean estimates of the unobserved values are returned. Including lags.
- X : Regressors including constant and time-trend. The mean of the unobserved values is returned.
- posterior : A struct with all the needed information to do posterior draws.

If empty, it is assumed that no variable is measured with more than one frequency.

Output:

- beta : A (extra + neq*nlags + h) x neq x draws matrix with the posterior draws of the estimated coefficients.
- sigma : A neq x neq x draws matrix with the posterior variance of the estimated coefficients.
- R : A nobs x 1 double matrix with the measurement error covariance matrix.
- yM : Observations on the dependent variables. Mean estimates of the unobserved values are returned. Including lags.
- X : Regressors including constant and time-trend. The mean of the unobserved values is returned.
- posterior : A struct with all the needed information to do posterior draws.

► **[nb_bVarEstimator.nwishartMFGibbs](#)** ↑

```
[beta,sigma,yDraws,PDraws] = nb_bVarEstimator.nwishartMFGibbs(draws, ...
y,x,H,R_prior,initBeta,initSigma,a_prior,V_prior_inv,S_prior, ...
v_post,restrictions,thin,burn,waitbar,maxTries, ...
dummyPriorOptions)
```

Description:

Gibbs sampling from a missing observation or mixed frequency B-VAR model using a normal wishart prior.

Input:

See `nb_bVarEstimator.nwishart`

Output:

See `nb_bVarEstimator.nwishart`

Written by Kenneth SÃ¶terhagen Paulsen

► **`nb_bVarEstimator.openWaitbar`** ↑

```
[h,note,isWaitbar] = nb_bVarEstimator.openWaitbar(waitbar,iter)
```

Description:

Open up waitbar for producing posterior draws.

Written by Kenneth SÃ¶terhagen Paulsen

► **`nb_bVarEstimator.print`** ↑

```
res = nb_bVarEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- `results` : A struct with the estimation results from the `nb_bVarEstimator.estimate` function.
- `options` : A struct with the estimation options from the `nb_bVarEstimator.estimate` function.
- `precision` : The precision of the printed result.

Output:

- `results` : A char with the estimation results.

Written by Kenneth SÃ¶terhagen Paulsen

► **`nb_bVarEstimator.priorTemplate`** ↑

```
template = nb_bVarEstimator.priorTemplate(type)
```

Description:

Get prior template for a given BVAR prior type. Assign it to the prior field of the main estimation template.

Input:

- type : A string with the prior type. See nb_var.priorTemplate or nb_mfvar.priorTemplate for more on the output.

Output:

- template : A struct with the options of the different priors

Examples:

```
template = nb_bVarEstimator.priorTemplate('jeffrey')
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **nb_bVarEstimator.recursiveEstimation** ↑

```
[res,options] = nb_bVarEstimator.recursiveEstimation(options,y,X,...  
mfvar,missing)
```

Description:

Estimate B-VAR model recursively.

Written by Kenneth Sæterhagen Paulsen

► **nb_bVarEstimator.removeZR** ↑

```
[x,indZR,restrictions] = nb_bVarEstimator.removeZR(x,constant,...  
timeTrend,numDep,nLags,restrictions)
```

Description:

Remove zero regressors.

Written by Kenneth Sæterhagen Paulsen

► **[nb_bVarEstimator.setUpPriorDIO](#)** ↑

```
[yPlus,XPlus] = nb_bVarEstimator.setUpPriorDIO(prior,y,x,lags,...  
constant,timeTrend)
```

Description:

Set up artificial series when using a dummy-initial-observation prior by Sims (1993).

See also:

[nb_bVarEstimator.applyDummyPrior](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_bVarEstimator.setUpPriorLR](#)** ↑

```
[yPlus,XPlus] = nb_bVarEstimator.setUpPriorLR(prior,y,x,lags,...  
constant,timeTrend)
```

Description:

Set up artificial series when using a prior for the long run as in Giannone et. al (2014).

See also:

[nb_bVarEstimator.applyDummyPrior](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_bVarEstimator.setUpPriorSC](#)** ↑

```
[yPlus,XPlus] = nb_bVarEstimator.setUpPriorSC(prior,y,x,lags,...  
constant,timeTrend)
```

Description:

Set up artificial series when using a sum-of-coefficients prior by Doan, Litterman, and Sims (1984).

See also:

[nb_bVarEstimator.applyDummyPrior](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_bVarEstimator.template** ↑

```
options = nb_bVarEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_bVarEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

See also:

```

Written by Kenneth Sæterhagen Paulsen

► **nb_dfmemlEstimator.bootstrapModel** ↑

```
[betaDraws,factorDraws] =
nb_dfmemlEstimator.bootstrapModel(options,res,iter)
```

Description:

Not possible to bootstrap this model.

Written by Kenneth S. Paulsen

► **nb_dfmemlEstimator.checkConvergence ↑**

```
converged = nb_dfmemlEstimator.checkConvergence(res,oldLogLik,tol)
```

Description:

Check for convergence of the EML-algorithm based on minus the log likelihood.

See also:

[nb_dfmemlEstimator.normalEstimation](#)

Written by Kenneth S. Paulsen

► **nb_dfmemlEstimator.emlIteration ↑**

```
results = nb_dfmemlEstimator.emlIteration(options,results,X)
```

Description:

Do one iteration of the expected maximum likelihood algorithm for estimating a dynamic factor model.

Inputs:

- options : A struct with estimation options. See [nb_dfmemlEstimator.template](#) or [nb_dfmemlEstimator.help](#).
- results : A struct with the output from [nb_dfmemlEstimator.initialize](#).
- X : A T x N double storing the data on the observables.

Output:

- results : A struct with the updated matrices and value of the likelihood at the current iteration.

Written by Kenneth S. Paulsen

► **nb_dfmemlEstimator.estimate ↑**

```
[results,options] = nb_dfmemlEstimator.estimate(options)
```

Description:

Estimate a dynamic factor model with the two step expected likelihood algorithm suggested by Banbura et al. (2010). Some small alteration to the algorithm may have been done in special cases. See the help on the nb_fmdyn class for more on the algorithm implemented by this package.

Input:

- options : A struct on the format given by nb_dfmemlEstimator.template. See also nb_dfmemlEstimator.help.

Output:

- result : A struct with the estimation results.
- options : Some options may be updated.

[nb_dfmemlEstimator.template](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_dfmemlEstimator.getBQ** ↑

```
results = nb_dfmemlEstimator.getBQ(results)
```

Description:

Standardize residuals of the idiosyncratic components to have a covariance matrix as the identity matrix.

See also:

[nb_dfmemlEstimator.initialize](#), [nb_dfmemlEstimator.emlIteration](#)

Written by Kenneth S. Paulsen

► **nb_dfmemlEstimator.getCoeff** ↑

```
[coeff,numCoeff] = nb_dfmemlEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_dfmemlEstimator.getDependent** ↑

```
dependent = nb_dfmemlEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object. There are none, see getObservables instead.

Written by Kenneth Sæterhagen Paulsen

► **nb_dfmemlEstimator.getEpsInd** ↑

```
indEps = nb_dfmemlEstimator.getEpsInd(options)
```

Written by Kenneth S. Paulsen

► **nb_dfmemlEstimator.getFactors** ↑

```
factors = nb_fmEstimator.getFactors(results,options)
```

Description:

Get the estimated factors of the estimated model as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_dfmemlEstimator.getIdiosyncraticMapping** ↑

```
Hlow = nb_dfmemlEstimator.getIdiosyncraticMapping(options)
```

Description:

Get the mixed frequency mapping matrix.

Inputs:

- options : A struct with estimation options. See
nb_dfmemlEstimator.template or nb_dfmemlEstimator.help.

Written by Kenneth S. Paulsen

► **`nb_dfmemlEstimator.getMapping`** ↑

```
[R,r] = nb_dfmemlEstimator.getMapping(options,index)
```

Description:

Get the mixed frequency mapping matrix.

Inputs:

- options : A struct with estimation options. See
 `nb_dfmemlEstimator.template` or `nb_dfmemlEstimator.help`.
- index : The index of the low frequency variable of interest.

Written by Kenneth S. Paulsen

► **`nb_dfmemlEstimator.getNumberOfCoeff`** ↑

```
nCoeff = nb_dfmemlEstimator.getNumberOfCoeff(options)
```

Description:

Get the number of estimated coefficients of the dynamic factor model.

Written by Kenneth S. Paulsen

► **`nb_dfmemlEstimator.getObservables`** ↑

```
observables = nb_dfmemlEstimator.getObservables(results,options)
```

Description:

Get the observables of the estimated model as a `nb_ts` object

Written by Kenneth Sætherhagen Paulsen

► **`nb_dfmemlEstimator.getPredicted`** ↑

```
predicted = nb_dfmemlEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_dfmemlEstimator.getResidual** ↑

```
residual = nb_dfmemlEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object. This is the idiosyncratic component of the measurement error, and not the residual of the transition equation.

Written by Kenneth Sæterhagen Paulsen

► **nb_dfmemlEstimator.getSolution** ↑

```
results = nb_dfmemlEstimator.getSolution(options,H,AF,QF,AI,QI,R)
```

Description:

We want the solution on the form of equation 12 of Banbura et al. (2010), "Nowcasting", but introduce the residual impact matrix to reduce the dimension of Q:

X(t) = Z*alpha(t) + nu(t)

alpha(t) = T*alpha(t-1) + BQ*e(t)

where e(t) ~ N(0,I) and nu(t) ~ N(0,R).

Written by Kenneth S. Paulsen

► **nb_dfmemlEstimator.getStateNames** ↑

```
[stateNames,resNames] = nb_dfmemlEstimator.getStateNames(options)
```

Description:

Selects the wanted model class and estimate the model.

Written by Kenneth S. Paulsen

► **`nb_dfmemlEstimator.help`** ↑

```
helpText = nb_dfmemlEstimator.help  
helpText = nb_dfmemlEstimator.help(option)  
helpText = nb_dfmemlEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sætherhagen Paulsen

► **`nb_dfmemlEstimator.initialize`** ↑

```
results = nb_dfmemlEstimator.initialize(options,X)
```

Description:

Initialization of the expected maximum likelihood estimator of the dynamic factor model.

Inputs:

- options : A struct with estimation options. See `nb_dfmemlEstimator.template` or `nb_dfmemlEstimator.help`.
- X : A T x N double storing the data on the observables.

Written by Kenneth S. Paulsen

► **`nb_dfmemlEstimator.intiKF`** ↑

```
[alpha0,P0,Pinf0] = nb_dfmemlEstimator.intiKF(results)
```

Description:

Initialize Kalman filter.

See also:

[nb_dfmemlEstimator.emlIteration](#), [nb_dfmemlEstimator.normalEstimation](#)

Written by Kenneth S. Paulsen

► **[nb_dfmemlEstimator.normalEstimation](#)** ↑

```
[res,options] = nb_dfmemlEstimator.normalEstimation(options,results)
```

Description:

Selects the wanted model class and estimate the model.

Inputs:

- options : A struct on the format returned by
`nb_dfmemlEstimator.template`.
- results : A struct with initial conditions for EML iterations. Can be used for recursive estimation. If empty or not provided this struct is provided by `nb_dfmemlEstimator.initialize`

Written by Kenneth S. Paulsen

► **[nb_dfmemlEstimator.print](#)** ↑

```
res = nb_dfmemlEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the `nb_dfmemlEstimator.estimate` function.
- options : A struct with the estimation options from the `nb_dfmemlEstimator.estimate` function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_dfmemlEstimator.recursiveEstimation** ↑

```
[results,options] = nb_dfmemlEstimator.recursiveEstimation(options)
```

Description:

Selects the wanted model class and recursively estimate the model.

Written by Kenneth S. Paulsen

► **nb_dfmemlEstimator.removeLeadingAndTrailingNaN** ↑

```
options = nb_dfmemlEstimator.removeLeadingAndTrailingNaN(options)
```

Description:

Remove leading and trailing nans from dataset.

Written by Kenneth S. Paulsen

► **nb_dfmemlEstimator.template** ↑

```
options = nb_dfmemlEstimator.template()
```

Description:

Construct a struct which must be provided to the
nb_dfmemlEstimator.estimate function.

This structure provided the user the possibility to set different
estimation options.

Output:

- options : A struct.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_dynareEstimator.print** ↑

```
res = nb_dynareEstimator.print(results,options,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_dsgen object when running a Dynare model file that does estimation.
- options : A struct with the estimation options from the nb_dsgen object when running a Dynare model file that does estimation.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_ecmEstimator.addECMLags** ↑

► **nb_ecmEstimator.bootstrapModel** ↑

```
[betaDraws,sigmaDraws,estOpt] = nb_ecmEstimator.bootstrapModel(...  
model,options,results,method,draws,iter)
```

Description:

Bootstrap model.

Written by Kenneth Sæterhagen Paulsen

► **nb_ecmEstimator.estimate** ↑

```
[results,options] = nb_ecmEstimator.estimate(options)
```

Description:

Estimate a ECM model with ols.

Input:

- options : A struct on the format given by nb_ecmEstimator.template.
See also nb_ecmEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example using the 'modelSelection' options.

See also:

Written by Kenneth Sæterhagen Paulsen

► **nb_ecmEstimator.getCoeff** ↑

[coeff,numCoeff] = nb_ecmEstimator.getCoeff(options)

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_ecmEstimator.getDependent** ↑

dependent = nb_ecmEstimator.getDependent(results,options)

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_ecmEstimator.getPredicted** ↑

predicted = nb_ecmEstimator.getPredicted(results,options)

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_ecmEstimator.getResidual** ↑

```
residual = nb_ecmEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_ecmEstimator.help** ↑

```
helpText = nb_ecmEstimator.help  
helpText = nb_ecmEstimator.help(option)  
helpText = nb_ecmEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_ecmEstimator.makeArtificial** ↑

```
[YDRAW,start,finish,indy,startEst] = nb_ecmEstimator.makeArtificial(...  
model,options,results,method,...  
draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► nb_ecmEstimator.print ↑

```
res = nb_ecmEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_ecmEstimator.estimate function.
- options : A struct with the estimation options from the nb_ecmEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► nb_ecmEstimator.template ↑

```
options = nb_ecmEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_ecmEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.correctResultsGivenUnbalanced** ↑

```
[res,options] = nb_estimator.correctResultsGivenUnbalanced(options,res)
```

Description:

Expand beta and exogeneous to be equal when exogenous variables are leaded and not.

See also:

[nb_olsEstimator.estimate](#), [nb_quantileEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.fillInForMissing** ↑

```
[X,nanInd] = nb_estimator.fillInForMissing(X)
```

Description:

Fill in for missing values.

Input:

- X : A T x N double storing the data on the observables.

Output:

- X : A T x N double storing the balanced dataset on the observables.

- nanInd : A T x N logical. true at the elements where data is missing.

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.getBlockExogenousRestrictions** ↑

```
restrictions = nb_estimator.getBlockExogenousRestrictions(options)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.getBounds** ↑

```
[lbo,ubo] = nb_estimator.getBounds(prior,lb,ub)
```

Description:

This function can be used for finding the finite support for those optimizers that needs that. E.g. nb_abc and bee_gate.

Input:

- prior : A struct with the prior specification.
- lb : The lower bound, as a nParam x 1 double.
- ub : The upper bound, as a nParam x 1 double.

Output:

- lbo : The lower bound where all non-finite elements are substituted with their 1 percentile.
- ubo : The upper bound where all non-finite elements are substituted with their 99 percentile.

See also:

[nb_abc](#), [bee_gate](#), [nb_statespaceEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.getSpecificPriors** ↑

```
options = nb_estimator.getSpecificPriors(options)
```

Description:

Get indicies of priors on specific coefficients

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.getVariables** ↑

```
[vars,indV] = nb_estimator.getVariables(options)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.interpretPrecision** ↑

```
precision = nb_estimator.interpretPrecision(precision)
```

Description:

Interpret the precision input to the print function of the different estimator packages.

Input:

- precision : The precision input to the different print functions.

Output:

- precision : The interpreted precision input.

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.notifyWaitbar** ↑

```
nb_estimator.notifyWaitbar(h,kk,iter,note)
```

Description:

Notify waitbar for recursive estimation.

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.openWaitbar** ↑

```
[h,doDelete] = nb_estimator.openWaitbar(options,iter)
```

Description:

Open up waitbar for recursive estimation.

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.print** ↑

```
res = nb_estimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from for example the nb_olsEstimator.estimate function.
- options : A struct with the estimation options from for example the nb_olsEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_estimator.printCov ↑**

```
res = nb_estimator.printCov(results,precision)
```

Description:

Get the estimated covariance matrix results as a char.

Input:

- results : A struct with the estimation results from for example the nb_olsEstimator.estimate function.
- options : A struct with the estimation options from for example the nb_olsEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sætherhagen Paulsen

► **nb_estimator.removeLeadingAndTrailingNaN ↑**

```
[X,keep] = nb_estimator.removeLeadingAndTrailingNaN(X)
```

Description:

Remove leading and trailing nans from dataset.

Written by Kenneth S. Paulsen

► **nb_estimator.set2nan ↑**

```
X = nb_estimator.set2nan(X,observables,set2nan)
```

Description:

Set observations of the data to nan.

Input:

```
- X : A T x N double.  
  
- startDate : The start date of the data in X.  
  
- observables : A 1 x N cellstr with the names of the variables.  
  
- set2nan : A struct on the format struct('VarName1',dates1,  
    'VarName2',dates2). See examples on the use of this input  
    under examples. If you use the name 'all', then the  
    data of all variables are set to nan!
```

Output:

```
- X : A T x N double.
```

Examples:

```
set2nanA = struct('all',{nb_quarter(2,2000):nb_quarter(4,2001)})  
set2nan1 = struct('VarName',{nb_quarter(2,2000):nb_quarter(4,2001)})  
set2nan2 = struct('VarName1',{nb_quarter(2,2000):nb_quarter(4,2001)},...  
    'VarName2',{nb_quarter(2,2000):nb_quarter(2,2001)})
```

► **nb_exprEstimator.bootstrapModel** ↑

```
[betaDraws,sigmaDraws,options] = nb_exprEstimator.bootstrapModel(model,...  
options,results,method,draws,iter)
```

Description:

Bootstrap model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_exprEstimator.eqs2funcSub ↑**

```
[eqFunc,nLags,varsOut] = nb_exprEstimator.eqs2funcSub(vars,eq,type)
```

Description:

Convert equation of the model to a function handle. Subroutine.

Input:

- vars : Allowed variables in the expression.
- eq : A one line char with one equation of the model.
- type : Give 1 to indicate that you are interpreting the left hand side variables.

See also:

[nb_exprEstimator.estimate](#)

helpText = nb_olsEstimator.help  
helpText = nb_olsEstimator.help(option)  
helpText = nb_olsEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **nb_exprEstimator.makeArtificial** ↑

```
[YDRAW,X] = nb_exprEstimator.makeArtificial(model,options,results,...  
method,draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_exprEstimator.modelSelectionAlgorithm** ↑

```
options = nb_olsEstimator.modelSelectionAlgorithm(options,minLags)
```

Description:

Function to automatically select model.

See also:

[nb_olsEstimator.estimate](#), [nb_bVarEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_exprEstimator.print](#)** ↑

```
res = nb_exprEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the `nb_exprEstimator.estimate` function.
- options : A struct with the estimation options from the `nb_exprEstimator.estimate` function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **[nb_exprEstimator.secureAllLags](#)** ↑

```
options = nb_olsEstimator.secureAllLags(options)
```

Description:

Secure that all lags are added to the data, as they are needed for forecasting, shock decomposition etc. later.

Written by Kenneth Sæterhagen Paulsen

► **nb_exprEstimator.template** ↑

```
options = nb_olsEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_olsEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_exprEstimator.varModifications** ↑

```
options = nb_olsEstimator.varModifications(options)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_fmEstimator.bootstrapModel** ↑

Bootstrap parameters and factors of the Factor model

See Aastveit, Gerdrup, Jore and Thorsrud (2013)

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth S. Paulsen

► **nb_fmEstimator.estimate** ↑

```
[results,options] = nb_fmEstimator.estimate(options)
```

Description:

Estimate a factor model with ols using principal components.

Input:

- options : A struct on the format given by nb_fmEstimator.template.
See also nb_fmEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example using the 'modelSelection' options.

[res,options] = nb_fmEstimator.normalEstimationFAVAR(options,res)
```

Description:

Recursive estimation algorithm of factor augmented VAR models with factors estimated by principal components.

Written by Kenneth S. Paulsen

► **nb_fmEstimator.recursiveEstimationSingleEq** ↑

```
[res,options] = nb_fmEstimator.recursiveEstimationSingleEq(options,res)
```

Description:

Recursive estimation algorithm of steep ahead factor models with factors estimated by principal components.

Written by Kenneth S. Paulsen

► **nb_fmEstimator.recursiveEstimationStepAhead** ↑

```
[res,options] = nb_fmEstimator.recursiveEstimationStepAhead(options,res)
```

Description:

Recursive estimation algorithm of steep ahead factor models with factors estimated by principal components.

Written by Kenneth S. Paulsen

► **nb_fmEstimator.template** ↑

```
options = nb_fmEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_fmEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_hpEstimator.estimate ↑**

[results,options] = nb_hpEstimator.estimate(options)

Description:

Estimate HP-filtered series.

Input:

- options : A struct on the format given by nb_hpEstimator.template.
See also nb_hpEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change depending on inputs.

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **nb_hpEstimator.print** ↑

```
res = nb_shorteningEstimator.print(results,options,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_shorteningEstimator.estimate function.
- options : A struct with the estimation options from the nb_shorteningEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_hpEstimator.template** ↑

```
options = nb_shorteningEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_shorteningEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **[nb_lassoEstimator.bootstrapModel](#)** ↑

```
[betaDraws,sigmaDraws,estOpt] = nb_lassoEstimator.bootstrapModel(model,...

► **nb_lassoEstimator.help** ↑

```
helpText = nb_lassoEstimator.help
helpText = nb_lassoEstimator.help(option)
helpText = nb_lassoEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_lassoEstimator.makeArtificial ↑**

```
[YDRAW,start,finish,indy,startEst] = nb_lassoEstimator.makeArtificial(...  
    model,options,results,method,...  
    draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_lassoEstimator.print ↑**

```
res = nb_lassoEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_lassoEstimator.estimate function.
- options : A struct with the estimation options from the nb_lassoEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- res : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_lassoEstimator.template** ↑

```
options = nb_lassoEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_lassoEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_midasEstimator.addLags** ↑

```
[options,freqMapping] = nb_midasEstimator.addLags(options)
```

Description:

Add lags to right hand side of estimation equation.

Written by Kenneth Sæterhagen Paulsen

► **nb_midasEstimator.bootstrapModel** ↑

```
[betaDraws,sigmaDraws,estOpt] = nb_midasEstimator.bootstrapModel(model,...  
options,results,method,draws,iter,forceNewDraws)
```

Description:

Bootstrap MIDAS model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

Description:

Function to automatically select model.

See also:

[nb_midasEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_midasEstimator.normalEstimation** ↑

```
[results,options] = nb_midasEstimator.normalEstimation(options,y,X,nExo)
```

Description:

Estimate MIDAS model over the full sample.

See also:

[nb_midasEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_midasEstimator.print** ↑

```
res = nb_midasEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_midasEstimator.estimate function.
- options : A struct with the estimation options from the nb_midasEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_midasEstimator.recursiveEstimation** ↑

```
[results,options] = nb_midasEstimator.recursiveEstimation(options,...  
y,X,nExo,startLowPeriods)
```

Description:

Estimate MIDAS model recursivly.

See also:

[nb_midasEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_midasEstimator.template** ↑

```
options = nb_midasEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_midasEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **[nb_missingEstimator.arMethod](#)** ↑

```
options = nb_missingEstimator.arMethod(options)
```

Description:

Fill in for missing observations using AR models.

Written by Kenneth Sæterhagen Paulsen

► **[nb_missingEstimator.bootstrapModel](#)** ↑

```
[betaDraws,sigmaDraws,estOpt] = nb_missingEstimator.bootstrapModel(...  
model,options,results,method,draws,iter)
```

Description:

Bootstrap model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **[nb_missingEstimator.checkForMissing](#)** ↑

```
options = nb_missingEstimator.checkForMissing(options,...  
startInd,endInd)
```

Description:

Check for missing observations.

Written by Kenneth Sæterhagen Paulsen

► **[nb_missingEstimator.copulaMethod](#)** ↑

```
options = nb_missingEstimator.copulaMethod(options)
```

Description:

Fill in for missing observations using a copula model.

Written by Kenneth Sæterhagen Paulsen

► **nb_missingEstimator.estimate** ↑

```
[results,options] = nb_missingEstimator.estimate(options)
```

Description:

Estimate a model with missing data (possibly with real-time data).

Input:

- options : A struct on the format given by underlying estimators template function. See for example nb_olsEstimator.template.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example using the 'modelSelection' options.

Written by Kenneth Sæterhagen Paulsen

► **nb_missingEstimator.fillInForMissing** ↑

```
options = nb_missingEstimator.fillInForMissing(options,check)
```

Description:

Fill in for missing observations.

Written by Kenneth Sæterhagen Paulsen

► **nb_missingEstimator.forecastMethod** ↑

```
options = nb_missingEstimator.forecastMethod(options)
```

Description:

Fill in for missing observations using forecast with information up until time t-1, when the first missing observation is at time t.

Written by Kenneth Sæterhagen Paulsen

► **nb_missingEstimator.getStateSpace** ↑

```
[x0,P0,d,H,R,T,c,A,B,Q,G] = nb_missingEstimator.getStateSpace(...  
options,model)
```

Description:

Go from the state space representation in the model struct to the state space matrices needed by the nb_kalmansmooth_missing function.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_missingEstimator.getVariables ↑**

```
[endo,exo] = nb_missingEstimator.getVariables(options)
```

Description:

Get the variables of the model.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_missingEstimator.kalmanMethod ↑**

```
options = nb_missingEstimator.kalmanMethod(options)
```

Description:

Fill in for missing observations a Kalman filter.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_mlEstimator.bootstrapModel ↑**

```
[betaDraws,sigmaDraws,estOpt] = nb_mlEstimator.bootstrapModel(...  
model,options,results,method,draws,iter)
```

Description:

Bootstrap model.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_mlEstimator.drawParameters ↑**

```
[betaDraws,sigmaDraws,yD,pD] = nb_mlEstimator.drawParameters(results,...  
draws,iter)
```

Description:

Draw parameters using asymptotic normality assumption and numerically calculated Hessian from ML estimation. Do not draw from the distribution of the std of the residual.

If the model include missing observation these are observations are re-estimated using the Kalman filter for each draw from the confidence set of the parameters.

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.estimate ↑**

```
[results,options] = nb_mlEstimator.estimate(options)
```

Description:

Estimate a model with maximum likelihood using a Kalman filter.

Input:

- options : A struct on the format given by nb_mlEstimator.template.
See also nb_mlEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example using
the 'modelSelection' options.

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.getDependent ↑**

```
dependent = nb_olsEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.getInitMFVAR ↑**

```
[betaExo,betaDyn,sigmaPar] = nb_mlEstimator.getInitMFVAR(y,X,options,...  
method,H)
```

Description:

Get initial values for optimization routine when dealing with a MF-VAR model.

See also:

[nb_mlEstimator.mfvarEstimator](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.getMeasurementEqMFVAR ↑**

```
[H,freqD,extraAdded] = nb_mlEstimator.getMeasurementEqMFVAR(options,extra)
```

Description:

Get measurement equation of a mixed frequency VAR.

See also:

[nb_mlEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.getPredicted ↑**

```
predicted = nb_olsEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.getResidual** ↑

```
residual = nb_olsEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.help** ↑

```
helpText = nb_mlEstimator.help  
helpText = nb_mlEstimator.help(option)  
helpText = nb_mlEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.interpretMeasurementError** ↑

```
options = nb_mlEstimator.interpretMeasurementError(options)
```

Description:

Get indicies of the measurement error parameters to estimate.

Written by Kenneth Sæterhagen Paulsen

► **[nb_mlEstimator.makeArtificial](#)** ↑

```
YDRAW = nb_mlEstimator.makeArtificial(model,options,results,...  
method,draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **[nb_mlEstimator.mfvarEstimator](#)** ↑

```
[beta,stdBeta,tStatBeta,pValBeta,sigma,residual,ys,ysl,lik,Omega,pD] =  
nb_mlEstimator.mfvarEstimator(y,X,options,H,init)
```

Written by Kenneth Sæterhagen Paulsen

► **[nb_mlEstimator.print](#)** ↑

```
res = nb_olsEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_olsEstimator.estimate function.
- options : A struct with the estimation options from the nb_olsEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **[nb_mlEstimator.template](#)** ↑

```
options = nb_mlEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_mlEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.translateOptimization** ↑

```
nb_mlEstimator.translateOptimization(exitflag)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_mlEstimator.varEstimator** ↑

```
[beta, stdBeta, tStatBeta, pValBeta, sigma, residual, ys, XX, lik, Omega, pD] =  
nb_mlEstimator.varEstimator(y, X, options, init)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_nlsEstimator.bootstrapModel** ↑

```
[betaDraws, sigmaDraws, estOpt] = nb_nlsEstimator.bootstrapModel(model,...  
options, results, method, draws, iter)
```

Description:

Bootstrap model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_nlsEstimator.doTest** ↑

```
res = nb_nlsEstimator.doTest(res,options,residual)
```

Description:

Do different test based on the residuals.

See also:

[nb_nlsEstimator.estimate](#)

Written by Kenneth Sætherhagen Paulsen

► **[nb_nlsEstimator.estimate](#)** ↑

```
[results,options] = nb_nlsEstimator.estimate(options)
```

Description:

Estimate a model with nls.

Input:

- options : A struct on the format given by nb_nlsEstimator.template.
See also nb_nlsEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change.

See also:

[nb_nlsEstimator.print](#), [nb_nlsEstimator.help](#), [nb_nlsEstimator.template](#)

Written by Kenneth Sætherhagen Paulsen

► **[nb_nlsEstimator.getCoeff](#)** ↑

```
[coeff,numCoeff] = nb_nlsEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sætherhagen Paulsen

► **nb_nlsEstimator.getDependent** ↑

```
dependent = nb_nlsEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts or nb_cs object

Written by Kenneth Sæterhagen Paulsen

► **nb_nlsEstimator.getPredicted** ↑

```
predicted = nb_nlsEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts or nb_cs object

Written by Kenneth Sæterhagen Paulsen

► **nb_nlsEstimator.getResidual** ↑

```
residual = nb_nlsEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts or nb_cs object

Written by Kenneth Sæterhagen Paulsen

► **nb_nlsEstimator.help** ↑

```
helpText = nb_nlsEstimator.help
helpText = nb_nlsEstimator.help(option)
helpText = nb_nlsEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **nb_nlsEstimator.makeArtificial ↑**

```
[YDRAW,start,finish,indY,startEst] = nb_nlsEstimator.makeArtificial(...  
    model,options,results,method,...  
    draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_nlsEstimator.print ↑**

```
res = nb_nlsEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_nlsEstimator.estimate function.
- options : A struct with the estimation options from the nb_nlsEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **`nb_nlsEstimator.template`** ↑

```
options = nb_olsEstimator.template()
```

Description:

Construct a struct which must be provided to the `nb_nlsEstimator.estimate` function.

This structure provided the user the possibility to set different estimation options.

Output:

- `options` : A struct.

Written by Kenneth Sætherhagen Paulsen

► **`nb_olsEstimator.addLags`** ↑

```
options = nb_olsEstimator.addLags(options)
```

Description:

Add lags to right hand side of estimation equation.

Written by Kenneth Sætherhagen Paulsen

► **`nb_olsEstimator.addLeads`** ↑

```
options = nb_olsEstimator.addLeads(options)
```

Description:

Add leads to right hand side of estimation equation. Only in the case that the unbalanced options is set to true.

Written by Kenneth Sætherhagen Paulsen

► **`nb_olsEstimator.addSeasonalDummies`** ↑

```
options = nb_olsEstimator.addSeasonalDummies(options)
```

Description:

Add seasonal dummies to model.

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.bootstrapModel ↑**

```
[betaDraws,sigmaDraws,estOpt] = nb_olsEstimator.bootstrapModel(model,...  
options,results,method,draws,iter)
```

Description:

Bootstrap model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.doTest ↑**

```
res = nb_olsEstimator.doTest(res,options,beta,y,X,residual)
```

Description:

Do different test based on OLS residuals.

See also:

[nb_olsEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.estimate ↑**

```
[results,options] = nb_olsEstimator.estimate(options)
```

Description:

Estimate a model with ols.

Input:

- options : A struct on the format given by nb_olsEstimator.template.
See also nb_olsEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example using the 'modelSelection' options.

See also:

[nb_olsEstimator.print](#), [nb_olsEstimator.help](#), [nb_olsEstimator.template](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.getCoeff** ↑

```
[coeff,numCoeff] = nb_olsEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.getDependent** ↑

```
dependent = nb_olsEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.getPredicted** ↑

```
predicted = nb_olsEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.getResidual** ↑

```
residual = nb_olsEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.help** ↑

```
helpText = nb_olsEstimator.help  
helpText = nb_olsEstimator.help(option)  
helpText = nb_olsEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.makeArtificial** ↑

```
[YDRAW,start,finish,indY,startEst] = nb_olsEstimator.makeArtificial(...  
model,options,results,method,...  
draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.modelSelectionAlgorithm** ↑

```
options = nb_olsEstimator.modelSelectionAlgorithm(options,minLags)
```

Description:

Function to automatically select model.

See also:

[nb_olsEstimator.estimate](#), [nb_bVarEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.print** ↑

```
res = nb_olsEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the `nb_olsEstimator.estimate` function.
- options : A struct with the estimation options from the `nb_olsEstimator.estimate` function.
- precision : The precision of the printed result.

Output:

- res : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_olsEstimator.secureAllLags** ↑

```
options = nb_olsEstimator.secureAllLags(options)
```

Description:

Secure that all lags are added to the data, as they are needed for forecasting, shock decomposition etc. later.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_olsEstimator.template** ↑

```
options = nb_olsEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_olsEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_olsEstimator.varModifications** ↑

```
options = nb_olsEstimator.varModifications(options)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_pcaEstimator.estimate** ↑

```
[results,options] = nb_pcaEstimator.estimate(options)
```

Description:

Estimate a factors using principal components.

Input:

- options : A struct on the format given by nb_pcaEstimator.template.
See also nb_pcaEstimator.help.

Output:

```
- result : A struct with the estimation results.  
- options : The return model options, can change depending on inputs.
```

See also:

[nb_pcaEstimator.print](#), [nb_pcaEstimator.help](#), [nb_pcaEstimator.template](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_pcaEstimator.estimateFactors** ↑

No documentation

Written by Kenneth S. Paulsen

► **nb_pcaEstimator.getCoeff** ↑

```
[coeff,numCoeff] = nb_pcaEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_pcaEstimator.getFactors** ↑

```
factors = nb_pcaEstimator.getFactors(results,options)
```

Description:

Get the estimated factors as a nb_ts object

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_pcaEstimator.getObservables** ↑

```
observables = nb_pcaEstimator.getObservables(results,options)
```

Description:

Get the observables of the estimated model as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_pcaEstimator.help** ↑

```
helpText = nb_pcaEstimator.help  
helpText = nb_pcaEstimator.help(option)  
helpText = nb_pcaEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **nb_pcaEstimator.print** ↑

```
res = nb_pcaEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_fmEstimator.estimate function.
- options : A struct with the estimation options from the nb_fmEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_pcaEstimator.template** ↑

```
options = nb_pcaEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_pcaEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.bootstrapModel** ↑

```
[betaDraws,sigmaDraws,estOpt] = nb_quantileEstimator.bootstrapModel(...  
model,options,results,method,draws,iter)
```

Description:

Bootstrap model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.closeWaitbar** ↑

```
nb_quantileEstimator.closeWaitbar(h)
```

Description:

Close waitbar for producing posterior draws.

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.estimate** ↑

```
[results,options] = nb_quantileEstimator.estimate(options)
```

Description:

Estimate a model with quantile regression.

Input:

- options : A struct on the format given by
nb_quantileEstimator.template. See also
nb_quantileEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example using
the 'modelSelection' options.

See also:

[nb_quantileEstimator.template](#)

Written by Kenneth Sætherhagen Paulsen

► **nb_quantileEstimator.getCoeff** ↑

```
[coeff,numCoeff] = nb_quantileEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sætherhagen Paulsen

► **nb_quantileEstimator.getDependent** ↑

```
dependent = nb_quantileEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.getPredicted** ↑

```
predicted = nb_quantileEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.getResidual** ↑

```
residual = nb_quantileEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.help** ↑

```
helpText = nb_quantileEstimator.help  
helpText = nb_quantileEstimator.help(option)  
helpText = nb_quantileEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_quantileEstimator.makeArtificial** ↑

```
[YDRAW,start,finish,indY,startEst] = nb_quantileEstimator.makeArtificial(...  
    model,options,results,method,...  
    draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_quantileEstimator.notifyWaitbar** ↑

```
nb_quantileEstimator.notifyWaitbar(h,ii,tt,note)
```

Description:

Notify waitbar for producing bootstrapped draws.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_quantileEstimator.notifyWaitbarQuantile** ↑

```
nb_quantileEstimator.notifyWaitbarQuantile(h,qq,note,numQ)
```

Description:

Notify waitbar for producing bootstrapped draws.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_quantileEstimator.openWaitbar** ↑

```
[h,note,isWaitbar] = nb_quantileEstimator.openWaitbar(waitbar,iter)
```

Description:

Open up waitbar for producing bootstrapped draws.

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.print** ↑

```
res = nb_quantileEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_quantileEstimator.estimate function.
- options : A struct with the estimation options from the nb_quantileEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.template** ↑

```
options = nb_olsEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_olsEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_quantileEstimator.varModifications** ↑

```
options = nb_olsEstimator.varModifications(options)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_realTimeEstimator.estimate** ↑

```
[results,options] = nb_realTimeEstimator.estimate(options)
```

Description:

Estimate a model with real-time data.

Caution : May run estimation in parallel on a given set of cores.

Input:

- options : A struct on the format given by underlying estimators template function. See for example nb_olsEstimator.template.

Output:

- result : A struct with the estimation results.

- options : The return model options, can change when for example using the 'modelSelection' options.

Written by Kenneth Sæterhagen Paulsen

► **nb_realTimeEstimator.mergeResults** ↑

```
res = nb_realTimeEstimator.mergeResults(res,resTemp)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_ridgeEstimator.bootstrapModel** ↑

```
[betaDraws,sigmaDraws,estOpt] = nb_ridgeEstimator.bootstrapModel(model,...  
options,results,method,draws,iter)
```

Description:

Bootstrap model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► nb_ridgeEstimator.estimate ↑

```
[results,options] = nb_ridgeEstimator.estimate(options)
```

Description:

Estimate a model with LASSO.

Input:

- options : A struct on the format given by nb_ridgeEstimator.template.
See also nb_ridgeEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example using
the 'modelSelection' options.

Written by Kenneth Sæterhagen Paulsen

► nb_ridgeEstimator.getCoeff ↑

```
[coeff,numCoeff] = nb_ridgeEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► nb_ridgeEstimator.getDependent ↑

```
dependent = nb_ridgeEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_ridgeEstimator.getPredicted** ↑

```
predicted = nb_ridgeEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_ridgeEstimator.getResidual** ↑

```
residual = nb_ridgeEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_ridgeEstimator.help** ↑

```
helpText = nb_ridgeEstimator.help  
helpText = nb_ridgeEstimator.help(option)  
helpText = nb_ridgeEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **nb_ridgeEstimator.makeArtificial ↑**

```
[YDRAW,start,finish,indy,startEst] = nb_ridgeEstimator.makeArtificial(...  
    model,options,results,method,...  
    draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_ridgeEstimator.print ↑**

```
res = nb_ridgeEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_ridgeEstimator.estimate function.
- options : A struct with the estimation options from the nb_ridgeEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- res : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_ridgeEstimator.template ↑**

```
options = nb_ridgeEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_ridgeEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_rwEstimator.bootstrapModel ↑**

```
[betaDraws,sigmaDraws,estOpt] = nb_rwEstimator.bootstrapModel(model,...  
options,results,method,draws,iter)
```

Description:

Bootstrap model.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth Sæterhagen Paulsen

► **nb_rwEstimator.estimate ↑**

```
[results,options] = nb_rwEstimator.estimate(options)
```

Description:

Estimate a random walk model.

Input:

- options : A struct on the format given by nb_rwEstimator.template.
See also nb_rwEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options.

See also:

```

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_rwEstimator.getDependent** ↑

```
dependent = nb_rwEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_rwEstimator.getPredicted** ↑

```
predicted = nb_rwEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_rwEstimator.getResidual** ↑

```
residual = nb_rwEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_rwEstimator.help** ↑

```
helpText = nb_rwEstimator.help  
helpText = nb_rwEstimator.help(option)  
helpText = nb_rwEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_rwEstimator.makeArtificial** ↑

```
[YDRAW,start,finish,indY,startEst] = nb_rwEstimator.makeArtificial(...  
model,options,results,method,...  
draws,iter)
```

Description:

Make artificial data from model by simulation.

Caution: The options struct is assumed to already be index by iter!

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_rwEstimator.print** ↑

```
res = nb_rwEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_rwEstimator.estimate function.
- options : A struct with the estimation options from the nb_rwEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- res : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► nb_rwEstimator.template ↑

```
options = nb_rwEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_rwEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► nb_seasonalEstimator.estimate ↑

```
[results,options] = nb_seasonalEstimator.estimate(options)
```

Description:

Estimate seasonally adjusted series.

Input:

```
- options : A struct on the format given by  
          nb_seasonalEstimator.template.  
          See also nb_seasonalEstimator.help.
```

Output:

- result : A struct with the estimation results.
- options : The return model options, can change depending on inputs.

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **nb_shorteningEstimator.print ↑**

```
res = nb_hpEstimator.print(results,options,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_hpEstimator.estimate function.
- options : A struct with the estimation options from the nb_hpEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_shorteningEstimator.template** ↑

```
options = nb_shorteningEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_shorteningEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_statespaceEstimator.checkCalibration** ↑

```
estimated = nb_statespaceEstimator.checkCalibration(options,parser)
```

Description:

Check if all parameters has some values before we start the estimation.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_statespaceEstimator.estimate** ↑

```
[results,options] = nb_statespaceEstimator.estimate(options)
```

Description:

Estimate a state-space model using the NB Toolbox.

Input:

- options : A struct on the format given by
nb_statespaceEstimator.template. See also
nb_statespaceEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change when for example setting default estimation dates.

[nb_statespaceEstimator.template](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_statespaceEstimator.getBounds** ↑

```
[lb,ub] = nb_statespaceEstimator.getBounds(options)
```

Description:

Get lower and upper bound on priors.

Written by Kenneth Sæterhagen Paulsen

► **nb_statespaceEstimator.getCoeff** ↑

```
[coeff,numCoeff] = nb_statespaceEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_statespaceEstimator.getDependent** ↑

```
dependent = nb_statespaceEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_statespaceEstimator.getPredicted** ↑

```
predicted = nb_statespaceEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_statespaceEstimator.getResidual** ↑

```
residual = nb_statespaceEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_statespaceEstimator.help** ↑

```
helpText = nb_statespaceEstimator.help  
helpText = nb_statespaceEstimator.help(option)  
helpText = nb_statespaceEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **`nb_statespaceEstimator.loadData`** ↑

```
[y,options] = nb_statespaceEstimator.loadData(options,parser)
```

Description:

Load data on observables.

Written by Kenneth Sæterhagen Paulsen

► **`nb_statespaceEstimator.print`** ↑

```
res = nb_statespaceEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the `nb_statespaceEstimator.estimate` function.
- options : A struct with the estimation options from the `nb_statespaceEstimator.estimate` function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **`nb_statespaceEstimator.sampler`** ↑

```
[betaD,sigmaD,posterior] = ...
nb_statespaceEstimator.sampler(posterior,draws)
```

Description:

Sample from the posterior of a estimated state space model.

See also:

[nb_drawFromPosterior](#), [nb_statespaceEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► nb_statespaceEstimator.template ↑

```
options = nb_statespaceEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_olsEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► nb_tslsEstimator.bootstrapModel ↑

```
[betaDraws,sigmaDraws,estOpt] = nb_tslsEstimator.bootstrapModel(model,...  
options,results,method,draws,iter)
```

Description:

Bootstrap model.

Written by Kenneth Sæterhagen Paulsen

► nb_tslsEstimator.estimate ↑

```
[results,options] = nb_tslsEstimator.estimate(options)
```

Description:

Estimate a model with two stage least squares.

Input:

- options : A struct on the format given by nb_tslsEstimator.template.
See also nb_tslsEstimator.help.

Output:

```
- result : A struct with the estimation results.  
- options : The return model options, can be updated.
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **[nb_tsEstimator.getCoeff](#)** ↑

```
[coeff,numCoeff] = nb_tsEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► **[nb_tsEstimator.getDependent](#)** ↑

```
residual = nb_tsEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **[nb_tsEstimator.getPredicted](#)** ↑

```
residual = nb_tsEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **[nb_tsEstimator.getResidual](#)** ↑

```
residual = nb_tsclsEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_tsclsEstimator.help ↑**

```
helpText = nb_tsclsEstimator.help  
helpText = nb_tsclsEstimator.help(option)  
helpText = nb_tsclsEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_tsclsEstimator.print ↑**

```
res = nb_tsclsEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_tsclsEstimator.estimate function.
- options : A struct with the estimation options from the nb_tsclsEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **nb_tslsEstimator.template** ↑

```
options = nb_olsEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_olsEstimator class constructor.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_tvpmpfsvEstimator.bootstrapModel** ↑

```
[betaDraws,factorDraws] =
    nb_tvpmpfsvEstimator.bootstrapModel(options,res,iter)
```

Description:

Not possible to bootstrap this model.

Written by Kenneth S. Paulsen

► **nb_tvpmpfsvEstimator.estimate** ↑

```
[results,options] = nb_tvpmpfsvEstimator.estimate(options)
```

Description:

Estimate a dynamic factor model with the algorithm of Schräder and Eraslan (2021), "Nowcasting GDP with a large factor model space".

Input:

- options : A struct on the format given by
nb_tvpmsvEstimator.template. See also
nb_tvpmsvEstimator.help.

Output:

- result : A struct with the estimation results.
- options : Some options may be updated.

See also:

► **nb_tvpmsvEstimator.f_KFS_fac ↑**

[f_sm, H_t, ef_t, var_f_sm] = nb_tvpmsvEstimator.f_KFS_fac(prior, XY, ...
lambda_sm, beta_sm, Q_t_sm, V_t_sm)

Description:

This function is greatly inspired by Koop and Korobilis (2014) and adapted to the TVP-MF-DFM framework as described in the paper by Schroder and Eraslan (2021), "Nowcasting GDP with a large factor model space".

The purpose of this function is to estimate the factors conditional on the parameter estimates obtained from [nb_tvpmsvEstimator.f_KFS_params](#).

Input:

- priors : A struct, see the [nb_tvpmsvEstimator.getPriors](#) function.
- XY : The data on the observed variables.
- lambda_sm : The smoothed factor loadings estimates
- beta_sm : The smoothed VAR parameter estimates
- Q_t_sm : The smoothed Q_t estimates
- V_t_sm : The smoothed V_t estimates

Output:

- f_sm : The smoothed factor estimates
- H_t : The state-space matrix "H_t" containing all loadings (with aggregation scheme)
- ef_t : Measurement error.
- var_f_sm : Smoothed estimates of the one-step-ahead forecast error variance.

Written by Maximilian Schröder
Edited by Kenneth Sæterhagen Paulsen
- Formated the documentation to fit NB toolbox
- Changed inputs. Many of them are now calculated inside function instead.
- Returned the smoothed estimates of the one-step-ahead forecast error variance.

► **[nb_tvpmsvEstimator.f_KFS_params](#)** ↑

```
[lambda_sm,beta_sm,beta_t_sm,Q_t_sm,V_t_sm] =  
nb_tvpmsvEstimator.f_KFS_params(priors,f,XY)
```

Description:

This function is greatly inspired by Koop and Korobilis (2014) and adapted to the TVP-MF-DFM framework as described in the paper by Schroder and Eraslan (2021), "Nowcasting GDP with a large factor model space".

This function estimates the model parameters conditional on the preliminary factor estimates.

Input:

- priors : A struct, see the [nb_tvpmsvEstimator.getPriors](#) function.
- f : the preliminary factor estimates
- XY : the data on the observed variables.

Output:

- lambda_sm : the array of smoothed factor loadings estimates
- beta_sm : the reordered smoothed estimates of the VAR coefficients
- beta_t_sm : the matrix of smoothed estimate of the VAR coefficients
- Q_t_sm : the array of smoothed Q_t estimates
- V_t_sm : the array of smoothed V_t estimates

► **nb_tpmfsvEstimator.f_em_mf ↑**

=====

DESCRIPTION

This program estimates a set of factors for a given dataset using principal component analysis. The number of factors estimated is determined by an information criterion specified by the user. Missing values in the original dataset are handled using an iterative expectation-maximization (EM) algorithm.

INPUTS

x = dataset (one series per column)
x_freq = frequency of each indicator
nFac = (predefined) number of factors
standardise = an integer indicating the type of transformation performed on each series in x before the factors are estimated.

OUTPUTS

ehat = difference between x and values of x predicted by the factors
Fhat = set of factors
lamhat = factor loadings
xhat = values of x predicted by the factors
eig = eigenvalues of $x3' * x3$ (where x3 is the dataset x post transformation and with missing values filled in)
y_em = x with missing values replaced from the EM algorithm

SUBFUNCTIONS

f_pca() - runs principal component analysis
f_standardise() - performs demeaning/standardisation of the data for PCA

BREAKDOWN OF THE FUNCTION

Part 1: Check that inputs are specified correctly.
Part 2: Setup.
Part 3: Initialize the EM algorithm -- fill in missing values with unconditional mean and estimate factors using the updated dataset.
Part 4: Perform the EM algorithm -- update missing values using factors, construct a new set of factors from the updated dataset, and repeat until the factor estimates do not change.

NOTES

Authors: Michael W. McCracken and Serena Ng
Date: 9/5/2017
Version: MATLAB 2014a
Required Toolboxes: None

Details for the three possible information criteria can be found in the paper "Determining the Number of Factors in Approximate Factor Models" by

Bai and Ng (2002).

The EM algorithm is essentially the one given in the paper "Macroeconomic Forecasting Using Diffusion Indexes" by Stock and Watson (2002). The algorithm is initialized by filling in missing values with the unconditional mean of the series, demeaning and standardizing the updated dataset, estimating factors from this demeaned and standardized dataset, and then using these factors to predict the dataset. The algorithm then proceeds as follows: update missing values using values predicted by the latest set of factors, demean and standardize the updated dataset, estimate a new set of factors using the demeaned and standardized updated dataset, and repeat the process until the factor estimates do not change.

Edited by Sercan Eraslan on 20/07/2020

The code is reduced to factor estimates with a fixed number of factors. The EM algorithm (part on updating missing values) is adjusted to incorporate mixed frequency data, such as monthly and quarterly according to Stock & Watson (2002) Appendix A.E p. 157.

=====

PART 1: CHECKS

► **nb_tvpmsvEstimator.f_factor_minnesotastruc ↑**

```
F_aux = nb_tvpmsvEstimator.f_factor_minnesotastruc(f_aux, lags_f, ...
n_f, t, k, p)
```

Description:

f_factor_minnesotastruc written by Maximilian Schröder. This function is mostly taken from Koop and Korobilis (2014) but modified to fit the current framework.

Input:

- f_aux : an auxilliary factor matrix of lagged factors
- lags_f : the number of factor lags
- n_f : the number of factors
- t : the time series length
- k : the size of the state vector
- p : the number of VAR parameters

Output:

- F_aux : the final auxilliary factor matrix

Written by Maximilian Schröder

Edited by Kenneth Sæterhagen Paulsen

- Formated the documentation to fit NB toolbox

► **nb_tvpmsvEstimator.f_smoothed_fac_shocks ↑**

```
[eps_f_sm] = nb_tvpmsvEstimator.f_smoothed_fac_shocks(priors, f_sm, beta_sm)
```

Description:

This function backs out the residuals of the factor state equation based on the smoothed factors and smoothed beta (factor VAR) coefficients.

Input:

- priors : A struct, see the nb_tvpmsvEstimator.getPriors function.
- f_sm : The smoothed factor estimates
- beta_am : the reordered smoothed estimates of the VAR coefficients (Companion form)

Output:

- eps_f_sm : A matrix containing the "smoothed" residuals of the factor state equation. The rows identify the factors, the columns identify the time dimension.

[nb_tvpmsvEstimator.template](#)

Written by Maximilian Schräder

► **[nb_tvpmsvEstimator.getAggregationScheme](#)** ↑

```
agg = nb_tvpmsvEstimator.getAggregationScheme(options, index)
```

Description:

Get the mixed frequency aggregation scheme for the selected variable.

Inputs:

- options : A struct with estimation options. See [nb_tvpmsvEstimator.template](#) or [nb_tvpmsvEstimator.help](#).
- index : The index of the low frequency variable of interest.

Written by Kenneth S. Paulsen

► **[nb_tvpmsvEstimator.getBeta](#)** ↑

```
beta = nb_tvpmsvEstimator.getBeta(options, results)
```

Description:

Get all estimated coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_tvpmpfsvEstimator.getCoeff ↑**

```
[coeff,numCoeff] = nb_tvpmpfsvEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_tvpmpfsvEstimator.getDependent ↑**

```
dependent = nb_tvpmpfsvEstimator.getDependent(results,options)
```

Description:

Get the estimated model dependent values as a nb_ts object. There are none, see getObservables instead.

Written by Kenneth Sæterhagen Paulsen

► **nb_tvpmpfsvEstimator.getFactors ↑**

```
factors = nb_tvpmpfsvEstimator.getFactors(results,options)
```

Description:

Get the estimated factors of the estimated model as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_tvpmpfsvEstimator.getNumberOfCoeff ↑**

```
nCoeff = nb_tvpmpfsvEstimator.getNumberOfCoeff(options)
```

Description:

Get the number of estimated coefficients of the dynamic factor model.

Written by Kenneth S. Paulsen

► **nb_tvpmsvEstimator.getObservables** ↑

```
observables = nb_tvpmsvEstimator.getObservables(results,options)
```

Description:

Get the observables of the estimated model as a nb_ts object

Written by Kenneth Sætherhagen Paulsen

► **nb_tvpmsvEstimator.getPredicted** ↑

```
predicted = nb_tvpmsvEstimator.getPredicted(results,options)
```

Description:

Get the estimated model predicted values as a nb_ts object

Written by Kenneth Sætherhagen Paulsen

► **nb_tvpmsvEstimator.getPriors** ↑

```
priors = nb_tvpmsvEstimator.getPriors(options)
```

Description:

Get the priors and a few other settings needed for estimation.

Input:

- options : A struct on the format returned by
nb_tvpmsvEstimator.template.

Output:

- priors : A struct with fields;
 - > f_0 : the prior distribution of the factors (structure)
 - > lambda_0 : the prior distribution of the factor loadings
(structure)
 - > beta_0 : the prior distribution of the VAR coefficients

```
        (structure)
> V_0      : the prior of the obervation equation's variance
> Q_0      : the prior of the factor state equation's variance
> agg      : the aggregation scheme
> l_1m     : the decay factor for V_t^M
> l1_q     : the decay factor for V_t^Q
> l_2      : the decay factor for Q_t
> l_3      : the forgetting factor for W_t
> l_4      : the forgetting factor for R_t
> nLags    : the number of factor lags in the VAR
> n_m      : the number of indicators at monthly frequency
> n_q      : the number of indicators at quarterly frequency
```

See also:

[nb_tvpmsvEstimator.normalEstimation](#)
[nb_tvpmsvEstimator.recursiveEstimation](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_tvpmsvEstimator.getResidual** ↑

```
residual = nb_tvpmsvEstimator.getResidual(results,options)
```

Description:

Get the estimated model residuals as a nb_ts object. This is the idiosyncatic component of the measurement error, and not the residual of the transition equation.

Written by Kenneth Sæterhagen Paulsen

► **nb_tvpmsvEstimator.getStateNames** ↑

```
[stateNames,resNames] = nb_tvpmsvEstimator.getStateNames(options)
```

Description:

Constructs variable names for printing results.

Written by Kenneth S. Paulsen

► **nb_tvpmsvEstimator.help** ↑

```
helpText = nb_tvpmsvEstimator.help
helpText = nb_tvpmsvEstimator.help(option)
helpText = nb_tvpmsvEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sætherhagen Paulsen

► nb_tvpmpfsvEstimator.initialize ↑

```
results = nb_tvpmpfsvEstimator.initialize(options,X)
```

Description:

Initialization of the estimator of the dynamic factor model.

Inputs:

- options : A struct with estimation options. See
nb_tvpmpfsvEstimator.template or
nb_tvpmpfsvEstimator.help.
- X : A T x N double storing the data on the observables.

Written by Kenneth S. Paulsen

► nb_tvpmpfsvEstimator.normalEstimation ↑

```
[res,options] = nb_tvpmpfsvEstimator.normalEstimation(options,results)
```

Description:

Selects the wanted model class and estimate the model.

Inputs:

- options : A struct on the format returned by
nb_tvpmpfsvEstimator.template.

- results : A struct with initial conditions for EML iterations. Can be used for recursive estimation. If empty or not provided this struct is provided by nb_tvpmsvEstimator.initialize

Written by Kenneth S. Paulsen and Maximilian Schröder

► nb_tvpmsvEstimator.print ↑

```
res = nb_tvpmsvEstimator.print(results,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_tvpmsvEstimator.estimate function.
- options : A struct with the estimation options from the nb_tvpmsvEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Schröder Paulsen

► nb_tvpmsvEstimator.recursiveEstimation ↑

```
[results,options] = nb_tvpmsvEstimator.recursiveEstimation(options)
```

Description:

Selects the wanted model class and recursively estimate the model.

Written by Kenneth S. Paulsen and Maximilian Schröder

► nb_tvpmsvEstimator.template ↑

```
options = nb_tvpmsvEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_tvpmsvEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **nb_whitenEstimator.estimate** ↑

```
[results,options] = nb_whitenEstimator.estimate(options)
```

Description:

Estimate a factors that have variance one and covariances 0 using whitening.

Input:

- options : A struct on the format given by nb_whitenEstimator.template.
See also nb_whitenEstimator.help.

Output:

- result : A struct with the estimation results.
- options : The return model options, can change depending on inputs.

See also:

Written by Kenneth Sæterhagen Paulsen

► **nb_whitenEstimator.estimateFactors** ↑

No documentation

Written by Kenneth S. Paulsen

► **nb_whitenEstimator.getCoeff** ↑

```
[coeff,numCoeff] = nb_whitenEstimator.getCoeff(options)
```

Description:

Get names of coefficients.

Written by Kenneth Sæterhagen Paulsen

► **nb_whitenEstimator.getFactors ↑**

```
factors = nb_whitenEstimator.getFactors(results,options)
```

Description:

Get the estimated factors as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_whitenEstimator.getObservables ↑**

```
observables = nb_whitenEstimator.getObservables(results,options)
```

Description:

Get the observables of the estimated model as a nb_ts object

Written by Kenneth Sæterhagen Paulsen

► **nb_whitenEstimator.help ↑**

```
helpText = nb_whitenEstimator.help  
helpText = nb_whitenEstimator.help(option)  
helpText = nb_whitenEstimator.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_whitenEstimator.print** ↑

```
res = nb_whitenEstimator.print(results,options,precision)
```

Description:

Get the estimation results as a char.

Input:

- results : A struct with the estimation results from the nb_fmEstimator.estimate function.
- options : A struct with the estimation options from the nb_fmEstimator.estimate function.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_whitenEstimator.template** ↑

```
options = nb_whitenEstimator.template()
```

Description:

Construct a struct which must be provided to the nb_whitenEstimator.estimate function.

This structure provided the user the possibility to set different estimation options.

Output:

- options : A struct.

Written by Kenneth SÃ¶terhagen Paulsen

◆ nb_loadDraws

```
posterior = nb_loadDraws(pathToLoad)
```

Description:

Load posterior draws from file.

Written by Kenneth Sæterhagen Paulsen

◆ nb_saveDraws

```
pathToSave = nb_saveDraws(modelName,posterior)
```

Description:

Save posterior draws to file, and return the saved location.

Written by Kenneth Sæterhagen Paulsen

◆ nb_addStars

```
tests = nb_addStars(results,tests,indNT,indW,indARCH,indAT)
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_almonLag

```
x = nb_almonLag(theta,K)
```

Description:

Implementation of the Almon lag polynominal.

Input:

- theta : A 1 x Q x P double with the hyperparameters of the almon lag polynominal; $\exp(\theta_1 \cdot k + \dots + \theta_Q \cdot k^Q) / \sum_k \exp(\theta_1 \cdot k + \dots + \theta_Q \cdot k^Q)$
- K : Number of lags of the polynominal.

Output:

- x : A 1 x K double with the value of the Almon lag polynominal for $k = 1:K$.

See also:

[nb_midasFunc](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_almonPoly

`Q = nb_almonPoly(P, K, E)`

Description:

Implementation of the Almon lag polynominal.

Input:

- `P` : Number of lags of the polynomial. If empty it will default to `K`. Either as a scalar integer or a vector of integers with length `E`.
- `K` : Number of lags of the regressor. Either as a scalar integer or a vector of integers with length `E`.
- `E` : Number of variables.

Output:

- `Q` : A $P \times E$ x $K \times E$ (or $\text{sum}(P(i)) \times \text{sum}(K(i))$) double with the mapping matrix.

See also:

[nb_midasFunc](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_arimaFunc

`results = nb_arimaFunc(y)`
`results = nb_arimaFunc(y, p, i, q, sp, sq, varargin)`

Description:

Estimate a ARIMA(p, i, q) model to a time-series represented as a double.

$$\begin{aligned}y(t) &= b * \text{exo} + u(t) \\u(t) &= \lambda * u(t-1) + c * \text{exo} + \epsilon(t)\end{aligned}$$

If the `p`, `i` or `q` are given by nan values they are being selected by this function.

i is found by the adf unit root test. I.e. the first degree of integration which reject the null of a unit root.

p and q are found by the minimizing the model selection criterion provided by the 'criterion' input. Default is to use the corrected Akaike information criterion. ('aicc')

Input:

- y : A nobs x 1 double vector with the time-series.
- p : The AR degree. As a number. Provide nan if you want to use a model selection criterion to find it.
- i : The degree of integration. I.e. the number of times the time-series have to be differenced. Provide nan if you want to use a unit root test to find it.
Will use the Augmented Dickey-Fuller test for unit root.
- q : The MA degree. As a number. Provide nan if you want to use a model selection criterion to find it.
- sp : Seasonal autoregressive (SAR) component. E.g. 0 to exclude, 4 for quarterly data, 12 for monthly. Only an option if 'method' is set to 'ml'.
- sq : Seasonal moving average (SMA) component. E.g. 0 to exclude, 4 for quarterly data, 12 for monthly. Only an option if 'method' is set to 'ml'.

Optional inputs:

- 'constant' : Give 1 to include constant, otherwise give 0.
Default is 0.
- 'criterion' : The criterion to use when selecting between ARIMA models. See the function nb_infoCriterion for more. Default is 'aicc'.
- 'exo' : Exogenous regressors in the observation equation. As a nobs x nvars. Defualt is [].
- 'texo' : Exogenous regressors in the transition equation. As a nobs x mvars. Defualt is [].
- 'maxAR' : Maximal number of AR coefficient. Default is 3.
- 'maxMA' : Maximal number of MA coefficient. Default is 3.
- 'method' : Either:
 - > 'ml' : Maximum likelihood
 - > 'hr' : Hannan-Rissanen algorithm. Default.
(Same as OLS if only AR terms are included)
- 'optimizer' : See the output from the nb_getOptimizers('arima').

- 'filter' : Give 1 if you want to run the kalman filter to estimate the residual. Otherwise give 0. Default is not to run filter. Only for 'ml'.
- 'alpha' : The significance level used by the ADF test for unit root when i is set to empty. Default is 0.05.
- 'test' : Test for roots outside the unit circle. Default is true. Must be true or false.
- 'options' : Inputs given to the optimset function. If no optional inputs are given default settings are used. Must be given as a struct or a cell array. If given as a cell array it is given to the optimset function. struct is recommended. See nb_getDefaultOptimset.
- 'covrepair' : See help on nb_mlarima. Only an option if 'method' is set to 'ml'.

Output:

- results : A struct consisting of:
 - > beta : The estimated coefficients. Order; constant, AR, MA, (SAR, SMA then exogenous).
 - > stdBeta : The standard deviation of the estimated coefficients. Constant, AR coefficients then MA coefficients.
 - > tStatBeta : The t-statistics of the estimated coefficients. Constant, AR coefficients then MA coefficients.
 - > pValBeta : The p-values of the estimated coefficients. Constant, AR coefficients then MA coefficients.
 - > likelihood : The log likelihood.
 - > i : The degree of integration.
 - > residual : The estimated residual. As a nsample x 1 double.
 - > X : The model regressors. As a nsample x nlags double. Is empty if 'method' is set to 'ml'
 - > y : The model dependent variable. As a nsample x 1 double.
 - > u : See same output of nb_mlarima or nb_hrarima.
 - > z : See same output of nb_mlarima or nb_hrarima.
 - > AR : Number of AR terms.

> MA : Number of MA terms.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_arimaStateSpace**

```
[x0,P0,d,H,R,T,c,A,B,Q,G,obs,failed] = nb_arimaStateSpace(par,p,q,sp,...  
sq,constant,nExoT,stabilityTest)
```

Description:

Returns a state-space representation of an ARIMA(p,0,q,sq,sq) model with seasonal autoregressive and seasonal moving average terms.

Observation equation:

$$y = d + Hx + Tz + v$$

State equation:

$$x = c + Ax_{-1} + Gz + Bu$$

Where $u \sim N(0, Q)$ meaning u is gaussian noise with covariance Q

$v \sim N(0, R)$ meaning v is gaussian noise with covariance R

Input:

- par : The parameter vector of the ARIMA model. Order:
 - constant
 - AR terms
 - MA terms
 - SAR terms
 - SMA terms
 - Exogenous regressors
 - Std of residual
- p : The number of AR terms.
- q : the number of MA terms.
- constant : Include constant or not. true or false.
- stabilityTest : Check stability of system. Sets failed to true if model is not stationary. Default is false.
- nExoT : Number of exogenous variables included in the state equation.

Output:

- `x0` : Initial state vector.
- `P0` : Initial variance.
- See equation above
- `obs` : Index of observables in the state vector.
- `failed` : See stabilityTest input. true if model fail test.

[nb_kalmanlikelihood](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_bayesEst**

```
[exitflag,beta,fval,H] = nb_bayesEst(init,ub,lb,opt,optimizer,...  
func,priorFunc,varargin)
```

Description:

Estimate multiple (related) equations using Bayesian (mode) estimation.

The minimized objective is: `func(beta) - priorFunc(beta)`.

Input:

- `init` : Initial values of the parameters of the model to estimate.
As a `nParam x 1 double`.
- `ub` : Upper bound on the parameters of the model to estimate.
As a `nParam x 1` or `nParam x 1 double`. If given as empty
`inf` is default. Only applies if optimizer is set to
`'fmincon'` or `'nb_abc'`.
- `lb` : Lower bound on the parameters of the model to estimate.
As a `nParam x 1` or `nParam x 1 double`. If given as empty
`-inf` is default. Only applies if optimizer is set to
`'fmincon'` or `'nb_abc'`.
- `opt` : See the optimset function for more on this input. Default
values will be used if it is given as `[]`.
- `optimizer` : The optimizer to be used; `'fminunc'`, `'fminsearch'`,
`'fmincon'` or `'nb_abc'`. `'fmincon'` is default.
- `func` : A function handle that takes the inputs in the following
order:
> The parameter matrix as a `(nParam x nEq) x 1 double`,
i.e. `vec(beta)`.
> The `y` input.
> The `x` input.
> The rest of the optional inputs given to this function

(varargin)

The output should be a 1 x 1 double with minus the log likelihood of the model.

- priorFunc : A function handle that takes the inputs in the following order:
 - > The parameter matrix as a (nParam x nEq) x 1 double, i.e. vec(beta).

The output should be a 1 x 1 double log prior evaluated at the current parameter values.

Optional input:

- 'NONLCON' : A function handle that return the values of C(beta) and Ceq(beta), where C(beta) <= 0 and Ceq(beta) == 0. E.g. [C,Ceq] = nonlinconstr(beta).
For more see; help nb_abc.constraints
- 'highValue' : The highest possible value for the objective being minimized. Default is 1000000.
- varargin : The rest will be given as optional inputs to the func input.

Output:

- exitflag : The reason for exiting the minimization. Positive numbers and 0 means success, otherwise failure.
- beta : A nxvar x neq matrix with the estimated parameters.
- residual : Residual from the estimated equation. As an nobs x neq matrix.
- H : Hessian matrix at the mode of the objective function.
As a

nb_midasFunc

Written by Kenneth S. Paulsen

◆ **nb_betaLag**

x = nb_betaLag(theta, K)

Description:

Implementation of the Beta lag polynominal.

Input:

- theta : A 1 x Q x P double with the hyperparameters of the Beta lag polynominal. See page 5 of Ghysels et al. (2006). In equation (3) we have used K+1 instead of K. Q must be equal to 2.
- K : Number of lags of the polynominal.

Output:

- x : A 1 x K double with the value of the Beta lag polynominal for k = 1:K.

See also:

[nb_midasFunc](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_betaPoly**

`Q = nb_betaPoly(theta,K,E)`

Description:

Implementation of the Beta lag polynominal.

Input:

- theta : A scalar double with the last hyperparameter of the Beta lag polynominal. See page 5 of Ghysels et al. (2006). In equation (3) we have used K+1 instead of K. The first hyperparameter is assumed to be 1!
- P : Number of lags of the polynomial. If empty it will default to K. Either as a scalar integer or a vector of integers with length E.
- K : Number of lags of the regressor. Either as a scalar integer or a vector of integers with length E.
- E : Number of variables.

Output:

- Q : A E x K*E (or E x sum(K(i))) double with the mapping matrix.

[nb_betaProfiling](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_betaProfiling

```
[b,e,X_tilda] = nb_betaProfiling(y,X,constant,AR,nExo,nLags,upper,nGrid)
```

Description:

Beta profiling as in Ghysels and Qian (2019), Estimating MIDAS regressions via OLS with polynomial parameter profiling.

Input:

- y : Left hand side variable of the model. At low frequency.
With size T x 1.
- X : A double matrix of size nobs x nxvar of the right hand side variables of all equations of the regression. These are of a higher frequency than y. Lags of regressors should already be added. The nExo input must be set.

The order of the regressors must be;
var1_lag1, var2_lag1, var1_lag2, var2_lag2, var1_lag3
i.e. they can have different number of lags. See the nLags input!
- constant : Set to true to add constant term to the regression model.
Caution: Is not assumed to be included in X!
- AR : Set to true to indicate that the first column of X is the lagged series of y.
- nExo : Number of exogenous variables excluding the lags.
- nLags : Either a scalar integer with the number of lags of all the regressors, or a vector of integers with length nExo with the number of lags of each regressor.
- upper : The upper limit on the grid of the second parameter of the beta lag polynomial. Default is 40. Lower limit is always set to 1!
- nGrid : The number of grid points profiled over. Default is 80.

Output:

- b : The estimated parameters of the model $y = X_{\text{tilda}} \cdot \beta + e$. The ordering is constant term, AR term, the OLS estimates and the last element is the selected value of the profiled parameter beta lag polynomial. Size is constant + AR + nExo x 1.
- e : The residual from the regression model $y = X_{\text{tilda}} \cdot \beta + e$. With size T x 1.
- X_tilda : The regressors of the model $y = X_{\text{tilda}} \cdot \beta + e$. With size T x (constant + AR + nExo).

Written by Kenneth Sætherhagen Paulsen

◆ nb_checkSample

```
nb_checkSample(y,X)
[endInd,startInd,varargout] = nb_checkSample(varargin)
```

Description:

Check data first and last real observations.

Input:

- varargin : Matrices that can be horcat

Output:

- endInd : Last real data point in the data
- startInd : First real data point in the data
- varargout : Same as varargin, but may have been shortened due to trailing and leading nan values

Written by Kenneth Sætherhagen Paulsen

◆ nb_drawFromPosterior

```
[beta,sigma]      = nb_drawFromPosterior(posterior,draws,waitbar)
[beta,sigma,yD,pD] = nb_drawFromPosterior(posterior,draws,waitbar)
```

Description:

Make draws from a posterior.

Caution: Will use the last parameter draw given by the `posterior.betaD(:,:,end)` and `posterior.sigmaD(:,:,end)`, where that applies.

Input:

- posterior : A struct with the needed inputs to the different functions to make posterior draws. See the posterior output of;
 - > `nb_bVarEstimator.minnesota`
 - > `nb_bVarEstimator.minnesotaMF`
 - > `nb_bVarEstimator.jeffrey`
 - > `nb_bVarEstimator.laplace`
 - > `nb_bVarEstimator.glp`
 - > `nb_bVarEstimator.glpMF`

```

> nb_bVarEstimator.nwishart
> nb_bVarEstimator.nwishartMF
> nb_bVarEstimator.inwishart
> nb_bVarEstimator.inwishartMF
> nb_bVarEstimator.laplace
> nb_bVarEstimator.horseshoe
> nb_bVarEstimator.dsge
> nb_risedsgeEstimator.sampler
> nb_statespaceEstimator.sampler
> nb_dsge.priorPredictiveAnalysis

- nDraws      : Number of draws from the posterior distribution

- waitbar    : true, false or an object of class nb_waitbar5.

```

Output:

```

- beta       : The posterior draws of the model coefficients, as a nCoeff
               x nEq x nDraws double.

- sigma      : The posterior draws of the residual covariance matrix as a
               nEq x nEq x nDraws double.

- yD         : Sampling from the posterior of missing observations. [] if
               models does not handle missing observations.

- pD         : The covariance matrix of the missing observations at the
               end of the sample. As a nEq x nEq x nNowcast x nDraws
               double, where nNowcast is the number of missing
               observations from where all endogenous variables has
               non-missing observations.

```

See also:

[nb_bVarEstimator](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_estvarols**

```
varargout = nb_estvarols(y,nlag,x,constant)
```

Description:

Estimate a VAR model using OLS

Input:

```

- y          : A nobs x nvar matrix with endogenous regressors.

- nlag       : The number of lags of the VAR. Default is 1.

- constant   : If a constant should be included in the regression.
               Default is 1, i.e. include constant.

```

- timeTrend : If a linear time trend is wanted in the estimation.
Will be added first/second in the right hand side
variables. Default is not to add it (0).
- x : A nobs x nxvar matrix with exogenous regressors.
- stdType : - 'w' : Will return White heteroskedasticity
robust standard errors.
- 'nw' : Will return Newey-West heteroskedasticity
and autocorrelation robust standard errors.

To estimate the covariance matrix of the estimated parameters the bartlett kernel is used with the bandwidth set to $\text{floor}(4(T/100)^{(2/9)})$ as Eviews also uses.

- 'h' : Will return homoskedasticity only robust standard errors. Default.

Output:

- beta : A nxvar x neqs vector with the estimated parameters.
- stdBeta : A nxvar x neqs vector with the standard deviation of the estimated parameters.
- tStatBeta : A nxvar x neqs vector with t-statistics of the estimated parameters.
- pValBeta : A nxvar x neqs vector with the p-values of the estimated parameters.
- residual : Residual from the estimated equation. As an nobs x neq matrix.
- x : Regressors including constant and time-trend.

Written by Kenneth S. Paulsen

◆ nb_getMidasIndex

```
ind = nb_getMidasIndex(I,K,E)
```

Description:

Get index of the lags of regressor I in the list of all regressors in a MIDAS model.

Input:

- I : The variable number. In [1,E].
- K : Number of lags of the regressor. As a vector of integers with

length E.

- E : The number of regressors in the MIDAS model.

Output:

- ind : The index of the regressors associated with the variable I.

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_homoOnlySTD**

```
stdBeta = nb_homoOnlySTD(x,residual)
```

Description:

Estimation of homoscedasticity only standard errors.

Input:

- x : The regressors of the equation, as a nobs x nvar double.
- u : Residual from regression, as a nobs x neq double.
- xpxi : $(x'x)^{-1}$. If not given it will be calculated.
- restr : A 1 x neq where each element is a 1 x nxvar + extra logical. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included. Each logical element must be true to include in the regression equation of the corresponding equation.

Output:

- stdBeta : Std as a nvar x neq double.

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_hrarima**

```
results = nb_hrarima(y,p,i,q,constant)
results = nb_hrarima(y,p,i,q,constant,test,z,x)
```

Description:

Estimate a ARIMA(p,i,q) or ARIMAX(p,i,q) model using the Hannan-Rissanen algorithm.

$$\begin{aligned}y(t) &= b \cdot z + u(t) \\u(t) &= \lambda \cdot u(t-1) + c \cdot x + \epsilon(t)\end{aligned}$$

Input:

```
- y          : A nobs x 1 double vector with the time-series.  
- p          : The AR degree. As a number.  
- i          : The degree of integration. I.e. the number of times  
               the time-series have to be differenced.  
- q          : The MA degree. As a number.  
- constant   : Give 1 if a constant should be included, otherwise  
               0. Default is 1.  
- test       : Give error if any of the roots of the AR process is outside  
               the unit circle.  
- z          : Exogenous regressors in the observation equation. As a  
               nobs x nvars. Default is [].  
- x          : Exogenous regressors in the transition equation. As  
               a nobs x mvars. Default is [].
```

Output:

```
- results : A struct consisting of:  
  
> beta      : The estimated coefficient of the  
               constant. Constant, AR coefficients  
               then MA coefficients.  
  
> stdBeta   : The standard deviation of the estimated  
               coefficients. Constant, AR  
               coefficients then MA coefficients.  
  
> tStatBeta : The t-statistics of the estimated  
               coefficients. Constant, AR  
               coefficients then MA coefficients.  
  
> pValBeta  : The p-values of the estimated  
               coefficients. Constant, AR  
               coefficients then MA coefficients.  
  
> sigma      : Estimated std of the residual.  
  
> likelihood : The log likelihood.  
  
> residual   : The estimated residual. As a  
               nsample x 1 double.  
  
> X          : The model regressors. As a  
               nsample x nlags double.  
  
> y          : The model dependent variable. As a  
               nsample x 1 double.  
  
> u          : The residual from the first stage regression  
               of the dependent variable on the exogenous  
               and constant. If no constant and z is empty
```

this will be equal to y.

> z : The exogenous variables included in the observation equation.

> x : The exogenous variables included in the transition equation.

Written by Kenneth Sæterhagen Paulsen

◆ nb_jeffrey

```
beta          = nb_jeffrey(y,x)
[beta,sigma,residual,X] = nb_jeffrey(y,x,prior,constant,timeTrend, ...
    restrictions)
```

Description:

Estimate multiple (related) equations using Jeffrey priors.

$y = X\beta + \text{residual}$, $\text{residual} \sim N(0, \sigma)$ (1)

Prior on beta : Diffuse

Prior on sigma : Diffuse

Input:

- y : A double matrix of size T x Q of the dependent variable of the regression(s).

- x : A double matrix of size T x N of the right hand side variables of all equations of the regression.

- prior : A structure with the prior specification. If not given the default priors are:
> draws : 1

For more on this prior see nb_jeffreyPrior.

- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables. Default is false.

- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second). Default is false.

- restrictions :

Output:

- beta : A (extra + nxvar) x nEq x draws matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.

- sigma : A nEq x nEq x draws matrix with the covariance matrix of residuals.
- residual : Residual from the estimated equation. As an nobs x nEq matrix. If draws > 1, this is calculated at the mean.
- X : Regressors including constant and time-trend. If more than one equation this will be given as kron(I,x).

[nb_jeffreyPrior](#), [nb_bayesEstimator](#), [nb_singleEq](#)

Written by Kenneth S. Paulsen

◆ **nb_jeffreyPrior**

prior = nb_jeffreyPrior(varargin)

Description:

Set the priors of the type:

y = X*beta + residual, residual ~ N(0,sigma) (1)

y has size T x Q
X has size T x N

Prior on beta : Diffuse
Prior on sigma : Diffuse

Optionsl input:

- Run without inputs to get default priors.
- Run with 'list' as the first input to get a cellstr with the supported prior options.
- Run with 'help' to get a char with help on each option.
- Run with 'optionName' to get help on a particular option, i.e. only one input.
- Use 'optionName', optionValue pairs to set options of the returned struct.

Output:

- Depends on the input.

[nb_jeffrey](#)

◆ nb_kalmanLikelihoodBreakPointDSGE

```
lik = nb_kalmanLikelihoodBreakPointDSGE(par,model,y,varargin)
```

Description:

The model function must return the given matrices in the system below:

Observation equation:

$$y(t) = H \cdot x(t)$$

State equation:

$$x(t) = ss(t) + A(t) \cdot (x(t-1) - ss(t)) + C(t) \cdot u(t)$$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I

Input:

- par : A parameter vector which is given as the first input to the function handle given by the model input.
- model : A function handle returning the following matrices (in this order):
 - > H : Observation matrix. As a nObs x nEndo double.
 - > A : State transition matrix. A cell with size 1 x nStates. Each element as a nEndo x nEndo double.
 - > C : The impact of shock matrix. A cell with size 1 x nStates. Each element as a nEndo x nExo double.
 - > x : Initial state vector. As a nEndo x 1 double.
 - > P : Initial covariance of state variables, as a nEndo x nEndo double.
 - > options : A struct with the fields:
 - * kf_riccatiTol : Converge criteria on the Kalman gain.
 - * kf_preset : Discarded observation of the likelihood at the begining.
 - * states : A nobs vector with the states at the given period.
 - * ss : The steady-state of the model in each regime. As a cell array.
 - > err : A empty string if success, otherwise the error message as a char (lik = 1e10 in this case).

- y : Observation vector. A nObs x T double.

Optional input:

- varargin : Optional inputs given to the function handle given by the model input.

Output:

- lik : Minus the log likelihood. As a 1 x 1 double.

See also:

Written by Kenneth Åström Paulsen

◆ **nb_kalmanLikelihoodDSGE**

lik = nb_kalmanLikelihoodDSGE(par, model, y, varargin)

Description:

The model function must return the given matrices in the system below:

Observation equation:
 $y(t) = H*x(t)$

State equation:
 $x(t) = A*x(t-1) + C*u(t)$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I

See for example: Koopman and Durbin (1998), "Fast filtering and smoothing for multivariate state space models".

Input:

- par : A parameter vector which is given as the first input to the function handle given by the model input.

- model : A function handle returning the following matrices (in this order):

> H : Observation matrix. As a nObs x nEndo double.
> A : State transition matrix. As a nEndo x nEndo double.
> C : The impact of shock matrix. As a nEndo x nExo double.
> x : Initial state vector. As a nEndo x 1 double.

```

> P      : Initial covariance of state variables, as a nEndo x
           nEndo double.

> options : A struct with the fields:

    * kf_riccatiTol : Converge criteria on the Kalman
           gain.

    * kf_presample  : Discarded observation of the
           likelihood at the begining.

> err     : A empty string if success, otherwise the error
           message as a char (lik = le10 in this case).

- y : Observation vector. A nObs x T double.

```

Optional input:

- varargin : Optional inputs given to the function handle given by the model input.

Output:

- lik : Minus the log likelihood. As a 1 x 1 double.

Written by Kenneth Å!terhagen Paulsen

◆ **nb_kalmanLikelihoodDiffuseBreakPointDSGE**

lik = nb_kalmanLikelihoodDiffuseBreakPointDSGE(par,model,y,varargin)

Description:

Diffuse piecewise linear Kalman filter. With potentially missing observations!

The model function must return the given matrices in the system below:

Observation equation:

$$y(t) = H \cdot x(t)$$

State equation:

$$x(t) = s(t) + A(t) \cdot (x(t-1) - s(t)) + C(t) \cdot u(t)$$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I

Input:

```

- par    : A parameter vector which is given as the first input to
          the function handle given by the model input.

- model : A function handle returning the following matrices (in
          this order):

    > H      : Observation matrix. As a nObs x nEndo double.

    > A      : State transition matrix. A cell with size 1 x
              nStates. Each element as a nEndo x nEndo double.

    > C      : The impact of shock matrix. A cell with size 1 x
              nStates. Each element as a nEndo x nExo double.

    > x      : Initial state vector. As a nEndo x 1 double.

    > P      : Initial state variance. As a nStationaryVar x
              nStationaryVar double.

    > Pinf   : Initial state variance of the non-stationary
              variables. As a nNonStationaryVar x
              nNonStationaryVar double.

    > options : A struct with the fields:

        * kf_riccatiTol : Converge criteria on the Kalman
                           gain.

        * kf_presample  : Discarded observation of the
                           likelihood at the begining.

        * states         : A nobs vector with the states
                           at the given period.

        * ss             : The steady-state of the model in
                           each regime. As a cell array.

    > err    : A empty string if success, otherwise the error
              message as a char (lik = 1e10 in this case).

- y : Observation vector. A nObs x T double.

```

Optional input:

```
- varargin : Optional inputs given to the function handle given
            by the model input.
```

Output:

```
- lik : Minus the log likelihood. As a 1 x 1 double.
```

◆ nb_kalmanLikelihoodDiffuseDSGE

```
lik = nb_kalmanLikelihoodDiffuseDSGE(par,model,y,varargin)
```

Description:

The model function must return the given matrices in the system below:

Observation equation:

$$y(t) = H \cdot x(t)$$

State equation:

$$x(t) = A \cdot x(t-1) + B \cdot u(t)$$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance Q

See for example: Koopman and Durbin (1998), "Fast filtering and smoothing for multivariate state space models".

Input:

- par : A parameter vector which is given as the first input to the function handle given by the model input.
- model : A function handle returning the following matrices (in this order):
 - > H : Observation matrix. As a nObs x nEndo double.
 - > A : State transition matrix. As a nEndo x nEndo double.
 - > C : The impact of shock matrix. As a nEndo x nExo double.
 - > x : Initial state vector. As a nEndo x 1 double.
 - > P : Initial state variance. As a nStationaryVar x nStationaryVar double.
 - > Pinf : Initial state variance of the non-stationary variables. As a nNonStationaryVar x nNonStationaryVar double.
 - > options : A struct with the fields:
 - * kf_riccatiTol : Convergence criteria on the Kalman gain.
 - * kf_presample : Discarded observation of the likelihood at the beginning.
- y : Observation vector. A nObs x T double.

Optional input:

- varargin : Optional inputs given to the function handle given by the model input.

Output:

- lik : Minus the log likelihood. As a 1 x 1 double.

◆ **nb_kalmanLikelihoodDiffuseStochasticTrendDSGE**

lik = nb_kalmanLikelihoodDiffuseStochasticTrendDSGE(par,estStruct)

Description:

Diffuse piecewise linear Kalman filter with updating of the "steady state" based on some stochastic trends of the observation part of the model. Will also handle potentially missing observations!

Observation equation:

$$y(t) = H \cdot x(t)$$

State equation:

$$x(t) = ss(t) + A(t) \cdot (x(t-1) - ss(t)) + B(t) \cdot z(t) + C(t) \cdot u(t)$$

where $ss(t) = G(theta, x(t-1))$ and $A(t)$, $B(t)$ and $C(t)$ are the solution around this updated approximation point (or steady state).

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I

Input:

- par : Current vector of the estimated parameters.
- estStruct : See the `nb_dsge.getObjectiveForEstimation` method.

Output:

- xf : The filtered estimates of the x in the equation above.
- xs : The smoothed estimates of the x in the equation above.
- us : The smoothed estimates of the u in the equation above.
- xu : The updated estimates of the x in the equation above.
- uu : The updated estimates of the u in the equation above.

- A : The updated estimates of the transition matrix.
- B : The updated estimates of the contant term of the state equation.
- C : The updated estimates of the shock impact matrix.
- ss : The updated estimates of the approximation point (steady state).
- p : The updated estimates of the parameters of the model.

A,B,obs,x0,P0,y,kalmanTol,kf_presample,G,z,s)
```

Description:

Kalman smoother. With potentially missing observations!

Observation equation:

$$y(t) = H \cdot x(t) + v(t)$$

State equation:

$$x(t) = A \cdot x(t-1) + B \cdot u(t)$$

or if G and z is given

$$x(t) = A \cdot x(t-1) + G \cdot z(t) + s(t) \cdot B \cdot u(t)$$

Where $u \sim N(0, I)$ and $v \sim N(0, R)$.

See for example: Koopman and Durbin (1998), "Fast filtering and smoothing for multivariate state space models" and Hamilton (1994), "Time Series Analysis"

Input:

- H : Observation matrix. As a nObs x nEndo double.
- R : Measurement error covariance matrix. As a nObs x nObs double. If you assume no measurement error, give zeros(nObs).
- A : State transition matrix. As a size nEndo x nEndo.
- B : The impact of shock matrix. As a size nEndo x nExo.
- x0 : Initial state vector. As a nEndo x 1 double.
- P0 : Initial state variance. As a nEndo x nEndo double.
- y : Observation vector. A nObs x T double.
- kalmanTol : Kalman tolerance.
- kf_presample : Number of periods before the likelihood is calculated.

- G : A nEndo x nExo double.
- z : A nExo x T double
- s : A 1 x T double. With the stochastic-volatility process.
Defaults to 1.

Output:

- xf : The filtered estimates ($x_{t+1|t}$) of the x in the equation above.
A nEndo x T + 1 double. $xf(:,1)$ is set to x_0 , and is interpreted as $x_{1|0}$.
- xu : The updated estimates ($x_{t|t}$) of the x in the equation above.

```
[xf, xs, us, xu, uu] = nb_kalmanSmoothenBreakPointDSGE(H, A, C, ss, obs, x0, P0, ...
y, kalmanTol, states)
```

Description:

Piecewise linear Kalman smoother. With potentially missing observations!

Observation equation:

$$y(t) = H \cdot x(t) + v(t)$$

State equation:

$$x(t) = ss\{s(t)\} + A\{s(t)\} \cdot (x(t-1) - ss\{s(t)\}) + C\{s(t)\} \cdot u(t)$$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I

Input:

- H : Observation matrix. As a nObs x nEndo double.
- A : State transition matrix. A cell with size 1 x nStates.
Each element as a nEndo x nEndo double.

- C : The impact of shock matrix. A cell with size 1 x nStates.
Each element as a nEndo x nExo double.
- ss : Steady-state of the endogenous variables. A cell with size 1 x nStates. Each element as a nEndo x 1 double.
- obs : Index of observables in the vector of state variables. A logical vector with size size(A,1) x 1.
- x0 : Initial state vector. As a nEndo x 1 double.
- P0 : Initial state variance. As a nEndo x nEndo double.
- y : Observation vector. A nObs x T double.
- kalmanTol : Tolerance level for rcond of the forecast variance.
- states : A 1 x nObs double with the break period to use for each period, i.e. how to index A, C and ss at each period.

Output:

- xf : The filtered estimates of the x in the equation above.
- xs : The smoothed estimates of the x in the equation above.
- us : The smoothed estimates of the u in the equation above.
- xu : The updated estimates of the x in the equation above.
- uu : The updated estimates of the u in the equation above.

◆ **nb_kalmanSmoothenDSGE**

[xf, xs, us, xu, uu] = nb_kalmanSmoothenDSGE(H, A, B, obs, x0, P0, y, kalmanTol)

Description:

Kalman smoother. No missing observations!

Observation equation:

$$y(t) = H \cdot x(t)$$

State equation:

$$x(t) = A \cdot x(t-1) + B \cdot u(t)$$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I

See for example: Koopman and Durbin (1998), "Fast filtering and smoothing for multivariate state space models".

Input:

- H : Observation matrix. As a nObs x nEndo double.
- A : State transition matrix. As a nEndo x nEndo double.
- B : The impact of shock matrix. As a nEndo x nExo double.
- obs : Index of observables in the vector of state variables. A logical vector with size size(A,1) x 1.
- x0 : Initial state vector. As a nEndo x 1 double.
- P0 : Initial state variance. As a nEndo x nEndo double.
- y : Observation vector. A nObs x T double.
- kalmanTol : Kalman tolerance.

Output:

- xf : The filtered estimates of the x in the equation above.
- xs : The smoothed estimates of the x in the equation above.
- us : The smoothed estimates of the u in the equation above.
- xu : The updated estimates of the x in the equation above.
- uu : The updated estimates of the u in the equation above.

◆ nb_kalmanSmoothenDiffuseBreakPointDSGE

```
[xf,xs,us,xu,uu] = nb_kalmanSmoothenDiffuseBreakPointDSGE(H,A,C,ss,obs,...  
x0,P0,P0INF,y,kalmanTol,states)
```

Description:

Diffuse piecewise linear Kalman smoother. With potentially missing observations!

Observation equation:
 $y(t) = H*x(t) + v(t)$

State equation:
 $x(t) = ss(t) + A(t)*(x(t-1) - ss(t)) + C(t)*u(t)$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I

Input:

- H : Observation matrix. As a nObs x nEndo double.
- A : State transition matrix. A cell with size 1 x nStates.
Each element as a nEndo x nEndo double.
- C : The impact of shock matrix. A cell with size 1 x nStates.
Each element as a nEndo x nExo double.
- ss : Steady-state of the endogenous variables. A cell with size 1 x nStates. Each element as a nEndo x 1 double.
- obs : Index of observables in the vector of state variables. A logical vector with size size(A,1) x 1.
- x0 : Initial state vector. As a nEndo x 1 double.
- P0 : Initial state variance. As a nEndo x nEndo double.
- P0INF : Initial state variance of the non-stationary variables.
As a nEndo x nEndo double.
- y : Observation vector. A nObs x T double.
- kalmanTol : Tolerance level for rcond of the forecast variance.
- states : A 1 x nobs double with the break period to use for each period, i.e. how to index A,B and ss at each period.

Output:

- xf : The filtered estimates of the x in the equation above.
- xs : The smoothed estimates of the x in the equation above.
- us : The smoothed estimates of the u in the equation above.
- xu : The updated estimates of the x in the equation above.
- uu : The updated estimates of the u in the equation above.

[xf,xs,us,xu,uu] = nb_kalmanSmootherDiffuseStochasticTrendDSGE(H, ...
    solution,options,results,obs,x0,P0,P0INF,y, ...
    kalmanTol)
```

Description:

Diffuse piecewise linear Kalman smoother with updating of the "steady state" based on some stochastic trends of the observation part of the model. Will also handle potentially missing observations!

Observation equation:
 $y(t) = H*x(t)$

State equation:
 $x(t) = ss(t) + A(t)*(x(t-1) - ss(t)) + B(t)*z(t) + C(t)*u(t)$

where $ss(t) = G(theta, x(t-1))$ and $A(t)$, $B(t)$ and $C(t)$ are the solution around this updated approximation point (or steady state).

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I

Input:

- H : Observation matrix. As a nObs x nEndo double.
- solution : A struct containing the initial solution of the model. See nb_dsge.solution property for more on this input.
- options : A struct with the model options. See the nb_dsge.createEstOptionsStruct method for more on this input.
- results : A struct storing the estimation or calibration of the model. See nb_dsge.results property for more on this input.
- obs : Index of observables in the vector of state variables. A logical vector with size size(A,1) x 1.
- x0 : Initial state vector. As a nEndo x 1 double.
- P0 : Initial state variance. As a nEndo x nEndo double.
- P0INF : Initial state variance of the non-stationary variables. As a nEndo x nEndo double.
- y : Observation vector. A nObs x T double.
- kalmanTol : Tolerance level for rcond of the forecast variance.

Output:

- xf : The filtered estimates of the x in the equation above. As a T x nEndo double.
- xs : The smoothed estimates of the x in the equation above. As a T x nEndo double.

- us : The smoothed estimates of the u in the equation above. As a T x nExo double.
- xu : The updated estimates of the x in the equation above. As a T x nEndo double.
- uu : The updated estimates of the u in the equation above. As a T x nExo double.
- A : The updated estimates of the transition matrix.
A nEndo x nEndo x T + 1 double, starting from A 0|0 to A T|T.
- B : The updated estimates of the contant term of the state equation.
A nEndo x nDet x T + 1 double, starting from B 0|0 to B T|T.
nDet are either 0 or 1.
- C : The updated estimates of the shock impact matrix.
A nEndo x nExo x T + 1 double, starting from C 0|0 to C T|T.
- ss : The updated estimates of the approximation point (steady state).
A nEndo x 1 x T + 1 double, starting from ss 0|0 to ss T|T.
- p : The updated estimates of the parameters of the model. As a T x nParam double.

◆ **nb_kalmanfilter**

[x,u,v] = nb_kalmanfilter(model,y,z,varargin)

Description:

The model function must return the given matrices in the system below (I.e. d,H,R,T,c,A,B,Q,G) :

Observation equation:
 $y = d + Hx + Gz + v$

State equation:
 $x = c + Ax_{-1} + Tz + Bu$

Where $u \sim N(0, Q)$ meaning u is gaussian noise with covariance Q
 $v \sim N(0, R)$ meaning v is gaussian noise with covariance R

See for example: Koopman and Durbin (1998), "Fast filtering and smoothing for multivariate state space models".

Input:

- model : A function handle returning the following matrices (in this order) :

```
> x      : Initial state vector.  
> P      : Initial state variance.  
> d      : Constant in the observation equation.  
> H      : Observation matrix.  
> R      : Measurement noise covariance.  
> T      : Matrix on exogenous variables in the observation  
          equation. Set it to 0 if not needed!  
> c      : Constant in the state equation.  
> A      : State transition matrix.  
> Q      : Process noise covariance.  
> B      : Input matrix, optional.  
> G      : Matrix on exogenous variables in the state  
          equation. Set it to 0 if not needed!  
> u      : Input control vector, optional.  
> obs    : Index of observables in the state vector.  
> failed : Give true if model cannot be solved. lik will  
          be returned a value of 1e10 in this case.
```

- y : Observation vector. A nvar x nobs double.

- z : Observation vector of exogenous. A nxvar x nobs double.

Optional input:

- varargin : Optional inputs given to the function handle given by the model input.

Output:

- x : The filtered estimates of the x in the equation above. (x t|t)
- u : The filtered estimates of the u in the equation above. (u t|t)
- v : The filtered estimates of the v in the equation above. (v t|t)

◆ **nb_kalmanlikelihood**

lik = nb_kalmanlikelihood(par,model,y,z,start,varargin)

Description:

The model function must return the given matrices in the system below (I.e. d,H,R,T,c,A,B,Q,G) :

Observation equation:

$$y(t) = d + H*x(t) + T*z(t) + v(t)$$

State equation:

$$x(t) = c + A*x(t-1) + G*z(t) + B*u(t)$$

Where $u \sim N(0, Q)$ meaning u is gaussian noise with covariance Q
 $v \sim N(0, R)$ meaning v is gaussian noise with covariance R

See for example: Koopman and Durbin (1998), "Fast filtering and smoothing for multivariate state space models".

Input:

- par : A parameter vector which is given as the first input to the function handle given by the model input.
- model : A function handle returning the following matrices (in this order):
 - > x : Initial state vector.
 - > P : Initial state variance.
 - > d : Constant in the observation equation.
 - > H : Observation matrix.
 - > R : Measurement noise covariance.
 - > T : Matrix on exogenous variables in the observation equation. Set it to 0 if not needed!
 - > c : Constant in the state equation.
 - > A : State transition matrix.
 - > Q : Process noise covariance.
 - > B : Input matrix, optional.
 - > G : Matrix on exogenous variables in the state equation. Set it to 0 if not needed!
 - > u : Input control vector, optional.
 - > obs : Index of observables in the state vector.
 - > failed : Give true if model cannot be solved. lik = 1e10 in this case.
- y : Observation vector. A nvar x nobs double.
- z : Observation vector of exogenous. A nxvar x nobs double.
- start : Start observation of the likelihood calculation.

Optional input:

- varargin : Optional inputs given to the function handle given by the model input.

Output:

- lik : Minus the log likelihood. As a 1 x 1 double.

See also:

nb_kalmanlikelihood_missing, nb_kalmansmooth

Written by Kenneth Sæterhagen Paulsen

◆ nb_kalmanlikelihood_missing

```
lik = nb_kalmanlikelihood_missing(par,model,y,z,varargin)
```

Description:

The model function must return the given matrices in the system below (I.e. d,H,R,T,c,A,B,Q,G) :

Observation equation:

$$y(t) = d + H*x(t) + T*z(t) + v(t)$$

State equation:

$$x(t) = c + A*x(t-1) + G*z(t) + B*u(t)$$

Where $u \sim N(0, Q)$ meaning u is gaussian noise with covariance Q
 $v \sim N(0, R)$ meaning v is gaussian noise with covariance R

See for example: Koopman and Durbin (1998), "Fast filtering and smoothing for multivariate state space models".

Input:

- par : A parameter vector which is given as the first input to the function handle given by the model input.

- model : A function handle returning the following matrices (in this order):

```
> x      : Initial state vector.  
> P      : Initial state variance.  
> d      : Constant in the observation equation.  
> H      : Observation matrix.  
> R      : Measurement noise covariance.  
> T      : Matrix on exogenous variables in the observation equation. Set it to 0 if not needed!  
> c      : Constant in the state equation.  
> A      : State transition matrix.  
> Q      : Process noise covariance.  
> B      : Input matrix, optional.  
> G      : Matrix on exogenous variables in the state equation. Set it to 0 if not needed!  
> u      : Input control vector, optional.  
> obs    : Index of observables in the state vector.  
> failed : Give true if model cannot be solved. lik = 1e10 in this case.
```

- y : Observation vector. A nvar x nobs double.

- z : Observation vector of exogenous. A nxvar x nobs double.

- start : Start observation of the likelihood calculation.

Optional input:

- varargin : Optional inputs given to the function handle given by the model input.

Output:

- lik : Minus the log likelihood. As a 1 x 1 double.

[nb_kalmanlikelihood](#), [nb_kalmansmootherr_missing](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_kalmansmootherr

[xf, xs, us, vs, xu] = nb_kalmansmootherr(model, y, z, varargin)

Description:

Kalman smoother. No missing observations!

The model function must return the given matrices in the system below (I.e. d, H, R, T, c, A, B, Q, G) :

Observation equation:

$$y(t) = d + H*x(t) + T*z(t) + v(t)$$

State equation:

$$x(t) = c + A*x(t-1) + G*z(t) + B*u(t)$$

Where $u \sim N(0, Q)$ meaning u is gaussian noise with covariance Q
 $v \sim N(0, R)$ meaning v is gaussian noise with covariance R

See for example: Koopman and Durbin (1998), "Fast filtering and smoothing for multivariate state space models".

Input:

- model : A function handle returning the following matrices (in this order):

> x	: Initial state vector.
> P	: Initial state variance.
> d	: Constant in the observation equation.
> H	: Observation matrix.
> R	: Measurement noise covariance.
> T	: Matrix on exogenous variables in the observation equation. Set it to 0 if not needed!
> c	: Constant in the state equation.
> A	: State transition matrix.
> Q	: Process noise covariance.
> B	: Input matrix, optional.

```

> G      : Matrix on exogenous variables in the state
           equation. Set it to 0 if not needed!
> u      : Input control vector, optional.
> obs    : Index of observables in the state vector.
> failed : Give true if model cannot be solved. lik will
           be returned a value of 1e10 in this case.

- y   : Observation vector. A nvar x nobs double.

- z   : Observation vector of exogenous. A nxvar x nobs double.

```

Optional input:

- varargin : Optional inputs given to the function handle given by the model input.

Output:

- xf : The filtered estimates of the x in the equation above. ($x_{t+1|t}$)
- xs : The smoothed estimates of the x in the equation above. ($x_{t|T}$)
- us : The smoothed estimates of the u in the equation above. ($u_{t|T}$)
- vs : The smoothed estimates of the v in the equation above. ($v_{t|T}$)
- xu : The updated estimates of the x in the equation above. ($x_{t|t}$)

See also:

[nb_kalmansmooth_missing](#), [nb_kalmanlikelihood](#)

Written by Kenneth Sæterhagen Paulsen

◆ [nb_kalmansmooth_missing](#)

[xf, xs, us, vs, xu, uu, Ps] = nb_kalmansmooth_missing(par, model, y, z, varargin)

Description:

Kalman smoother. With potentially missing observations!

The model function must return the given matrices in the system below (I.e. d, H, R, T, c, A, B, Q, G) :

Observation equation:

$$y(t) = d + H \cdot x(t) + T \cdot z(t) + v(t)$$

State equation:

$$x(t) = c + A \cdot x(t-1) + G \cdot z(t) + B \cdot u(t)$$

Where $u \sim N(0, Q)$ meaning u is gaussian noise with covariance Q
 $v \sim N(0, R)$ meaning v is gaussian noise with covariance R

See for example: Koopman and Durbin (1998), "Fast filtering ans smoothing for multivariate state space models".

Input:

- model : A function handle returning the following matrices (in this order):

- > x0 : Initial state vector. As a nvar x 1 double.
- > P0 : Initial state variance. As a nvar x nvar double.
- > d : Constant in the observation equation.
- > H : Observation matrix (defaults to identity).
- > R : Measurement noise covariance (required).
- > c : Constant in the state equation.
- > A : State transition matrix (defaults to identity).
- > Q : Process noise covariance (defaults to zero).
- > B : Input matrix, optional (defaults to zero).
- > u : Input control vector, optional (defaults to zero).
- > obs : Index of observables in the vector of state variables. A logical vector with size size(A,1) x 1.

- y : Observation vector. A nvar x nobs double.

- z : Observation vector of exogenous. A nxvar x nobs double.

Optional input:

- varargin : Optional inputs given to the function handle given by the model input.

Output:

- xf : The filtered estimates of the x in the equation above. (x t+1|t)
- xs : The smoothed estimates of the x in the equation above. (x t|T)
- us : The smoothed estimates of the u in the equation above. (u t|T)
- vs : The smoothed estimates of the v in the equation above. (v t|T)
- xu : The updated estimates of the x in the equation above. (x t|t)
- uu : The updated estimates of the u in the equation above. (u t|t)
- Ps : Smoothed one step ahead covariance matrices. P t|T. Ps(:,1) is interpreted as P 1|T.

[nb_kalmansmoothes](#), [nb_kalmanlikelihood_missing](#)

◆ nb_lasso

```
[beta,exitflag,residual,X] = nb_lasso(y,X,t,constant,options)
```

Description:

LASSO estimation using the local linearization and active set method proposed in [Osborne et al., 2000], [Osborne et al., 2000b].

Solves the constrained optimization problem:

```
min (y - X*beta)^2  
s.t. sum(abs(beta)) <= 1/t
```

The code is an adaption of code written by M. Schmidt. See:

- <https://www.cs.ubc.ca/~schmidtm/Software/lasso.html>
- M. Schmidt. Least Squares Optimization with L1-Norm Regularization. CS542B Project Report, 2005.

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- X : A double matrix of size nobs x nxvar of the right hand side variables of all equations of the regression.
- t : The value of t in the minimization problem. Default is inf. Must be a scalar number greater or equal to 0.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables. Default is false. The constant term is first estimate by the mean of y, and then y is demeaned before doing the LASSO estimation.
- options : Optimization options. As a struct. See nb_lasso.optimset.

Output:

- beta : A (extra + nxvar) x neq matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- exitflag : The reason for exiting. One of:
 - > -1 : Numerical breakdown, check for dependent columns.
 - > -2 : Maximum number of iteration reached (maxIter).

See also: nb_interpretExitFlag. Set type to 'nb_lasso'.

- residual : Residual from the estimated equation. As an nobs x neq matrix.

- X : Regressors including constant. If more than one equation this will be given as `kron(I,x)`.

See also:

[nb_lasso.optimset](#), [nb_ols](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_legendrePoly**

`Q = nb_legendrePoly(P,K,E)`

Description:

Implementation of the Legendre lag polynominal.

Input:

- P : Number of lags of the polynomial. If empty it will default to K. Either as a scalar integer or a vector of integers with length E.
- K : Number of lags of the regressor. Either as a scalar integer or a vector of integers with length E.
- E : Number of variables.

Output:

- Q : A $P \times E$ x $K \times E$ (or $\text{sum}(P(i)) \times \text{sum}(K(i))$) double with the mapping matrix.

See also:

[nb_midasFunc](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_midasBootstrap**

`ysim = nb_midasBootstrap(p,resid,x,constant,func,nExo,AR,draws,method)`

Description:

Calculate residuals of the MIDAS model given a parameter set.

Input:

- p : A nParam x 1 double vector.
- resid : A nobs x 1 double with the residuals of the model.
- x : A nobs x nExo*nLags double with the exogenous variables of the model. Except constant.
- constant : true or false. true if constant is included in the model.
- func : A function handle that map from the non-linear parameters to the linear once. If empty the MIDAS model is unrestricted.
- nExo : Number of exogenous variables of the model, excluding lag and constant.
- AR : true or false. true if AR specification of the MIDAS model is used.
- draws : Number of draws from the distribution of the dependent variable.
- method : See the method input to the nb_bootstrap function. Default is 'bootstrap'.

Output:

- ysim : A nobs x draws double with the simulated dependent variable of the model.

See also:

[nb_midasMapToLinear](#), [nb_midasFunc](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_midasFunc**

```
beta = nb_midasFunc(y,x)
[beta, stdBeta, tStatBeta, pValBeta, residual, sigma, betaD, sigmaD] = nb_midasFunc(y,x, ...
    constant, type, nSteps, stdType, nExo, nLags, varargin)
```

Description:

Estimate MIDAS model.

$y = x*f(beta) + \epsilon$, $\epsilon \sim N(0, \epsilon^* \epsilon / nobs)$ (1)

Input:

- y : A double matrix of size nobs x 1 of the dependent variable of the regression(s).
- x : A double matrix of size nobs x nxvar of the right hand side variables of all equations of the

regression. These are of a higher frequency than y. Lags of regressors should already be added. The nExo input must be set.

The order of the regressors must be;
var1_lag1, var2_lag1, var1_lag2, var2_lag2, var1_lag3
i.e. they can have different number of lags. See the nLags input!

- constant : true or false. If true a constant is included.
- AR : true or false. Indicate that you are estimating a AR specification of the MIDAS model.
- type : The type of MIDAS model to estimate. Either; 'unrestricted', 'beta', 'legendre', 'mean' or 'almon'. If set to 'beta' profiling is used, otherwise OLS is used.
- nSteps : Add leads to make the MIDAS models able to produce direct forecast longer than 1 period forward. Default is 1. Must be an integer larger than 0.
- stdType :
 - 'w' : Will return White heteroskedasticity robust standard errors.
 - 'nw' : Will return Newey-West heteroskedasticity and autocorrelation robust standard errors.
- To estimate the covariance matrix of the estimated parameters the bartlett kernel is used with the bandwidth set to $\text{floor}(4(T/100)^{(2/9)})$ as Eviews also uses.
- 'h' : Will return homoskedasticity only robust standard errors. Default.
- nExo : Number of exogenous variables excluding the lags.
- nLags : Either a scalar integer with the number of lags of all the regressors, or a vector of integers with length nExo with the number of lags of each regressor. Default is 1!

Optional inputs:

- 'draws' : Number of draws from the parameter distribution when bootstrapping the standard error of the parameters.
- 'polyLags' : The number of polynomial lags to use when type is set to 'legendre' or 'almon'. Either as a scalar integer or a vector of integers with length nExo.

Output:

- beta : A nxvar x nSteps matrix with the estimated parameters.
- stdBeta : A nxvar x nSteps matrix with the standard deviation of the estimated parameters.
- tStatBeta : A nxvar x nSteps matrix with t-statistics of the

estimated paramteres.

- pValBeta : A nxvar x nSteps matrix with the p-values of the estimated paramteres.
- residual : Residual from the estimated equation. As an nobs x nSteps matrix.
- sigma : Covariance matrix of estimated residuals. Will be a diagonal matrix with size nSteps x nSteps.
- betaD : The bootstrapped parameters of the model. As a nxvar x nSteps x draws double.
- sigmaD : The bootstrapped covariances of the residuals of the model. Assumed to be diagonal. As a nSteps x nSteps x draws double.

Written by Kenneth S. Paulsen

◆ **`nb_midasMapToLinear`**

```
beta = nb_midasMapToLinear(p,AR,constant,nExo,nLags)
```

Description:

Map from the non-linear estimated parameter to the linear coefficient of the MIDAS model, i.e. map from

$y = X \cdot f(p) + \epsilon$, $\epsilon \sim N(0, \epsilon' \cdot \epsilon / nobs)$ (1)

to

$y = X \cdot \beta + \epsilon$, $\epsilon \sim N(0, \epsilon' \cdot \epsilon / nobs)$ (1)

Input:

- p : A nParam x 1 double vector.
- func : A function handle that map from the non-linear parameters to the linear once.
- AR : true or false. true if AR specification of the MIDAS model is used.
- constant : true or false. true if constant is included in the model.
- nExo : Number of exogenous variables of the model, exluding lag and constant.
- nLags : Number of lags of the exogenous variables.

Output:

- beta : A constant + AR + nExo*nLags x 1 double vector.

See also:

[nb_midasFunc](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_midasResiduals**

resid = nb_midasResiduals(p,y,x,constant,func,nExo,AR)

Description:

Calculate residuals of the MIDAS model given a parameter set.

Input:

- p : A nParam x 1 double vector.
- y : A nobs x 1 double with the dependent variable of the model.
- x : A nobs x nExo*nLags double with the exogenous variables of the model. Except constant.
- constant : true or false. true if constant is included in the model.
- func : A function handle that map from the non-linear parameters to the linear once.
- nExo : Number of exogenous variables of the model, excluding lag and constant.
- AR : true or false. true if AR specification of the MIDAS model is used.

Output:

- resid : A nobs x 1 double with the residuals of the model.

See also:

[nb_midasMapToLinear](#), [nb_midasFunc](#)

◆ **nb_mlarima**

results = nb_mlarima(y,p,i,q)
results = nb_mlarima(y,p,i,q,sp,sq,constant,z,x,varargin)

Description:

Estimate a ARIMA(p,i,q) or ARIMAX(p,i,q) model using maximum likelihood.

$$\begin{aligned}y(t) &= b \cdot z + u(t) \\u(t) &= \lambda \cdot u(t-1) + c \cdot q + \epsilon(t)\end{aligned}$$

Input:

- y : A nobs x 1 double vector with the time-series.
- p : The AR degree. As a number.
- i : The degree of integration. I.e. the number of times the time-series have to be differenced.
- q : The MA degree. As a number.
- sp : Seasonal autoregressive (SAR) component. E.g. 0 to exclude, 4 for quarterly data, 12 for monthly.
- sq : Seasonal moving average (SMA) component. E.g. 0 to exclude, 4 for quarterly data, 12 for monthly.
- constant : Give 1 if a constant should be included, otherwise 0. Default is 1.
- z : Exogenous regressors in the observation equation. As a nobs x nvards. Default is [].
- x : Exogenous regressors in the transition equation. As a nobs x mvars. Default is [].

Optional inputs:

- 'stabilityTest' : true or false. If true, stability is forced on the model during estimation. Default is true.
- 'test' : true or false. If true an error will be thrown if the model is not stable. Default is true.
- 'optimizer' : See the output from the nb_getOptimizers('arima').
- 'filter' : Give true if you want to run the kalman filter to estimate the residual. Otherwise give 1. Default is false.
- 'covrepair' : Give true to repair the covariance matrix of the estimated parameters if found to not be positive definite. Default is false, i.e. to throw an error if the covariance matrix is not positive definite.
- 'options' : Inputs given to the optimset function. If no optional inputs are given default settings are used. Must be given as a struct or a cell array. If given as a cell array it is given to the optimset function. struct is recommended. See nb_getDefaultOptimset.

Output:

- results : A struct consisting of:

- > beta : The estimated coefficients. Order; constant, AR, MA, SAR, SMA then exogenous.
- > stdBeta : The standard deviation of the estimated coefficients. Order; constant, AR, MA, SAR, SMA then exogenous.
- > tStatBeta : The t-statistics of the estimated coefficients. Order; constant, AR, MA, SAR, SMA then exogenous.
- > pValBeta : The p-values of the estimated coefficients. Order; constant, AR, MA, SAR, SMA then exogenous.
- > sigma : Estimated std of the residual.
- > omega : Covariance matrix of the estimated coefficients including the residual std. Order; constant, AR, MA, SAR, SMA, exogenous then residual std.
- > likelihood : The log likelihood.
- > residual : The filter estimate of the residual. As a nsample x 1 double. Only if the filter input is set to 1.
- > X : Will be empty.
- > y : The model dependent variable. As a nsample x 1 double.
- > u : The residual from the observation equation. If no constant and z is empty this will be equal to y.
- > z : The exogenous variables included in the observation equation.
- > x : The exogenous variables included in the transition equation.

See also:

[nb_getDefaultOptimset](#), [nb_getOptimizers](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_neweyWestRobustSTD**

stdBeta = nb_neweyWestRobustSTD(x, residual)

Description:

Estimation of Newey-West heteroscedasticity and autocorrelation robust standard errors.

See page 36 of Eviews User's Guide 2.

Input:

- x : The regressors of the equation, as a nobs x nvar double.
- u : Residual from regression, as a nobs x neq double.
- xpxi : $(x'x)^{-1}$. If not given it will be calculated.
- restr : A 1 x neq where each element is a 1 x nxvar + extra logical. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included. Each logical element must be true to include in the regression equation of the corresponding equation.

Output:

- stdBeta : Std as a nvar x neq double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_nls

```
[message,beta,stdBeta,tStatBeta,pValBeta,residual,omega] = ...
    nb_nls(init,ub,lb,opt,optimizer,covrepair,func,y,x,constant, ...
    varargin)
```

Description:

Estimate multiple (unrelated) equations using nls.

$y = X \cdot func(beta) + residual$, $residual \sim N(0, residual' \cdot residual/nobs)$ (1)

Input:

- init : Initial values of the parameters of the model to estimate. As a nParam x nEq double.
- ub : Upper bound on the parameters of the model to estimate. As a nParam x nEq or nParam x 1 double. If given as empty inf is default. Only applies if optimizer is set to 'fmincon'.
- lb : Lower bound on the parameters of the model to estimate. As a nParam x nEq or nParam x 1 double. If given as empty -inf is default. Only applies if optimizer is set to 'fmincon'.

- opt : See the optimset function for more on this input. Default values will be used if it is given as [].
- optimizer : The optimizer to be used; 'fminunc', 'fminsearch' or 'fmincon'. 'fmincon' is default, i.e. if not 'fminunc' or 'fminsearch' is provided.
- covrepair : Give true to repair the covariance matrix of the estimated parameters if found to not be positive definite. Default is false, i.e. to throw an error if the covariance matrix is not positive definite.
- func : A function handle that takes the inputs in the following order:
 - > One column from the parameter matrix (i.e. the parameters for one equation at the time)
 - > One column from the y input, i.e. a double with size nobs x 1.
 - > The x input.
 - > The constant input.
 - > The rest of the optional inputs given to this function (varargin)

The output should be a nobs x 1 double with the residuals given the provided parameters.
- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x nxvar of the right hand side variables of all equations of the regression.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.

Optional input:

- 'Aeq' : Aeq*beta = Beq (linear constraints).
- 'Beq' : Aeq*beta = Beq (linear constraints).
- 'NONLCON' : A function handle that return the values of C(beta) and Ceq(beta), where C(beta) <= 0 and Ceq(beta) == 0. E.g. [C,Ceq] = nonlinconstr(beta).
- varargin : The rest will be given as optional inputs to the func input.

Output:

- message : Non-empty if some error are thrown during estimation.
- beta : A (constant + nxvar) x neq matrix with the estimated parameters.
- stdBeta : A (constant + nxvar) x neq matrix with the standard

deviation of the estimated parameters.

- tStatBeta : A (constant + nxvar) x neq matrix with t-statistics of the estimated parameters.
- pValBeta : A (extra + nxvar) x neq matrix with the p-values of the estimated parameters.
- residual : Residual from the estimated equation. As an nobs x neq matrix.
- omega : Covariance matrix of estimated parameters. As (extra + nxvar) x (extra + nxvar) x neq

◆ nb_nwhishart

```
beta = nb_nwhishart(y,x)
[beta,sigma,residual,X] = nb_nwhishart(y,x,prior,constant,timeTrend)
```

Description:

Estimate multiple (related) equations using Normal-Wishart priors.

$y = X\beta + \text{residual}$, $\text{residual} \sim N(0, \sigma)$ (1)

Prior on β : $N(A_{prior}, V_{prior})$
Prior on σ : $IW(S_{prior}, v_{prior})$

Input:

- y : A double matrix of size T x Q of the dependent variable of the regression(s).
- x : A double matrix of size T x N of the right hand side variables of all equations of the regression.
- prior : A structure with the prior specification. If not given the default priors are:
 - > A_prior : 0
 - > V_prior : Identity matrix times 10.
 - > S_prior : 0
 - > v_prior : N + 1
 - > draws : 1For more on this prior see nb_nwhishartPrior.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables. Default is false.

- timeTrend : If a linear time trend is wanted in the estimation.
Will be added first/second in the right hand side
variables. (First if constant is not given, else
second). Default is false.

Output:

- beta : A (extra + nxvar) x nEq x draws matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- sigma : A nEq x nEq x draws matrix with the covariance matrix of residuals.
- residual : Residual from the estimated equation. As an nobs x nEq matrix. If draws > 1, this is calculated at the mean.
- X : Regressors including constant and time-trend. If more than one equation this will be given as kron(I,x).

`nb_nwhishartPrior`, `nb_bayesEstimator`, `nb_singleEq`

Written by Kenneth S. Paulsen

◆ **nb_nwhishartPrior**

`prior = nb_nwhishartPrior(varargin)`

Description:

Set the priors of the type:

`y = X*beta + residual, residual ~ N(0,sigma) (1)`

`y` has size `T x Q`
`X` has size `T x N`

Prior on `beta` : `N(A_prior,V_prior)`
Prior on `sigma` : `IW(S_prior,v_prior)`

- `A_prior` : A scalar double (automatically expanded) or a double with size `N x Q`
- `V_prior` : A scalar double (automatically expanded) or a double with size `(N x Q) x 1` or `(N x Q) x (N x Q)`.
- `S_prior` : A scalar double (automatically expanded) or a double with size `Q x 1`.
- `v_prior` : A scalar double.

Optionsl input:

- Run without inputs to get default priors.
- Run with 'list' as the first input to get a cellstr with the supported prior options.

- Run with 'help' to get a char with help on each option.
- Run with 'optionName' to get help on a particular option, i.e. only one input.
- Use 'optionName', optionValue pairs to set options of the returned struct.

Output:

- Depends on the input.

◆ **nb_ols**

```
beta = nb_ols(y,x)
[beta, stdBeta, tStatBeta, pValBeta, residual, x] = ...
    nb_ols(y,x,constant,timeTrend)
```

Description:

Estimate multiple (unrelated) equations using ols.

$y = X\beta + \text{residual}$, $\text{residual} \sim N(0, \text{residual}' * \text{residual}/nobs)$ (1)

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x nxvar of the right hand side variables of all equations of the regression.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables. Default is false.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second). Default is false.
- stdType : - 'w' : Will return White heteroskedasticity robust standard errors.
- 'nw' : Will return Newey-West heteroskedasticity and autocorrelation robust standard errors.

To estimate the covariance matrix of the estimated parameters the bartlett kernel is used with the bandwidth set to $\text{floor}(4(T/100)^{(2/9)})$ as Eviews also uses.

- 'h' : Will return homoskedasticity only robust standard errors. Default.

Output:

- beta : A (extra + nxvar) x neq matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- stdBeta : A (extra + nxvar) x neq matrix with the standard deviation of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- tStatBeta : A (extra + nxvar) x neq matrix with t-statistics of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- pValBeta : A (extra + nxvar) x neq matrix with the p-values of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- residual : Residual from the estimated equation. As an nobs x neq matrix.
- x : Regressors including constant and time-trend. If more than one equation this will be given as $\text{kron}(I, x)$.

`nb_olsEstimator`, `nb_singleEq`

Written by Kenneth S. Paulsen

◆ **nb_olsRestricted**

```
beta = nb_ols(y,x)
[beta,stdBeta,tStatBeta,pValBeta,residual,x] = ...
    nb_olsRestricted(y,x,restrictions,constant,timeTrend)
```

Description:

Estimate multiple (unrelated) equations using ols.

$y = X\beta + \text{residual}$, $\text{residual} \sim N(0, \text{residual}' * \text{residual}/nobs)$ (1)

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x nxvar of the right hand side variables of all equations of the regression.
- restr : A 1 x neq cell where each element is a 1 x nxvar + extra logical. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included. Each logical element must be true to include in the regressor in the corresponding equation.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables. Default is false.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second). Default is false.
- stdType : - 'w' : Will return White heteroskedasticity robust standard errors.
- 'nw' : Will return Newey-West heteroskedasticity and autocorrelation robust standard errors.

To estimate the covariance matrix of the estimated parameters the bartlett kernel is used with the bandwidth set to floor(4(T/100)^(2/9)) as Eviews also uses.

- 'h' : Will return homoskedasticity only robust standard errors. Default.

Output:

- beta : A (extra + nxvar) x neq matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- stdBeta : A (extra + nxvar) x neq matrix with the standard deviation of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- tStatBeta : A (extra + nxvar) x neq matrix with t-statistics of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- pValBeta : A (extra + nxvar) x neq matrix with the p-values of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- residual : Residual from the estimated equation. As an nobs x neq matrix.

- x : Regressors including constant and time-trend.

Written by Kenneth S. Paulsen

◆ nb_pca

```
F = nb_pca(X)
[F,LAMBDA,R,varF,expl,c,sigma,e] = nb_pca(X,r,method,varargin)
```

Description:

Calculate principal component using either eigenvalue decomposition or single value decomposition.

The following equation applies:

```
X = (c + F*LAMBDA + e).*sigma, e ~ N(0,R) (1)
```

Input:

- x : The data as a nobs x nvar double.

- r : The number of principal component. If empty this number will be found by the Bai and Ng (2002) test, see the optional option crit below, i.e choose the CT part of the selection criterion; $\log(V(ii,F)) + CT$. Where;

```
V(ii,F) = sum(diag(e_ii'*e_ii/T))/ii
```

and e_ii is the residual when ii factors are used

- method : Either 'svd' or 'eig'. Default is 'svd'.

> 'svd' : Uses single value deomposition to construct the principal components. This is the numerically best way, as the 'eig' method could be very unprecise!

> 'eig' : Uses the eigenvalue decomposition approach instead

- Z : Normalized (and rebalanced) version of X.

Optional inputs:

- 'crit' : You can choose between the follwing selection criterion

> 1,10: ii*(NT1/NT)*log(NT/NT1); % IC_p1 and PC_p1 (default)

> 2,11: ii*(NT1/NT)*log(CNT2); % IC_p2 and PC_p1

> 3,12: ii*log(CNT2)/CNT2; % IC_p3 and PC_p1

> 4: ii*2/T; % AIC_1

```

> 5: ii*log(T)/T; % BIC_1
> 6: CT = ii*2/N; % AIC_2
> 7: ii*log(N)/N; % BIC_2
> 8: ii*2*(NT1/NT); % AIC_3
> 9: (ii*NT1*log(NT))/NT; % BIC_3

```

where NT1 = N + T, CNT2 = min(N,T), NT = N*T and ii = 1:rMax.

- 'rMax' : The maximal number of factors to test for. Must be less than or equal to N. Default is N.
- 'trans' : Give 'demean' if you want to demean the data in the matrix X. Give 'standardize' (default) if you want to standardise the data in the matrix X. Give 'none' to drop any kind of transformation of the data in the matrix X.

Caution: To get back X when 'demean' is given you need to add the constant terms in c. I.e;

```
X = c(ones(T,1),1) + F*LAMBDA + e, e ~ N(0,R) (1*)
```

To get back X when 'standardise' you need to add the constant term and multiply with sigma. I.e.

```
X = c(ones(T,1),:) + F*LAMBDA.*sigma(ones(T,1),:)
      eps, eps ~ N(0,R*) (1*)
```

Be aware that the eps differ from e, as e is the residual from the standardised regression.

- 'unbalanced' : true or false. Set to true to allow for unbalanced dataset. Default is false. If false all rows of the dataset containing nan value are removed from calculations. The EM algorithm is essentially the one given in the paper "Macroeconomic Forecasting Using Diffusion Indexes" by Stock and Watson (2002). The algorithm is initialized by filling in missing values with the function nb_estimator.fillInForMissing.
Caution: If all variables has leading or trailing nan, these observations will be discarded.

Output:

- F : The principal component, as a nobs x r double.
- LAMBDA : The estimated loadings, as a r x nvar
- R : The covariance matrix of the residual in (1), as a nvar x nvar double.
- varF : A 1 x r double. Each column will be the variance of the corresponding column of F.
- expl : The percentage of the total variance explained by each

```

    principal component. As a 1 x r double

- c      : Constant in the factor equation. Double with 1 x nvar.

- sigma   : See 'trans'. Double with size 1 x nvar.

- e       : Residual of the equation (1) above. As a nobs x nvar double.

- z       : The normalized version of the input x.

```

Examples:

```

load halld;
[F,LAMBDA,R,varF,expl] = nb_pca(ingredients)
[F2,LAMBDA2,R2,varF2,expl2] = nb_pca(ingredients,[],'eig')

```

◆ **nb_qreg**

```

beta = nb_qreg(y,x)
[beta, stdBeta, tStatBeta, pValBeta, residual, x, betaB] = ...
    nb_qreg(q,y,x,constant,timeTrend,method,draws,restr,waitbar,algo)

```

Description:

Estimate multiple (unrelated) equations using quantile regression.

$y = X\beta + \text{residual}$

Caution: Statistics package needed.

Input:

```

- q      : The quantile(s) of the regression. As a row vector of
            doubles between 0 and 1. If size(y,2) this input must be
            a scalar.

- y      : A double matrix of size nobs x neq of the dependent
            variable of the regression(s).

- x      : A double matrix of size nobs x nxvar of the right
            hand side variables of all equations of the
            regression.

- constant : If a constant is wanted in the estimation. Will be
            added first in the right hand side variables.

- timeTrend : If a linear time trend is wanted in the estimation.
            Will be added first/second in the right hand side

```

variables. (First if constant is not given, else second)

- method : A string with the method to be used to bootstrap the standard errors. See nb_bootstrap for the supported methods or use 'sparsity'. 'sparsity' is default and it uses the asymptotic formulas found in; <https://support.sas.com/documentation/onlinedoc/stat/141/qreg.pdf>
- draws : Number of draws when bootstrapping the standard errors.
- restr : A 1 x neq cell where each element is a 1 x nxvar + extra logical. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included. Each logical element must be true to include in the regression of the corresponding equation. May also be empty, which is default, i.e. no restrictions added.
- waitbar : Add waitbar during estimation. Default is false. true or false.

Output:

- beta : A (extra + nxvar) x neq x numQuantiles matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- stdBeta : A (extra + nxvar) x neq matrix with the standard deviation of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- tStatBeta : A (extra + nxvar) x neq matrix with t-statistics of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- pValBeta : A (extra + nxvar) x neq matrix with the p-values of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- residual : Residual from the estimated equation. As an nobs x neq matrix.
- x : Regressors including constant and time-trend.
- betaB : Distribution of parameters produced by bootstrapping. A (extra + nxvar) x neq x numQuantiles x nDraws matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.

◆ nb_ridge

```
[beta,residual,X] = nb_ridge(y,X,k,constant)
```

Description:

RIDGE estimation. Solves the constrained optimization problem:

$$\min (y - X\beta)^2 + k \sum (\beta(i))^2$$

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- X : A double matrix of size nobs x nxvar of the right hand side variables of all equations of the regression.
- k : The value of k in the minimization problem. Default is $nxvar * \sigma_{ols}^2 / (\beta_{ols}' * \beta_{ols})$, where σ_{ols} is the ols estimator of the residual variance, and β_{ols} is the ols estimate of the model parameters. Must be a scalar number greater or equal to 0.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables. Default is false. The constant term is first estimate by the mean of y, and then y is demeaned before doing the RIDGE estimation.

Output:

- beta : A (extra + nxvar) x neq matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- residual : Residual from the estimated equation. As an nobs x neq matrix.
- X : Regressors including constant. If more than one equation this will be given as $kron(I, x)$.

Written by Kenneth Sæterhagen Paulsen

◆ nb_tsls

```
beta = nb_tsls(y,x,z,inst)
[beta, stdBeta, tStatBeta, pValBeta, residual, x] = ...
    nb_tsls(y,x,z,inst,constant,timeTrend)
```

Description:

Estimate multiple (unrelated) equations using tsls.

Input:

- y : A double matrix of size nobs x neq of the dependent variable of the regression(s).
- x : A double matrix of size nobs x nxvar of the exogenous variables of all equations of the regression.
- z : A double matrix of size nobs x nzvar of the endogenous variables of all equations of the regression.
- inst : A 1 x nzvar cell of the instruments for each endogenous variable. Each element must be a double with size nobs x nzivar. nzivar must be greater than 0.
- constant : If a constant is wanted in the estimation. Will be added first in the right hand side variables.
- timeTrend : If a linear time trend is wanted in the estimation. Will be added first/second in the right hand side variables. (First if constant is not given, else second)

Output:

- beta : A (extra + nxvar + nzvar) x neq matrix with the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- stdBeta : A (extra + nxvar + nzvar) x neq matrix with the standard deviation of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant

and/or time trend is included.

- tStatBeta : A (extra + nxvar + nzvar) x neq matrix with t-statistics of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- pValBeta : A (extra + nxvar + nzvar) x neq matrix with the p-values of the estimated parameters. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included.
- residual : Residual from the estimated equation. As an nobs x neq matrix.
- x : Regressors of final regression including constant, time-trend and instrumented endogenous variables.

◆ **`nb_varStateSpace`**

```
[d,H,R,c,A,B,Q,G,obs] = nb_arimaStateSpace(par,nExo)
```

Description:

Returns a state-space representation of an VARX(nLags) model.

Observation equation:

$y = d + Hx + v$

State equation:

$x = c + Ax_{-1} + Gz + Bu$

Input:

- par : The parameter vector of the VARX model.
 - Order:
 - constant
 - exogenous
 - lagged endogenous
 - residual std
- nDep : The number of dependent variables of the model.
- nLags : the number of lags of the VAR.
- constant : Include constant or not. true or false.
- nExo : Number of exogenous variables included in the model.
- restr : A nDep x nDep*nLags logical matrix. true fro the

non-restricted parameters.

- restrVal : Values of the restricted parameters.

Output:

- See equation above

- obs : Index of observables in the state vector.

Examples:

See also:

[nb_kalmanlikelihood](#)

Written by Kenneth Åtterhagen Paulsen

◆ **nb_whiteRobustSTD**

stdBeta = nb_whiteRobustSTD(x, residual)

Description:

Estimation of White heteroscedasticity robust standard errors.

See page 35 of Eviews User's Guide 2.

Input:

- x : The regressors of the equation, as a nobs x nvar double.
- u : Residual from regression, as a nobs x neq double.
- xpxi : $(x'x)^{-1}$. If not given it will be calculated.
- restr : A 1 x neq where each element is a 1 x nxvar + extra logical. Where extra is 0, 1 or 2 dependent on the constant and/or time trend is included. Each logical element must be true to include in the regression equation of the corresponding equation.

Output:

- stdBeta : Std as a nvar x neq double.

Written by Kenneth Åtterhagen Paulsen

◆ **nb_whiten**

```
F = nb_whiten(X,r)
F = nb_whiten(X,r,varargin)
```

Description:

Calculate of factors from X that have variance one and covariances 0.

Input:

- X : The data as a nobs x nvar double.
- r : The number of principal component. If empty nvar factors are returned.

Optional input:

- 'missing' : Either '' (don't handle missing observations), 'zeros' or 'interpolate'.

Output:

- F : The principal component, as a nobs x r double.

Examples:

```
load hald;
F = nb_whiten(ingredients)
```

See also:

[nb_pca](#), [nb_ts.whiten](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_zeroSpectrumEstimation**

```
[lambda,gamma,bandWidth] = nb_zeroSpectrumEstimation(residual, ...
freqZeroSpectrumEstimator,bandWidth,bandWithCrit)
```

Description:

Estimation of frequency zero spectrum.

Input:

- u : Residual from regression nobs x 1 double.
- kernel : Either:
 - > 'bartlett' : Bartlett kernel function.
Default.

```
> 'parzen'      : Parzen kernel function.  
> 'quadratic'  : Quadratic Spectral kernel  
function.  
  
- bandWidth     : The selected band width of the frequency zero  
spectrum estimation. Default is 3.  
  
- bandWithCrit : Band width selection criterion. Either:  
  
    > 'nw'       : Newey-West selection method.  
                    Default.  
  
    > 'a'        : Andrews selection method. AR(1)  
                    specification.  
  
    > ''         : Manually set by the bandWidth  
                    input.
```

Output:

- lambda : Freq zero spectrum. As a double.
- gamma : Autocorrelation. As a 1 x bandWidth double.
- bandWidth : Selected band width.

► **nb_forecast.addZContribution ↑**

```
[Y,Z] = nb_forecast.addZContribution(Y,model,options,restrictions, ...
inputs,draws,iter)
```

Description:

Add contributions of exogenous variables to idiosyncratic component of the observation equation.

X = G*Z + Y

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.boundedConditionalProjectionEngine ↑**

```
[Emean,Xmean,states,solution]...
= nb_forecast.boundedConditionalProjectionEngine(Y0,A, ...
B,CE,ss,Qfunc,nSteps,restrictions,solution,inputs)
```

Description:

Identify the shocks/residuals to meet the conditional restriction given bounds on some endogenous variables.

See also:

[nb_forecast.conditionalProjectionEngine](#)
[nb_forecast.condShockForecastEngine](#)
[nb_forecast.pointForecast](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.buildShockRestrictions ↑**

```
[R,shocksNumOfAnt,states] = nb_forecast.buildShockRestrictions(AA,B, ...
endoRestInd,numRestShocks,numCondPer,numAntPer,states,append)
```

Description:

Build the a matrix representing the restrictions made by the conditional information. Used to identify the shocks/residual to match the conditional information.

See Kenneth Sæterhagen Paulsen (2010), "Conditional forecast in DSGE models - A conditional copula approach".

Implements the steps in section 3 of setting up the matrix R.

The model is on the form $y(t) = A y(t-1) + \sum_{j=1}^n [B(j) \epsilon_j(t+j)]$

Inputs:

- AA : Model transition matrix raised to the $j - 1$, i.e. page AA(1) = A, AA(2) = A^2 and so on. As a nEndo x nEndo x j double.

- B : Impact matrices for the shocks. (Also anticipated). As a nEndo x nExo x nAnt double.

Outputs:

- R : See equation (20) on page 7 of Kenneth Sæterhagen Paulsen (2010).

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.checkForMissing ↑**

```
[nowcast,missing] = nb_forecast.checkForMissing(options,inputs,dep)
```

Description:

Check for missing data at the end of sample. Only handle one missing observation at the end here!

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.checkSVDPrior ↑**

```
svd = nb_forecast.checkSVDPrior(options)
```

Description:

Check if the stochastic-volatility-dummy prior is used for a VAR model.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.cleanUpInputs ↑**

```
inputs = nb_forecast.cleanUpInputs(inputs)
```

Description:

Clean up inputs so it may be given back to nb_model_generic.forecast when object is being updated.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.computeBoundedForecasts ↑**

```
[Y,E] = computeBoundedForecasts(A,B,C,ss,YF,restrictions,MUX,MUs,inputs,...  
solution,lower,upper,belowL,aboveL,Y,E,iter)
```

Description:

Compute bounded forecast using expected shocks.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.condShockForecastEngine** ↑

```
[Y,states,PAI] = nb_forecast.condShockForecastEngine(y0,A,B,C,ss,Qfunc,MUX,...  
MUs,states,restrictions,nSteps,inputs)
```

Description:

Produce forecast conditional on shocks only forecast with or without
Markov-switching

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.conditionalOnDistributionEngine** ↑

```
[E,X,states,solution] = nb_forecast.conditionalOnDistributionEngine(y0,  
model,ss,nSteps,draws,restrictions,...  
solution)
```

Description:

Conditional on restrictions given by marginal distributions. A copula is used to draw from the marginal given a correlation matrix. For each draw the shocks/residual to match the drawn conditional information is identified. And as a result you end up with the wanted number of draws from the distributions of the shocks/residual to match the conditional information.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.conditionalProjectionEngine** ↑

```
[Emean,Xmean,states,solution]...  
= nb_forecast.conditionalProjectionEngine(Y0,model,ss,nSteps,...  
restrictions,solution,s)
```

Description:

Identify the shocks/residuals to meet the conditional restriction.

See Kenneth Sæterhagen Paulsen (2010), "Conditional forecast in DSGE models - A conditional copula approach".

Implements the steps in section 3.1.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.createParameterUncertaintyWaitbar** ↑

```
[h,inputs] = nb_forecast.createParameterUncertaintyWaitbar(inputs)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.createReportedVariables** ↑

```
[Yout,dep] = nb_forecast.createReportedVariables(options,inputs,Y,...  
dep,start,iter)
```

Description:

Create reported variables based on simulated forecast.

See also:

[nb_forecast.pointForecast](#), [nb_forecast.densityForecast](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.createWaitbar** ↑

```
[h,iter,closeWaitbar] = nb_forecast.createWaitbar(inputs,start,finish)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.defaultInputs** ↑

```
default = nb_forecast.defaultInputs(convert)
```

Description:

Get default struct to give as the input to the inputs input of the nb_forecast function.

Input:

- convert : Convert to struct if set to true, otherwise not. Default is true.

Output:

- default : A N x 3 cell matrix or a struct with N fields.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.densityBootstrap ↑**

```
[Y,XE,solution] = nb_forecast.densityBootstrap(y0,restrictions, ...
                                                 model,options,results,nSteps,iter,inputs,solution)
```

Description:

Produce density forecast of a model using bootstrap.

This function does not handle Markov switching models!

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.densityBootstrapFactorModel ↑**

```
[Y,XE,solution] = nb_forecast.densityBootstrapFactorModel(y0, ...
                                                 restrictions,model,options,results,nSteps,iter,inputs,solution)
```

Description:

Produce density forecast of a factor model using bootstrap.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.densityBootstrapStepAheadFactorModel ↑**

```
[Y,XE] = nb_forecast.densityBootstrapStepAheadFactorModel(y0, ...
                                                 restrictions,model,options,results,iter,inputs)
```

Description:

Produce density forecast of a step ahead factor model using bootstrap.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.densityBootstrapStepAheadModel** ↑

```
[Y,XE] = nb_forecast.densityBootstrapStepAheadModel(...  
    restrictions,model,options,results,nSteps,iter,inputs)
```

Description:

Produce density forecast of a step ahead model using bootstrap.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.densityForecast** ↑

```
[fData,evalFcst,solution] = nb_forecast.densityForecast(y0,...  
    restrictions,model,options,results,nSteps,start,iter,actual,...  
    inputs,solution)
```

Description:

Produce density forecast with wanted method

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.densityFoundReplic** ↑

```
[Y,XE,states,PAI] = nb_forecast.densityFoundReplic(y0,...  
    restrictions,model,options,results,nSteps,iter,inputs)
```

Description:

Produce density forecast using already solved models.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.densityPosterior** ↑

```
[Y,XE,states,solution] = nb_forecast.densityPosterior(y0,restrictions,...  
    model,options,results,nSteps,draws,parameterDraws,iter,inputs,...  
    solution)
```

Description:

Produce density forecast using posterior draws.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.doMeasurementEq** ↑

```
[dep,Y] = nb_forecast.doMeasurementEq(options,results,inputs,nSteps,...  
model,Y,X,dep,iter)
```

Description:

Produce forecast of measurement equation of a model with an observation equation.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.drawMoreFromPosterior** ↑

```
[extra,betaD,sigmaD,yD,pD] = nb_forecast.drawMoreFromPosterior(inputs,...  
coeffDraws)
```

Description:

Check if there has been done enough posterior draws. If there isn't we draw more.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.drawNowcast** ↑

```
y0 = nb_forecast.drawNowcast(options,results,model,inputs,iter)
```

Description:

Produce density nowcast.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.drawNowcastFromKalmanFilter** ↑

```
y0 = nb_forecast.drawNowcastFromKalmanFilter(yD,pD,draws)
```

Description:

Produce density nowcast from kalman filter output.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.drawRegimes ↑**

```
[E,X,states,solution] = nb_forecast.drawRegimes(y0,model,ss,...  
nSteps,draws,restrictions,solution,inputs,options)
```

Description:

Draw regimes.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.drawShocksAndExogenous ↑**

```
[E,X,solution] = nb_forecast.drawShocksAndExogenous(y0,model,ss,nSteps,  
draws,restrictions,solution,inputs,options)
```

Description:

Draw from the shock distribution given the conditional information.

For Markov switching model this method return only one simulated horizon of states. I.e. to take into account the state uncertainty you need to loop this function. This give much more flexibility for the user on how to produce the density forecast.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.estimateAndBootstrapX ↑**

```
XAR = nb_forecast.estimateAndBootstrapX(opt,restr,draws,index,...  
inputs,type)
```

Description:

This is the function that project the exogenous variables of the model when the 'exoProj' input is not empty.

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.evaluateDensityForecast](#)** ↑

```
[fData,evalFcst] = nb_forecast.evaluateDensityForecast(Y,actual,dep,...  
model,options,inputs)
```

Description:

Evalaute density forecasts.

See also:

[nb_forecast.densityForecast](#), [nb_forecast.exprModelDensityForecast](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.evaluatePointForecast](#)** ↑

```
evalFcst = nb_forecast.evaluatePointForecast(Y,actual,dep,model,inputs)
```

Description:

Evaluate point forecast.

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.evaluatePointForecastLowFreq](#)** ↑

```
evalFcst = nb_forecast.evaluatePointForecastLowFreq(evalFcst,options,...  
Y,dep,model,inputs,start)
```

Description:

Evaluate point forecast of low frequency variable of mixed frequency models.

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.expandRestrictionsForBoundedForecast](#)** ↑

```
restrictions = nb_forecast.expandRestrictionsForBoundedForecast(...  
restrictions,nSteps,model)
```

See also:

`nb_forecast.pointForecast`

Written by Kenneth Sæterhagen Paulsen

► `nb_forecast.exprModel` ↑

```
fcst = nb_forecast.exprModel(model,options,results,startInd,endInd,...  
nSteps,inputs)
```

Description:

Produce forecast of a model using expressions, see the `nb_exprModel` class.

Written by Kenneth Sæterhagen Paulsen

► `nb_forecast.exprModelDensityForecast` ↑

```
[fData,evalFcst] = nb_forecast.exprModelDensityForecast(Z,...  
restrictions,model,options,results,nSteps,iter,actual,inputs)
```

Description:

Produce density forecast of a model using expressions using bootstrap.

This function does not handle Markov switching models!

Written by Kenneth Sæterhagen Paulsen

► `nb_forecast.exprModelForecast` ↑

```
[Y,X,dep] = nb_forecast.exprModelForecast(Z,E,nSteps,options,...  
restrictions,results,inputs,model,iter)
```

Description:

Core function for producing forecast from a model using expressions.

This function does not handle Markov switching models!

See also:

[nb_forecast.exprModelPointForecast](#), [nb_forecast.exprModelDensityForecast](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.exprModelPointForecast](#)** ↑

```
[Y,evalFcst] = nb_forecast.exprModelPointForecast(Z,restrictions,...  
model,options,results,nSteps,iter,actual,inputs)
```

Description:

Produce point forecast of a model using expressions.

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.fillInForMissing](#)** ↑

```
MUc = nb_forecast.fillInForMissing(DYbar,myv,nVarY,nCondPer,...  
mev,nVarE,nCondPerE)
```

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.forecastStochasticTrend](#)** ↑

```
[Y,X,E] = nb_forecast.forecastStochasticTrend(y0,restrictions,solution,...  
options,results,nSteps,iter,inputs)
```

Description:

Produce forecast of a DSGE model with a stochastic trends.

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.getActual](#)** ↑

```
actual = nb_forecast.getActual(options,inputs,model,nSteps,dep,startFcst,split)
```

Description:

Get historical data to compare forecast with.

See also:

[nb_forecast](#)

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.getDeterministic`** ↑

```
[X,exo] = nb_forecast.getDeterministic(options,inputs,nSteps,exo,constant)
```

Description:

Add deterministic exogenous vars to conditional information.

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.getDeterministicVariables`** ↑

```
deterministic = nb_forecast.getDeterministicVariables(exo)
```

Description:

Get the deterministic exogenous variables.

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.getEvaluatedVariables`** ↑

```
[Y,dep] = nb_forecast.getEvaluatedVariables(Y,actual,dep,model,inputs)
```

Description:

Get evaluated variables and forecast.

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.getForecastVariables`** ↑

```
dep = nb_forecast.getForecastVariables(options,model,inputs,type)
```

Description:

Get forecast variables from model

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.getMissingFromCondInfo`** ↑

```
[nowcast,missing] = nb_forecast.getMissingFromCondInfo(...  
    options,inputs,restrictions)
```

Description:

Get missing info when conditional information is used. I.e. the conditional information introduce ragged-edge in forecast.

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_forecast.getModelMatrices** ↑

```
model = nb_forecast.getModelMatrices(model,iter,irf,options,nSteps)
```

Description:

Get the model matrices of a given iterative estimation.

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_forecast.getQuantileModel** ↑

```
model = nb_forecast.getQuantileModel(options,model,quantile)
```

Description:

Get the median model when it is estimated with quantile regression.

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_forecast.getSVProcess** ↑

```
s = nb_forecast.getSVProcess(options,start,nSteps,fcstOnly)
```

Description:

Get the stochastic volatility process when the stochastic-volatility-dummy prior

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_forecast.getStartAndEnd** ↑

```
[start,finish,start_est,startFcst] = nb_forecast.getStartAndEnd(...  
inputs,model,options,start,finish)
```

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.getStartingValues ↑**

```
Y0 = nb_forecast.getStartingValues(startingValues,options,solution,...  
results,last)
```

Description:

Get the selected starting values.

See also:

[nb_forecast](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.getStateSpace ↑**

```
[x0,P0,d,H,R,T,c,A,B,Q,G] = nb_forecast.getStateSpace(model,nObs,...  
yHist,nSteps)
```

Description:

Go from the state space representation in the model struct to the state space matrices needed by the [nb_kalmansmooth_missing](#) function.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.interpretBins ↑**

```
inputs = interpretBins(options,inputs)
```

Description:

Interpret the 'bins' input.

See also:

[nb_forecast](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.interpretRestrictions** ↑

```
[bounds, indY] = nb_forecast.interpretRestrictions(bounds, endo, shocks)
```

Description:

Interpret the restrictions given on bounded variables, e.g. zero lower bound

See also:

[nb_forecast.setUpForBoundedForecast](#)
[nb_forecast.boundedConditionalProjectionEngine](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.isMissingVar** ↑

```
missingVar = nb_mlEstimator.isMissingVar(options)
```

Description:

Is the model a missing observation VAR or MF-VAR model estimated with using a kalman filter?

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.kalmanConditionalProjectionEngine** ↑

```
[E,Xmean,solution] = nb_forecast.kalmanConditionalProjectionEngine(...  
    draws,model,s,nSteps,restrictions,solution)
```

Description:

Uses the kalman filter to draw the shocks distributions to match the uncertainty of the endogenous variables returned by the kalman filter.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.map2Density** ↑

```
[Y,X] = nb_forecast.map2Density(dist,Y,X)
```

Description:

Map normalized data to estimated distribution.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_forecast.mapToObservablesMFVAR** ↑

```
[Y,dep] = nb_forecast.mapToObservablesMFVAR(Y,options,model,inputs,start)
```

Description:

Get forecast on the observable variables of a MF-VAR and merge with rest.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_forecast.midas** ↑

```
fcst = nb_forecast.midas(model,options,results,startInd,endInd,...  
nSteps,inputs)
```

Description:

Produce forecast of MIDAS models.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_forecast.midasDensityForecast** ↑

```
[fData,evalFcst] = nb_forecast.midasDensityForecast(y0,restrictions,...  
model,options,results,nSteps,iter,actual,inputs)
```

Description:

Produce density forecast of MIDAS models.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_forecast.midasPointForecast** ↑

```
[Y,evalFcst] = nb_forecast.midasPointForecast(y0,restrictions,model,...  
options,results,nSteps,index,actual,inputs)
```

Description:

Produce point forecast of MIDAS models.

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.midasPrepareForReporting** ↑

```
optLow = nb_forecast.midasPrepareForReporting(options)
```

Description:

Create reported variables based on simulated forecast.

See also:

[nb_forecast.midasPointForecast](#), [nb_forecast.midasDensityForecast](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.multvnrnd** ↑

```
E = nb_forecast.multvnrnd(sigma,nSteps,nSim)
```

Description:

Draw from the multivariate normal distribution

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.pointForecast** ↑

```
[Y,evalFcst,solution] = nb_forecast.pointForecast(y0,restrictions,...  
model,options,results,nSteps,start,iter,...  
actual,inputs,solution)
```

Description:

Produce point forecast.

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.prepareRestrictions`** ↑

```
restrictions = nb_forecast.prepareRestrictions(model,...  
options,results,nSteps,condDB,condDBVars,inputs,shockProps)
```

Description:

Prepare the conditional information for forecasting routines

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.quantileDensityForecast`** ↑

```
YQ = nb_forecast.quantileDensityForecast(y0,restrictions,model,...  
options,results,nSteps,iter,inputs)
```

Description:

Produce density forecast of a model that is estimated with quantile regression. I.e. one "point" forecast given one quantile.

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.removeBeforeEvaluated`** ↑

```
remove = nb_forecast.removeBeforeEvaluated(model,inputs)
```

Description:

Removed variables from evaluated forecast.

Written by Kenneth Sæterhagen Paulsen

► **`nb_forecast.saveToFile`** ↑

```
[evalFcst,saveToFile] = nb_forecast.saveToFile(evalFcst,inputs)
```

Description:

Save forecast evaluation to file.

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.setInitialValues2CondDB](#)** ↑

```
Y0 = nb_forecast.setInitialValues2CondDB(Y0,model,restrictions)
```

Description:

Set intial values to conditional information.

See also:

[nb_forecast](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.setUpForBoundedForecast](#)** ↑

```
inputs = nb_forecast.setUpForBoundedForecast(nSteps,model,restrictions,inputs,nSim)
```

Description:

Prepare stuff for bounded forecast.

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.tvp](#)** ↑

```
[Y,XE] = nb_forecast.tvp(restrictions,model,options,results,nSteps,...  
iter,inputs,type)
```

Description:

Produce forecast of time-varying parameter models.

Written by Kenneth Sæterhagen Paulsen

► **[nb_forecast.uncondForecastEngine](#)** ↑

```
[Y,states,AA] = nb_forecast.uncondForecastEngine(y0,A,B,ss,Qfunc,E,...  
states,transProbInit,maxiter)
```

Description:

Produce unconditional forecast with or without Markov-switching or a break point model.

See also:

[nb_forecast.conditionalProjectionEngine](#), [ms.uncondForecastEngine](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_forecast.undiffARIMA** ↑

```
Y = nb_forecast.undiffARIMA(options,start,Y)
```

Description:

Undiff the forecast to the original level of integration.

Written by Kenneth Sæterhagen Paulsen

► **nb_irfEngine.checkInputFile** ↑

```
[paused, canceling] = nb_irfEngine.checkInputFile(filename)
```

Description:

Check input file

Written by Kenneth Sæterhagen Paulsen

► **nb_irfEngine.collect** ↑

```
irfData = nb_irfEngine.collect(options,inputs,Y,dep,results,ss)
```

Description:

Collect IRFs.

See also:

[nb_irfEngine.irfPoint](#), [nb_irfEngine.irfPointStochTrend](#)

Written by Kenneth Sæterhagen Paulsen

► **`nb_irfEngine.createReportedVariables`** ↑

```
[Y,dep] = nb_irfEngine.createReportedVariables(options,inputs,y0,Y,...  
    dep,results,ss)
```

Description:

Create reported variables based on simulated forecast.

See also:

[nb_irfEngine.collect](#)

Written by Kenneth Sæterhagen Paulsen

► **`nb_irfEngine.doParallel`** ↑

```
[irfDataD,pause] = nb_irfEngine.doParallel(method,model,options,...  
    results,inputs)
```

Description:

Produce IRFs with error bands in parallel.

Written by Kenneth Sæterhagen Paulsen

► **`nb_irfEngine.irfBootstrap`** ↑

```
[irfDataD,pause] = nb_irfEngine.irfBootstrap(model,options,results,...  
    inputs)
```

Description:

Produce IRFs with error bands using bootstrap methods

Written by Kenneth Sæterhagen Paulsen

► **`nb_irfEngine.irfFactorModelBootstrap`** ↑

```
[irfDataD,pause] = nb_irfEngine.irfFactorModelBootstrap(model,...  
    options,results,inputs)
```

Description:

Produce IRFs with error bands of factor models using bootstrap methods.

Written by Kenneth Sæterhagen Paulsen

► **nb_irfEngine.irfIdentDraws** ↑

```
irfDataD = nb_irfEngine.irfIdentDraws(model,options,results,inputs)
```

Description:

Produce IRFs with error bands using uncertainty in identification.

Written by Kenneth Sæterhagen Paulsen

► **nb_irfEngine.irfPoint** ↑

```
irfData = nb_irfEngine.irfPoint(model,options,inputs,results)
```

Description:

Produce point IRF.

Written by Kenneth Sæterhagen Paulsen

► **nb_irfEngine.irfPointStochTrend** ↑

```
irfData = nb_irfEngine.irfPointStochTrend(modelObj,options,inputs)
```

Description:

Produce point IRF of nb_dsgen model with stochastic trend.

Written by Kenneth Sæterhagen Paulsen

► **nb_irfEngine.irfPosterior** ↑

```
[irfDataD,pause] = nb_irfEngine.irfPosterior(model,options,inputs)
```

Description:

Produce IRFs with error bands using posterior draws.

Written by Kenneth Sæterhagen Paulsen

► **[nb_irfEngine.irfWithStochasticTrend](#)** ↑

```
irfData = nb_irfEngine.irfWithStochasticTrend(solution,options,...  
      inputs,results)
```

Description:

Produce point IRF of a DSGE model with stochastic trend.

Written by Kenneth Sæterhagen Paulsen

► **[nb_irfEngine.normalizeToMean](#)** ↑

```
irfData = nb_irfEngine.normalizeToMean(options,inputs,irfData)
```

Description:

Normalize IRFs to mean.

See also:

[nb_irfEngine](#)

Written by Kenneth Sæterhagen Paulsen

► **[nb_irfEngine.report](#)** ↑

```
paused = nb_irfEngine.report(inputs,h,index,kk,jj,display)
```

Description:

Report status

Written by Kenneth Sæterhagen Paulsen

◆ **[nb_calculatePIT](#)**

```
pit = nb_calculatePIT(density, domain, actual)  
pit = nb_calculatePIT(density, domain, actual, fcst)
```

Description:

Calculate PIT of a density forecast given actual data. If the density forecasts are well calibrated, the returned output should be distributed uniformly.

Input:

- density : A nHor x nDomain double with the forecast density at forecast horizons 1 to nHor.

Or a 1 x nHor cell, where each element is a 1 x 2 cell array on the format {typeOfDistribution,parameters}. E.g. {'normal',{0,1}}. See the nb_distribution class for more. the properties type and parameters.
- domain : A nHor x nDomain double storing the domain of the density forecast. I.e.

Caution : Can also be of size 1 x nDomain, but then it is assumed that the domain is the same at all horizons!
- Caution : It is assumed that the domain is equally spaced.
- actual : A nHor x 1 double with the actual data for the horizon of interest
- fcst : If the density is taken from another forecast we need the difference in the mean forecast to move the domain accordingly. A nHor x 1 double.

Output:

- pit : A nHor x 1 double with the PITs

See also:

[nb_model_generic.getPIT](#)

Written by Kenneth Sætherhagen Paulsen

◆ nb_computeForecast

`Y = nb_computeForecast(A,B,C,Y,X,E)`

Description:

Compute forcast of equations on the form;

$$Y(:,t+1) = A*Y(:,t) + B*X + C*E$$

Input:

- A : See the equation above. A nEndo x nEndo double.
- B : See the equation above. A nEndo x nExo double.
- C : See the equation above. A nEndo x nRes double.

- Y : A nEndo x nSteps + 1 double, where the Y(:,1) element must be the initial values.
- X : A nExo x nSteps double with the exogenous forecast data.
- E : A nRes x nSteps double with the residual data. E.g. simulated shocks.

Output:

- Y : The forecast of the endogenous variables as a nendo x nSteps double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_computeForecastAnticipated

Y = nb_computeForecastAnticipated(A,B,C,Y,X,E)

Description:

Compute forcast of equations on the form;

$$Y(:,t+1) = A*Y(:,t) + B*X + C*E$$

Input:

- A : See the equation above. A nEndo x nEndo double.
- B : See the equation above. A nEndo x nExo double.
- C : See the equation above. A nEndo x nResidual double. If C have more pages, it means anticipated shocks.
- Y : A nendo x nSteps + 1 double, where the Y(:,1) element must be the initial values.
- X : A nexo x nSteps double with the exogenous forecast data.
- E : A nres x nSteps double with the residual data. E.g. simulated shocks.

Output:

- Y : The forecast of the endogenous variables as a nendo x nSteps double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_computeForecastAnticipatedBP

```
Y = nb_computeForecastAnticipatedBP(A,B,C,ss,Y,X,E,states)
```

Description:

Compute forecast of equations on the form;

```
Y(:,t+1) = ss{s(t+1)} + A{s(t+1)}*(Y(:,t) - ss{s(t+1)}) +  
B{s(t+1})*X(:,t+1) + C{s(t+1})*E(:,t+1)
```

With unanticipated switching of parameters (also possibly affecting the steady-state)

Input:

- A : See the equation above. A cell array, each element must be a nEndo x nEndo double.
- B : See the equation above. A cell array, each element must be a nEndo x nExo double.
- C : See the equation above. A cell array, each element must be a nEndo x nResidual double. If C have more pages, it means anticipated shocks.
- ss : A cell array with the steady-state of the model. Each element must be a nEndo x 1 double.
- Y : A nEndo x nSteps + 1 double, where the Y(:,1) element must be the initial values.
- X : A nExo x nSteps double with the exogenous forecast data.
- E : A nRes x nSteps double with the residual data. E.g. simulated shocks.
- states : A vector indicating which state we are going to be in at each forecasting steps. A nSteps double, not including the state of the period of the initial condition.

Output:

- Y : The forecast of the endogenous variables as a nEndo x nSteps double.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_computeMidasForecast**

```
Y = nb_computeMidasForecast(A,B,Y,X,E)
```

Description:

Compute forecast of a MIDAS model

Input:

- A : See the equation above. A 1 x 1 double or empty. If not empty a AR component is added to the MIDAS model.
- B : See the equation above. A nSteps x nexo double.
- Y : A 1 x nSteps + 1 double, where the Y(:,1) element must be the initial values.
- X : A nexo x 1 double with the exogenous variables of the model or a nexo x 1 x nSteps double (if the regressors change with the forecasting step (e.g. MIDAS beta lag model!))
- E : A 1 x nSteps double with the residual data. E.g. simulated shocks.

Output:

- Y : The forecast of the endogenous variables as a 1 x nSteps double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_conditionalSecondOrderMoments

```
c = nb_conditionalSecondOrderMoments(A,B,C,vcv,varX,nSteps)
c = nb_conditionalSecondOrderMoments(A,B,C,vcv,varX,nSteps,...  
type,depInd)
```

Description:

Calculate conditional second order moments of a model on a state space form.

$$y(t) = A(s)y(t-1) + B(s)x(t) + C(s)e(t)$$

where:

$$\begin{aligned}x(t) &\sim N(0, varX) \\ e(t) &\sim N(0, vcv(s))\end{aligned}$$

Input:

- A : See above.
- B : See above.
- C : See above.
- vcv : See above.
- varX : See above.
- Q : Transition probability matrix. If this is not empty the A, B, C and vcv inputs must be of class cell.

- nSteps : Numbr of steps ahead to calculate the condition second order moments.
- type : Either 'covariance' (default) or 'correlation'.
- depInd : Index of the endogneous variables you want the second order matrix of. As a 1 x N integer. Defualt is to return the covariance/correlation matrix of all endogneous variables.

Output:

- c : A nVar*nSteps x nVar*nSteps double.

See also:

[nb_forecast.buildShockRestrictions](#)

Written by Kenneth Sætherhagen Paulsen

◆ nb_defaultWeights

`weights = nb_defaultWeights(scores, varargin)`

Description:

Convert scores into weights using the formula:

`weight(h, v, c, i) = score(h, v, c, i) / sum_i(score(h, v, c, i))`

where h is the horizon, v is the variable, c is the context and i is the model.

Input:

- scores : A nHor x nVar x nContexts x nModel double.

Optional input:

- 'num' : Only keep X number of models. Must be a scalar integer > 0. If this number is larger than the number of models, all models are selected. The rest of the model is weights as described.
- 'perc' : Only keep the X% best models. Must be a scalar double between 1 and 100. Caution: Will use the ceil operator, to ensure that the number of selected models are strictly positive and an integer. The rest of the model is weights as described. Must be a scalar integer > 0.
- 'remove' : Remove X number of models. Must be a scalar integer > 0. If this number is larger than the number of models, one model is selected.

Output:

- weights : A nHor x nVar x nContexts x nModel double.

See also:

[nb_model_group_vintages.constructWeights](#)
[nb_model_group_vintages.combineForecast](#)

Written by Kenneth Å!terhagen Paulsen

◆ nb_dieboldMarianoTest

```
[test,pval] = nb_dieboldMarianoTest(y1,y2,actual,bandWidth,...  
    bandWidthCrit)  
[test,pval] = nb_dieboldMarianoTest(y1,y2,actual,bandWidth,...  
    bandWidthCrit,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Implements section of Timmermann and Zhu (2019), Comparing Forecasting Performance with Panel Data when multivariate is set to true.

Caution: Handle nan values in y1, y2 and actual.

Input:

- y1 : Forecast of model 1. A double with size nobs x nvar x nhor.
- y2 : Forecast of model 2. A double with size nobs x nvar x nhor.
- actual : Actual data. A double with size nobs x nvar.
- bandWidth : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the bandWithCrit input. Must be set to an integer greater then 0.
- bandWidthCrit : Band width selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.

Optional inputs:

- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : Test statistic. As a nhor x nvar (1) double.
- pval : P-value of test statistic. As a nhor x nvar (1) double.

◆ nb_estimateKernelDensity

```
density = nb_estimateKernelDensity(Y,int,varargin)
```

Description:

Get kernel density estimate given forecast and evalutaion points

Input:

- Y : A nHor x nVar x nDraws double with the simulated forecasts.
- int : The output from nb_getDensityPoints
- varargin : Optional inputs given to the nb_ksdensity function

Output:

- density : A 1 x nVar cell with the stored densities of the forecast.

See also:

Written by Kenneth Sætherhagen Paulsen

◆ nb_evaluateDensity

```
fcstEval = nb_evaluateDensityForecast(type,data,density,domain,...  
                                         meanForecastData,forecastData,dist)
```

Description:

Evaluate density forecast given a density and mean forecast.

Input:

```

- type          : Type of evaluation (Could be a cellstr with more
                  of these):
                  - 'se'           : Square error
                  - 'abs'          : Absolute error
                  - 'diff'         : Forecast error
                  - 'logscore'     : Log score

- data          : The true data to be evaluated against. As a nobs x
                  nvar double.

- density       : A 1 x nVars x nPeriods cell. Each element is a double
                  with size nHor x nDomain.

- int           : A 1 x nVars x nPeriod cell. Each element is a double
                  with size 1 x nDomain.

- meanForecastData : A double with size nobs x nvar with the mean
                  forecast. If empty it will be calculated.

- forecastData  : A double with size nobs x nvar x nsim with the
                  density forecast.

- dist          : A nHor x nVars x nPeriods nb_distribution object.
                  If this input is provided, these distributions will
                  be the basis for the calculated log scores.

```

Output:

```

- fcstEval : A Struct with the following properties:

    > (x)      : The evaluation score. As a nHor x nvar
                  double.

    > density : A 1 x nVar cell. Each element consist of nHor
                  x nPoints. For each variable the values of
                  the density at the given points is stored.

    > int      : A 1 x nVar cell. Each element consist of nHor
                  x nPoints. For each variable the points where
                  the density is evaluated is stored.

```

Written by Kenneth Sæterhagen Paulsen

◆ nb_evaluateDensityForecast

```
fcstEval = nb_evaluateDensityForecast(type,data, ...
                                       forecastData,meanForecastData,inputs)
```

Description:

Evaluate density forecast given a simulated density and mean forecast.

Input:

```

- type          : Type of evaluation (Could be a cellstr with more
                  of these):
                  - 'se'           : Square error
                  - 'abs'          : Absolute error
                  - 'diff'         : Forecast error
                  - 'logscore'     : Log score

- data          : The true data to be evaluated against. As a nobs x
                  nvar double.

- forecastData : A double with size nobs x nvar x nsim with the
                  density forecast.

- meanForecastData : A double with size nobs x nvar with the mean
                  forecast. If empty it will be calculated.

- inputs        : A struct with the following fields (You don't need
                  to provide this input):
                  > 'bins'          : See the 'bins' option of the
                                      uncondForecast method of the
                                      nb_model_generic class.
                  > 'estDensity'    : See the 'estDensity' option of the
                                      uncondForecast method of the
                                      nb_model_generic class.

```

Output:

```

- fcstEval : A Struct with the following properties:
              > <type>   : The evaluation score. As a nHor x nvar
                            double.

              > density   : A 1 x nVar cell. Each element consist of
                            nHor x nPoints. For each variable the
                            values of the density at the given points
                            is stored.

              > int       : A 1 x nVar cell. Each element consist of
                            nHor x nPoints. For each variable the
                            points where the density is evaluated is
                            stored.

```

Written by Kenneth Sæterhagen Paulsen

◆ nb_evaluateDensityForecastOnlyScore

```
score = nb_evaluateDensityForecastOnlyScore(type,data,forecastData,...  
meanForecastData)
```

Description:

Evaluate density forecast given a simulated density and mean forecast.

Input:

- type : Type of evaluation (Could be a cellstr with more of these):
 - 'se' : Square error
 - 'abs' : Absolute error
 - 'diff' : Forecast error
 - 'logscore' : Log score (Based on a normal distribution)
- data : The true data to be evaluated against. As a nobs x nvar double.
- forecastData : A double with size nobs x nvar x nsim with the density forecast.
- meanForecastData : A double with size nobs x nvar with the mean forecast. If empty it will be calculated.

Output:

- fcstEval : The evaluation score. As a nHor x nvar double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_evaluateForecast

```
score = nb_evaluateForecast(type,data,forecastData)
```

Description:

Evaluate

Input:

- type : Type of evaluation:
 - 'se' : Square errors
 - 'abs' : Absolute error
 - 'diff' : Forecast error
- data : The true data to be evaluated against. As a nobs x nvar double.
- forecastData : A double with size nobs x nvar.

Output:

- score : The evaluation score. As a nSteps x nvar double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_forecast

```
forecastDB = nb_forecast(model,options,results,startInd,endInd,nSteps,...  
                         inputs,condDB,condDBVars,shockProps)
```

Description:

Do conditional forecast with a model written on a companion form.

See Junior Maih (2010), Conditional forecast in DSGE models and Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

This function makes it also possible to use arbitrary distribution to draw from to make uncertainty bands:

1. It is possible to identify the shock given the conditional information and then using the shockProps input to specify the distributions to draw from around the identified shocks. It is important that the mean of the specified distributions are the same as the identified shocks!
2. It is possible to use the condDB input to provide the distributions to condition on. Then by using the correlation matrix provided by inputs.sigma and a gaussian copula random draws are made from the multivariate conditional distribution. For each draw the shocks to match the conditional information are found and the conditional forecasts for that draw is produced. This will map the distribution of the conditional information into restrictions on the distribution of the shocks. You should check the distribution of the shocks after using this algorithm to assure you that the identification has succeeded.

Input:

- model : See the solution property to the model object being forecasted. E.g. the property solution of the nb_model_generic class.
- options : Estimation options. Output from the estimator functions. E.g. nb_olsEstimator.estimate.
- results : Estimation results. Output from the estimator functions. E.g. nb_olsEstimator.estimate.
- startInd : The start period of the forecast. (I.e. history + 1)
- endInd : If recursive conditional forecast is wanted this period must be provided. Be aware that the condDB input must then have its third dimension set to:

nPeriods = endInd - startInd + 1

If empty nPeriods = 1.
- nSteps : The number of steps to forecast. Default is 8.

- inputs : A struct with fields (See nb_model_generic.forecast)
- condDB : One of the following:
 - > A double with size nSteps x nCondVar x nPeriods with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A double with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on.

If you condition on endogenous variables (only) and no residuals/shocks this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced or forecast condition on exogenous variables set to zero (Except seasonals, constant and time-trend)
- condDBVars : A cellstr with the variables to condition on. Can include endogenous, exogenous and shock variables.
- shockProps : A 1xnExo struct with fields:
 - > Name : The name of the residual/shock to use to match the conditional information. If an exogenous variable is not included here, it means that it is not activated.

```

> StandardDeviation : Standard deviation of the shock.
    This option can be used to adjust
    the standard deviation away from the
    estimated one. If given as nan the
    estimated one is used.

> Horizon           : Anticipated horizon of the shocks.

> Periods            : The active periods of the shock. If
    nan, the shock is active for all
    periods.

```

Output:

- forecast : A struct with the forecast output.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_getDensityPoints**

```
int = nb_getDensityPoints(Y,bins,scale)
```

Description:

Get selected bins of the distribution. I.e. the stored points of the distribution

Input:

```

- Y      : A nHor x nVar x nDraws double with the simulated forecasts.

- bins   : The length between the points of the distribution.

> []      : The domain will be found. (default is that 1000
    observations of the density is stored).

> integer : The min and max is found but the length of the bins
    is given by the provided integer.

> cell    : Must be on the format:

    {indVar1,lowerLimit1,upperLimit1,binsL1;
     indVar2,lowerLimit2,upperLimit2,binsL2;
     ...}

- lowerLimit1 : An integer, can be nan, i.e. will
    be found.

- upperLimit1 : An integer, can be nan, i.e. will
    be found.

- binsL1      : An integer with the length of the
    bins. Can be nan. I.e. bins length
    will be adjusted to create a
    domain of 1000 elements.

```

```
- scale : Number of standard deviation to add at ends of the domain.  
Default is 2;
```

Output:

```
- int : A 1 x nVar cell with the selected evaluation points of the  
density. (Which is yet to be found, see  
nb_estimateKernelDensity)
```

See also:

[nb_estimateKernelDensity](#), [nb_evaluateDensityForecast](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_hdi

```
ci = nb_hdi(data)  
ci = nb_hdi(data,limits,dim,varargin)
```

Description:

Construct credibility interval by the highest density interval method

Input:

```
- data : A dim1 x dim2 x dim3 double. Can include nan values  
- limits : The wanted limits, as a 1 x nLim. E.g:  
    - 0.9      : Gives the 90 percent highest density interval.  
                  (Default)  
    - [0.1,0.2] : Gives the 10 and 20 percent highest density  
                  intervals.  
- dim : The dimension to calculate the highest density interval over.  
Default is 1.
```

Optional inputs:

```
- varargin : Optional input given to the nb_ksdensity function.
```

Output:

```
- ci : A double where the dimension given by dim has been changed to  
match the number of found intervals (these may be more than  
nLim*2, as this measure over intervals may be  
non-overlapping).  
- limInd : A double matching the return number of intervals. If  
ci is a dim1 x dim2 x rLim, then this output is 1 x 1 x rLim  
cellstr.
```

Examples:

```
[ci,limInd] = nb_hdi(randn(100,1),[0.1,0.2],1)
```

See also:

[nb_ksdensity](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_identifyShocks**

```
E = nb_identifyShocks(A,B,C,Y0,X,E,MUy,indY)
```

Description:

Compute forecast of equations on the form;

```
Y(:,t) = A*Y(:,t-1) + B*X(:,t) + C*E(:,t)
```

But where the $Y(:,t)$ for each iteration is set to its conditional restrictions.

Input:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nresidual double.
- Y0 : A nendo x 1 double, with the initial values.
- X : A nexo x nSteps double with the exogenous forecast data.
- E : A nres x nSteps double with the residual data. E.g. simulated shocks.
- MUy : A nvar (<nendo) x nSteps double.
- indY : The location of MUy in Y. First dimension.

Output:

- E : Identified shocks, as nShock x nSteps double.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_irfEngine**

```
[irfData,paused] = nb_irfEngine(solution,options,inputs)
```

Description:

Calculate irfs (with error bands) with a model written on a companion form.

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- solution : A struct storing the companion form of the model. See the help on the property nb_model_generic.solution for more on this input.
- options : Estimation options. Output from the estimator functions. E.g. nb_olsEstimator.estimate.
- results : Estimation results. Output from the estimator functions. E.g. nb_olsEstimator.estimate.
- inputs : A struct with different inputs. See nb_model_genric.irf.

Output:

- irfData : If perc is empty; A periods + 1 x nVar x nShocks otherwise; A periods + 1 x nVar x nShocks x nPerc + 1, where the mean will be at irfData(:,:, :, end)
- paused : true or false

Written by Kenneth Sætherhagen Paulsen

◆ **nb_kernelCDFBounds**

```
out = nb_kernelCDFBounds(type)
```

Description:

See output.

Input:

- type : 1: Lower. 0: Upper.

Output:

- out : Upper or lower bound on CDF estimation by kernel methods.

See also:

[nb_evaluateDensityForecast](#), [nb_simulateFromDensity](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_kolsrudJointPredictionBands**

KJPB = nb_kolsrudJointPredictionBands(fcst,percUL)

Description:

Calculate joint prediction bands due to Dag Kolsrud (2015):
"A time-simultaneous prediction box for a multivariate time series", Journal of Forecasting.

Input:

- fcst : A nHor x nVar x nDraws double
- percUL : A 1 x nPerc double with the percentiles to calculate.
E.g. [5,15,25,35,65,75,85,95]

Output:

- KJPB : A nHor x nVar x nDraws double.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_makeArtificial**

YDRAW = nb_makeArtificial(model,options,results,method,replic)

Description:

Make artificial data using bootstrap methods.

See also:

[nb_irfEngine](#), [nb_uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_mincerZarnowitz**

[test,pval] = nb_mincerZarnowitz(actual,predicted)

Description:

Do the Mincer-Zarnowitz test for bias in the forecast from a model.

```
actual = beta_0 + beta_1*predicted + e
```

Caution: Handles nan values in the predicted and the actual inputs!

Input:

- actual : A nobs x nvar double with the actual data to compare against.
- predicted : A nobs x nvar x nhor double with the predictions at horizon 1:nhor for observation 1:nobs.

Output:

- test : The F-test statistic of $\beta_0 = 0$ and $\beta_1 = 0$. Will be of size nhor x nvar.
- pval : The p-value of the test statistic. Found from the $F(2, nobs-2)$ distribution. Will be of size nhor x nvar.

See also:

[nb_uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_restrictedWeights

```
weights = nb_restrictedWeights(scores, limits, selectors)
```

Description:

Convert scores into weights using the formula:

```
weight(h,v,c,i) = score(h,v,c,i)/sum_i(score(h,v,c,i))
```

but were the number of kept models are given some criteria and dependent on the number of models that are being weighted.

Input:

- scores : A nHor x nVar x nContexts x nModel double.
- limits : A 1 x N - 1 double with the limits of the N selectors. Default is [10,100]. The limits apply to the number of models. By the default we use selector 1, if number of models are less than 10. Selector 2 if models are less than 100, and selector 3 if greater or equal to 100.
- selectors : A 1 x N cell array with the selectors for each interval. The selectors must take one input, and return the number of selected numbers out of the number provided models. Default is {@(x)max(3,round(x*0.5)), @(x)max(5,round(x*0.2)), @(x)20}

Output:

- weights : A nHor x nVar x nContexts x nModel double.

See also:

[nb_model_group_vintages.constructWeights](#)
[nb_model_group_vintages.combineForecast](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_scoreType2evalType

[evalType,type] = nb_scoreType2evalType(type)

Description:

Get evaluation type from score type.

Input:

- type : Score type, as a one line char. May include a frequency frequency postfix (_4 or _12).

Output:

- evalType : Evaluation type, as a one line char. With frequency postfix.
- type : Score type, as a one line char. Without frequency postfix.

Written by Kenneth Sæterhagen Paulsen

◆ nb_simulateFromDensity

Y = nb_simulateFromDensity(density,int,nDraws)

Description:

Simulate from known densities.

Inspired by the function density2Simulation from the PROFOR Team.

Input:

- density : One of:
> A 1 x nVars x nPer cell. Each element consist of a nHor x nDomain double storing the densities evaluated at a domain with nDomain elements at all forecasting horizons nHor. The dimension 2 of each element of the density cell matrix must match match the dimension 2 of each element of the cell matrix int.

```

> A nHor x nDomain x nPer double (int must also be a double).

- int      : A 1 x nVars x nPer cell. Each element must store a 1 x
              nDomain or a nHor x nDomain double, storing the domain of
              the density located at the same location in the density
              input.
> A nHor x nDomain x nPer double.

- nDraws   : An integer. Default is 1000.

```

Output:

```

- Y       : Dependent on input:
> cell    : A nHor x nVars x nPer x nDraws double.
> double  : A nHor x nDraws x nPer

```

See also:

[nb_model_group.combineForecast](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_varDecomp**

```
decomp = nb_varDecomp(model,options,results,inputs)
```

Description:

Variance decomposition of a model on the companion form.

Input:

```
- model    : A struct storing the companion form of the model:
```

```
    y_t = A*y_t_1 + B*x_t + C*e_t
```

Fields:

```
> A      : See the equation above. A nendo x nendo
            double.
```

```
> B      : See the equation above. A nendo x nexo
            double.
```

```
> C      : See the equation above. A nendo x nresidual
            double.
```

```
> endo : A cellstr with the decleared endogenous
            variables.
```

```
> exo  : A cellstr with the decleared exogenous
            variables.
```

```
> res  : A cellstr with the decleared
```

residuals/shocks.

```

> vcv   : Variance/covariance matrix of the
           residuals/shocks.

- options   : Estimation options. Output from the estimator functions.
              E.g. nb_olsEstimator.estimate.

- results   : Estimation results. Output from the estimator functions.
              E.g. nb_olsEstimator.estimate. Need the residual to
              bootstrap.

- inputs    : See nb_model_genric.variance_decomposition.

```

Output:

```

- decomp : If perc is empty; A nHor x nShocks + 1 x nVar
           otherwise; A nHor x nShocks + 1 x nVar x nPerc + 1,
           where the median will be at decomp(:,:, :, end).

```

Caution: The residual variance will be at decomp(:, end, :, :)

Caution: See the input output!

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.

As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

► **`appendData`** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters ↑**

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.

- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!

- 'instrument' : A one line char with the name of the instrument. Must be provided!

- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!

- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.

- 'perc' : Error band percentiles. As a 1 x nPerc double.
E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will
be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the
double method on this output to convert it to a double
matrix.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws
(bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see
[nb_bootstrap](#). For bayesian models 'posterior' is the only
option. Default is 'bootstrap' for classical models, while
'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is
1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property
is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterioriors** ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optional input:

- `'nLags'` : Number of lags to include in the autocorrelation plot. Default is 10.
- `'iter'` : The recursive iteration date. Either as a string or a `nb_date` object. If recursive estimation is done, this input must be provided.

Output:

- `DB` : A `nb_data` object with size `nDraws x numCoeff`.
- `plotter` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.
- `pAutocorr` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.

Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
                    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [convert ↑](#)

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► [convertEach ↑](#)

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_MODELDATA`

► `createVariables` ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM `nb_modelData` object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.

> third column : Any expression that can be interpreted by the `nb_ts.createShift` method.

> fourth column : Comments

- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name,    input,    shift,    description
  'VAR1_G',    'pcn(VAR1)', 'avg',    'VAR1 growth'
  'VAR2_G',    'pcn(VAR2)', 'avg',    'VAR2 growth'
  'VAR3_G',    'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

[nb_model_generic.transformations](#), [nb_model_generic.reporting](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► dieboldMarianoTest ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

[nb_arima.uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **doForecastPerc2Dist ↑**

```
obj = doForecastPerc2Dist(obj,draws)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_arima.forecast](#), [nb_arima.forecastPerc2Dist](#)

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity** ↑

`obj = doSimulateFromDensity(obj, draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `obj` : A `nb_model_forecast` object.
- `draws` : Number of draws to use for simulation.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_model_generic.forecast`, `nb_arima.simulateFromDensity`

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_generic` object. The `options.data` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
 - varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
 - varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.
- E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

Inherited from superclass NB_MODEL_GENERIC

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj        = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default

is to open max number of cores available. Only an option if 'parallel' is given.

- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecast** ↑

```
obj          = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for forward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters

for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
 - 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.
- If set to empty, all simulations will be returned.
- Caution: 'draws' must be set to produce density forecast.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

```

- 'bins'          : The length of the bins og the domain of the density.
                    Either;
                      > []      : The domain will be found. See
                        nb_getDensityPoints (default is that 1000
                        observations of the density is stored).
                      > integer : The min and max is found but the length
                        of the bins is given by the provided
                        integer.
                      > cell     : Must be on the format:
                        {'Var1',lowerLimit1,upperLimit1,binsL1;
                         'Var2',lowerLimit2,upperLimit2,binsL2;
                         ...}
                      - lowerLimit1 : An integer, can be nan,
                        i.e. will be found.
                      - upperLimit1 : An integer, can be nan,
                        i.e. will be found.
                      - binsL1      : An integer with the
                        length of the bins. Can
                        be nan. I.e. bins length
                        will be adjusted to
                        create a domain of 1000
                        elements.

Caution : The variables not included will be given
           the default domain. No warning will be
           given if a variable is provided in the
           cell but not forecast by the model. (This
           because different models can forecast
           different variables)

Caution : The combineForecast method of the
           nb_model_group class is much faster if the
           lower limit, upper limit! Or else
           it must simulate new draws and do kernel
           density estimation for each model again
           with the shared domain of all models
           densities.

- 'startDate'    : The start date of forecast. Must be a string or an
                    object of class nb_date. If empty the estim_end_date
                    + 1 will be used.

Caution: If 'fcstEval' is not empty this will set
         the start date of the recursive forecast.
         Default is to start from the first possible
         date.

- 'endDate'      : The end date of forecast. Must be a string or an
                    object of class nb_date. If empty the estim_end_date
                    + 1 will be used.

Caution: If 'fcstEval' is empty this input will

```

have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).
- All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous

variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
If not provided. Model stds are used.
- > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
- > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for

all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.
- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime

is not given, you will start in
 the ergodic steady-state for
 MS-model, and in the last regime
 for break-point models.

- 'startingProb' : Either a double or a char:
 > 'zero' : Start from zero on all variables
 (Except for the deterministic
 exogenous variables)

> [] : If the model is filtered the
 starting value is calculated
 on filtered transition
 probabilities. Otherwise the
 ergodic mean is used.

> double : A nPeriods x nRegime or a 1 x
 nRegime double. nPeriods refer to
 the number of recursive periods to
 forecast.

> 'ergodic' : Start from the ergodic transition
 probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws
 that give rise to an unstable model. Default
 is false.

- 'states' : Either an integer with the regime to
 forecast/simulate in, or an object of class nb_ts
 with the regimes to condition on. The name of the
 variable must be 'states'.

Caution: For break-point models this is decided by
 the dates of the breaks, and cannot be set
 by this option!

- 'compareToRev' : Which revision to compare to. Default is final
 revision, i.e. []. Give 5 to get fifth revision.
 must be an integer. Keep in mind that this number
 should be larger than the nSteps input.

- 'compareTo' : Sometime you want to evaluate the forecast of one
 variable against another variable which is not
 part of the model. E.g. if you use the first release
 of a variable and want to compare it against the
 final release. To do this you can give a cellstr
 with size n x 2, where n is the number of variables
 to change the the actual observations to test
 against. {'VAR_1','VAR_FINAL',...}.

- 'estimateDensities' : true or false. true if you want to do a
 kernel density estimation of the density
 forecast.

- 'exoProj' : Tolerate missing exogenous variables by projecting
 them by a fitted model. Only when the 'condDB'
 input is empty!

Options are:

- '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.

- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.

- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example

{'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when `exoProj` is set to 'AR'.

- 'bounds'
: A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps` double matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a 1x1 double or a `nSteps x 1` double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs'
: This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.

- 'foundReplic'
: A struct with size `1 x parameterDraws`. Each element must be on the same format as `obj.solution`. I.e. each element must be the solution of the model given a set of drawn parameters. See the `parameterDraws` method of the `nb_model_generic` class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.

```
- 'seed' : Set simulation seed. Default is 2.0719e+05.
```

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_arima.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_arima.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_arima.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
    nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getCondDB ↑

[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments ↑**

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

See also:

[nb_var](#), [nb_var.priorTemplate](#)

Inherited from superclass NB_MODEL_GENERIC

► **getDependent ↑**

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getFiltered ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables. I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsgen.filter](#), [nb_arima.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast** ↑

```
fcstData          = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();
```

```

    end

> 'date'      : A string or a nb_date object with the date of the
                 wanted forecast. E.g. '2012Q1'. The fcstData will
                 be a nb_ts object with size nHor x nVar x nPerc + 1,
                 while fcstPercData will be empty. nPerc will then be
                 the number of percentiles/simualtions. Mean will be at
                 last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'   : This option will return the forecast as a
                 nPeriods + nHor x nVar x nHor nb_ts object. This
                 option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).

```

Optional inputs:

```

> 'horizon'   : The fcstData output will be a nb_ts object with
                 size nRec x nVars. While the fcstPercData output
                 will be a nb_ts object with size nRec x nVars x nSim.
                 You can set the horizon to return by the optional
                 input 'horizon'. See the 'timing' option also.

```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_arima.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► [getForecastVariables ↑](#)

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

p = getParameters(obj,varargin)

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as

fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

- : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
- : Give 'double' to return the value as a numerical array.
- : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

See also:

[nb_graph_ts](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveScore ↑**

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

`nb_model_generic.forecast`, `nb_model_generic.constructScore`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **getResidual** ↑

`residual = getResidual(obj)`

Description:

Get residual from a estimated `nb_model_generic` object

Input:

- `obj` : An object of class `nb_model_generic`

Output:

- `residual` : Either a `nb_ts` or a `nb_cs` object with `residual(s)` stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualGraph** ↑

`plotter = getResidualGraph(obj)`

Description:

Get residual graph from the given estimator. The returned will be an object of class `nb_graph`, which you can call the `graphInfoStruct` method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- `obj` : An object of class `nb_model_generic` (or a subclass of this class).

Output:

- `plotter` : An object of class `nb_graph`. Use the `graphInfoStruct` method or the `nb_graphInfoStructGUI` class.

Examples:

```
plotter = getResidualGraph(obj);
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of `nb_model_generic` object

Input:

- `obj` : A vector of `nb_model_generic` objects

Output:

- `residualNames` : A cellstr with the unique residual names of all the models

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method `solve`.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getScore ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.

- type : A string with one of the following:
- 'RMSE' : One over root mean squared error
- 'MSE' : One over mean squared error
- 'MAE' : One over mean absolute error
- 'MEAN' : One over mean error
- 'STD' : One over standard error of the forecast error
- 'ESLS' : Exponential of the sum of the log scores
- 'EELS' : Exponential of the mean of the log scores
- 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.

- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution ↑**

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_arima.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **help ↑**

```
helpText = nb_arima.help
helpText = nb_arima.help(option)
helpText = nb_arima.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **initialize ↑**

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:**Input:**

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given,

otherwise this option does not apply.

- 'optimizer'
 - : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset'
 - : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel'
 - : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters'
 - : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.
- 'periods'
 - : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate'
 - : The start date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest'
 - : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch'
 - : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale'
 - : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights'
 - : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

[nb_arima.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf** ↑

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgc objects.
- 'compare' : Give true if you have a scalar nb_dsgc model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

```

- 'draws' : Number of draws for calculating girf. Default is
           1000. For Markov switching models this will set the
           number of simulated paths of states. For more see
           the 'type' input.

- 'factor' : A cell array with the factors to multiply the
             irf of the individual model variables.
             I.e. {'var1',100,...} or
                  {'var1','var2'},100,...}

If the string starts with a asterisk you will
multiply all the variables that contain that
string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This option sets the error band percentiles of the
               graph, when the 'perc' input is empty. As a 1 x
               numErrorBand double. E.g. [0.3,0.5,0.7,0.9].
               Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element
                  must be on the same format as obj.solution. I.e.
                  each element must be the solution of the model
                  given a set of drawn parameters. See the
                  parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from
                  this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

    > 'cumulative product' : cumprod(1 + X,1)

    > 'cumulative sum' : cumsum(X,1)

    > 'cumulative product (log)' : log(cumprod(1 + X,1))

    > 'cumulative sum (exponential)' : exp(cumsum(X,1))

    > 'cumulative product (%)' : cumprod(1 + X/100,1)

    > 'cumulative sum (%)' : cumsum(X/100,1)

    > 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))

    > 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))

    > '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
             Default is ''. See help on the method input of the
             nb_model_generic.parameterDraws method for more
             this input. An extra option is:

    > 'identDraws' : Uses the draws of the matrix with
                    the map from structural shocks to dependent

```

variables. See `nb_var.set_identification`. Of course this option only makes sense for VARs identified with sign restrictions.

- `'normalize'` : A 1 x 3 cell. First element must be the variable name as a string. The second element must be the value to normalize to, as an integer. While the third element is the period to be normalized, if set to `inf`, it will normalize the max impact period.
E.g. `{'Var',1,2}, {'Var',1,inf}`
Caution: 2 means observation 2 of the IRF, and as the IRF start at period 0, this means that observation 2 is period 1.
- `'normalizeTo'` : 'draws' or 'mean'. 'draws' normalize each draw of irfs, while 'mean' normalize the mean and scale percentiles/other draws accordingly. Default is 'draws'.
Caution: Setting this to 'mean' will not work for reported variables that is not measured as % deviation from steady-state/mean.
- `'newReplic'` : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the replic input.
- `'parallel'` : Give true if you want to do the irfs in parallel. This option will parallelize over models. Default is false.
- `'parallelL'` : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if `numel(obj) == 1`. Default is false.
- `'pause'` : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- `'perc'` : Error band percentiles. As a 1 x `numErrorBand` double. The input must be given as the coverage, and not the percentiles itself. E.g. `[0.3,0.5,0.7,0.9]`. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So `[0.3,0.5,0.7,0.9]` will get the percentiles `[5,15,25,35,65,75,85,95]`, i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- `'periods'` : Number of periods of the impulse responses.
- `'plotSS'` : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for `nb_dsg` objects.

```

- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the
initial steady state. Only an option if 'plotSS'
is set to true. Only for nb_dsg objects.

- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the
method 'identDraws'. See the option
'draws' of the method
nb_var.set_identification for more.

- 'settings' : Extra graphs settings given to nb_plots
function. Must be a cell.

- 'shocks' : Which shocks to create impulse responses of.
Default is the residuals defined by the first model.

For Markov switching or break point models it may
be wanted to only run a IRF when switching the
state. To do so set this option to {'states'}.
You should also set 'startingValues' to
'steadystate(r)', where r is the regime you start
in. For a Markov switching model also set
'startingProb' to the same r. This is only an
option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be
a vector of the same size as 'shocks' input.

- 'stabilityTest' : Give true if you want to discard the draws
that give rise to an unstable model. Default
is false.

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):

    > scalar : Select the the regime to take the
initial transition probabilities
from.

    > double : A draws x nRegime or a 1 x
nRegime double. draws refer to
the number set by the 'draws'
input.

    > 'ergodic' : Start from the ergodic transition
probabilities. Default for 'irf'.

    > 'random' : Randomize the starting values
using the simulated starting
points. Default for 'girf'.

- 'startingValues' : Either a double or a char:

    > double : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing

```

with a MS-model or a break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. For MS - models the default is the ergodic mean (default as long as 'girf' is not selected as 'type'), while for break-point models it is to start from the first regime.

```

> 'zero'          : Start from zero on all variables.

> 'random'        : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'         : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'           : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generlized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'   : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

- 'variables'       : The variables to create impulse responses of.
                     Default is the dependent variables defined by the
                     first model.

Caution: The variables reported by the reporting
          property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level
                     using the method specified by 'levelMethod'.

```

Output:

```

- irfs      : The (central) impulse response function stored in a
               structure of nb_ts object. Each field stores the the
               impulse responses of each shock. Where the variables
               of the nb_ts object is the impulse responses of the
               wanted endogenous variables.

               I.e. the impuls responses to the shock 'E_X_NW' is
               stored in irfs.('E_X_NW'). Which will then be a nb_ts
               object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the
          responses from each model are saved as
          different datasets (pages) of the nb_ts object.

```

```

Caution: Each nb_model_generic object can have different
variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store
  a nb_ts object with the error bands of all variables. The
  pages of the nb_ts object is the percentiles (from lower
  to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter   : An object of class nb_graph_ts.

  > 'compareShocks' set to false (default)
    Use the graphSubPlots method or the
    nb_graphSubPlotGUI class to produce the graphs.

  > 'compareShocks' set to true
    Use the graphSubPlots method or the
    nb_graphSubPlotGUI class to produce the graphs.

- obj       : If the process has been paused, some temporary output will
  be stored in the object, and if you want to continue at a
  later stage you can take up from this point using this
  returned output. If not paused this output is empty.

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast ↑**

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

```
ret = isMixedFrequency(obj)
```

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

ret = isbayesian(obj)

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint

```
prediction bands for  
macroeconomic risk management  
  
> 'copula' : Using a copula likelihood approach.  
  
> 'mostlik' : Group the paths based on how  
likely they are.  
  
- 'nSteps' : Number of forecasting steps to use when constructing the  
error bands. If empty (default) all forecasting steps stored  
in the object is used.
```

Output:

- JPB : An nb_ts object storing the joint prediction bands.
The percentiles are stored as datasets. See the
dataNames property for which page represent which
percentile.

The data of the nb_ts object has size nSteps x nVars
x nPerc.
- plotter : A nb_graph_ts object. Use the graphSubPlots method
to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend
on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_arima.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x)&&f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. `@(x)gt(x,0), @(x)gt(x,0)||lt(x,1)`, i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. `@(x,y)gt(x,y), @(x,y)gt(x-y,0)||lt(x-y,1)`, i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. `{'Var1','Var1',1,@(x)gt(x,0.1)}`, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. `{'Var1','Var2',0,@(x)lt(x,0.1)}`, to

test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.
 E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous variance.

> 'ss' : A N x 2 cell, where the elements of each row are:
 1. The expression using any of the endogenous variables of the model.
 2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_GENERIC](#)

► **mincerZarnowitzTest ↑**

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.

- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_GENERIC](#)

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj,draws,method,output,stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'wildBlockBootstrap' : Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'copulaBootstrap' : Uses a copula approach to draw residual that are autocorrelated, Does not handle heteroscedasticity. Only an option for models estimated with classical methods.
 - > 'posterior' : Posterior draws. Only for models estimated with bayesian methods.

Default for models estimated with
bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more on this option.
- stable : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores available.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.
- 'initialDraws' : When drawing parameters this factor decides how many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
 - > 'param' : Default. A struct with the following fields:
 - beta : A nPar x nEq x draws double with the estimated parameters.
 - sigma : A nEq x nEq x draws double with the estimated covariance matrix.
- For factor models these fields are also returned:
- lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.
 - R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.
- factors : Draws of the factors as a T x nFac x

```

draws double.

> 'solution' : Get the solution of the model for each draw from the
distribution of parameters. The output will be a struct
with size 1 x draws. The struct will have the same
format as the solution property of the underlying
object. I.e. only one output!

> 'object'   : Get the draws as a 1 x draws nb_model_generic object.
Each element will be a model representing a given draw
from the distribution of the parameters. I.e. only one
output!

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + ( +/- nb_distribution.t_icdf(alpha/2) ) * stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► plotForecast ↑

```

plotter          = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
                                         increment,varargin)

```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► plotMCF ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...  
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot.

'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- `plotter` : > 'allInOne' : A `nb_graph_cs` object. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
 > 'biplot' : A vector of `nb_graph_data` objects with size equal to the number of pairwise combination of the parameters that can be made. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotMCFDistTest ↑**

`plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)`

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `test` : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,valueName)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `nameValue` : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)
[nb_arima.getPosteriorDistributions](#)

Written by Kenneth Åtterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results ↑**

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_arima.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations ↑**

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties
of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition ↑**

[decomp, decompBand, plotter] = shock_decomposition(obj, varargin)

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : A vector of nb_model_generic objects

- 'packages' : Cell matrix with groups of shocks and
the names of the groups. If you have not
listed a shock it will be grouped in a
group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';  
'shock_name_1' , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with
a shock name or a cellstr array with the
shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

Caution: Two special identifiers can be used;
'Initial Conditions' and 'Steady-state'. The
first represent the impact of all shocks that
hit the system before the decomposition/
estimation started. The second summarizes the
impact of steady-state changes on the system,

i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. E.g. [0.3, 0.5, 0.7, 0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sence for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.

- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

See also:

[nb_arima.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulate ↑**

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be

a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the

simulation of.

- > 'endo' : All the endogenous variables are returned.
- > 'fullendo' : All the endogenous variables are returned included the lag variables.
- > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
- > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.

- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.
- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a spesific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:

- > double : A 1 x nVar double.
- > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsge models.
- > 'steadystate' : Start from the steady state. For now only an option for nb_dsge models. If you are dealing with a MS-model you can indicate the state by 'steadystate(state)'. E.g. to start in state 1 give; 'steadystate(1)'. Default for nb_dsge models.

```

> 'zero'           : Start from zero on all variables
                      (Except for the deterministic
                      exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws
                     that give rise to an unstable model. Default
                     is false.

- 'startingProb'  : Either a double or a char:

    > double        : A nPeriods x nRegime or a 1 x
                      nRegime double. nPeriods refer to
                      the number of recursive periods to
                      forecast.

    > 'ergodic'     : Start from the ergodic transition
                      probabilities. Default.

```

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity ↑**

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- `obj` : An object of class nb_model_generic.
- Optional inputs;
- `'output'` : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- `'stacked'` : If the output should be stacked in one matrix or not. true or false. Default is false.
- `'nLags'` : Number of lags to compute when 'stacked' is set to true.
- `'vars'` : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- `'type'` : Either 'covariance' or 'correlation'. Default is 'correlation'.
- `'draws'` : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- `'pDraws'` : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- `'perc'` : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: 'pDraws' or 'draws' must be set to a number > 1.
- `'nSteps'` : Number of simulation steps. As a 1x1 double. Default is 100.
- `'burn'` : The number of periods to remove at start of the simulations. This is to randomize the starting

values of the simulation. Default is 0.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Default is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
 - varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
 - varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.
- E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

[nb_arima.graphCorrelation](#), [nb_arima.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **solve ↑**

`obj = solve(obj)`

Description:

Solve estimated model(s) represented by nb_arima object(s).

Input:

- obj : A vector of nb_arima objects.

Output:

- obj : A vector of nb_arima objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveARIMAEq** ↑

tempSol = nb_arima.solveARIMAEq(results, opt)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

tempSol = nb_arima.solveNormal(results, opt)

Written by Kenneth Sæterhagen Paulsen

► **solveRecursive** ↑

tempSol = nb_arima.solveRecursive(results, opt)

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

obj = solveVector(obj)

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_arima.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

options = nb_arima.template()

Description:

Construct a struct which can be provided to the nb_arima class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► testForecastRestrictions ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast

- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.

> variable : The variable(s) to test,
as a string or cell array of strings.

> date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.

> test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as variables. See model.parameters.name.
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.
- type : Type of test:
 - > '=' : Two sided test. expression == 0 (default)
For two-sided tests it is assumed that the distribution is symmetric! Use confidenc/probabillty intervals instead.
 - > '>' : One sided test. expression > 0
 - > '<' : One sided test. expression < 0

Output:

- pval : > 'classical' : P-value of test.
> 'bayesian' : Probabilty of test.

A 1x1 double.
- ci : A 1 x 2 double with the lower and upper bound of the confidence/probabillty interval of the tested expression.
- dist : A nb_distribution object storing the distribution of the tested expression.

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c] = theoreticalMoments(obj,varargin)
[m,c,ac1] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is

```

'correlation'.

- 'pDraws'      : Number of parameter draws. Default is 1. I.e. to use
                   the estimate parameters.

- 'perc'        : Error band percentiles. As a 1 x numErrorBand double.
                   E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
                   all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method'       : The selected method to create confidenc/probability
                   bands. Default is ''. See help on the method input of
                   the nb_model_generic.parameterDraws method for more
                   this input.

- 'foundReplic'  : A struct with size 1 x pDraws. Each element
                   must be on the same format as obj.solution. I.e.
                   each element must be the solution of the model
                   given a set of drawn parameters. See the
                   parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
         to the number of draws you want to do.

```

Output:

```

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

- varargout{2} : The contemporaneous covariances/correlations, as a nVar
                 x nVar nb_cs object or double. The variance is along
                 the diagonal. (Will be symmetric)

- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar
                 x nVar nb_cs object or double. Along the diagonal is the
                 auto-covariance/correlation with the variable itself. In
                 the upper triangular part the you can find cov(x,y(-i)),
                 where x is the variable along the first dimension. In
                 the lower triangular part the you can find cov(x(-i),y),
                 where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find
      cov(x,y(-i)) you can use
      getVariable(varargout{i}, 'y', 'x'),
      while to get cov(x(-i),y) (== cov(x,y(+i))) you
      can use getVariable(varargout{i}, 'x', 'y'). (This
      example only works if the output is of class nb_cs)

```

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

```
[data,plotter] = uncertaintyDecomposition(obj,varargin)
```

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

obj = uncondForecast(obj,nSteps,varargin)

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_arima.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [unstruct](#) ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_arima.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► [update](#) ↑

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type : > '' : Only update data. Default
 > 'estimate' : Update data and estimate.
 > 'solve' : Update data, estimate and solve
 > 'forecast' : Update data, estimate, solve and forecast.

- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition ↑**

```
[decomp, decompBands, plotter, plotterBands] = ...
    variance_decomposition(obj, varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8, inf].

- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sence for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and

the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomosition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomosition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

■ nb_calculate_expr

Go to: [Properties](#) | [Methods](#)

A class for evaluation expression involving a set of series.

Constructor:

```
obj = nb_calculate_expr(varargin)
```

Optional input:

- See the set method for more on the inputs.

(nb_model_estimate.set)

Output:

- obj : A nb_calculate_expr object.

See also:

[nb_calculate_vintages](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [addAutoName](#)
- [addAutoNameIfLocal](#)
- [addID](#)
- [addIDIfLocal](#)
- [dependent](#)
- [estOptions](#)
- [name](#)
- [options](#)
- [reporting](#)
- [results](#)
- [transformations](#)
- [userData](#)

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[dependent](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) that you want to seasonally adjust, the tex_name holds the names in the tex format. The number field holds a double with the number of variables. To set it use the set function. E.g.
obj = set(obj,'dependent',{'Var1','Var2'});
or use the <className>.template() method.

- **[estOptions](#)** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined

functions, as long as they take and return a nb_math_ts object.
A nb_math_ts object is just a double with a time dimension!
To get a list of all the methods of the nb_math_ts class use;
methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

Inherited from superclass NB_CALCULATE_ONLY

Methods:

- appendData
- calculate
- checkReporting
- convert
- convertEach
- createVariables
- estimate

- removeObservations
- set
- struct
- template
- unstruct

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over
the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **calculate** ↑

calc = calculate(obj,varargin)

Description:

Do the calculation associated with the object.

Input:

- obj : An object array of class nb_calculate_generic.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- calc : An cell array of class nb_ts, each element stores the calculation results of the corresponding model. An element is empty if the corresponding model is found not to be valid.

See also:

[nb_calculate_expr.getCalculated](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► **checkReporting** ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **convert** ↑

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

obj = convert(obj,freq,methods,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
 - > third column : Any expression that can be interpreted by the nb_ts.createShift method.
 - > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,    shift,    description
    'VAR1_G',  'pcn(VAR1)', 'avg',   'VAR1 growth'
    'VAR2_G',  'pcn(VAR2)', 'avg',   'VAR2 growth'
    'VAR3_G',  'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

[nb_model_generic.transformations](#), [nb_model_generic.reporting](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **estimate** ↑

```
obj      = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **getCalculated** ↑

```
calc = getCalculated(obj)
```

Description:

Get calculated series from model.

Input:

- obj : A scalar nb_calculate_generic object.

Output:

- calc : An object of class nb_ts.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent and exogenous variables.

For factor models the observables are added as well.

Input:

- obj : A scalar nb_model_generic object.
- varsIn : Not in use!

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_ONLY

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

```
helpText = nb_calculate_expr.help
helpText = nb_calculate_expr.help(option)
helpText = nb_calculate_expr.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► isStatic ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► print ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_calculate_expr.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► print_estimation_results ↑

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_generic.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► removeObservations ↑

obj = removeObservations(obj,numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► set ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_calculate_expr.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

options = nb_calculate_expr.template()
options = nb_calculate_expr.template(num)

Description:

Construct a struct which can be provided to the nb_calculate_expr class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

obj = nb_model_estimate.unstruct(s)

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_calculate_expr.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

■ **nb_calculate_factors**

Go to: [Properties](#) | [Methods](#)

A class for calculating factors from a set of selected variables.

Constructor:

obj = nb_calculate_factors(varargin)

Optional input:

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : An nb_calculate_factors object.

See also:

[nb_calculate_vintages](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [addAutoName](#)
- [addAutoNameIfLocal](#)
- [addID](#)
- [addIDIfLocal](#)
- [estOptions](#)
- [name](#)
- [observables](#)
- [options](#)
- [reporting](#)
- [results](#)
- [transformations](#)
- [userData](#)

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[estOptions](#)** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **[name](#)** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **[observables](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) of the model observation equation, the tex_name holds the names in the tex format. The number field holds a double with the number of variables of the model observation equation. To set it use the set function. E.g. obj = set(obj,'observables',{'Var1','Var2'}); or use the <className>.template() method.

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

Inherited from superclass NB_CALCULATE_ONLY

Methods:

- appendData
- calculate
- checkReporting
- convert
- convertEach
- createVariables
- estimate
- getCalculated
- getEstimationOptions
- getModelNames
- getModelVars
- getOriginalVariables
- handleCondInfo
- handleMissing
- help
- isStatic
- print
- print_estimation_results
- removeObservations
- set
- struct
- template
- unstruct

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over
the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► calculate ↑

```
calc = calculate(obj,varargin)
```

Description:

Do the calculation associated with the object.

Input:

- obj : An object array of class nb_calculate_generic.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- calc : An cell array of class nb_ts, each element stores the calculation results of the corresponding model. An element is empty if the corresponding model is found not to be valid.

See also:

[nb_calculate_factors.getCalculated](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► [checkReporting ↑](#)

`obj = checkReporting(obj)`

Description:

Check reporting, and store historical observation of reported variables.

Input:

- `obj` : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► [convert ↑](#)

`obj = convert(obj,freq,method,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
- > third column : Any expression that can be interpreted by the nb_ts.createShift method.
- > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
  Name,    input,    shift,    description
  'VAR1_G', 'pcn(VAR1)', 'avg',   'VAR1 growth'
  'VAR2_G', 'pcn(VAR2)', 'avg',   'VAR2 growth'
  'VAR3_G', 'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODELDATA

► **estimate** ↑

```
obj      = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► getCalculated ↑

calc = getCalculated(obj)

Description:

Get calculated series from model.

Input:

- obj : A scalar nb_calculate_generic object.

Output:

- calc : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► **getEstimationOptions** ↑

outOpt = getEstimationOptions(obj)

Written by Kenneth Sæterhagen Paulsen

► **getModelNames** ↑

names = getModelNames(obj)

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)

Description:

Get all variables to the model. That include dependent and exogenous variables.

For factor models the observables are added as well.

Input:

- obj : A scalar nb_model_generic object.
- varsIn : Not in use!

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_ONLY

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

```
helpText = nb_calculate_factors.help
helpText = nb_calculate_factors.help(option)
helpText = nb_calculate_factors.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.

- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **print** ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

Inherited from superclass NB_MODEL_ESTIMATE

► **print_estimation_results** ↑

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_generic.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object

- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_calculate_factors.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template ↑**

```
options = nb_calculate_factors.template()
options = nb_calculate_factors.template(num)
```

Description:

Construct a struct which can be provided to the nb_calculate_factors class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **unstruct ↑**

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_calculate_factors.struct](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

■ **nb_calculate_hp**

Go to: [Properties](#) | [Methods](#)

A class for doing HP-filtering of series.

Constructor:

obj = nb_calculate_hp(varargin)

Optional input:

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : A nb_calculate_hp object.

See also:

[nb_calculate_vintages](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- | | | | | |
|-------------------|----------------------|-----------|----------------|-------------|
| • addAutoName | • addAutoNameIfLocal | • addID | • addIDIfLocal | • dependent |
| • estOptions | • name | • options | • reporting | • results |
| • transformations | • userData | | | |

- **addAutoName** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addAutoNameIfLocal** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) that you want to seasonally adjust, the tex_name holds the names in the tex format. The number field holds a double with the number of variables. To set it use the set function. E.g.
obj = set(obj,'dependent',{'Var1','Var2'});
or use the <className>.template() method.

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODEL DATA

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL ESTIMATE

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODEL DATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

Inherited from superclass NB_CALCULATE_ONLY

Methods:

- appendData
 - checkReporting
 - convertEach
 - estimate
 - getEstimationOptions
 - getModelVars
 - handleCondInfo
 - help
 - print
 - removeObservations
 - struct
 - unstruct
 - calculate
 - convert
 - createVariables
 - getCalculated
 - getModelNames
 - getOriginalVariables
 - handleMissing
 - isStatic
 - print_estimation_results
 - set
 - template
-

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODELDATA](#)

► **calculate** ↑

`calc = calculate(obj,varargin)`

Description:

Do the calculation associated with the object.

Input:

- `obj` : An object array of class `nb_calculate_generic`.
- `'parallel'` : Use this string as one of the optional inputs to run the estimation in parallel.
- `'cores'` : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if `'parallel'` is given.
- `'remove'` : Give `'remove'` to remove the models that return errors from the `obj` output. This input is not stored to the `forecastOutput` property of the objects.
- `'waitbar'` : Use this string to give a waitbar during estimation. I.e. when looping over models. If `'parallel'` is used this option is not supported!
- `'write'` : Use this option to write errors to a file instead of throwing the error.

Optional input:

- `varargin` : See the the set method.

Output:

- `calc` : An cell array of class `nb_ts`, each element stores the calculation results of the corresponding model. An element is empty if the corresponding model is found not to be valid.

See also:

[nb_calculate_hp.getCalculated](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_CALCULATE_GENERIC](#)

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **convert** ↑

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables ↑**

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

```

> second column : Any expression that can be interpreted
      by the nb_ts.createVariable method.

> third column : Any expression that can be interpreted
      by the nb_ts.createShift method.

> fourth column : Comments

- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is
      important that this option is higher than the number of
      forecasting/irf steps, or else the output will be nan!

```

Output:

- obj : The NxM object itself added the model variables. The
 expressions input is stored in the property
 transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending.
 Use the graphInfoStruct method or the nb_graphInfoStruct
 class to produce the graph.

Examples:

```

expressions = {%
  Name,    input,    shift,    description
  'VAR1_G', 'pcn(VAR1)', 'avg',   'VAR1 growth'
  'VAR2_G', 'pcn(VAR2)', 'avg',   'VAR2 growth'
  'VAR3_G', 'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)

```

See also:

[nb_model_generic.transformations](#), [nb_model_generic.reporting](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **estimate** ↑

```

obj        = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)

```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.

- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Åstergård Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **getCalculated ↑**

calc = getCalculated(obj)

Description:

Get calculated series from model.

Input:

- obj : A scalar nb_calculate_generic object.

Output:

- calc : An object of class nb_ts.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► getEstimationOptions ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth SÃ¶terhagen Paulsen

► getModelNames ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► getModelVars ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent and exogenous variables.

For factor models the observables are added as well.

Input:

- obj : A scalar nb_model_generic object.
- varsIn : Not in use!

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_CALCULATE_ONLY

► getOriginalVariables ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODELDATA

► handleCondInfo ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

```
- ret : true or false. true if the estimation settings is so that the  
model handle conditional info.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

```
- obj : A scalar nb_model_estimate object.
```

Output:

```
- ret : true or false. true if the estimation settings is so that the  
model handle missing data.
```

Written by Kenneth SÃ¶terhagen Paulsen

► **help** ↑

```
helpText = nb_calculate_hp.help  
helpText = nb_calculate_hp.help(option)  
helpText = nb_calculate_hp.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

```
- option : Either 'all' or the name of the option you want to get the  
help on.  
  
- maxChars : The max number of chars in the printout of (approx). This  
applies to the second column of the printout. Default is  
40.
```

Output:

```
- helpText : A char with the help.
```

Written by Kenneth SÃ¶terhagen Paulsen

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **print** ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_calculate_hp.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **print_estimation_results** ↑

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_generic.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **struct ↑**

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_calculate_hp.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template ↑**

```
options = nb_calculate_hp.template()
options = nb_calculate_hp.template(num)
```

Description:

Construct a struct which can be provided to the nb_calculate_hp class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **unstruct ↑**

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_calculate_hp.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

■ **nb_calculate_only**

Go to: [Properties](#) | [Methods](#)

An abstract superclass for all classes that has a calculate method but does not inherit the nb_model_generic class.

Superclasses:

[nb_calculate_generic](#)

Constructor:

This class is abstract, and has no constructor,

See also:

[nb_calculate_generic](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- addAutoName
- addAutoNameIfLocal
- addID
- addIDIfLocal
- estOptions
- name
- options
- reporting
- results
- transformations
- userData

- **addAutoName ↑**

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addAutoNameIfLocal** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

Methods:

- [handleCondInfo](#)
- [print](#)
- [set](#)

► **appendData** ↑

obj = appendData(obj,DB)

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► calculate ↑

calc = calculate(obj, varargin)

Description:

Do the calculation associated with the object.

Input:

- obj : An object array of class nb_calculate_generic.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e.

when looping over models. If 'parallel' is used this option is not supported!

- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- calc : An cell array of class nb_ts, each element stores the calculation results of the corresponding model. An element is empty if the corresponding model is found not to be valid.

See also:

[nb_calculate_only.getCalculated](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► **checkReporting** ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **convert** ↑

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach ↑**

obj = convert(obj,freq,methods,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
 - > third column : Any expression that can be interpreted by the nb_ts.createShift method.
 - > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,     shift,      description
'VAR1_G',   'pcn(VAR1)', 'avg',    'VAR1 growth'
'VAR2_G',   'pcn(VAR2)', 'avg',    'VAR2 growth'
'VAR3_G',   'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **estimate** ↑

```
obj      = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_ESTIMATE](#)

► **getCalculated** ↑

```
calc = getCalculated(obj)
```

Description:

Get calculated series from model.

Input:

- obj : A scalar [nb_calculate_generic](#) object.

Output:

- calc : An object of class [nb_ts](#).

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_CALCULATE_GENERIC](#)

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M [nb_model_forecast](#) object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_NAME](#)

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent and exogenous variables.

For factor models the observables are added as well.

Input:

- obj : A scalar nb_model_generic object.
- varsIn : Not in use!

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_calculate_only.print_estimation_results](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **print_estimation_results** ↑

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_generic.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **removeObservations ↑**

obj = removeObservations(obj,numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

obj = set(obj,varargin)

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► struct ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_calculate_only.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_calculate_only.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

■ **nb_calculate_seasonal**

Go to: [Properties](#) | [Methods](#)

A class for doing seasonal adjustment of series.

Constructor:

```
obj = nb_calculate_seasonal(varargin)
```

Optional input:

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : An nb_calculate_seasonal object.

See also:

[nb_calculate_vintages](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [addAutoName](#)
- [addAutoNameIfLocal](#)
- [addID](#)
- [addIDIfLocal](#)
- [dependent](#)
- [estOptions](#)
- [exogenous](#)
- [name](#)
- [options](#)
- [reporting](#)
- [results](#)
- [transformations](#)
- [userData](#)

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[dependent](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) that you want to seasonally adjust, the tex_name holds the names in the tex format. The number field holds a double with the number of variables. To set it use the set function. E.g.
obj = set(obj,'dependent',{'Var1','Var2'});
or use the <className>.template() method.

- **[estOptions](#)** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **[exogenous](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** [↑](#)

Adds the possibility to add user data. Can be of any type

Inherited from superclass NB_CALCULATE_ONLY

Methods:

- [appendData](#)
- [checkReporting](#)
- [convertEach](#)
- [estimate](#)
- [getEstimationOptions](#)
- [getModelVars](#)
- [handleCondInfo](#)
- [help](#)
- [print](#)
- [removeObservations](#)
- [struct](#)
- [unstruct](#)
- [calculate](#)
- [convert](#)
- [createVariables](#)
- [getCalculated](#)
- [getModelNames](#)
- [getOriginalVariables](#)
- [handleMissing](#)
- [isStatic](#)
- [print_estimation_results](#)
- [set](#)
- [template](#)

► **appendData** [↑](#)

obj = appendData(obj,DB)

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **calculate** ↑

calc = calculate(obj,varargin)

Description:

Do the calculation associated with the object.

Input:

- obj : An object array of class nb_calculate_generic.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- calc : An cell array of class nb_ts, each element stores the calculation results of the corresponding model. An element is empty if the corresponding model is found not to be valid.

See also:

[nb_calculate_seasonal.getCalculated](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► [checkReporting ↑](#)

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► [convert ↑](#)

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.

- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of `nb_ts.convert`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_MODELDATA`

► **convertEach** ↑

`obj = convert(obj, freq, methods, varargin)`

Description:

Convert the frequency of the data of the `nb_modelData` object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_MODELDATA`

► **createVariables** ↑

`obj = createVariables(obj, expressions, fcstHorizon)`
`[obj, plotter] = createVariables(obj, expressions, fcstHorizon)`

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.
 - > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
 - > third column : Any expression that can be interpreted by the nb_ts.createShift method.
 - > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,    shift,    description
'VAR1_G',   'pcn(VAR1)', 'avg',   'VAR1 growth'
'VAR2_G',   'pcn(VAR2)', 'avg',   'VAR2 growth'
'VAR3_G',   'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

[nb_model_generic.transformations](#), [nb_model_generic.reporting](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **estimate** ↑

```
obj          = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **getCalculated** ↑

```
calc = getCalculated(obj)
```

Description:

Get calculated series from model.

Input:

- obj : A scalar nb_calculate_generic object.

Output:

- calc : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent and exogenous variables.

For factor models the observables are added as well.

Input:

- obj : A scalar nb_model_generic object.
- varsIn : Not in use!

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_ONLY

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

```
helpText = nb_calculate_seasonal.help
helpText = nb_calculate_seasonal.help(option)
helpText = nb_calculate_seasonal.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► isStatic ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► print ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_calculate_seasonal.print_estimation_results](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **print_estimation_results** ↑

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_generic.print](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **removeObservations** ↑

obj = removeObservations(obj,numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

obj = set(obj,varargin)

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_ESTIMATE](#)

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class [nb_model_estimate](#).

Output:

- s : A struct representing the [nb_model_generic](#) object.

See also:

[nb_calculate_seasonal.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_ESTIMATE](#)

► **template** ↑

```
options = nb_calculate_seasonal.template()
options = nb_calculate_seasonal.template(num)
```

Description:

Construct a struct which can be provided to the [nb_calculate_seasonal](#) class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

obj = nb_model_estimate.unstruct(s)

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_calculate_seasonal.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

■ **nb_dsg**

Go to: [Properties](#) | [Methods](#)

If you use the 'nb_file' you will use the NB Toolbox parser and solver. How to write the model file in this case is documented in the DAG.pdf file, and there you will also find the documentation of the solution algorithm used in this case. See also the nb_dsg.solveNB method.

This class can also be used for converting RISE dsg objects and dynare structures to a nb_model_generic subclass. This makes it for example easy to compare for example IRF's from RISE and dynare with models estimated by the NB TOOLBOX, e.g. VARs.

It is also possible to give the model files directly to the nb_dsg class by using the 'rise_file' or 'dynare_file' options.

In the case the model is not parsed and solved with NB toolbox credits for solving the DSGE model should go to Junior Maih for his RISE toolbox or to the dynare development team, and not to the author of this code.

Superclasses:

`nb_model_generic, nb_model_sampling, nb_model_parse`

Constructor:

`obj = nb_dsge(varargin)`

Optional input:

- See the `nb_model_estimate.set` method for more.

See the method `assignParameters` to assign calibration, and the method `assignPosteriorDraws` to assign already found posterior draws. If the underlying object is a RISE dsge model, new draws can be made by `parameterDraws`, if the methods `irfs`, `forecast` etc. needs more draws this will be done automatically. On the other hand if `dynare` is used this is not possible.

OR

- If the first input is '`rise_file`', then the follwing can be given:

`> 'rise_file'` : The filename of the RISE model file.
Must return a dsge model. As a string.

Optional:

`> 'steady_state_file'` : The filename of the steady state file if needed. As a string.
`> 'steady_state_imposed'` : true (default) or false.

With this option the RISE model file will be parsed, and a dsge model will be returned. See the method `assignParameters` to assign calibration, or the method `estimate` to estimate the model.

OR

- If the first input is '`dynare_file`':

`> 'dynare_file'` : The filename of the dynare model file.
Must return a dsge model. As a string.

By this options dynare will be runned. This means that all options must be given to the dynare file, such as calibrated parameters or estimation of parameters. If the model is estimated the mode will be used for the parameter values, and the posterior draws will be saved for later used if they are produced.

To provide additional inputs when calling the `dynare` function, use the third input as a one line char with the additional code.

OR

- If the first input is '`nb_file`':

`> 'nb_file'` : The filename of the model file with extension `.nb` or `.mod`.

Optional:

- 'silent' : See nb_dsge.help('silent')

Use the set method to set other options found in the options structure. See nb_dsge.help for more on each option.

Caution: The observables can be set in a call to the set method,
e.g: set(obj,'observables',{'Var1','Var2'});

Output:

- obj : An nb_dsge object.

- [parser](#)
- [results](#)
- [unitRootVariables](#)
- [addID](#)
- [estOptions](#)
- [observables](#)
- [posteriorPath](#)
- [solution](#)
- [userData](#)
- [addIDIfLocal](#)
- [exogenous](#)
- [options](#)
- [reporting](#)
- [systemPriorPath](#)

- **[addAutoName](#) ↑**

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#) ↑**

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#) ↑**

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#) ↑**

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **observables** ↑

The declared observables. As a struct with fields name, tex_name and number.

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **parser** ↑

This property will store the info on the model, such as equations etc, otherwise it will be empty.

Caution: If you are dealing with an object of class nb_dsge, this property will be empty, if the DSGE model is parsed with RISE or Dynare.

Inherited from superclass NB_MODEL_PARSE

- **posteriorPath** ↑

The path to located the posterior sampling results. Use nb_loadDraws to return a struct with the posterior sampling options and output.

Inherited from superclass NB_MODEL_SAMPLING

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this property to be up to date!

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated

factors and/or exogenous variables of the measurement equation.

- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the declared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.
As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **systemPriorPath** ↑

The path to located the updated priors sampling results.
Use nb_loadDraws to return the output struct of the given sampler.

Inherited from superclass NB_MODEL_SAMPLING

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension!
To get a list of all the methods of the nb_math_ts class use;

```
methods('nb_math_ts').
```

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **unitRootVariables** ↑

The declared unit root variables. As a struct with fields name, tex_name and number.

- **userData** ↑

Adds the possibility to add user data. Can be of any type

► **addBreakPoint ↑**

```
obj = addBreakPoint(obj,parameters,values,date)
obj = addBreakPoint(obj,parameters,values,date,varargin)
```

Description:

To add a break in the structural parameters of the model.

Caution: To assign the parameter values the at or after the break you can also use use the nb_model_generic.assignParameters. Append the original parameter with the a subscript followed by a the date of the breakpoint, e.g. 'paramName_2012Q1'

If the 'expectedDate' option is used the model is solved with the algorithm of Kulish and Pagan (2017), Estimation ans Solution of Models with Expectations and Structural Changes.

Input:

- obj : An object of class nb_dsg.
- parameters : A cellstr with the parameters that you want to add an unexpected breakpoint to.
- values : A double with the same size as parameters with the value of the parameters at and after the break. Can be empty, if you want to use the nb_model_generic.assignParameters method to assign the values instead.
- date : Either a date string or an object of subclass of the nb_date class. This will be the date of the breakpoint.

Optional input:

- 'steady_state_exo' : A struct with the permanent shock associated with the given break point. Use nb_dsg.help('steady_state_exo') to get more help on this input. When this is added the new steady-state will be solved using numerical methods.
- 'expectedDate' : Either a date string or an object of subclass of the nb_date class. This will be the date from where the break is expected.

Optional inputs given to the nb_dsg.set method.

Output:

- obj : An object of class nb_dsg.

See also:

[nb_dsg.parse](#), [nb_dsg.set](#)

Written by Kenneth Sæterhagen Paulsen

► **addConstraints** ↑

obj = addConstraints(obj,constraints)

Description:

Add (more) constraints to the parameters during estimation. The constraints can only include parameters (and numbers).

Input:

- obj : An object of class nb_dsg or nb_nonLinearEq.
- constraints : A N x M char array or a N x 1 (or 1 x N) cellstr array. Each element will be counted as a new constraint.

Output:

- obj : An object of class nb_dsgc or nb_nonLinearEq.

See also:

[nb_dsgc.parse](#), [nb_nonLinearEq.parse](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_PARSE

► **addEquation** ↑

obj = addEquation(obj,varargin)

Description:

Add more equations to the model.

Input:

- obj : An object of class nb_dsgc.

Optional input:

- 'endogenous' : A char or cellstr with the added endogenous variable(s).
- 'exogenous' : A char or cellstr with the added exogenous variable(s).
- 'parameters' : A char or cellstr with the added parameter(s).
- 'equations' : A char or cellstr with the added equation(s).
- 'steady_state' : A double with the same length as the number of added endogenous variables (and in the same order!). This will use the 'steady_state_fixed' option, so do not override it!

Output:

- obj : An object of class nb_dsgc.

See also:

[nb_dsgc.parse](#)

Written by Kenneth Sæterhagen Paulsen

► **addObsModelSolver** ↑

```
[A,B,C,CE,err] = nb_dsgen.addObsModelSolver(A,B,C,CE,parser,solution,...  
options,expandedOnly)
```

Description:

Expand core model with obs_model equations.

Input:

- A : Transition matrix of core model, as a nEndo x nEndo.
- C : Shock impact matrix of core model as a nEndo x nExo.
- CE : Shock impact matrix of core model as a nEndo x nExo x nHor, when solved with anticipated shocks, otherwise [].
- parser : See nb_dsgen.solveNB
- solution : See nb_dsgen.solveNB
- options : See nb_dsgen.solveNB
- expandedOnly : true if only the expanded solution is to be solved for.

Output:

- A : Transition matrix, as a nEndoAll x nEndoAll.
- B : Constant term as a nEndoAll x 1.
- C : Shock impact matrix as a nEndoAll x nExoAll - 1.
- CE : Shock impact matrix as a nEndoAll x nExoAll - 1 x nHor, when solved with anticipated shocks, otherwise [].
- ss : Steady state, as a nEndo x 1 double.

See also:

[nb_solveLinearRationalExpModel](#), [nb_dsgen.selectSolveAlgorithm](#)

Written by Kenneth Sæterhagen Paulsen

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► assignParameters ↑

obj = assignParameters(obj,varargin)

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.

- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames** ↑

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.
- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

`nb_dsge.writeTex`, `nb_dsge.writePDF`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **backwardSolver** ↑

`[A,B,BE,err] = nb_dsge.backwardSolver(model,solution,options,expandedOnly)`

Description:

Solving purly backward looking models.

Input:

- `model` : See `nb_dsge.solveNB`
- `solution` : See `nb_dsge.solveNB`
- `options` : See `nb_dsge.solveNB`
- `expandedOnly` : true if only the expanded solution is to be solved for.

Output:

- `A` : Transition matrix, as a `nEndo x nEndo`.
- `B` : Shock impact matrix as a `nEndo x nExo`.
- `BE` : Shock impact matrix as a `nEndo x nExo x nHor`, when solved with anticipated shocks, otherwise [].

Written by Kenneth Sæterhagen Paulsen

► **blockDecompose** ↑

`obj = blockDecompose(obj,inEst)`
`obj = blockDecompose(obj,inEst,doPrologue)`

Description:

Block decompose model before solving. This will remove the epilogue from the model.

Caution: This method will be called inside `nb_dsge.solve` automatically, if the 'blockDecompose' option is set to true. But you can use this method to see how efficient the block decomposition is for your model by calling it before solving.

Caution: The jacobian is evaluated at the values provided by the steady-state.

Input:

- obj : A scalar object of class nb_dsg.
- inEst : Give true if it is called inside estimation, as in this case we need to calculate the steady-state and the derivatives.
- doPrologue : Give true to also separate out prologue. Default is false.

Output:

- obj : A scalar object of class nb_dsg, where the parser property has been updated with the block decomposition of the model.

See also:

[nb_dsg](#), [nb_dsg.parse](#), [nb_dsg.solve](#), [nb_dsg.solveNB](#)

Written by Kenneth Sæterhagen Paulsen

► calculateLoss ↑

[obj, loss] = calculateLoss(obj, varargin)

Description:

Calculate loss given a specified loss function.

Input:

- obj : A N x M matrix of class nb_dsg.

Optional inputs:

- 'simulations' : An nb_ts object with the simulate data from the model.
If this option is not given, it will calculate the loss analytically.
- The rest of the optional inputs will be passed on to the nb_dsg.set.

Output:

- obj : A N x M matrix of class nb_dsg. Where the results.loss is updated.
- loss : A N x M double with the calculated loss.

See also:

[nb_dsg.setLossFunction](#)

► **calculateMultipliers** ↑

```
mult = calculateMultipliers(obj,varargin)
```

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsgc.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!
- 'instrument' : A one line char with the name of the instrument. Must be provided!
- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!
- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!
- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.
- 'perc' : Error band percentiles. As a 1 x nPerc double. E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the double method on this output to convert it to a double matrix.

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError** ↑

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property is updated with the bootstrapped standard errors.
Extra outputs (all based on bootstrapped draws):
 - stdBeta : Standard deviation of coefficient of the main equation.
 - tStatBeta : T-statistic for the coefficient of the main equation.
 - pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
 - stdLambda : Standard deviation of coefficient of the observation equation.
 - tStatLambda : T-statistic for the coefficient of the observation equation.

- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► checkModel ↑

```
obj = checkModel(obj)
```

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► checkPosterioriors ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they were drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot.
Default is 10.
- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
- plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkReporting** ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **checkSteadyState** ↑

[obj,err] = checkSteadyState(obj,varargin)

Description:

If `isNB` is true for the `nb_dsge` object `obj`, this method must be ran to check that your solution of the steady-state of the model is correct.

Use `obj = set(obj,'steady_state_file','filename.m')` to give `nb_dsge` class the file that solves the steady-state or
`obj = checkSteadyState(obj,'steady_state_file','filename.m').`

Caution: If no steady-state file is provided and the option '`'steady_state_solve'`' is false a zero for all variable solution will be tested.

Caution: If some variable is not been given any value in the steady-state file it is assumed that it is 0 in steady-state.

Input:

- `obj` : An object of class `nb_dsge`.

Optional inputs:

- `'silent'` : See `nb_dsge.help('silent')`
- `'steady_state_file'` : See `nb_dsge.help('steady_state_file')`

Output:

- `obj` : An object of class `nb_dsge`, where the solution of the steady-state can be found at `obj.solution.ss`.
- `err` : If two outputs are called for a potential error message is not thrown, but instead return as a string. Is empty if not error occurs. Caution: This is only the case if `numel(obj) == 1`.

Examples:

See `Econometrics\test\DSGE\OptimalPolicy\FRWZ\frwz_nk_nb_steadystate.m`

See also:

[nb_dsge.help](#), [nb_dsge.solveSteadyState](#)

Written by Kenneth Åkerhagen Paulsen

► **checkUpdatedPriors ↑**

`[DB,plotter,pAutocorr] = checkUpdatedPriors(obj,varargin)`

Description:

Plot updated prior draws in the order they were drawn. This to check for problems with the draws being autocorrelated.

Input:

- obj : A scalar object of class nb_model_sampling. It must represent a bayesian model that uses system priors.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot. Default is 10.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
- plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_generic.checkPosteriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► cleanSolution ↑

```
obj = cleanSolution(obj)
obj = cleanSolution(obj,normalize)
```

Description:

Remove inactive shocks from solution.

Input:

- obj : A scalar nb_dsgen object.
- normalize : true or false. If true the shocks are normalized to be $N(0,1)$.

Output:

- obj : A scalar nb_dsgen object.

Written by Kenneth Sæterhagen Paulsen

► **conditionalTheoreticalMoments** ↑

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.

Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.
Default is ''. See below for what that means.

> 'bootstrap' : Create artificial data to bootstrap
the estimated parameters. Default
for models estimated with classical
methods.

> 'wildBootstrap' : Create artificial data by wild
bootstrap, and then "draw" parameters
based on estimation on these data.
Only an option for models estimated

with classical methods.

> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constraints ↑**

```
[C,Ceq] = nb_model_parse.constraints(pars,constrFuncEq,constrFuncIneq,
varargin)
```

Description:

Function that will be converted into a function handle during estimation when parameter constraints are added.

Input:

- pars : The current values of the parameters.
- constrFuncEq : A function handle, which is constructed in nb_model_parse.constraints2func, that evaluate the equality constraints on the parameters.
- constrFuncIneq : A function handle, which is constructed in nb_model_parse.constraints2func, that evaluate the inequality constraints on the parameters.

Output:

- C : The value of the evaluated inequality constraints. Parameter values are feasible as long as all(C <= 0).
- Ceq : The value of the evaluated equality constraints. Parameter values are feasible as long as all(abs(Ceq) < eps), for some small eps.

See also:

[nb_dsge.constraints2func](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_PARSE

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...  
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a

cellstr. Must be included as a variable of the data input.

- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast

```

                error.
- 'ESLS'   : Exponential of the sum of the log scores.
- 'EELS'   : Exponential of the mean of the log scores.
- 'MLS'    : Mean log score.

- allPeriods      : true if you want the scores to be calculated for all
                     periods recursively, or else give false, i.e. only
                     calculate the score for the last period. False is
                     default.

- startDate       : The date to begin constructing the score. Can be
                     empty.

- endDate         : The date to end constructing the score. Can be
                     empty.

- nSteps          : Select the number of forecasting steps. Can be
                     empty.

- rollingWindow   : Set it to a number if the combination weights are to
                     be calculated using a rolling window. Default is
                     empty, i.e. to calculate the weights recursively using
                     the full history at each recursive step.

- lambda          : Give the value of the parameter of the exponential
                     decaying weights on past forecast errors when
                     constructing the score. If empty the weights on all
                     past forecast errors are equal.

```

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **convert ↑**

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

obj = convert(obj,freq,methods,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
- > third column : Any expression that can be interpreted by the nb_ts.createShift method.
- > fourth column : Comments

- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,    shift,    description
    'VAR1_G',  'pcn(VAR1)', 'avg',   'VAR1 growth'
    'VAR2_G',  'pcn(VAR2)', 'avg',   'VAR2 growth'
    'VAR3_G',  'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

[nb_model_generic.transformations](#), [nb_model_generic.reporting](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► curvature ↑

```
plotter = curvature(obj,beta,varargin)
```

Description:

Calculate curvature of posterior, likelihood and/or prior, wrt the estimated parameters. Can be done in parallel.

Input:

- obj : A scalar nb_dsg object.
- beta : A nPar x 1 double with the point to evaluate the curvature. If not provided the parameter values are found at obj.results.beta. Be aware that only the parameters that has been selected a prior will be analyzed! (If the model has been estimated using the estimate method, the mode will be the default point of evaluation)

Optional input:

Any combination of:

- 'prior' : Give to evaluate the curvature of the prior, at the given point.
- 'systemPrior' : Give to evaluate the curvature of the system prior, at the given point.
- 'likelihood' : Give to evaluate the curvature of the likelihood, at the given point.
- 'posterior' : Give to evaluate the curvature of the posterior, at the given point.

If non of them are provided, all of them are plotted.

Other inputs:

- 'honourBounds' : Give true to honour the lower and upper bounds of the priors when 'incrFactor' is set. Default is false.
- 'incrFactor' : Sets the width of the evaluation window. A smaller number means wider window. The increment is calculated as; incr = (ub - lb)/incrFactor, where ub is the upper bound and lb is the lower bound. Then evaluation window is calculated as; [beta - incr, beta + incr]. The number of points to evaluate in this window is set by the 'numEvalPoints'

input. E.g. curvature(obj,beta,'incrFactor',10). Default is [], i.e. use [lb,ub] as the evaluation window.

To set different increment factors for different parameters use a nPar x 1 double.

- 'numEvalPoints' : Sets the number of evaluation points inside the evaluation window. Defualt is 10. E.g. curvature(obj,beta,'numEvalPoints',50)
- 'minObjective' : Set all values less than this number to nan. Default is -1e10.
- 'parallel' : true or false. Default is false. It will run in parallel over the number of selected parameters, so number of parameters should be >> than number of selected workers to make it efficient.
- 'parameters' : A 1 x nPar cellstr with the estimated parameters of interest.
- 'subplot' : Give to create a 4 x 4 subplot. Default is not.
- 'takeLog' : A nPar x 1 logical. Set element to true if you want to take log of the bound before calculation of the evaluation window.
- 'tolerance' : If the posterior is above this number, it will be assign a nan value. Default is 1e9.
- 'waitbar' : true or false. Default is false.
- 'workers' : Give the number of workers to use during parallel. 5 is max 5, if 'waitbar' is set to true. Otherwise max is given by nb_availablePoolSize. Default is [], use the max amount of workers.

Output:

- plotter : > Default : A nPar x 1 nb_graph_data object. Use the graph method or the nb_graphMultiGUI class.
- > 'subplot' : A nb_graph_data object. Use either the graphSubPlots method or the nb_graphSubPlotGUI class.

Written by Kenneth SÃ¶terhagen Paulsen

► **declareUncertainParameters** ↑

```
obj = declareUncertainParameters(obj,varargin)
```

Description:

Use this function to declare a parameter as uncertain.

Caution: This will automatically trigger calculations of optimal simple rules under parameter uncertainty in the method nb_dsge.optimalSimpleRules.

Input:

- obj : An object of class nb_dsge.
- parameters : A N x X char or a N x 1 cellstr with the parameters you want to declare as uncertain.
- multiDist : If N == 1:
 - A scalar nb_distribution object.
- Else:
 - A nb_copula object where the distributions property hold N nb_distribution objects.

Output:

- obj : An object where the parameters property is updated, i.e. the isUncertain field and the nb_copula object is stored in the parser property.

See also:

[nb_dsge.optimalSimpleRules](#), [nb_copula](#), [nb_distribution](#)

Written by Kenneth Å!terhagen Paulsen

► **derivative ↑**

```
obj = derivative(obj,varargin)
```

Description:

Calculates the derivatives of the model with respect to the variables of the model.

Caution only first order approximation is supported for the time being.

Input:

- obj : An object of class nb_dsge.

Optional input:

```
- 'solve_order' : See nb_dsge.help('solve_order')
```

Output:

- obj : An object of class nb_dsge. See the solution property:
 - > jacobian : Storing the first-order derivatives evaluated at the steady-state of the DSGE model. The ordering will depend on the solver used.
 - > NB Toolbox: See nb_dsge.getDerivOrder

See also:

[nb_dsge.getDerivOrder](#)

Written by Kenneth Sæterhagen Paulsen

► **dieboldMarianoTest** ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two

models.

- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_dsge.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity** ↑

```
obj = doSimulateFromDensity(obj,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_dsgen.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **doSymbolicDerivatives** ↑

```
[derivFunc,derivInd,symDeriv,jacobian] = doSymbolicDerivatives(obj,obs)
```

Description:

Create a function handle with the derivatives.

Input:

- obj : An object of class nb_dsgen.
- obs : Give true to calculate symbolic derivatives of the obs_model instead of the core model. Default is false

Output:

- derivFunc : A function handle returning the non trivial derivatives of the equations of the model. This function takes two inputs; the value of the variables (including lead, lags and exogenous), and the value of the parameters.
- derivInd : Let JT be the output from derivFunc, then the full jacobian is given by sparse(derivInd(:,1),derivInd(:,2),JT,...

nEqs,nCol). For more see nb_dsge.derivativeNB.

- symDeriv : A vector of nb_mySD storing the non-trivial derivatives of the model.
- jacobian : The jacobian as a sparse matrix of size nEqs x nCol. See the getDerivOrder for the ordering of the jacobian.

See also:

[nb_dsge.derivative](#), [nb_dsge.derivativeNB](#), [nb_dsge.getDerivOrder](#)

Written by Kenneth SÃ¶therhagen Paulsen

► **empiricalMoments** ↑

```
[m,c] = empiricalMoments(obj,varargin)
[m,c,ac1] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_generic object. The options.data property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.

- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
 - varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
 - varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.
- E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
getVariable(varargin{i}, 'y', 'x'),
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

Inherited from superclass NB_MODEL_GENERIC

► [eq](#) ↑

ret = eq(obj,other)

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density, ...
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

► **evalLikelihood** ↑

```
lik = evalLikelihood(obj)
```

Description:

Evaluate the likelihood at the current parameters.

Input:

- obj : A scalar nb_dsge object.

Output:

- lik : Minus the log likelihood.

Written by Kenneth Sæterhagen Paulsen

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

► **expectedBreakPointSolver** ↑

```
[A,B,C,CE,parser,err] =  
    nb_dsgc.expectedBreakPointSolver(parser,solution,options,expandedOnly)
```

Description:

This static method of the nb_dsgc class implements the algorithm presented by; Kulish and Pagan (2017), "Estimation ans Solution of Models with Expectations and Structural Changes".

Input:

- parser : See nb_dsgc.solveNB
- solution : See nb_dsgc.solveNB
- options : See nb_dsgc.solveNB
- expandedOnly : true if only the expanded solution is to be solved for.

Output:

- A : Transition matrix, as a 1 x nStates cell array. Each element is a nEndo x nEndo double matrix.
- B : Constant term in the solution, as a 1 x nStates cell array. Each element is a nEndo x 1 double vector.
- C : Shock impact matrix, as a 1 x nStates cell array. Each element is a nEndo + nMult x nExo.
- CE : Shock impact matrix, as a 1 x nStates cell array. Each element is a nEndo x nExo x nHor, when solved with anticipated shocks, otherwise [].

Written by Kenneth Sæterhagen Paulsen

► **extendedPath** ↑

```
sim = extendedPath(obj,nSteps,varargin)
```

Description:

Perform simulation from a model using extended path.

Input:

- obj : An object of class nb_dsgc.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional input:

- 'blockDecompose' : Set it to true to use block decomposition to solve the problem.
- 'derivativeMethod' : Either 'symbolic' (fastest) or 'automatic'.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
- 'exogenousPerm' : A cellstr with the exogenous variables of the 'exoPermVal' input.
- 'exogenous' : A cellstr with the exogenous variables of the model to simulate. If empty, all exogenous variables are simulated. All shocks are simulated from $N(0, I)$.
- 'exoPermVal' : A $N \times nExo \times draws$ double with the values of the permanent shocks to the exogenous variables used by the simulations. The value at each period is taken as the value that will be used for the entire perfect foresight of one step of the extended path simulation. If not given or given as empty, no permanent shocks will take place.

Caution: N must be equal to $nSteps$.
Caution: If this input only gives the values of a subset of the exogenous variable, the rest will be given 0 for all observations.
Caution: If this input is given, the end point of perfect foresight simulation is re-solved only when the permanent shock of this period has changed since last period. This is done before the loop of the extended path and can be done in parallel.
- 'exoVal' : A $nPer \times nExo \times nSteps \times draws$ double with the values of the exogenous variables for the simulations. If empty, the 'exogenous' input will decide which exogenous variables that is to be simulated, otherwise the 'exogenous' inputs set the name of each column of this input.

The third dimension will be equal to the number of steps to simulate, i.e. it will overrun the $nSteps$ input.
The fourth dimension will set the number of extended path simulations to be done, i.e. it will overrun the 'draws' input.

Caution: If $nPer < periods$ the values after this observation gets the values 0.
Caution: If this input only gives the values of a subset of the exogenous variable, the

rest will be given 0 for all observations.

Caution: This input must has as many pages as the nSteps input, i.e. each page is the set of anticipated shocks seen at the given period of the extended path simulation.

Caution: If this input us provided it will only give one simulation, i.e. the 'draws' is automatically set to 1.

- 'homotopyAlgorithm' : See nb_dsge.help('homotopyAlgorithm'). Default is 0, i.e. no homotopy.
- 'homotopySteps' : See nb_dsge.help('homotopySteps'). Default is 10.
- 'optimset' : A struct with the options used by the solver. See nb_perfectForesight.optimset for more.
- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread the simulation of the different extended paths to different threads. Default is false.
- 'periods' : The number of periods of the simulation. E.g. periods >>> number of period it takes to converge to the end values of the simulations. Default is 150.
- 'seed' : Set the seed of the pseudo random generated numbers when 'stochInitVal' is set to true. Default is 1.
- 'solver' : Name of the solver to use. Either 'nb_solve' or 'nb_abcSolve'. Default is 'nb_solve', i.e. using newton algorithm. See the 'optimset' options to adjust solving options.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a spesific start date (default). If provided the output will be an object of class nb_ts.

► **filter** ↑

```
obj = filter(obj,varargin)
```

Description:

Run the kalman filter on the DSGE model.

Caution : The data field of the options property must include all the observables of the model.

This method uses the RISE filter if the nb_dsge model represent a RISE object, and it uses the dynare developed filter if the underlying object is a dynare solved DSGE model (not supported in all versions of the NB toolbox). All credits should go to the authors of those codes in these cases.

Caution: Use `obj = set(obj,'data',data)` to assign the data on the observables.

Input:

- `obj` : An object of class nb_dsge

Optional Inputs:

- `varargin` : Will depend on the underlying software used:

> All:

- `'variables'` : A cellstr with the endogenous variables to store. Are you going to do shock decomposition you need all!
- `'startDate'` : Start date of filtering, as a string or a nb_date object. Default is the start date of the options.data property.
- `'endDate'` : End date of filtering, as a string or a nb_date object. Default is the end date of the options.data property.

> NBTOOLBOX:

- `'kf_init_variance'` : See `nb_dsge.help('kf_init_variance')`. Default is given by the option `'kf_init_variance'`.
- `'kf_kalmanTol'` : See `nb_dsge.help('kf_kalmanTol')`. Default is given by the option `'kf_kalmanTol'`.
- `'kf_method'` : See `nb_dsge.help('kf_method')`. Default is given by the option `'kf_method'`.
- `'kf_warning'` : See `nb_dsge.help('kf_warning')`. Default is given by the option `'kf_warning'`.
- `'smoother'` : true or false. If false only the filter is ran. Default is true.
- `'shockProps'` : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not anticipated. I.e all shocks/residuals not

provided by this input has anticipated horizon set to 1, which means that only contemporaneous shocks/residuals are seen.

> Horizon : Anticipated horizon of the shocks/residual. 1 is default.

> RISE (Must be added separately) :

- 'kf_ergodic' : Initialization at the ergodic distribution. True or false. true is default.
- 'kf_init_variance' : Initial variance factor (Harvey scale factor). If not empty, the information in T and R is ignored. Either empty or an integer.
- 'kf_user_init' : As a cell. User-defined initialization. When not empty, it can take three forms. {a0}, {a0,cov_a0}, {a0,cov_a0,PAI00} where a0 is the initial state vector with the same order as the rows of T, cov_a0 is the initial covariance of the state vector (same order as a0) and PAI00 is the initial vector of regime probabilities. Default is {}.
- 'kf_householder_chol' : If true, return the cholesky decomposition when taking the householder transformation. This option is primarily used in the switching divided difference filter. Default is false.

> Dynare (May not be supported in all version of NB toolbox) :

- 'diffuse_filter' : Either 0 or 1. See dynare documentation.
- 'lik_init' : An integer between 1 and 3. See dynare documentation.
- 'kalman_algo' : An integer between 1 and 4. See dynare documentation.
- 'Harvey_scale_factor' : See 'kf_init_variance' above.

Caution : If not provided (or empty) the default is to use the settings return while running dynare.

Output:

- obj : The results will be saved to the results property:
 - A struct with the filtering of each model stored in separate fields. Each field for each model then consist of a struct with the following fields:
 - > 'smoothed' : A struct consisting of fields of struct objects

storing the smoothed estimates.

- > 'filtered' : A struct consisting of fields of struct objects storing the filtered estimates.
- > 'updated' : A struct consisting of fields of struct objects storing the updated estimates.
- > 'likelihood' : The log likelihood. Only return when RISE is used.

[dsge.smooth](#), [dsge.filter](#), [nb_dynareSmoothe](#)

Written by Kenneth Sæterhagen Paulsen

► **findAniticipatedMatrices** ↑

B = nb_dsge.findAniticipatedMatrices(PHI,nsteps,T1AT0iT1)

Description:

Forward expansion when dealing with expected shocks.

This implements the formula find in appendiks A of Junior Maih (2010), "Conditional forecasts in DSGE models".

Let the linearized DSGE model be written as:

E_t[Theta_lead*y(t+1) + Theta_0*y(t) + Theta_lag*y(t-1) + PHI*eps(t)] = 0

And the normal solution:

y(t+1) = A*y(t) + B1*eps(t)

Input:

- B1 : Solution of the shock impact matrix, as a nEndo x nExo double. I.e.
- nAntSteps : Number of anticipated periods of the shocks.
- T1AT0iT1 : inv(Theta_lead*A + Theta_0)*Theta_lead

Written by Kenneth Sæterhagen Paulsen

► **forecast** ↑

```
obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for foward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.

- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
- 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density forecast.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'bins' : The length of the bins og the domain of the density. Either;
 - > [] : The domain will be found. See nb_getDensityPoints (default is that 1000 observations of the density is stored).
 - > integer : The min and max is found but the length

of the bins is given by the provided integer.

> cell : Must be on the format:

```
{'Var1',lowerLimit1,upperLimit1,binsL1;
 'Var2',lowerLimit2,upperLimit2,binsL2;
 ...}
```

- lowerLimit1 : An integer, can be nan, i.e. will be found.

- upperLimit1 : An integer, can be nan, i.e. will be found.

- binsL1 : An integer with the length of the bins. Can be nan. I.e. bins length will be adjusted to create a domain of 1000 elements.

Caution : The variables not included will be given the default domain. No warning will be given if a variable is provided in the cell but not forecast by the model. (This because different models can forecast different variables)

Caution : The combineForecast method of the nb_model_group class is much faster if the lower limit, upper limit! Or else it must simulate new draws and do kernel density estimation for each model again with the shared domain of all models densities.

- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is not empty this will set the start date of the recursive forecast. Default is to start from the first possible date.

- 'endDate' : The end date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is empty this input will have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).

- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.

- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.
 If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))
 If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).
- All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.
- To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.
- Caution : If empty unconditional forecast will be produced.
- 'condDBType' : 'hard' or 'soft'. When 'hard' is choosen it is assumed that all conditional information should be

interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.

- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.

Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.

If not provided. Model stds are used.

 - > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
 - > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!
- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogneous variables to

condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.

- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:
 - This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)

```

- 'startingProb'    : Either a double or a char:
                     > []          : If the model is filtered the
                           starting value is calculated
                           on filtered transition
                           probabilities. Otherwise the
                           ergodic mean is used.
                     > double       : A nPeriods x nRegime or a 1 x
                           nRegime double. nPeriods refer to
                           the number of recursive periods to
                           forecast.
                     > 'ergodic'    : Start from the ergodic transition
                           probabilities.

- 'stabilityTest'  : Give true if you want to discard the parameter draws
                     that give rise to an unstable model. Default
                     is false.

- 'states'         : Either an integer with the regime to
                     forecast/simulate in, or an object of class nb_ts
                     with the regimes to condition on. The name of the
                     variable must be 'states'.

Caution: For break-point models this is decided by
          the dates of the breaks, and cannot be set
          by this option!

- 'compareToRev'   : Which revision to compare to. Default is final
                     revision, i.e. []. Give 5 to get fifth revision.
                     must be an integer. Keep in mind that this number
                     should be larger than the nSteps input.

- 'compareTo'      : Sometime you want to evaluate the forecast of one
                     variable against another variable which is not
                     part of the model. E.g. if you use the first release
                     of a variable and want to compare it against the
                     final release. To do this you can give a cellstr
                     with size n x 2, where n is the number of variables
                     to change the the actual observations to test
                     against. {'VAR_1','VAR_FINAL',...}.

- 'estimateDensities' : true or false. true if you want to do a
                      kernel density estimation of the density
                      forecast.

- 'exoProj'        : Tolerate missing exogenous variables by projecting
                     them by a fitted model. Only when the 'condDB'
                     input is empty!

Options are:
- ''    : No projection are done. Error will be
           given if some exogenous variables are
           not given any conditional information.
           Default.

```

- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.
 - Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.
- Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.
- 'exoProjHist'
 - : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.
- 'exoProjDiff'
 - : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.
- 'exoProjAR'
 - : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.
- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.
 - Caution: Only applies when exoProj is set to 'AR'.
- 'exoProjCalib'
 - : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficent 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficent 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when exoProj is set to 'AR'.

- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
 - 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs' : This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.
- 'seed' : Set simulation seed. Default is 2.0719e+05.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if

forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist ↑**

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_dsge.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist ↑**

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

Inherited from superclass NB_MODEL_FORECAST

► gelmanRubin ↑

```
[res,plotter] = gelmanRubin(obj)
[res,plotter] = gelmanRubin(obj,type)
```

Description:

Calculates the recursive Gelman-Rubin diagnostic of multiple M-H chains.

Input:

- obj : A scalar nb_model_sampling object.
- type : 'posterior' to test posterior draws (default) or 'updated' to test updated prior draws.

Output:

- res : A nDraws x nParam nb_data object storing the test statistic.
If any element is >> 1 run the M-H for a longer period, as it has not converged to the stationary distribution.
- plotter : A object of class nb_graph_data. Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graph on screen.

See also:

[nb_mcmc.gelmanRubinRecursive](#), [nb_dsg.e.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst, ...
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getBalancedGrowthPath** ↑

```
bgp = getBalancedGrowthPath(obj)
bgp = getBalancedGrowthPath(obj, vars, out)
```

Description:

Get steady-state solution of model as a cell matrix.

Input:

- obj : A nb_dsgc model where the steady-state solution is solved for.
- vars : The variables you want the steady-state of. Can also be (an) expression(s). Either as a cellstr or a char.
- out : Either 'cell' (default), 'double' or 'headers' (include model names as headers to the output cell, only when numel(obj)>1).

Output:

- bgp : A nEndo x (1 + nRegimes) cell matrix if vars is empty, or else the first dimension is given by length(vars) ('cell').
A nEndo x nRegimes double if vars is empty, or else the first dimension is given by length(vars) ('double').

See also:

[nb_model_generic.solution](#)

Written by Kenneth Sæterhagen Paulsen

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provide recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getDSGEVARPriorMoments ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by `nb_var.priorTemplate('dsge')`.

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

See also:

[nb_var](#), [nb_var.priorTemplate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependent ↑**

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDerivOrder** ↑

```
[order,type,ss] = getDerivOrder(obj)
```

Description:

Get order of returned jacobian.

Input:

- obj : An object of class nb_dsge.

Output:

- order : A cellstr with the order of the returned jacobian.
- type : Indicate what the derivative is take w.r.t:
 - > 1 : Leaded variables.
 - > 0 : Current variables.
 - > -1 : Lagged variables.
 - > 2 : Innovations.

```
- ss      : The steady-state of the ordered variables. As a 1 x N double.  
           If model is not solved this will return [].
```

Written by Kenneth Sæterhagen Paulsen

► **getDiagCovarianceMatrix** ↑

```
vcv = getDiagCovarianceMatrix(obj)
```

Description:

Get diagonal covariance matrix of the DSGE model. For RISE it is assumed that the shock standard deviations are parameters starting with 'std_'.

Input:

```
- obj : An object of class nb_dsg
```

Output:

```
- vcv : A nShock x 1 double
```

Written by Kenneth Sæterhagen Paulsen

► **getEndVal** ↑

```
ss = getEndVal(obj,varargin)
```

Description:

Get end values when doing permanent shocks, i.e. resolve the steady-state given some values of the exogenous variables.

The initial values that are used is the steady-state of the original model.

Input:

```
- obj : An object of class nb_dsg.
```

Optional input:

Most relevant options are;

```
- 'steady_state_block' : See nb_dsg.help('steady_state_block'). Default  
                        is to use the current value of the  
                        'steady_state_block'.
```

```
- 'steady_state_exo'      : See nb_dsgc.help('steady_state_exo'). Must be provided!
- 'homotopyAlgorithm'    : See nb_dsgc.help('homotopyAlgorithm'). Default is 0, i.e. no homotopy.
- 'homotopySteps'        : The number of homotopy steps. Default is 10.

Caution : The homotopy option 'homotopySetup' does not do anything in this method!
```

Output:

```
- ss      : A struct with the new full steady-state solution.
```

See also:

[nb_dsgc.set](#), [nb_dsgc.help](#)

Written by Kenneth Sæterhagen Paulsen

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

```
- obj   : An object of class nb_model_generic
```

Output:

```
- start : An object of class nb_date.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationTable** ↑

```
latexTable = getEstimationTable(obj)
latexTable = getEstimationTable(obj,'preamble',false)
```

Description:

Get latex table of estimated parameters.

Input:

- obj : A nb_dsg object.

% Optional input:

- 'preamble' : Give 0 if you don't want to include the preamble in the returned output. Default is to include the preamble, i.e. 1.
- 'filename' : Provide a file name to write the latex code to tex file.
- 'writePDF' : Give true (1) to write PDF using pdflatex. In this case the tex file is deleted! 'preamble' must be set to true in this case!
- 'precision' : Default is '%8.2f'. For more see second input to num2str.
- 'lookUp' : Either a N x 3 cell array, or a file that can be run by eval to create a variable lookUp that is a N x 3 cell array. The first column must list the names of the estimated parameters, the second column the latex name, and the third the description of the estimated parameter.

Caution: The latex name is enclosed in \$\$, i.e. interpreted in math mode, but description is not!

Output:

- latexTable : A one line char with the latex table code.

See also:

[num2str](#)

Written by Kenneth Sæterhagen Paulsen
Inspired by code written by Thor Andreas Aursland

► **getFiltered** ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_dsge.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast ↑**

```
fcstData = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0, -1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.
```

For real-time forecast the vintage at the time is

returned as the historical data, when includeHist is true.

> 'horizon' : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.

If includeHist is true the actual data is added as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!

Caution : If the horizon input is set you will set nHor to one, and the fcstPercData will be non-empty, if density forecast has been produced.

- includeHist : Give true (1) to include history in the output. Only an options for the 'date' and 'horizon' outputType. Default is false (0).

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with size nRec x nVars. While the fcstPercData output will be a nb_ts object with size nRec x nVars x nSim. You can set the horizon to return by the optional input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_dsgc.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables ↑**

vars = getForecastVariables(obj)

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► getHistory ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getIRFMatchingFunc ↑

```
getObjectiveFunc = getIRFMatchingFunc(obj,irfs,weights,normFunc)
```

Description:

Get objective to minimize when doing IRF matching.

Input:

- obj : An object of class nb_dsg.
- irfs : Same as the irfs output of the nb_model_generic.irf method.
- weights : Same format as the irfs input. Must provide the same shocks and variables as the irfs input, or else it must be empty (i.e. equal weights).
- normFunc : A function that maps from $R^X \rightarrow R$, where X is the number of observation of the irf to match. Default is to use $\@(\text{w})\text{norm}(\text{w})$, where w are the vector of weighted IRFs.

Output:

- getObjectiveFunc : A function handle that can be assign to the getObjectiveFunc options of the nb_dsg class.

See also:

[nb_model_generic.irf](#), [nb_dsg.estimate](#), [nb_statespaceEstimator.estimate](#)
[nb_ts](#)

Written by Kenneth Sæterhagen Paulsen

► [getLHSVars](#) ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsg object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getLoss** ↑

```
loss           = getLoss(obj)
[loss,names,table] = getLoss(obj)
```

Description:

Get calculated loss from model. See nb_dsg.e.calculateLoss or nb_dsg.e.optimalSimpleRules for how to do this.

Input:

- obj : A N x M matrix of nb_dsg.e objects.

Output:

- loss : A N x M double with the losses of the different models.
- names : A N x M cellstr with the names of the models.
- table : A 2 x N*M cell with a table of the losses.

See also:

[nb_dsg.e.calculateLoss](#), [nb_dsg.e.optimalSimpleRules](#)

Written by Kenneth Sæterhagen Paulsen

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsg object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getObjective** ↑

```
[objective,beta,sigma,lb,ub] = getObjective(obj)
```

Description:

Get objective for doing sampling from the posterior distribution of an estimated DSGE model. This is what is being minimized.

Input:

- obj : An object of class nb_dsg.

Output:

- objective : A function handle calculating the objective function that where maximized.
- beta : A nParam x 1 double with the values of all the parameters of the model.
- sigma : Covariance matrix of the estimated parameters at the mode.
- lb : Lower bound of the support of the estimated parameters, as a nEst x 1 double.
- ub : Upper bound of the support of the estimated parameters, as a nEst x 1 double.

See also:

Written by Kenneth Sæterhagen Paulsen

► **getObjectiveForEstimation** ↑

```
[fh,estStruct,lb,ub,opt,options] = ...
    nb_dsgen.getObjectiveForEstimation(options,forSystemPrior)
```

Description:

Get objective to minimize. Used by the nb_statespaceEstimator.estimate function.

See also:

[nb_dsgen.estimate](#), [nb_statespaceEstimator.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **getOptimalMonetaryPolicyMatrices** ↑

```
[Hlead,H0,Hlag,D] = ...
    nb_dsgen.getOptimalMonetaryPolicyMatrices(Alead,A0,Alag,B,W,beta)
```

Description:

Form the optimal monetary policy matrices when the Klein algorithm is used to solve the problem.

See also:

[nb_dsgen.optimalMonetaryPolicySolver](#)

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit          = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will
get the PIT from the start date of the recursive forecast and
use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct
the PITs based on the period from the estimation start date
until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a
nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date

cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

p = getParameters(obj,varargin)

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

: Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.

: Give 'double' to return the value as a numerical array.

: Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions** ↑

```
distr = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.

- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPriorDistributions** ↑

```
[distr,paramNames] = getPriorDistributions(obj)
```

Description:

Get prior distributions of model.

Input:

- obj : An object of class nb_dsgc.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

► **getRecursiveEstimationGraph ↑**

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

See also:

[nb_graph_ts](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveScore** ↑

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

```
residual = getResidual(obj)
```

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph** ↑

```
plotter = getResidualGraph(obj)
```

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames** ↑

residualNames = getResidualNames(obj)

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

roots = getRoots(obj)

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursivly estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.
- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
 - type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- If the object input is a vector, the type input can also be a cellstr array with matching length.
- Caution: See comment to the invert input!
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
 - startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
 - endDate : The date to end constructiong the score. Can be

empty. Either as a string or an object of class nb_date.

- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution** ↑

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getSteadyState** ↑

```
ss = getSteadyState(obj)
ss = getSteadyState(obj,vars,out)
```

Description:

Get steady-state solution of model as a cell matrix.

Input:

- obj : A nb_dsge model where the steady-state solution is solved for.
- vars : The variables you want the steady-state of. Can also be (an) expression(s). Either as a cellstr or a char.
- out : Either 'cell' (default), 'struct', 'double' or 'headers' (include model names as headers to the output cell, only when numel(obj)>1).

Output:

- ss : A nEndo x (1 + nRegimes) cell matrix if vars is empty, or else the first dimension is given by length(vars) ('cell').
A nEndo x nRegimes double if vars is empty, or else the first dimension is given by length(vars) ('double').

See also:

Written by Kenneth Åkerhagen Paulsen

► **getUpdatedPriorDistributions** ↑

```
distr          = getUpdatedPriorDistributions(obj)
[distr,paramNames] = getUpdatedPriorDistributions(obj,'draws',1000)
```

Description:

Get the updated prior distributions of model. Only from the first chain.

Input:

- obj : An object of class nb_model_sampling.

Optional input:

- 'draws' : The number of draws to sample from the updated prior to base the kernel estimation on, if empty or not provided all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► getVariablesList ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► geweke ↑

```
res = geweke(obj)
res = geweke(obj,chain,type)
```

Description:

Geweke (1992) test. This test split sample into two parts. The first 10% and the last 50%. If the chain is at stationarity, the means of two samples should be equal. The null hypothesis is that the subsamples has the same mean.

Input:

- obj : A scalar nb_model_sampling object.
- chain : Give the chain to test. If [] all chains are tested (default).
- type : 'posterior' to test posterior draws (default) or 'updated' to test updated prior draws.

Output:

- res : A 2 x nParam x nChains nb_cs with the difference in mean statistics ('statistic') and p-values ('P-value').

See also:

[nb_mcmc.geweke](#), [nb_dsge.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► graphCorrelation ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against emprirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- `plotter` : An object of class `nb_graph_cs`. Use the `graph` method or the `nb_graphPagesGUI` class.

See also:

`nb_dsg.e.simulatedMoments`, `nb_dsg.e.theoreticalMoments`
`nb_dsg.e.empiricalMoments`, `nb_graphPagesGUI`, `nb_graph_cs`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a `nb_model_estimate` object handle conditional info.

Input:

- `obj` : A scalar `nb_model_etimate` object.

Output:

- `ret` : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a `nb_model_estimate` object handle missing observations.

Input:

- `obj` : A scalar `nb_model_etimate` object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

► **help** ↑

```
helpText = nb_dsge.help
helpText = nb_dsge.help(option)
helpText = nb_dsge.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize** ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **interpretForecast** ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you

need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsgc.

- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_dsgc.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **interpretStochasticTrendInit** ↑

```
stInit = nb_dsgc.interpretStochasticTrendInit(parser, ...
                                               stochasticTrendInit, beta)
```

Description:

Interpret the stochasticTrendInit options.

Input:

- parser : A struct. See the property nb_dsge.parser.
- stochasticTrendInit : Either a struct or function_handle. See the examples in the folder Examples\Econometrics\... DSGE\StochasticTrend for both options.
- beta : A nParam x 1 double with the parameter values. In the case that the stochasticTrendInit input is a function handle these are passed as a struct, where the fieldnames are the parameter names and the field are their values.
- parameters : A nParam x 1 cellstr with the parameter names.

Output:

- stInit : A nEndo x 1 double with the initial condition. Useful for models with level variables.

Written by Kenneth Sæterhagen Paulsen

► irf ↑

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsge objects.
- 'compare' : Give true if you have a scalar nb_dsge model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.

- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.
I.e. {'var1',100,...} or {{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This options sets the error band percentiles of the graph, when the 'perc' input is empty. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

```

> 'cumulative product' : cumprod(1 + X,1)
> 'cumulative sum' : cumsum(X,1)
> 'cumulative product (log)' : log(cumprod(1 + X,1))
> 'cumulative sum (exponential)' : exp(cumsum(X,1))
> 'cumulative product (%)' : cumprod(1 + X/100,1)
> 'cumulative sum (%)' : cumsum(X/100,1)
> 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
> 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
> '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
  Default is ''. See help on the method input of the
  nb_model_generic.parameterDraws method for more
  this input. An extra option is:

    > 'identDraws' : Uses the draws of the matrix with
      the map from structural shocks to dependent
      variables. See nb_var.set_identification. Of
      course this option only makes sense for VARs
      identified with sign restrictions.

- 'normalize' : A 1 x 3 cell. First element must be the variable
  name as a string. The second element must be the
  value to normalize to, as an integer. While the
  third element is the period to be normalized, if
  set to inf, it will normalize the max impact
  period.

  E.g. {'Var',1,2}, {'Var',1,inf}

  Caution: 2 means observation 2 of the IRF, and as
  the IRF start at period 0, this means that
  observation 2 is period 1.

- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of
  irfs, while 'mean' normalize the mean and scale
  percentiles/other draws accordingly. Default is
  'draws'.

  Caution: Setting this to 'mean' will not work for
  reported variables that is not measured
  as % deviation from steady-state/mean.

- 'newReplic' : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the replic input.

- 'parallel' : Give true if you want to do the irfs in parallel.
  This option will parallelize over models. Default
  is false.

```

- 'parallelL' : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if numel(obj) == 1. Default is false.
- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for nb_dsg objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for nb_dsg objects.
- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'settings' : Extra graphs settings given to nb_plots function. Must be a cell.
- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.

For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.
- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.

```

- 'startingProb'      : Either a double or a char (Only for Markov-switching
models):

    > scalar           : Select the the regime to take the
                           initial transition probabilities
                           from.

    > double            : A draws x nRegime or a 1 x
                           nRegime double. draws refer to
                           the number set by the 'draws'
                           input.

    > 'ergodic'         : Start from the ergodic transition
                           probabilities. Default for 'irf'.

    > 'random'          : Randomize the starting values
                           using the simulated starting
                           points. Default for 'girf'.

- 'startingValues'   : Either a double or a char:

    > double            : A nVar x 1 double.

    > 'steadystate'     : Start from the steady state. If you are dealing
                           with a MS-model or a break-point model you can
                           indicate the regime by 'steadystate(regime)'. E.g.
                           to start in regime 1 give; 'steadystate(1)'. For
                           MS - models the default is the ergodic mean
                           (default as long as 'girf' is not selected as
                           'type'), while for break-point models it is to
                           start from the first regime.

    > 'zero'             : Start from zero on all variables.

    > 'random'           : Randomize the starting values using the simulated
                           starting points. Default when 'type' set to
                           'girf'.

- 'states'            : Either an integer with the states to produce irf in,
                           or a double with the states to condition on. Must
                           have size periods x 1 in the last case. Applies to
                           both MS - models and break-point models.

- 'type'               : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf'             : Generlized impulse response function
                           calculated as the mean difference between
                           shocking the model with a one period shock
                           (1 std) and no shock at all. Use the 'draws'
                           input to set the number of simulations to use
                           to base the calculation on. This type of
                           irfs must be used for non-linear models.

    > 'irf'                : Standard irf for linear models. Calculated by
                           shocking the model with a one period shock
                           (1 std).

- 'variables'          : The variables to create impulse responses of.

```

Default is the dependent variables defined by the first model.

Caution: The variables reported by the reporting property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.('E_X_NW'). Which will then be a nb_ts object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.

> 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

> 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isBreakPoint** ↑

```
ret = isBreakPoint(obj)
```

Description:

Is the nb_dsge object using the NB Toolbox solver for DSGE models with unanticipated break points or not.

Input:

- obj : A nb_dsge object.

Output:

- ret : 1 if true, else 0.

Written by Kenneth Sæterhagen Paulsen

► **isDensityForecast** ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsge object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

```
ret = isMixedFrequency(obj)
```

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsg objects!

For nb_dsg objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isRise** ↑

```
ret = isRise(obj)
```

Description:

Is the nb_dsg object a wrapper of a RISE dsg object or not.

Input:

- obj : A nb_dsg object

Output:

- ret : 1 if true, else 0.

Written by Kenneth SÃ¶terhagen Paulsen

► **isSampled** ↑

```
ret = isSampled(obj)
```

Description:

Is the nb_model_sampling object sampled or not.

Input:

- obj : A nb_model_sampling object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isStationary** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

ret = isestimated(obj)

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

ret = isforecasted(obj)

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint

```
prediction bands for
macroeconomic risk management

> 'copula' : Using a copula likelihood approach.

> 'mostlik' : Group the paths based on how
likely they are.

- 'nSteps' : Number of forecasting steps to use when constructing the
error bands. If empty (default) all forecasting steps stored
in the object is used.
```

Output:

- JPB : An nb_ts object storing the joint prediction bands.
The percentiles are stored as datasets. See the
dataNames property for which page represent which
percentile.

The data of the nb_ts object has size nSteps x nVars
x nPerc.
- plotter : A nb_graph_ts object. Use the graphSubPlots method
to produce the graphs.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **kleinSolver** ↑

```
[A,D,err] = nb_dsge.kleinSolver(parser,FF,F0,FB,FU)
```

Description:

Uses the Klein algorithm to solve the rational expectation mode.

See also:

[nb_solveLinearRationalExpModel](#)

Written by Kenneth Sætherhagen Paulsen

► **likelihood** ↑

```
[fval,sol] = nb_dsge.likelihood(par,estStruct)
```

Description:

Evaluate minus the log likelihood.

Input:

- See the method `nb_model_generic.objective` for description of inputs.

Output:

- `fval` : Value of minus the log likelihood at the given parameters.
- `sol` : A struct with the solution of the model. See output from `nb_dsg.e.stateSpace`,

See also:

`nb_dsg.e.objective`, `nb_dsg.e.stateSpace`, `nb_dsg.e.stateSpaceBreakPoint`
`nb_dsg.e.stateSpaceTVP`, `nb_kalmanLikelihoodMissingDSGE`
`nb_kalmanLikelihoodBreakPointDSGE`, `nb_kalmanLikelihoodTVPDSGE`
`nb_kalmanLikelihoodUnivariateStochasticTrendDSGE`

Written by Kenneth Sæterhagen Paulsen

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- `obj` : An object of class `nb_model_generic`.

Output:

- `posterior` : A struct with the posterior output (The format will depend on the sampling method used).

See also:

`nb_model_estimate.estimate`, `nb_dsg.e.assignPosteriorDraws`
`nb_model_sampling.sample`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **looseOptimalMonetaryPolicySolver ↑**

```
[H,D,DE,parser,err] = ...
    nb_dsge.looseOptimalMonetaryPolicySolver(parser,solution, ...
        options,expandedOnly)
```

Description:

This static method of the nb_dsge class implements the algorithm presented by; Debortoli, Maih and Nunes (2010) "Loose commitment in medium-scale macroeconomic models: Theory and an application".

All credits should go to the authors of that paper for the solution and not the writer of this code.

Input:

- parser : See nb_dsge.solveNB
- solution : See nb_dsge.solveNB
- options : See nb_dsge.solveNB
- expandedOnly : true if only the expanded solution is to be solved for.

Output:

- H : Transition matrix, as a nEndo + nMult x nEndo + nMult.
- D : Shock impact matrix as a nEndo + nMult x nExo.
- DE : Shock impact matrix as a nEndo x nExo x nHor, when solved with anticipated shocks, otherwise [].

Written by Kenneth Sæterhagen Paulsen

► **makeObservationEq ↑**

```
H = nb_dsge.makeObservationEq(obsInd,nEndo)
```

Description:

Make observation equation of NB toolbox solved DSGE model.

Input:

- obsInd : A vector of integers with length nObs storing the location of the observables in the vector of endogenous variables.
- nEndo : The number of endogenous variables.

Output:

- H : A nObs x nEndo matrix.

Written by Kenneth Sæterhagen Paulsen

► mcfRestriction ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use @(x)f1(x)&&f2(x), where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. @(x)gt(x,0),
@(x)gt(x,0)||lt(x,1), i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. @(x,y)gt(x,y),
@(x,y)gt(x-y,0)||lt(x-y,1), i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. {'Var1','Var1',1,@(x)gt(x,0.1)}, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. {'Var1','Var2',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous variance.

> 'ss' : A N x 2 cell, where the elements of each row are:
 1. The expression using any of the endogenous variables of the model.
 2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

► [meanPlot](#) ↑

```
[res,plotter] = meanPlot(obj)
[res,plotter] = meanPlot(obj,periods,type)
```

Description:

Calculates the (moving) mean of each sampled chain and plot it.

Input:

- obj : A scalar nb_model_sampling object.
- periods : Maximum period length when calculating the moving mean.
 Default is to use the full sample.
- type : 'posterior' to test posterior draws (default) or 'updated' to test updated prior draws.

Output:

- res : A nDraws x nParam x nChain nb_data object with the (moving) mean of the parameters.
- plotter : A object of class nb_graph_data. Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graph on screen.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► mincerZarnowitzTest ↑

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_GENERIC

► monteCarloFiltering ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

► nb2RisePreparser ↑

```
newFile = nb_dsg.e.nb2RisePreparser(rise_file,silent,macroProcessor,...  
macroVars)
```

Description:

This static method may be useful to convert a nb model file to a rise model file.

Caution: This is provided with no guarantee it will work, and a lot of the special options in a nb model file is not supported in RISE, and these options are not checked by this method!

Input:

- rise_file : A .mod or .nb file with the model to run in RISE instead of using the NB toolbox parser and solver.
- silent : If the parsing should be silent or not.
- macroProcessor : Run NB macroprocessor before writing it to a .rs file.
- macroVars : A vector of nb_macro objects. Use for the macroprocessing. Default is an empty nb_macro array.

Output:

- newFile : A .rs file with the file you can run with RISE.

See also:

[nb_dsg](#)

Written by Kenneth Sæterhagen Paulsen

► **objective** ↑

```
fval = nb_dsg.objective(par,estStruct)
```

Description:

The objective to minimize when doing estimation

Input:

```
- par : Current vector of the estimated parameters.  
- estStruct : A struct with at least the following fields;  
    > indPar : Index for where in the full parameter vector to find  
        the estimated parameters.  
    > beta : A vector of the values of all parameters. As a  
        nParam x 1.  
    > model : The obj.parser property of the nb_dsg class.  
    > options : The obj.estOptions property of the nb_dsg class.  
        (After calling getEstimationOptions, i.e. calling  
        the estimate method.)  
    > y : A nObservables x nPeriods double with the data to  
        estimate the model on. The data may contain missing  
        observations.  
    > z : Not in use. To make it generic to other classes of  
        models.  
    > observables : A logical vector. An element is true if the variable  
        is observable.
```

Output:

```
- fval : Value of the objective at the given parameters.
```

Written by Kenneth Sæterhagen Paulsen

► **optimalMonetaryPolicySolver** ↑

```
[H,D,DE,parser,err] = ...
nb_dsge.optimalMonetaryPolicySolver(parser,solution,options, ...
expandedOnly,solveForEpi)
```

Description:

This static method of the nb_dsge class implements the Klein algorithm to solve the problem.

Caution: This algorithm can only solve optimal monetary policy under full commitment or full discretion.

Input:

- parser : See nb_dsge.solveNB
- solution : See nb_dsge.solveNB
- options : See nb_dsge.solveNB
- expandedOnly : true if only the expanded solution is to be solved for.

Output:

- H : Transition matrix, as a nEndo + nMult x nEndo + nMult.
- D : Shock impact matrix as a nEndo + nMult x nExo.
- DE : Shock impact matrix as a nEndo x nExo x nHor, when solved with anticipated shocks, otherwise [].

Written by Kenneth Sæterhagen Paulsen

► **optimalSimpleRules** ↑

```
obj = optimalSimpleRules(obj,simpleRules)
obj = optimalSimpleRules(obj,simpleRules,varargin)
[obj,loss,osr_coeff,std_osr_coeff] = ...
optimalSimpleRules(obj,simpleRules,varargin)
```

Description:

Compute optimal simple rules given a loss function. The loss function can either be specified in the model file or by the nb_dsge.setLossFunction.

To set the discount factor of the optimizing authorities set the 'lc_discount' option. E.g. obj = set(obj,'lc_discount',0.99). This option can also be set in the model file, for more on this see DAG.pdf.

Caution: The return object is solved with the optimized simple rules.

Input:

- obj : An object of class nb_dsg.e.
- simpleRules : A char or cellstr array with the rules to maximize.
Each rule must have the instrument as its only left hand variable. E.g. ' $i = lam1*pi + lam2*y$ ' or
 $\{i = lam1*pi + lam2*y; tau = lam3*pi + lam4*y\}$. The lamX parameters are in this case the parameters that is optimized over.
- type : Either 'commitment' or 'discretion'. If 'discretion' the interest rate rule can only respond to state variables! Default is 'commitment'.

Optional inputs:

- 'init' : Initial values of the optimization routine. As a struct with the fieldnames as the parameter names of the simple rules and the fields as the initial values.

Caution: If the parameters are declared in the model file (.nb file) you may use nb_dsg.e.assignParameters before calling this function instead, i.e. the calibration is used as the initial values.
- 'lowerBound' : Sets the lower bound on the coefficients of the simple rules.
- 'osr_type' : Either 'commitment' or 'discretion'. If 'discretion' the interest rate rule can only respond to state variables! Default is 'commitment'.
- 'upperBound' : Sets the upper bound on the coefficients of the simple rules.

Else:

- varargin : See the the set method.

Output:

- obj : An object of class nb_dsg.e. The model is solved with the optimized simple rule.

Examples:

```
obj = optimalSimpleRules(obj,'i = lam1*pi + lam2*y');
```

See also:

[nb_dsg.e](#), [nb_dsg.e.parse](#), [nb_dsg.e.setLossFunction](#)

Written by Kenneth Sæterhagen Paulsen

► parameterDraws ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated

with classical methods.

```

> 'wildBlockBootstrap' : Create artificial data by wild
  overlapping random block length
  bootstrap., and then "draw" parameters
  based on estimation on these data.
  Only an option for models estimated
  with classical methods.

> 'copulaBootstrap'      : Uses a copula approach to draw residual
  that are autocorrelated, Does not handle
  heteroscedasticity. Only an option for
  models estimated with classical methods.

> 'posterior'           : Posterior draws. Only for models
  estimated with bayesian methods.
  Default for models estimated with
  bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
  on this option.

- stable : Give true if you want to discard the parameter draws
  that give rise to an unstable model. Default is false.

```

Optional input:

```

- 'parallel'      : Run in parallel. true or false.

- 'cores'         : Number of cores to use. Default is to use all cores
  available.

- 'newDraws'       : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the draws input.

  Caution: When setting 'parallel' to true on MATLAB
  version later than R2017B this number will
  be the number of new draws, and not the
  factor!!! E.g. set it to 100. If it is given
  as a number less than 1, it will by default
  be set to 100.

- 'initialDraws'  : When drawing parameters this factor decides how many
  many draws that are produced before solving the model.
  Default is 1. I.e. it is equal to draws input. For
  VAR models with underidentification it may be a good
  idea to set this to a value > 1 as you may drop a
  lot of parameters when identification fails. Default
  is 1.

```

Output:

```

- out          : The output depend on the input output:

> 'param'      : Default. A struct with the following fields:

  beta   : A nPar x nEq x draws double with the

```

estimated parameters.

sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:

lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.

R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.

factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

ci = parameterIntervals(obj,alpha)

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

```
- ci      : A nPar x 3 cell matrix.  
Written by Kenneth SÃ¶terhagen Paulsen  
Inherited from superclass NB_MODEL_GENERIC
```

► **parse** ↑

```
obj = nb_dsgc.parse(filename,varargin)
```

Description:

Parse model file on the .nb format.

Input:

- filename : A string with the name of the model file with extension .nb.

Optional inputs:

(Most relevant to parsing)

- 'macroProcessor' : See nb_dsgc.help('macroProcessor').
- 'macroVars' : See nb_dsgc.help('macroVars').
- 'silent' : See nb_dsgc.help('silent').

Output:

- obj : An object of class nb_dsgc.

See also:

[nb_dsgc.solve](#), [nb_dsgc.help](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **parseTempParameters** ↑

```
out = nb_model_parse.parseTempParameters(eqs,verbose)
```

Description:

Parse terms starting with #, and substitue out for where these terms are used.

Input:

- eqs : A N x 1 cellstr with the equations of the model.
- verbose : Set to true to print resulting equations.

Output:

- out : A N x 1 cellstr with the parsed equations of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_PARSE

► **perfectForesight** ↑

```
[sim,plotter,distr] = perfectForesight(obj,varargin)
```

Description:

Perform perfect foresight simulation.

Input:

- obj : An object of class nb_dsg.

Optional input:

- 'addEndVal' : Add end value as the last observation of the simulation results, i.e. if the 'periods' input is set to 100, the sim output will return a nb_data object with 101 observation. nan is given to the variable not assign a end value with the 'endVal' input. Default is true.
- 'addSS' : Set to false to not add the steady-state to the simulation. Default is true.
- 'blockDecompose' : Set it to true to use block decomposition to solve the problem.
- 'derivativeMethod' : Either 'symbolic' (fastest) or 'automatic'.
- 'draws' : Number of draws from the distribution of the initial values. Default is 500. See 'stochInitVal'.
- 'endVal' : Sets the end values of the simulation of all the endogenous variables of the model. Must be given as a struct where the fieldnames are the names of the endogenous variables of the model, and the fields are their end value. If not provided the end values will be the original steady-state. See the nb_dsg.getEndVal method to find the end values after a permanent shock.

- 'exoVal' : A nb_data object with the values of the exogenous variable for the wanted simulation.
 - Caution: If startObs > 1, the values before this observation gets the values 0.
 - Caution: If endObs < periods the values after this observation gets the values 0.
 - Caution: If this input only gives the values of a subset of the exogenous variable, the rest will be given 0 for all observations.
- 'homotopyAlgorithm' : See nb_dsge.help('homotopyAlgorithm'). Default is 0, i.e. no homotopy.
- 'homotopySteps' : See nb_dsge.help('homotopySteps'). Default is 10.
- 'initVal' : Sets the initial values of the simulation of all the backward looking variables. Must be given as a struct where the fieldnames are the names of the backward looking variables of the model, and the fields are their initial value. If not provided the initial values will be the original steady-state.
 - Caution: If 'stochInitVal' is set to true, this option will set the conditional information of the initial condition. For more on this case see doc on the input 'stochInitVal'.
- 'optimset' : A struct with the options used by the solver. See nb_perfectForesight.optimset for more.
- 'periods' : The number of periods of the simulation. E.g. periods >>> number of period it takes to converge to the end values of the simulations. Default is 150.
- 'plotInitSS' : Plot initial steady-state in the return graphs, if 'addSS' is set to false, zero lines will be plotted. The period 0 will also be included, and will be set to the initial steady-state (zero). true or false. Default is false.
- 'plotSS' : Plot steady-state values during simulation. 'plotInitSS' will be set to true in this case.
- 'seed' : Set the seed of the pseudo random generated numbers when 'stochInitVal' is set to true. Default is 1.
- 'solver' : Name of the solver to use. Either 'nb_solve' or 'nb_abcSolve'. Default is 'nb_solve', i.e. using newton algorithm. See the 'optimset' options to adjust solving options.

- 'startingValues' : How to find the starting values of the problem to solve, i.e. the initial values of the full path.
 - > 'steady_state' : All variables for all periods are set to their initial steady-state values. Default.
- 'stochInitVal' : Set to true to draw initial conditions. If 'initVal' is not provided it will draw from unconditional distribution of the initial condition, or else it will draw from the conditional distribution of the initial values. In the latter case you can fix the value of a variable by giving a scalar double to a field of the 'initVal' input, or you can specify a truncated interval by providing a 1x2 double with the lower and upper bound to a field of the 'initVal' input. E.g:
 1. Condition on a point: init.Var1 = 2;
 2. Condition on an interval: init.Var1 = [1.5,2.5];

Output:

- sim : The perfect foresight simulation stored as a periods x nVar nb_data object
- plotter : A nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the figures.

See also:

[nb_model_generic.irf](#), [nb_dsge.getEndVal](#), [nb_dsge.checkSteadyState](#)

Written by Kenneth Sæterhagen Paulsen

► **permanentShock ↑**

[sim,plotter,ssTable] = permanentShock(obj,varargin)

Description:

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'algo' : Either 'breakPoint' or 'perfectForesight', default is 'perfectForesight'.
- 'delta' : Give true, if you want to run the delta on the

shock hitting, not hitting. This can be utilized to explore the differences in IRFs from shocks when initial values are different from the initial steady-state. I.e. when using the 'initVal' input. Default is false.

Caution: This option is not accepted for 'algo' set to 'breakPoint'.

- 'periods' : See the 'periods' input to the perfectForesight method.
- 'steady_state_block' : See nb_dsge.help('steady_state_block'). Default is to use the current value of the 'steady_state_block'. Default is true.
- 'steady_state_exo' : The exogenous innovations that are subject to a permanent shock. See nb_dsge.help('steady_state_exo') for the format of this input. Must be provided!
- All the inputs to the nb_dsge.perfectForesight method except; 'endVal', 'exoVal' and 'periods'. Inputs like 'initVal' and 'stochInitVal' will have no impact when 'algo' is set to 'breakPoint'.

Output:

- sim : See the doc of the same output from the nb_dsge.perfectForesight method.
- plotter : See the doc of the same output from the nb_dsge.perfectForesight method.
- ssTable : A nEndo x 3 nb_cs object with the old steady state, new steady state and the difference.

Written by Kenneth Sæterhagen Paulsen

► **plotForecast ↑**

```
plotter = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF ↑**

plotter = nb_model_generic.plotMCF(paramD, params, lowerBound, ...
upperBound, method)

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- `plotter` : > 'allInOne' : A `nb_graph_cs` object. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
- > 'biplot' : A vector of `nb_graph_data` objects with size equal to the number of pairwise combination of the parameters that can be made. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

[nb_dsgc.monteCarloFiltering](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► `plotMCFDistTest` ↑

`plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)`

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `test` : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,valueName)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_dsgc.monteCarloFiltering](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

[nb_dsgc.getPosteriorDistributions](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [plotPriors](#) ↑

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotUpdatedPriors** ↑

```
plotter = plotUpdatedPriors(obj)
plotter = plotUpdatedPriors(obj,varargin)
```

Description:

Plot updated priors (and priors) drawn during estimation. Only for bayesian models. Only from the first chain.

Input:

- obj : A scalar object of class nb_model_sampling. It must represent a bayesian model that is estimated using system priors. See nb_model_sampling.sampleSystemPrior.

Optitonal input:

- 'prior' : Give this string as an input to compare updated priors with the prior distribution (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the updated prior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- `plotter` : A 1 x numCoeff vector of objects of class `nb_graph_data`. Use either the `graph` method or the `nb_graphMultiGUI` class to plot the updated priors on screen.

Caution: If '`subplot`' is given it will return a scalar `nb_graph_data` object. Use the `graphSubPlots` method or the `nb_graphSubPlotGUI` class to plot the updated priors on screen.

`nb_graph_data`, `nb_graphMultiGUI`, `nb_graphSubPlotGUI`
`nb_dsgc.getUpdatedPriorDistributions`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_SAMPLING`

► **print** ↑

`printed = print(obj)`

Description:

Get the estimation result printed to a char array.

Input:

- `obj` : A vector of `nb_model_estimate` objects.

Output:

- `printed` : A char array with the estimation results.

See also:

`nb_model_estimate.print_estimation_results`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **printCov** ↑

`printed = printCov(obj)`

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► printDecisionRules ↑

```
str = printDecisionRules(obj)
str = printDecisionRules(obj,variables)
str = printDecisionRules(obj,variables,precision,asCell)
```

Description:

Print decision rules.

If the model is solved by RISE this calls the dsge.print_solution method made by Junior Maih, which is part of the RISE toolbox.

Input:

- obj : An object of class nb_dsge.
- variables : A cellstr with the variables to print the solution for.
- precision : The precision of the printed decision rules.
- asCell : Give true to return decion rules table as cell. Not supported if numel(obj) > 1 && (length(variables) > 1 || length(variables) == 0). Default is false.

Output:

- str : A char with the printed decision rules of the model. If numel(obj) > 1 the output will be a 1 x nobj cell array.

If asCell is set to true it will be a cell array instead.

See also:

[nb_dsge.solve](#), [nb_dsge.findRESolution](#), [dsge.print_solution](#)

Written by Kenneth Sæterhagen Paulsen

► **printOSR** ↑

```
res = nb_dsgc.printOSR(results,options,precision)
```

Description:

Get the results od the optimization of the simple rules as a char.

Input:

- results : A struct with the results from the optimization of the simple rules.
- options : The options property of the nb_dsgc object.
- precision : The precision of the printed result.

Output:

- results : A char with the estimation results.

Written by Kenneth Sæterhagen Paulsen

► **print_estimation_results** ↑

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_dsgc.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **priorPredictiveAnalysis** ↑

```
varargout = priorPredictiveAnalysis(obj,method,draws,rmsd,varargin)
```

Description:

Draw from the independent prior distributions and get the prior predictive distribution of the object of interest.

Input:

- obj : An object of class nb_dsge.
- method : The method of study. A string with the name of the method. One of; 'irf','calculateMultipliers', 'simulatedMoments' or 'theoreticalMoments'.
- draws : The number of draws made from the independent priors.
- rmsd : Calculate RMSD. See more under the documentation of the outputs.

Optional input:

- The inputs that are passed to the specified method, i.e.
varargout = method(obj,varargin). See also the examples.

Output:

- The optional outputs return by the specified method, i.e.
varargout = method(obj,varargin). See also the examples.

Caution: If the rmsd input is set to true all the outputs are returned as structures. One field called the 'prior' contain the prior predictive analysis when all parameters are varied. The fields that have the names of a parameter, we have kept that parameter at its mean (Be aware that some simulation may fail in this case and that the simulation in this case may be lower than the draws input). The corresponding RMSD is reported in in the <paramName>RMSD. This only applies to output that are nb_ts, nb_data, nb_cs or a struct of the already mentioned classes.

Examples:

```
[irfs,~,plotter] = priorPredictiveAnalysis(obj,'irf',1000,,false,...  
    'shocks',{'E_X'},'variables',{'X','Y'},...)  
  
mult = priorPredictiveAnalysis(obj,'calculateMultipliers',1000,true,...  
    'variables',{'Y','Z'},'instrument','X',...  
    'rate','R','shocks',{'E_X'})
```

See also:

[nb_model_generic.irf](#), [nb_model_generic.calculateMultipliers](#)

Written by Kenneth Sætherhagen Paulsen

► **rationalExpectationSolver** ↑

```
[A,D,DE,err] = nb_dsge.rationalExpectationSolver(parser,solution,...  
options)
```

Description:

Solving forward looking models under the rational expectation assumption.

This uses the solution approach put forward by Paul Klein. See
nb_solveLinearRationalExpModel.

Input:

- parser : See nb_dsge.solveNB
- solution : See nb_dsge.solveNB
- options : See nb_dsge.solveNB
- expandedOnly : true if only the expanded solution is to be solved for.

Output:

- A : Transition matrix, as a nEndo x nEndo.
- D : Shock impact matrix as a nEndo x nExo.
- DE : Shock impact matrix as a nEndo x nExo x nHor, when solved with anticipated shocks, otherwise [].

See also:

[nb_solveLinearRationalExpModel](#), [nb_dsge.selectSolveAlgorithm](#)

Written by Kenneth Sæterhagen Paulsen

► **removeBreakPoints** ↑

```
obj = removeBreakPoints(obj)
```

Description:

Remove all break-points added to the structural parameters of the model.

Input:

- obj : An object of class nb_dsge.

Output:

- obj : An object of class nb_dsg.

See also:

[nb_dsg.addBreakPoint](#)

Written by Kenneth Sæterhagen Paulsen

► **removeObservations** ↑

obj = removeObservations(obj,numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **reparse** ↑

obj = reparse(obj,varargin)

Description:

Re-parse model given new parsing options.

Input:

- obj : An object of class nb_dsg.

Optional input:

(Most relevant to parsing)

- 'macroVars' : See nb_dsge.help('macroVars').
- 'silent' : See nb_dsge.help('silent').

Output:

- obj : An object of class nb_dsge.

See also:

[nb_dsge.set](#), [nb_dsge.parse](#)

Written by Kenneth Å!terhagen Paulsen

► **reportFiltered** ↑

```
[reported,raw] = reportFiltered(obj,expression)
[reported,raw] = reportFiltered(obj,expression,extra)
[reported,raw] = reportFiltered(obj,expression,extra,type,normalize, ...
    econometricians)
```

Description:

Input:

- obj : An object of class nb_dsge.
- expression : See the documentation of the reporting property of the nb_dsge class.
- extra : An object of class nb_ts with additional variables used for reporting purposes.
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be $N(0,1)$. Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.

Output:

- reported : An object of class nb_ts with the reported variables.
- raw : An object of class nb_ts with the raw filtered variables.

Written by Kenneth Å!terhagen Paulsen

► **sample** ↑

```
obj = sample(obj,varargin)
```

Description:

Sample from the posterior distribution using some type of sampling algorithm.

Caution: Be aware that the 'draws' options only decides the number of draws used to produce error bands of IRF, forecast etc., while the the 'draws' field of the 'sampler_options' options sets the number of the sampler itself. The draws to keep are randomly selected out of the sampled draws!

Caution: If you use an external sampler, you can use the nb_model_generic.assignPosteriorDraws method to assign this to the object. Be caution to not assign too many draws, as you may run out of memory (i.e. don't assing 1 000 000 draws)!

Caution: To manually inspect the posterior draws use nb_model_generic.loadPosterior, and see the field output. This is the output from the sampler function specified.

Input:

- obj : An object of class nb_model_sampling.

Optional input:

- varargin : Optional input pairs given to the set method. See nb_model_estimate.set. I.e. these input can be used to set fields of the options property. Most relevant is 'sampler_options'

Output:

- obj : An object of class nb_model_sampling.

See also:

[nb_model_estimate](#), [nb_model_generic.assignPosteriorDraws](#)
[nb_model_generic.checkPosteriors](#), [nb_model_generic.plotPosteriors](#)
[nb_dsge.geweke](#), [nb_dsge.gelmanRubin](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► **sampleSystemPrior** ↑

```
obj = sampleSystemPrior(obj,varargin)
```

Description:

Sample from the system prior distribution using some type of sampling algorithm, i.e. get the prior distribution of the parameters given the system priors.

Input:

- obj : An object of class nb_model_sampling.

Optional input:

- varargin : Optional input pairs given to the set method. See nb_model_estimate.set. I.e. these input can be used to set fields of the options property. Most relevant is 'sample_options'

Output:

- obj : An object of class nb_model_sampling.

See also:

[nb_model_estimate](#), [nb_model_generic.assignPosteriorDraws](#)
[nb_dsgc.systemPriorObjective](#)

Written by Kenneth Åstrehagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► [set ↑](#)

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **setLossFunction ↑**

obj = setLossFunction(obj, lossFunction, optimal)

Description:

Set the loss function to optimize, be it with optimal simple rules, with full optimal monetary policy solution or for calculating the loss using the calculateLoss method.

Caution: If you already have solved the model under optimal policy, you can reset the loss function with the optimal input set to true, and then call the solve method to re-solve the model.

Tip : If you already have solved the model under optimal policy, and you for some reason want to calculate the loss with another loss function than in the model, you can use this method with the optimal input set to true. Do not call the solve method in this case!

Input:

- obj : An object of class nb_dsgen.

- lossFunction : A string with the loss function. E.g.
`'0.5*(INF2+LAM_Y*Y2)'.`
- optimal : Set it to false to not trigger solving the model under optimal monetary policy, i.e. this loss function can then be used to calculate the loss of a DSGE solved with taylor type rule. Default is true.

Output:

- obj : An object of class nb_dsge, where the parser property has been updated with the new loss function.

See also:

`nb_dsge.solve`, `nb_dsge.optimalSimpleRules`
`nb_dsge.looseOptimalMonetaryPolicySolver`
`nb_dsge.optimalMonetaryPolicySolver`, `nb_dsge.calculateLoss`

Written by Kenneth Å!terhagen Paulsen

► **setParametersInUse** ↑

`obj = setParametersInUse(obj,parameters)`

Description:

Indicate that the parameter is in use even if the parser has failed to detect that.

Input:

- obj : An object of class nb_dsge.
- parameters : A cellstr with the parameters to indicate are in use.

Output:

- obj : An object of class nb_dsge.

Written by Kenneth Å!terhagen Paulsen

► **setPrior** ↑

`obj = setPrior(obj,prior)`

Description:

Set priors of a vector of nb_dsg objects. The prior input must either be a struct or nb_struct with same size as obj or have size 1.

The provided struct will be added to the property options as the field prior.

The supported prior distributions for the NB Toolbox are:

- For backing out from mean and std. See the mean and variance only supported distribution listed in the static method nb_distribution.parametrization.
- For the parametrized prior distribution option see the help on the type property of the nb_distribution class, as well as the help on the parameters property for how many parameters each distribution takes.

Caution : If no priors are set maximum likelihood is done when the estimate method is called. Initial values must then be set by the nb_model_generic.assignParameters method.

Input:

- obj : A vector of nb_dsg objects.
- prior : One of;
 - > A struct or a nb_struct with either matching numel of obj or size 1. If size is 1 all models gets the same prior settings.
 - For each element of the struct array:
 - > The fieldnames should be names of the parameters to estimate.
 - > The fields must be one of the following:
 - * Uniform prior:
 {startValue,lowerBound,upperBound}
 - * Prior distribution backed out from mean and standard deviation:
 {startValue,priorMean,priorSTD,'distribution'}
 - * Same as above, but adds a lower bound to the prior distribution:
 {startValue,priorMean,priorSTD,'distribution',lowerBound}
 - * Same as above, but adds a upper bound to the prior distribution:
 {startValue,priorMean,priorSTD,'distribution',lowerBound,...
 upperBound}
 - * Parametrized prior distribution:
 {startValue,parameters,'distribution'}
 - * Same as above, but adds a lower bound to the prior distribution:
 {startValue,parameters,'distribution',lowerBound}
 - * Same as above, but adds a upper bound to the prior distribution:
 {startValue,parameters,'distribution',lowerBound,upperBound}
 where parameters is a 1 x nParam cell array given as the parameters of the selected distribution.
 - > To estimate the the timing of break point use 'break_dateOfBreak' as the fieldname and the field on the the following syntax:
 {lowerBound,upperBound}
 where both lowerBound and upperBound either must be a date as string or a nb_date object. Example:
 prior.break_2001Q1 = {'1999Q1','2001Q1'};

> A nParam x 1 nb_distribution object. Set the name property of the nb_distribution objects to link it to a parameter and use the userData property to set the starting value of the optimization (if it is empty it will use the prior mean as the starting value).

Output:

- obj : A vector of nb_dsg objects with the priors set.

See also:

[nb_model_generic.assignParameters](#), [rise_generic.setup_priors](#)
[nb_model_estimate.set](#)

Written by Kenneth Sæterhagen Paulsen

► **setRisePosteriorSettings** ↑

obj = setRisePosteriorSettings(obj,varargin)

Description:

Set setting on how to sample from the posterior.

Inputs.

- obj : A 1x1 nb_dsg object.

Input:

- 'burnin' : The number of draws to burn at the start of the sampling process.
- 'thin' : Give 1 to keep every draw, 2 to keep every second draw, etc.
- 'algorithm' : Either;
 - > 'mh_sampler' : Uses the mh_sampler function of the RISE toolbox
 - > 'rff_sampler' : Uses the rrf_sampler function of the RISE toolbox

Output:

obj : The object itself with the options reset.

Written by Kenneth Sæterhagen Paulsen

► **setSystemPrior** ↑

```
obj = setSystemPrior(obj,varargin)
```

Description:

Set system priors used for estimation.

The system priors implemented are described in the paper Andrle and Benes (2013), "System Priors: Formulating Priors about DSGE Models'', Properties"

Input:

- obj : A scalar object of class nb_dsge.

Optional input:

- 'irf' : System priors on IRFs. A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1.
 4. Prior function as a function_handle. E.g.
@(x) log(nb_distribution.normal_pdf(x,0,1)), i.e. it must return the log prior density.

See nb_distribution.parametrization or
nb_distribution.qestimation to back out the
hyperparameters of a distribution given some moments.

E.g. {'E_X','X',1,@(x) log(nb_distribution.normal_pdf(x,0,1))}

- 'cov' : System priors on the correlation matrix. A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. {'X','X',0,@(x) log(nb_distribution.invgamma_pdf(x,1,1))},
i.e. prior on the variance of 'X'.

> 'corr' : Same as for 'cov', but now the system prior is on the correlation matrix. (Be aware that the example above makes no sense in this case as the contemporaneous correlation with itself is always 1!)

> 'fevd' : System priors on forecast error variance decomposition.
A N x 4 cell, where the format is as in the 'irf' case.

Output:

- obj : A scalar object of class nb_dsge, where the systemPrior options has been assign a function_handle that evaluates the wanted priors.

See also:

`nb_dsgc.setPrior`, `nb_model_generic.estimate`, `nb_model_sampling.sample`
`nb_model_sampling.sampleSystemPrior`

Written by Kenneth Åkerhagen Paulsen

► **shock_decomposition ↑**

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of `nb_model_generic` objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- `obj` : A vector of `nb_model_generic` objects
- `'packages'` : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1','...','shock_group_name_N';  
'shock_name_1' ,..., 'shock_name_N'}
```

Where '`shock_name_x`' must be a string with a shock name or a cellstr array with the shock names. E.g '`E_X_NW`' or `{'E_X_NW','E_Y_NW'}`.

Caution: Two special identifiers can be used; '`Initial Conditions`' and '`Steady-state`'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- `'variables'` : The variables to decompose. Default is the dependent variables defined by the first model.
- `'startDate'` : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- `'endDate'` : End date of the decomposition. As a string. If

different models has different frequency this date will be converted.

- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. E.g. [0.3, 0.5, 0.7, 0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.
- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.

- `decompBand` : A nested structure of `nb_ts` objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- `plotter` : A $1 \times nModel$ vector of `nb_graph_ts` objects. Use the `graph` method to produce the graphs or use the `nb_graphPagesGUI` on each element of the graph objects.

See also:

[nb_dsge.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **simulate** ↑

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- `obj` : A vector of `nb_model_generic` objects.
- `nSteps` : Number of simulation steps. As a 1×1 double. Default is 100.

Optional inputs:

- `'burn'` : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- `'bounds'` : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - `'shock'` : Name of the shock to match the restriction on the bounds of the given variable.
 - `'lower'` : The lower bound of the selected variable. Either a 1×1 double value or a function handle to a probability distribution to draw from.
 - `'upper'` : The upper bound of the selected variable. Either a 1×1 double value

or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not

the lags). Also including exogenous and shocks.

- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.
- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a spesific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:
 - > double : A 1 x nVar double.
 - > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsg models.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsg models. If you are dealing with a MS-model you can indicate the state by 'steadystate(state)'. E.g. to start in state 1 give; 'steadystate(1)'. Default for nb_dsg models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char:
 - > double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to

the number of recursive periods to forecast.

> 'ergodic' : Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.

- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulateStructuralMatrices** ↑

[Alead, A0, Alag, B] = simulateStructuralMatrices(obj, method, headings)

Description:

```
Alead*y(+1) + A0*y + Alag*y(-1) + B*e
```

Input:

- obj : An object of class nb_dsge.
- method : Either 'mean', 'median', 'var', 'std', 'skewness', 'kurtosis' or 'sim' (default). 'sim' will return the simulation where the pages are the different draws.
- headings : Give true to add table headings to the outputs. Not supported for method set to 'sim'. Default is false.

Output:

- [Alead,A0,Alag,B] : The structural representation of the DSGE model. Ax has size nEndo x nEndo x N, and B has size nEndo x nExo x N. N is equal to options.uncertain_draws if method is equal to 'sim', otherwise 1.

See also:

[nb_dsge.declareUncertainParameters](#)

Written by Kenneth Sæterhagen Paulsen

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.
- Optional inputs;
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to

true.

- 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: 'pDraws' or 'draws' must be set to a number > 1.

- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)),

where x is the variable along the first dimension. In the lower triangular part the you can find $\text{cov}(x(-i), y)$, where x is the variable along the first dimension.

E.g: You have two variables x and y , then to find $\text{cov}(x, y(-i))$ you can use $\text{getVariable}(\text{varargin}\{i\}, 'y', 'x')$, while to get $\text{cov}(x(-i), y) (= \text{cov}(x, y(+i)))$ you can use $\text{getVariable}(\text{varargin}\{i\}, 'x', 'y')$. (This example only works if the output is of class nb_cs)

See also:

[nb_dsge.graphCorrelation](#), [nb_dsge.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **solve** ↑

```
obj = solve(obj)
obj = solve(obj, numAntSteps, shockProperties)
obj = solve(obj, varargin)
```

Description:

Solve estimated/calibrated model(s) represented by nb_dsge object(s).

This method uses the RISE model solver if the nb_dsge model represent a RISE object, and it uses the dynare developed solver if the underlying object is a dynare solved DSGE model. All credits should go to the authors of those codes.

If the model file is of the .nb extension the solver should be credited the author of this function, but again this solver is based on papers published by the dynare team and other. See:

```
> "Solving rational expectations models at first order: what Dynare does"
   by Sebastian Villemot
> "Loose commitment in medium-scale macroeconomic models:
   Theory and an application" by Debortoli, Maih and Nunes (2010).
> "Conditional forecast in DSGE models." by Maih (2010).
```

Input:

- obj : A vector of nb_model_generic objects.

Optional inputs:

Only two extra inputs (and the varargin{1} input is numeric):

- varargin{1} : See nb_dsge.help('numAntSteps').

```

- varargin{2} : See nb_dsge.help('shockProperties') .

OR (optionName, optionValue pairs):

- 'numAntSteps'      : See nb_dsge.help('numAntSteps') .

- 'silent'           : See nb_dsge.help('silent') .

- 'shockProperties' : See nb_dsge.help('shockProperties') .

- 'waitbar'          : Set to nb_waitbar5 object. Only if numel(obj) > 1 .
It will use the maxIterations2 and status2
properties.

```

Can also set all options of the options property. Same as
 nb_model_estimate.set.

Output:

```

- obj    : A vector of nb_model_generic objects, where the
solved model(s) is/are stored in the property
solution.

- solved : If nargout == 2 this method will not throw an error in the
case an element does not solve, instead it will set the
corresponding element of this output to false, and return the
un-solved nb_dsge object array.

```

[nb_model_generic](#), [nb_model_estimate.set](#), [nb_dsge.solveNormal](#)
[nb_dsge.solveExpanded](#)

Written by Kenneth Å!terhagen Paulsen

► **solveBalancedGrowthPath ↑**

obj = solveBalancedGrowthPath(obj)

Description:

Solve for the balanced growth path of the model.

Input:

- obj : An object of class nb_dsge.

Output:

- obj : An object of class nb_dsge.

See also:

[nb_dsge.stationarize](#)

Written by Kenneth Sæterhagen Paulsen

► **solveBreakPoints** ↑

```
[AB,BB,CB,CEB,ssB,JACB,err] = nb_dsge.solveBreakPoints(options,...  
beta,A,B,C,CE,ss,JAC,silent)
```

Description:

Solve for all the break-points regimes.

Input:

- options : See the estOptions property of the nb_dsge class.
- beta : A nParam x 1 double with the parameter values in the main regime.
- A : State transition matrix in main regime.
- B : Constant term
- C : The impact of shock matrix in main regime.
- CE : The impact of anticipated shock matrix in main regime.
- ss : The steady-state in the main regime.
- JAC : The jacobian of the main regime.

Output:

- AB : A 1 x nBreaks + 1 cell with the state transition matrices of all regimes.
- BB : A 1 x nBreaks + 1 cell with the constant term.
- CB : A 1 x nBreaks + 1 cell with the impact of shock matrices of all regimes.
- CEB : A 1 x nBreaks + 1 cell with the impact of anticipated shock matrices of all regimes.
- ssB : A 1 x nBreaks + 1 cell with the steady-state of all regimes.
- JACB : A 1 x nBreaks + 1 cell with the jacobian matrices of all regimes.
- err : Non-empty if an error is thrown. If this output is not returned a standard error is thrown in the command window.

Written by Kenneth Sæterhagen Paulsen

► **solveExpanded** ↑

```
tempSol = nb_dsg.e.solveExpanded(model, results, opt, numAntSteps, ...
                                  shockProperties)
```

Written by Kenneth Sæterhagen Paulsen

► **solveForEpilogue** ↑

```
[A,B,parser] = nb_dsg.e.solveForEpilogue(parser, solution, H, D, Alead, Alag, algorithm)
```

Description:

Solve for the epilogue when it is remove during normal solving.

See also:

[nb_dsg.e.looseOptimalMonetaryPolicySolver](#)
[nb_dsg.e.optimalMonetaryPolicySolver](#), [nb_dsg.e.rationalExpectationSolver](#)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_dsg.e.solveNormal(results, opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveOneIteration** ↑

```
[A,B,C,CE,ss,paramV,err] = nb_dsg.e.solveOneIteration(options, results, obs)
```

Description:

Solve model given current level of trends.

Input:

- options : See the `estOptions` property of the `nb_dsg.e` class.
- results : See the `results` property of the `nb_dsg.e` class.
- obs : A struct with the current values of the endogenous variables of the model.

Output:

- A : State transition matrix.
- B : The impact of exogenous variables matrix.
- C : The impact of shock matrix.
- CE : The impact of anticipated shock matrix.
- ss : The steady state, or point of approximation.
- err : Non-empty if an error is thrown. If this output is not return a standard error is thrown in the command window.

Written by Kenneth Sæterhagen Paulsen

► solveOneRegime ↑

```
[A,B,C,CE,ss,JAC,err] = nb_dsge.solveOneRegime(options,beta,skipSolve,silent)
```

Description:

Solve one regime.

Input:

- options : See the estOptions property of the nb_dsge class.
- beta : The parameters of the current regime.
- skipSolve : Skip solving for A, B and BE. (They are returned as [])

Output:

- A : State transition matrix.
- B : Constant term.
- C : The impact of shock matrix.
- CE : The impact of anticipated shock matrix.
- ss : Steady state.
- JAC : Jacobian.
- err : Non-empty if an error is thrown. If this output is not return a standard error is thrown in the command window.

Written by Kenneth Sæterhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_dsgc.solveRecursive(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveSteadyState** ↑

```
[obj,err] = solveSteadyState(obj,varargin)
```

Description:

If the 'steady_state_solve' is set to true, the solution will be solved for analytically. If the 'steady_state_file' option is not empty, it is assumed to provided the solution (see comment below also!). If neither of them is used the steady-state is assumed to be 0 for all variables.

Caution: This function is automatically called inside
nb_dsgc.checkSteadyState if the option 'steady_state_solve' is
set to true and is not called by the user manually!

Caution: If the 'steady_state_file' option is not empty and the option
'steady_state_solve' is set to true, the provided file
will be used as the starting point for the solver, i.e.
use this file can be used to set initial values for the
solution of the steady-state.

Caution: If some variable is not been given any value in the
steady-state file it is assumed that it is 0 in steady-state.

Input:

- obj : An object of class nb_dsgc.

Optional inputs:

- 'silent' : See nb_dsgc.help('silent')
- 'steady_state_file' : See nb_dsgc.help('steady_state_file')
- 'steady_state_solve' : See nb_dsgc.help('steady_state_solve')
- 'solver' : See nb_dsgc.help('solver')

Output:

- obj : An object of class nb_dsgc, where the solution of the
steady-state can be found at obj.solution.ss.
- err : If two outputs are called for a potential error message is not
thrown, but instead return as a string. Is empty if not error
occure. Caution: This is only the case if numel(obj) == 1.

See also:

[nb_dsgc.help](#), [nb_dsgc.checkSteadyState](#), [nb_dsgc.solveSteadyStateStatic](#)

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

obj = solveVector(obj)

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **split** ↑

objVec = split(obj)

Description:

Split a NB toolbox or RISE solved DSGE model into separates objects for each regime.

Caution : In the case of a RISE object, calling solve again on the object will result in the a object with more regimes!

Input:

- obj : An object of class nb_dsgc, either solved with the NBToolbox or RISE.

Output:

- objVec : A vector of nb_dsgc object representing each regime.

See also:

nb_dsg.e.solve

Written by Kenneth Sæterhagen Paulsen

► stateSpace ↑

```
sol = nb_dsg.e.stateSpace(par,estStruct)
```

Description:

Returns a state-space representation of a DSGE model.

Observation equation:

$$y(t) = H \cdot x(t)$$

State equation:

$$x(t) = A \cdot x(t-1) + B \cdot z(t) + C \cdot u(t)$$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I .

Input:

- par : Current vector of the estimated parameters.
- estStruct : See the nb_dsg.e.getObjectiveForEstimation method.

Output:

- sol : A struct with the fields:
 - > H : Observation matrix.
 - > A : State transition matrix.
 - > B : Constant term.
 - > C : B is impact of shock matrix.
 - > x : The "a priori" state estimate (after the new measurement information is included).
 - > P : Covariance of the state vector "a priori" estimate.
 - > Pinf : Covariance of the state vector "a priori" estimate used during diffuse steps.
 - > options : Same as the input options + the ss fields will be added.
 - > err : A char with the error message. Empty if no error have occurred.
 - > ss : The steady-state of the model.

See also:

Written by Kenneth Å!terhagen Paulsen

► **stateSpaceBreakPoint** ↑

```
sol = nb_dsge.stateSpaceBreakPoint(par,estStruct)
```

Description:

Returns a state-space representation of a break-point DSGE model.

Observation equation:

$$y = H \cdot x(t)$$

State equation:

$$x(t) = ss(t) + A(t) \cdot (x(t-1) - ss(t)) + B(t) \cdot z(t) + C(t) \cdot u(t)$$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I .

Input:

- par : Current vector of the estimated parameters.
- estStruct : See the `nb_dsge.getObjectiveForEstimation` method.

Output:

- sol : A struct with the fields:
 - > H : Observation matrix.
 - > A : State transition matrix.
 - > B : Constant term.
 - > C : B is impact of shock matrix.
 - > x : The "a priori" state estimate (after the new measurement information is included).
 - > P : Covariance of the state vector "a priori" estimate.
 - > Pinf : Covariance of the state vector "a priori" estimate used during diffuse steps.
 - > options : Same as the input options + the states and ss fields will be added.
 - > err : A char with the error message. Empty if no error have occurred.

```
> ss      : The steady-state of the model.  
> states  : The states used for each step of the Kalman filter.
```

See also:

[nb_kalmanlikelihoodDSGE](#), [nb_model_generic.estimate](#), [nb_dsge.objective](#)

Written by Kenneth Åkerhagen Paulsen

► **stateSpaceTVP ↑**

```
sol = nb_dsge.stateSpaceTVP(par,estStruct)
```

Description:

Returns a state-space representation of a DSGE model.

Observation equation:
 $y(t) = H*x(t)$

State equation:
 $x(t) = A(t)*x(t-1) + B(t)*z(t) + C(t)*u(t)$

Where $u \sim N(0, I)$ meaning u is gaussian noise with covariance I .

Input:

- par : Current vector of the estimated parameters.
- estStruct : See the [nb_dsge.getObjectiveForEstimation](#) method.

Output:

- sol : A struct with the fields:
 - > H : Observation matrix.
 - > A : State transition matrix.
 - > B : B is impact of shock matrix.
 - > x : The "a priori" state estimate (after the new measurement information is included).
 - > P : Covariance of the state vector "a priori" estimate.
 - > Pinf : Covariance of the state vector "a priori" estimate used during diffuse steps.
 - > options : Same as the input options + the ss fields will be added.

```
> err      : A char with the error message. Empty if no error have  
occured.  
  
> ss       : The steady-state of the model.
```

See also:

[nb_kalmanlikelihoodDSGE](#), [nb_model_generic.estimate](#), [nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

► **stationarize ↑**

```
obj = stationarize(obj,varargin)
```

Description:

Stationarize model.

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'waitbar' : Give this to trigger waitbar during stationarization.

Output:

- obj : An object of class nb_dsge.

See also:

Written by Kenneth Sæterhagen Paulsen

► **struct ↑**

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_dsgen.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **structuralMatrices2JacobianNB ↑**

```
jacobian = nb_dsgen.structuralMatrices2JacobianNB(Alead,A0,Alag,B,...  
leadCurrentLag)
```

Description:

Derive the jacobian given the structural matrices.

On the form: $A_{lead} \cdot y(t+1) + A_0 \cdot y + A_{lag} \cdot y(t-1) + B \cdot \epsilon = 0$

Input:

- Alead : The structural matrix of the endogenous variables in the period t+1.
- A0 : The structural matrix of the endogenous variables in the period t.
- Alag : The structural matrix of the endogenous variables in the period t-1.
- B : The structural matrix of the exogenous variables in period t.
- leadCurrentLag : A nEndo x 3 double with the lead, current and lag indices of the endogenous variables of the model.

Output:

- jacobian : A matrix with the jacobian of the DSGE model.

Written by Kenneth Sæterhagen Paulsen

► **systemPriorObjective ↑**

```
fval = nb_dsgen.systemPriorObjective(par,estStruct)
```

Description:

The objective to sample from to get the final prior distribution which also takes into account the system priors.

Input:

- par : Current vector of the estimated parameters.
- estStruct : A struct with at least the following fields;
 - > indPar : Index for where in the full parameter vector to find the estimated parameters.
 - > beta : A vector of the values of all parameters. As a nParam x 1.
 - > model : The obj.parser property of the nb_dsg class.
 - > options : The obj.estOptions property of the nb_dsg class.
(After calling getEstimationOptions, i.e. calling the estimate method.)
 - > y : A nObservables x nPeriods double with the data to estimate the model on. The data may contain missing observations.
 - > z : Not in use. To make it generic to other classes of models.
 - > observables : A logical vector. An element is true if the variable is observable.

Output:

- fval : Value of minus the log system prior at the given parameters.

See also:

[nb_model_sampling.sampleSystemPrior](#)

Written by Kenneth Å!terhagen Paulsen

► template ↑

```
options = nb_dsg.template()  
options = nb_dsg.template(num)
```

Description:

Construct a struct which can be provided to the nb_dsg class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► testForecastRestrictions ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as variables. See model.parameters.name.
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.
- type : Type of test:
 - > '=' : Two sided test. expression == 0 (default)
For two-sided tests it is assumed that the distribution is symmetric! Use confidenc/probabillty intervals instead.
 - > '>' : One sided test. expression > 0
 - > '<' : One sided test. expression < 0

Output:

- pval : > 'classical' : P-value of test.
> 'bayesian' : Probabilty of test.

A 1x1 double.
- ci : A 1 x 2 double with the lower and upper bound of the confidence/probabillty interval of the tested expression.
- dist : A nb_distribution object storing the distribution of the tested expression.

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c] = theoreticalMoments(obj,varargin)
[m,c,ac1] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is

'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
 - varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
 - varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.
- E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargout{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargout{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

See also:

[nb_dsgc.graphCorrelation](#), [nb_dsgc.parameterDraws](#)

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **tracePlot ↑**

```
[DB,plotter] = tracePlot(obj)
```

Description:

Redirect to checkPosteriors.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_SAMPLING

► **uncertaintyDecomposition ↑**

```
[data,plotter] = uncertaintyDecomposition(obj,varargin)
```

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and

the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_dsg.e.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

obj = nb_model_estimate.unstruct(s)

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_dsg.e.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **update** ↑

```
obj          = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type : > '' : Only update data. Default
> 'estimate' : Update data and estimate.
> 'solve' : Update data, estimate and solve
> 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **updateParams** ↑

```
model = nb_dsge.updateParams(model, results)
```

Description:

Update parameter values of a RS-DSGE model.

Written by Kenneth Sæterhagen Paulsen

► **updateSolution** ↑

```
[A,B,C,ss,p,err] = nb_dsge.updateSolution(options,results,xu,p,tt)
```

Description:

Resolve the model when dealing with stochastic trend.

See also:

[nb_kalmanSmotherUnivariateStochasticTrendDSGE](#)
[nb_kalmanLikelihoodUnivariateStochasticTrendDSGE](#)
[nb_kalmanSmotherDiffuseStochasticTrendDSGE](#)
[nb_kalmanLikelihoodDiffuseStochasticTrendDSGE](#)

Written by Kenneth Sæterhagen Paulsen

► **variance_decomposition** ↑

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the

method nb_var.set_identification for more.

- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidenc/probability bands. Default is '''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomosition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomosition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **writeModel2File ↑**

```
writeModel2File(obj,filename,varargin)
```

Description:

Write model to .nb file.

Input:

- obj : A scalar nb_dsge object.
- filename : A one line char with the file name to write to. Must have .nb or no extension.

Optional input:

```

- 'parameters' : One of:
    > 'file'   : Write the parameters to a seperate file
                  with name [filename '_param.mat'].
                  Default.
    > 'block'  : Write the assignment of the parameters
                  to the parameterization block of the
                  model file.
    > 'off'    : Don't write the parameter values to any
                  format.

- 'precision' : See nb_num2str. Default is 14.

- 'steady_state' : One of:
    > 'file'   : Write the intitial condition for solving
                  the steady state to a seperate file
                  with name [filename '_ss.mat'].
                  Default.
    > 'block'  : Write the assignment of the intitial
                  condition for solving the steady state
                  to the steady_state_model block of the
                  model file.
    > 'off'    : Don't write the intitial condition for
                  solving the steady state to any format.

```

Output:

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

► **writePDF** ↑

```

writePDF(obj,filename)
writePDF(obj,filename,type)

```

Description:

Write the equations of the model to PDF.

Input:

```

- obj      : An object of class nb_dsgen.

- filename : The filename of the saved pdf file. As a one line char.
             Extension is ignored.

- type     : Either 'names' or 'values'. Default is 'names'. If 'values'
             is given the parameters will be substituted with their
             values instead of their name.

```

Examples:

```
obj.writePDF('test')
```

See also:

[nb_dsge.writeTex](#), [nb_model_generic.assignTexNames](#)

Written by Kenneth S. Paulsen

► **writeTex ↑**

```
code = writeTex(obj)
code = writeTex(obj,filename,type)
writeTex(obj,filename,type)
```

Description:

Write latex code of model equations.

Input:

- obj : An object of class nb_dsge.
- filename : Give the name of the written .tex file. If not given or empty no file will be written. Extension is ignored.
- type : Either 'names' or 'values'. Default is 'names'. If 'values' is given the parameters will be substituted with their values instead of their name.

Output:

- code : A cellstr with the latex code of the model equations.

See also:

[nb_dsge.writePDF](#), [nb_model_generic.assignTexNames](#)

Written by Kenneth Sæterhagen Paulsen

■ **nb_ecm**

Go to: [Properties](#) | [Methods](#)

A class for estimation of error correction models.

Superclasses:

[nb_model_generic](#)

Constructor:

```
obj = nb_ecm(varargin)

Optional input:
```

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : An nb_ecm object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#), [nb_ecm.help](#), [nb_ecm.template](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- addAutoName
- addAutoNameIfLocal
- addID
- addIDIfLocal
- dependent
- endogenous
- estOptions
- exogenous
- forecastOutput
- name
- options
- parameters
- reporting
- residuals
- results
- solution
- transformations
- userData

- **addAutoName** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addAutoNameIfLocal** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj =

```
set(obj,'dependent',{'Var1','Var2'}); or use the  
<className>.template() method.
```

Caution: For nb_dsgc models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t$, $e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t$, $u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation. As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.

- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters ↑**

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.

- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!

- 'instrument' : A one line char with the name of the instrument. Must be provided!

- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!

- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.

- 'perc' : Error band percentiles. As a 1 x nPerc double.
E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will
be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the
double method on this output to convert it to a double
matrix.

See also:

[nb_ecm.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws
(bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see
[nb_bootstrap](#). For bayesian models 'posterior' is the only
option. Default is 'bootstrap' for classical models, while
'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is
1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property
is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterioriors** ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optional input:

- `'nLags'` : Number of lags to include in the autocorrelation plot. Default is 10.
- `'iter'` : The recursive iteration date. Either as a string or a `nb_date` object. If recursive estimation is done, this input must be provided.

Output:

- `DB` : A `nb_data` object with size `nDraws x numCoeff`.
- `plotter` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.
- `pAutocorr` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.

Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
                    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

► [convert ↑](#)

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► [convertEach ↑](#)

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

See also:

[nb_ts.convert](#)

► `createVariables` ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM `nb_modelData` object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.

> third column : Any expression that can be interpreted by the `nb_ts.createShift` method.

> fourth column : Comments

- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name,    input,    shift,    description
  'VAR1_G',    'pcn(VAR1)', 'avg',    'VAR1 growth'
  'VAR2_G',    'pcn(VAR2)', 'avg',    'VAR2 growth'
  'VAR3_G',    'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► dieboldMarianoTest ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

`nb_ecm.forecast`, `nb_distribution.perc2ParamDist`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity** ↑

`obj = doSimulateFromDensity(obj, draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `obj` : A `nb_model_forecast` object.
- `draws` : Number of draws to use for simulation.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_model_generic.forecast`, `nb_ecm.simulateFromDensity`

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass `NB_MODEL_FORECAST`

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_generic` object. The `options.data` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

See also:

[nb_ecm.graphCorrelation](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj        = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default

is to open max number of cores available. Only an option if 'parallel' is given.

- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast ↑**

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecast** ↑

```
obj          = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for forward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters

for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
 - 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.
- If set to empty, all simulations will be returned.
- Caution: 'draws' must be set to produce density forecast.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

```

- 'bins'      : The length of the bins og the domain of the density.
  Either;
    > []       : The domain will be found. See
      nb_getDensityPoints (default is that 1000
      observations of the density is stored).
    > integer   : The min and max is found but the length
      of the bins is given by the provided
      integer.
    > cell       : Must be on the format:
      {'Var1',lowerLimit1,upperLimit1,binsL1;
       'Var2',lowerLimit2,upperLimit2,binsL2;
       ...}
    - lowerLimit1 : An integer, can be nan,
      i.e. will be found.
    - upperLimit1 : An integer, can be nan,
      i.e. will be found.
    - binsL1      : An integer with the
      length of the bins. Can
      be nan. I.e. bins length
      will be adjusted to
      create a domain of 1000
      elements.

Caution : The variables not included will be given
          the default domain. No warning will be
          given if a variable is provided in the
          cell but not forecast by the model. (This
          because different models can forecast
          different variables)

Caution : The combineForecast method of the
          nb_model_group class is much faster if the
          lower limit, upper limit! Or else
          it must simulate new draws and do kernel
          density estimation for each model again
          with the shared domain of all models
          densities.

- 'startDate'   : The start date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

Caution: If 'fcstEval' is not empty this will set
        the start date of the recursive forecast.
        Default is to start from the first possible
        date.

- 'endDate'     : The end date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

Caution: If 'fcstEval' is empty this input will

```

have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous

variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
If not provided. Model stds are used.
 - > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
 - > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for

all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.
- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime

is not given, you will start in
the ergodic steady-state for
MS-model, and in the last regime
for break-point models.

- 'startingProb' : Either a double or a char:
 - > 'zero' : Start from zero on all variables
(Except for the deterministic
exogenous variables)
 - > [] : If the model is filtered the
starting value is calculated
on filtered transition
probabilities. Otherwise the
ergodic mean is used.
 - > double : A nPeriods x nRegime or a 1 x
nRegime double. nPeriods refer to
the number of recursive periods to
forecast.
 - > 'ergodic' : Start from the ergodic transition
probabilities.
- 'stabilityTest' : Give true if you want to discard the parameter draws
that give rise to an unstable model. Default
is false.
- 'states' : Either an integer with the regime to
forecast/simulate in, or an object of class nb_ts
with the regimes to condition on. The name of the
variable must be 'states'.

Caution: For break-point models this is decided by
the dates of the breaks, and cannot be set
by this option!

- 'compareToRev' : Which revision to compare to. Default is final
revision, i.e. []. Give 5 to get fifth revision.
must be an integer. Keep in mind that this number
should be larger than the nSteps input.
- 'compareTo' : Sometime you want to evaluate the forecast of one
variable against another variable which is not
part of the model. E.g. if you use the first release
of a variable and want to compare it against the
final release. To do this you can give a cellstr
with size n x 2, where n is the number of variables
to change the the actual observations to test
against. {'VAR_1','VAR_FINAL',...}.
- 'estimateDensities' : true or false. true if you want to do a
kernel density estimation of the density
forecast.
- 'exoProj' : Tolerate missing exogenous variables by projecting
them by a fitted model. Only when the 'condDB'
input is empty!

Options are:

- '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.

- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.

- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example

{'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when `exoProj` is set to 'AR'.

- 'bounds'
: A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps` double matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a 1x1 double or a `nSteps x 1` double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs'
: This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.

- 'foundReplic'
: A struct with size `1 x parameterDraws`. Each element must be on the same format as `obj.solution`. I.e. each element must be the solution of the model given a set of drawn parameters. See the `parameterDraws` method of the `nb_model_generic` class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.

```
- 'seed' : Set simulation seed. Default is 2.0719e+05.
```

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_ecm.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_ecm.forecast](#), [nb_distribution.perc2ParamDist](#)

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
    nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getCondDB ↑

[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments ↑**

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependent ↑**

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getFiltered ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be $N(0,1)$. Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a $N \times 3$ cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs \times nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_ecm.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast** ↑

```
fcstData          = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();
```

```

    end

> 'date'      : A string or a nb_date object with the date of the
                 wanted forecast. E.g. '2012Q1'. The fcstData will
                 be a nb_ts object with size nHor x nVar x nPerc + 1,
                 while fcstPercData will be empty. nPerc will then be
                 the number of percentiles/simualtions. Mean will be at
                 last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'   : This option will return the forecast as a
                 nPeriods + nHor x nVar x nHor nb_ts object. This
                 option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).

```

Optional inputs:

```

> 'horizon'   : The fcstData output will be a nb_ts object with
                 size nRec x nVars. While the fcstPercData output
                 will be a nb_ts object with size nRec x nVars x nSim.
                 You can set the horizon to return by the optional
                 input 'horizon'. See the 'timing' option also.

```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_ecm.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables** ↑

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

p = getParameters(obj,varargin)

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as

fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

- : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
- : Give 'double' to return the value as a numerical array.
- : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

► **getRecursiveScore** ↑

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

`nb_model_generic.forecast`, `nb_model_generic.constructScore`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **getResidual** ↑

`residual = getResidual(obj)`

Description:

Get residual from a estimated `nb_model_generic` object

Input:

- `obj` : An object of class `nb_model_generic`

Output:

- `residual` : Either a `nb_ts` or a `nb_cs` object with `residual(s)` stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualGraph** ↑

`plotter = getResidualGraph(obj)`

Description:

Get residual graph from the given estimator. The returned will be an object of class `nb_graph`, which you can call the `graphInfoStruct` method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- `obj` : An object of class `nb_model_generic` (or a subclass of this class).

Output:

- `plotter` : An object of class `nb_graph`. Use the `graphInfoStruct` method or the `nb_graphInfoStructGUI` class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of `nb_model_generic` object

Input:

- `obj` : A vector of `nb_model_generic` objects

Output:

- `residualNames` : A cellstr with the unique residual names of all the models

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method `solve`.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getScore ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.

- type : A string with one of the following:
- 'RMSE' : One over root mean squared error
- 'MSE' : One over mean squared error
- 'MAE' : One over mean absolute error
- 'MEAN' : One over mean error
- 'STD' : One over standard error of the forecast error
- 'ESLS' : Exponential of the sum of the log scores
- 'EELS' : Exponential of the mean of the log scores
- 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.

- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Inherited from superclass NB_MODEL_FORECAST

► **getSolution ↑**

```
value = getSolution(obj,type)
```

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_ecm.simulatedMoments](#), [nb_ecm.theoreticalMoments](#)
[nb_ecm.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **grouped_decomposition** ↑

[dec, plotter] = grouped_decomposition(obj, varargin)

Description:

Produce historical decomposition of a ECM model where contribution related to one variable is grouped automatically.

Input:

- obj : An object of class nb_ecm.

Optional input:

- 'method' : One of
 - > 'shock_decomposition' : This uses the shock_decomposition method to do the decomposition, and then it aggregates all the contributions that relates to one variable, e.g. aggregates the contributions from different lags and the lagged level of the endogenous variables. Default method.

> 'recursive_forecast' : This method uses recursive forecasting to produce the decomposition. It creates a baseline recursive forecast. In this baseline it condition on all right hand side variables, where all level variable are kept at 0 and all difference variables are kept at their mean. Then it sets one variable at the time to its actual value, and produce a recursive forecast in this case. The contribution from this variable are then the difference between this forecast compared to the baseline (both being transformed using the function specified by the 'transformation' input).

This method are wrong for the first periods in the 'diff' transformation is used, but it converges to the correct solution at the end. If 'level' is chosen it does not converge to the true solution!

- 'transformation' : Either 'level' (no transformation) or 'diff' (difference).

Caution: If the dependent variable is in log 'diff' will give the growth rate.

- 'nLags' : The number of lags used by the diff operator. Default is 1.

- 'inputVars' : true or false. Set it to true if you want to further decompose the ECM model into contribution of each input variable instead of each model variable. Use the nb_modelData.createVariables to be able to do this. Default is false. This will automatically switch to the method 'recursive_forecast'!

Caution: The the expressions are non-linear this will only be an "linear" approaximation of the contribution of each series. The approximation error will end up the 'Rest' variable.

- 'seasonalPattern' : Set it to true if you want to keep the seasonal pattern in the level data when constructing the "steady state" values of the level variables. Used only when 'method' is set to 'recursive_forecast'. false is default.

- 'modelCond' : A nb_ecm object which has produced conditional forecast.

Output:

- dec : The final decomposition as a nb_ts object with size nObs x (nEndo + nExo + 1). 'Rest' includes the residual.

- plotter : A nb_graph_ts object that can produce a graph of the

decomposition. Use the graph method or the nb_graphPagesGUI class.

Examples:

```
\NBTOOLBOX\Econometrics\test\test_nb_ecm.m  
\NBTOOLBOX\Econometrics\test\test_nb_ecm_dec.m
```

See also:

[nb_model_generic.shock_decomposition](#)

Written by Kenneth Sæterhagen Paulsen

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

```
- ret : true or false. true if the estimation settings is so that the  
model handle missing data.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **help ↑**

```
helpText = nb_ecm.help  
helpText = nb_ecm.help(option)  
helpText = nb_ecm.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

```
- option : Either 'all' or the name of the option you want to get the  
help on.  
  
- maxChars : The max number of chars in the printout of (approx). This  
applies to the second column of the printout. Default is  
40.
```

Output:

```
- helpText : A char with the help.
```

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize ↑**

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

```
- objClass : The name of any of the subclasses of the nb_model_generic  
class. As a string.  
  
- template : The output from the template method of each subclass of the  
nb_model_generic class. Multiple model objects will be  
initialized if the num input that method is greater than one.
```

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **interpretForecast** ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you

need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.

- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_ecm.forecast](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf ↑**

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsg objects.
- 'compare' : Give true if you have a scalar nb_dsg model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.
- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.
- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.

I.e. {'var1',100,...} or {{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}

```

- 'fanPerc'          : This options sets the error band percentiles of the
                      graph, when the 'perc' input is empty. As a 1 x
                      numErrorBand double. E.g. [0.3,0.5,0.7,0.9].
                      Default is 0.68.

- 'foundReplic'      : A struct with size 1 x replic. Each element
                      must be on the same format as obj.solution. I.e.
                      each element must be the solution of the model
                      given a set of drawn parameters. See the
                      parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

- 'irfCompare'       : A struct on the same format as the irfs output from
                      this function with the IRFs to compare to.

- 'levelMethod'       : One of the following:

> 'cumulative product'           : cumprod(1 + X,1)
> 'cumulative sum'              : cumsum(X,1)
> 'cumulative product (log)'    : log(cumprod(1 + X,1))
> 'cumulative sum (exponential)' : exp(cumsum(X,1))
> 'cumulative product (%)'       : cumprod(1 + X/100,1)
> 'cumulative sum (%)'          : cumsum(X/100,1)
> 'cumulative product (log) (%)': log(cumprod(1 + X/100,1))
> 'cumulative sum (exponential) (%)': exp(cumsum(X/100,1))
> '4 period growth (log approx)': nb_msum(X,3)

- 'method'             : The selected method to create error bands.
                      Default is ''. See help on the method input of the
                      nb_model_generic.parameterDraws method for more
                      this input. An extra option is:

> 'identDraws' : Uses the draws of the matrix with
                  the map from structural shocks to dependent
                  variables. See nb_var.set_identification. Of
                  course this option only makes sense for VARs
                  identified with sign restrictions.

- 'normalize'          : A 1 x 3 cell. First element must be the variable
                      name as a string. The second element must be the
                      value to normalize to, as an integer. While the
                      third element is the period to be normalized, if
                      set to inf, it will normalize the max impact
                      period.

E.g. {'Var',1,2}, {'Var',1,inf}

Caution: 2 means observation 2 of the IRF, and as
          the IRF start at period 0, this means that

```

observation 2 is period 1.

- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of irfs, while 'mean' normalize the mean and scale percentiles/other draws accordingly. Default is 'draws'.

Caution: Setting this to 'mean' will not work for reported variables that is not measured as % deviation from steady-state/mean.

- 'newReplic' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the replic input.
- 'parallel' : Give true if you want to do the irfs in parallel. This option will parallelize over models. Default is false.
- 'parallelL' : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if numel(obj) == 1. Default is false.
- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for nb_dsg objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for nb_dsg objects.
- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.

- 'settings' : Extra graphs settings given to nb_plots function. Must be a cell.

```

- 'shocks'           : Which shocks to create impulse responses of.
                      Default is the residuals defined by the first model.

For Markov switching or break point models it may
be wanted to only run a IRF when switching the
state. To do so set this option to {'states'}.
You should also set 'startingValues' to
'steadystate(r)', where r is the regime you start
in. For a Markov switching model also set
'startingProb' to the same r. This is only an
option if 'type' is set to 'irf'.

- 'sign'             : Sign of the impulse. Either 1 or -1. Can also be
                      a vector of the same size as 'shocks' input.

- 'stabilityTest'   : Give true if you want to discard the draws
                      that give rise to an unstable model. Default
                      is false.

- 'startingProb'    : Either a double or a char (Only for Markov-switching
                      models):

    > scalar          : Select the the regime to take the
                          initial transition probabilities
                          from.

    > double           : A draws x nRegime or a 1 x
                          nRegime double. draws refer to
                          the number set by the 'draws'
                          input.

    > 'ergodic'        : Start from the ergodic transition
                          probabilities. Default for 'irf'.

    > 'random'         : Randomize the starting values
                          using the simulated starting
                          points. Default for 'girf'.

- 'startingValues'  : Either a double or a char:

    > double           : A nVar x 1 double.

    > 'steadystate'    : Start from the steady state. If you are dealing
                          with a MS-model or a break-point model you can
                          indicate the regime by 'steadystate(regime)'. E.g.
                          to start in regime 1 give; 'steadystate(1)'. For
                          MS - models the default is the ergodic mean
                          (default as long as 'girf' is not selected as
                          'type'), while for break-point models it is to
                          start from the first regime.

    > 'zero'            : Start from zero on all variables.

    > 'random'          : Randomize the starting values using the simulated
                          starting points. Default when 'type' set to
                          'girf'.

- 'states'           : Either an integer with the states to produce irf in,

```

or a double with the states to condition on. Must have size periods x 1 in the last case. Applies to both MS - models and break-point models.

- 'type' : 'girf' or 'irf'. (If empty 'irf' will be used)
 - > 'girf' : Generalized impulse response function calculated as the mean difference between shocking the model with a one period shock (1 std) and no shock at all. Use the 'draws' input to set the number of simulations to use to base the calculation on. This type of irfs must be used for non-linear models.
 - > 'irf' : Standard irf for linear models. Calculated by shocking the model with a one period shock (1 std).
- 'variables' : The variables to create impulse responses of. Default is the dependent variables defined by the first model.

Caution: The variables reported by the reporting property may also be asked for here!
- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.'(E_X_NW)'). Which will then be a nb_ts object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different variables and shocks.
- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!
- plotter : An object of class nb_graph_ts.
 - > 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

```
> 'compareShocks' set to true
    Use the graphSubPlots method or the
    nb_graphSubPlotGUI class to produce the graphs.

- obj      : If the process has been paused, some temporary output will
              be stored in the object, and if you want to continue at a
              later stage you can take up from this point using this
              returned output. If not paused this output is empty.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast** ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

```
- obj : A nb_model_forecast object (matrix)
```

Output:

```
- ret : A logical with same size as obj.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsgen object is filtered or not.

Input:

```
- obj      : An object of class nb_dsgen.
```

```
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is
          'smoothed'.
```

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► isMS ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► isMixedFrequency ↑

```
ret = isMixedFrequency(obj)
```

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsg objects!

For nb_dsg objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

ret = isforecasted(obj)

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

ret = issolved(obj)

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► jointPredictionBands ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint prediction bands for macroeconomic risk management
 - > 'copula' : Using a copula likelihood approach.
 - > 'mostlik' : Group the paths based on how likely they are.
- 'nSteps' : Number of forecasting steps to use when constructing the error bands. If empty (default) all forecasting steps stored in the object is used.

Output:

- JPB : An nb_ts object storing the joint prediction bands. The percentiles are stored as datasets. See the dataNames property for which page represent which percentile.

The data of the nb_ts object has size nSteps x nVars x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior** ↑

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_ecm.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x) && f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.

- type : The type of restriction. Either 'irf', 'corr' or 'cov'.

- restriction : Depends on the type input:

```

> 'irf'      : A N x 4 cell, where the elements of each
               row are:
               1. Name of the shock. 'E_X'
               2. Name of the variable. 'X'
               3. Horizon. E.g. 1 or 1:3.
               4. Restriction. E.g. @(x)gt(x,0),
                  @(x)gt(x,0)||lt(x,1), i.e. a
                  function_handle that takes a scalar
                  double as input and a scalar logical as
                  output.

> 'rirf'     : A N x 7 cell, where the elements of each
               row are:
               1. Name of the shock 1. 'E_X'
               2. Name of the variable 1. 'X'
               3. Horizon of variable 1. E.g. 1.
               4. Name of the shock 2. 'E_Y'
               5. Name of the variable 2. 'Y'
               6. Horizon of variable 2. E.g. 2.
               7. Restriction. E.g. @(x,y)gt(x,y),
                  @(x,y)gt(x-y,0)||lt(x-y,1), i.e. a
                  function_handle that takes a two scalar
                  double as inputs and a scalar logical
                  as output.

> 'corr'     : A N x 4 cell, where the elements of each
               row are:
               1. Name of the first variable.
               2. Name of the second variable.
               3. Number of periods to lag the 2. variable.
               4. Same as 4 for 'irf'.

               E.g. {'Var1','Var1',1,@(x)gt(x,0.1)}, to
               test a restriction on the autocorrelation
               at lag for variable 'Var1'.

               E.g. {'Var1','Var2',0,@(x)lt(x,0.1)}, to
               test a restriction on the contemporaneous
               correlation between 'Var1' and 'Var2'.

> 'cov'       : Same as for 'corr'.

               E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to
               test a restriction on the contemporaneous
               variance.

> 'ss'        : A N x 2 cell, where the elements of each
               row are:
               1. The expression using any of the
                  endogenous variables of the model.
               2. Same as 4 for 'irf'.

```

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mincerZarnowitzTest ↑**

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

► **monteCarloFiltering ↑**

```
paramD           = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if

the model where solved and the test function returned a value.

- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.

```

> 'blockBootstrap'      : Create artificial data by
                           non-overlapping block bootstrap,
                           and then "draw" parameters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'mblockBootstrap'    : Create artificial data by
                           overlapping block bootstrap,
                           and then "draw" parameters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'rblockBootstrap'    : Create artificial data by
                           overlapping random block length
                           bootstrap, and then "draw" parameters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'wildBlockBootstrap' : Create artificial data by wild
                           overlapping random block length
                           bootstrap., and then "draw" parameters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'copulaBootstrap'    : Uses a copula approach to draw residual
                           that are autocorrelated, Does not handle
                           heteroscedasticity. Only an option for
                           models estimated with classical methods.

> 'posterior'          : Posterior draws. Only for models
                           estimated with bayesian methods.
                           Default for models estimated with
                           bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
  on this option.

- stable : Give true if you want to discard the parameter draws
  that give rise to an unstable model. Default is false.

```

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores
 available.
- 'newDraws' : When out of parameter draws, this factor decides how
 many new draws are going to be made. Default is 0.1.
 I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given

as a number less than 1, it will by default be set to 100.

- 'initialDraws' : When drawing parameters this factor decides how many many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:

> 'param' : Default. A struct with the following fields:

 beta : A nPar x nEq x draws double with the estimated parameters.

 sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:

 lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.

 R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.

 factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **parameterIntervals** ↑

ci = parameterIntervals(obj,alpha)

Description:

```
Get confidence intervals (classic) or probability intervals (bayesian).
```

```
Confidence intervals are constructed as:
```

```
beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.
```

```
Probability intervals are constructed as the per
```

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

```
Written by Kenneth Sæterhagen Paulsen
```

```
Inherited from superclass NB_MODEL_GENERIC
```

► **plotForecast** ↑

```
plotter = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
increment,varargin)
```

Description:

```
Plot forecast.
```

```
Caution density forecast will only be displayed for the first model
in the vector of nb_model_forecast objects
```

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.

```
- increment : Number of periods between the hairs when doing a  
hairy-plot. Default is 1.
```

Optional input:

```
- 'type' : If the history is of some variables are filtered, you can  
use this input to choose to plot the smoothed or updated  
estimates of the filtered variables. Either 'smoothed' or  
'updated'. Default is 'smoothed'.
```

Output:

```
- plotter : An object of class nb_graph. Use the graphSubPlots  
method or the nb_graphSubPlotGUI class.  
  
- plotFunction2Use : A string with the name of the method to call on the  
plotter object to produce the graphs.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

```
plotter = plotForecastDensity(obj,date,variable)
```

Description:

Plot the density forecast at a given date for a given variable. It will
be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the
provided date. See the dataNames property of the DB
property of the returned plotter object. If the model has
produced nowcast the names will 'horizon0' (a variable lag one
period), 'horizon-1' (a variable lag two periods), etc.

Input:

```
- obj : A 1x1 nb_model_forecast object.  
  
- date : A string or nb_date object with the date of the wanted  
forecast.  
  
- variable : A string with the variable of interest.
```

Output:

```
plotter = A nb_graph_data object. Use the graph method to produce the
figure, or the nb_graphPagesGUI class.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF** ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound, ...
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest** ↑

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,nameValue)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [plotPriors](#) ↑

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results** ↑

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_ecm.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

```
- obj      : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA
```

► **set ↑**

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

```
- obj : A vector of nb_model_estimate objects.
```

Optional input:

If number of inputs equals 1:

```
- varargin{1} : A structure of fields to be set. See the
               template method of each model class for more.
```

Else:

```
- varargin     : ...,'inputName', inputValue,... arguments.
```

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

```
- obj : A vector of nb_model_estimate objects.
```

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition** ↑

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';  
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the

nb_model_generic.parameterDraws method for more this input. An extra option is:

```
> 'identDraws' : Uses the draws of the matrix with  
      the map from structural shocks to dependent variables.  
      See nb_var.set_identification. Of course this option  
      only makes sense for VARs identified with sign  
      restrictions.  
  
- 'replic'          : The number of simulation for posterior, bootstrap and  
      MC methods. Default is 1. Only used when 'perc' is  
      provided.  
  
      Caution: Will not have anything to say for the method  
      'identDraws'. See the option 'draws' of the  
      method nb_var.set_identification for more.  
  
- 'stabilityTest' : Give true if you want to discard the draws  
      that give rise to an unstable model. Default  
      is false.  
  
- 'parallel'        : Give true if you want to do the shock decomp in  
      parallel. Default is false.  
  
- 'fcstDB'          : An object of class nb_ts with the forecast to  
      decompose. must contain all model variables and  
      shocks/residuals, and must start the period after  
      the estimation/filtering end date or at the  
      estimation/filtering start date. See  
      the nb_model_generic.getForecast method.  
  
- 'type'            : Choose 'updated' or 'smoothed'. 'smoothed' is  
      default.  
  
- 'anticipationStartDate' : Start date of anticipating shocks. As a  
      string. If different models has different  
      frequency this date will be converted.  
  
- 'model2'          : A struct with the solution of the second  
      model to use for decomposition.  
  
- 'secondModelStartDate' : Start date of second model. As a string.  
      If different models has different frequency  
      this date will be converted.
```

Output:

- decomp : A structure of nb_ts objects with the shock
 decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty
 bounds of the shock decomposition for each model at each
 percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the
 graph method to produce the graphs or use the
 nb_graphPagesGUI on each element of the graph objects.

`nb_ecm.parameterDraws, nb_shockDecomp`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **simulate** ↑

`out = simulate(obj,nSteps,varargin)`

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- `obj` : A vector of `nb_model_generic` objects.
- `nSteps` : Number of simulation steps. As a `1x1 double`. Default is 100.

Optional inputs:

- `'burn'` : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- `'bounds'` : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - `'shock'` : Name of the shock to match the restriction on the bounds of the given variable.
 - `'lower'` : The lower bound of the selected variable. Either a `1x1 double` value or a function handle to a probability distribution to draw from.
 - `'upper'` : The upper bound of the selected variable. Either a `1x1 double` value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps double` matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a `1x1 double` or a `nSteps x 1 double`.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.
- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty

the simulation will switch between regimes. Only an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a specific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:
 - > double : A 1 x nVar double.
 - > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsg models.
 - > 'steadyState' : Start from the steady state. For now only an option for nb_dsg models. If you are dealing with a MS-model you can indicate the state by 'steadyState(state)'. E.g. to start in state 1 give; 'steadyState(1)'. Default for nb_dsg models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char:
 - > double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
 - > 'ergodic' : Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consists of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the

'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.
 Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.
 Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
 Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i},'y','x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i},'x','y'). (This example only works if the output is of class nb_cs)

See also:

[nb_ecm.graphCorrelation](#), [nb_ecm.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_ecm object(s).

Input:

- obj : A vector of nb_ecm objects.

Output:

- obj : A vector of nb_ecm objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveLevel** ↑

```
sol = solveLevel(obj)
```

Description:

Convert the standard solution into a solution in only levels.

Input:

- obj : An object of class nb_ecm.

Output:

- sol : A struct on the same format as the solution property, but now the solution is in level variable only (dependent only!).

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_ecm.solveNormal(results,opt,iter)
```

Written by Kenneth Sæterhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_ecm.solveRecursive(results,opt,ident)
```

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_ecm.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

options = nb_ecm.template()
options = nb_ecm.template(num)

Description:

Construct a struct which can be provided to the nb_ecm class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as variables. See model.parameters.name.
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.
- type : Type of test:
 - > '=' : Two sided test. expression == 0 (default)
For two-sided tests it is assumed that the distribution is symmetric! Use confidenc/probabillty intervals instead.
 - > '>' : One sided test. expression > 0
 - > '<' : One sided test. expression < 0

Output:

- pval : > 'classical' : P-value of test.
> 'bayesian' : Probabilty of test.

A 1x1 double.
- ci : A 1 x 2 double with the lower and upper bound of the confidence/probabillty interval of the tested expression.
- dist : A nb_distribution object storing the distribution of the tested expression.

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c] = theoreticalMoments(obj,varargin)
[m,c,ac1] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargout{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';  
 'shock_name_1' , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

obj = uncondForecast(obj,nSteps,varargin)

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_ecm.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_ecm.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **update** ↑

```
obj          = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic

- type : > '' : Only update data. Default
> 'estimate' : Update data and estimate.
> 'solve' : Update data, estimate and solve
> 'forecast' : Update data, estimate, solve and forecast.

- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.

- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition ↑**

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
 - 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
 - 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.
- Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the

method nb_var.set_identification for more.

- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidenc/probability bands. Default is '''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N' }
```

Where '`shock_name_x`' must be a string with a shock name or a cellstr array with the shock names. E.g '`E_X_NW`' or `{'E_X_NW','E_Y_NW'}`.

If empty no packing will be done.

Output:

- `decomp` : A structure of `nb_ts` objects with the variance decomosition for each model. (If simulated it will store the median or closest to median dependent on the '`output`' option)
- `decompBands` : A structure of structs with the percentiles of the variance decomosition for each model. For each percentiles the output is as `decomp`.
- `plotter` : A $1 \times nModel$ vector of `nb_graph_cs` objects. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
- `plotterBands`: A $1 \times nModel$ struct. Each field is a $1 \times nVars$ vector of `nb_graph_cs` objects. Use the `graphSubPlots` method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

■ nb_exprModel

Go to: [Properties](#) | [Methods](#)

A class for estimation a model where each variable is allowed to be an expression of different variables, e.g.

```
diff(y(t)) = beta(1)*diff(x(t)) + beta(2)*(log(y(t-1)) - log(x(t-1)))
```

Superclasses:

`nb_model_generic`

Constructor:

```
obj = nb_exprModel(varargin)
```

Optional input:

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : An nb_exprModel object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [addAutoName](#)

- [estOptions](#)
- [exogenous](#)
- [forecastOutput](#)
- [name](#)
- [options](#)
- [parameters](#)
- [reporting](#)
- [residuals](#)
- [results](#)
- [solution](#)
- [transformations](#)
- [userData](#)

- **[addAutoName](#) ↑**

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#) ↑**

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#) ↑**

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#) ↑**

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[dependent](#) ↑**

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgen models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this property to be up to date!

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.

- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.
As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

► **`appendData`** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters ↑**

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames** ↑

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.

- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!

- 'instrument' : A one line char with the name of the instrument. Must be provided!

- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!

- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.

- 'perc' : Error band percentiles. As a 1 x nPerc double.
E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will
be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the
double method on this output to convert it to a double
matrix.

See also:

[nb_exprmodel.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws
(bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see
[nb_bootstrap](#). For bayesian models 'posterior' is the only
option. Default is 'bootstrap' for classical models, while
'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is
1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property
is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterioriors** ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optional input:

- `'nLags'` : Number of lags to include in the autocorrelation plot. Default is 10.
- `'iter'` : The recursive iteration date. Either as a string or a `nb_date` object. If recursive estimation is done, this input must be provided.

Output:

- `DB` : A `nb_data` object with size `nDraws x numCoeff`.
- `plotter` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.
- `pAutocorr` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.

Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
                    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

Inherited from superclass NB_MODEL_GENERIC

► [convert ↑](#)

`obj = convert(obj,freq,method,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convert`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convert`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► [convertEach ↑](#)

`obj = convert(obj,freq,methods,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_MODELDATA`

► `createVariables` ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM `nb_modelData` object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.

> third column : Any expression that can be interpreted by the `nb_ts.createShift` method.

> fourth column : Comments

- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name,    input,    shift,    description
  'VAR1_G',    'pcn(VAR1)', 'avg',    'VAR1 growth'
  'VAR2_G',    'pcn(VAR2)', 'avg',    'VAR2 growth'
  'VAR3_G',    'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► dieboldMarianoTest ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

`nb_exprmodel.forecast, nb_distribution.perc2ParamDist`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity** ↑

`obj = doSimulateFromDensity(obj, draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `obj` : A `nb_model_forecast` object.
- `draws` : Number of draws to use for simulation.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_model_generic.forecast, nb_exprModel.simulateFromDensity`

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass `NB_MODEL_FORECAST`

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_generic` object. The `options.data` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

```

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables.
            'dependent' will return the moment of the dependent
            variables. 'dependent' is default.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or
               not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to
             true.

- 'type' : Either 'covariance' or 'correlation'. Default is
            'correlation'.

- 'startDate' : The start date of the calculations. Default is the start
                date of the options.data property. Only for time-series!
                Must be a string or a nb_date object.

- 'endDate' : The end date of the calculations. Default is the end
               date of the options.data property. Only for time-series!
               Must be a string or a nb_date object.

- 'demean' : true (demean data during estimation of the
              autocovariance matrix), false (do not). Default is true.

```

Output:

```

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.

- varargout{2} : The contemporaneous covariances/correlations, as a nVar
                x nVar nb_cs object or double. The variance is along
                the diagonal. (Will be symmetric)

- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar
                x nVar nb_cs object or double. Along the diagonal is the
                auto-covariance/correlation with the variable itself. In
                the upper triangular part the you can find cov(x,y(-i)),
                where x is the variable along the first dimension. In
                the lower triangular part the you can find cov(x(-i),y),
                where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find
      cov(x,y(-i)) you can use
      getVariable(varargin{i}, 'y', 'x'),
      while to get cov(x(-i),y) (== cov(x,y(+i))) you
      can use getVariable(varargin{i}, 'x', 'y'). (This
      example only works if the output is of class nb_cs)

```

See also:

[nb_exprModel.graphCorrelation](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj          = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default

is to open max number of cores available. Only an option if 'parallel' is given.

- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecast** ↑

```
obj          = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for forward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters

for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
 - 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.
- If set to empty, all simulations will be returned.
- Caution: 'draws' must be set to produce density forecast.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

```

- 'bins'      : The length of the bins og the domain of the density.
  Either;
    > []       : The domain will be found. See
      nb_getDensityPoints (default is that 1000
      observations of the density is stored).
    > integer   : The min and max is found but the length
      of the bins is given by the provided
      integer.
    > cell       : Must be on the format:
      {'Var1',lowerLimit1,upperLimit1,binsL1;
       'Var2',lowerLimit2,upperLimit2,binsL2;
       ...}
    - lowerLimit1 : An integer, can be nan,
      i.e. will be found.
    - upperLimit1 : An integer, can be nan,
      i.e. will be found.
    - binsL1      : An integer with the
      length of the bins. Can
      be nan. I.e. bins length
      will be adjusted to
      create a domain of 1000
      elements.

Caution : The variables not included will be given
          the default domain. No warning will be
          given if a variable is provided in the
          cell but not forecast by the model. (This
          because different models can forecast
          different variables)

Caution : The combineForecast method of the
          nb_model_group class is much faster if the
          lower limit, upper limit! Or else
          it must simulate new draws and do kernel
          density estimation for each model again
          with the shared domain of all models
          densities.

- 'startDate'   : The start date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

Caution: If 'fcstEval' is not empty this will set
        the start date of the recursive forecast.
        Default is to start from the first possible
        date.

- 'endDate'     : The end date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

Caution: If 'fcstEval' is empty this input will

```

have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous

variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
If not provided. Model stds are used.
 - > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
 - > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for

all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.
- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime

is not given, you will start in
the ergodic steady-state for
MS-model, and in the last regime
for break-point models.

- 'startingProb' : Either a double or a char:
 - > 'zero' : Start from zero on all variables
(Except for the deterministic
exogenous variables)
 - > [] : If the model is filtered the
starting value is calculated
on filtered transition
probabilities. Otherwise the
ergodic mean is used.
 - > double : A nPeriods x nRegime or a 1 x
nRegime double. nPeriods refer to
the number of recursive periods to
forecast.
 - > 'ergodic' : Start from the ergodic transition
probabilities.
- 'stabilityTest' : Give true if you want to discard the parameter draws
that give rise to an unstable model. Default
is false.
- 'states' : Either an integer with the regime to
forecast/simulate in, or an object of class nb_ts
with the regimes to condition on. The name of the
variable must be 'states'.

Caution: For break-point models this is decided by
the dates of the breaks, and cannot be set
by this option!

- 'compareToRev' : Which revision to compare to. Default is final
revision, i.e. []. Give 5 to get fifth revision.
must be an integer. Keep in mind that this number
should be larger than the nSteps input.
- 'compareTo' : Sometime you want to evaluate the forecast of one
variable against another variable which is not
part of the model. E.g. if you use the first release
of a variable and want to compare it against the
final release. To do this you can give a cellstr
with size n x 2, where n is the number of variables
to change the the actual observations to test
against. {'VAR_1','VAR_FINAL',...}.
- 'estimateDensities' : true or false. true if you want to do a
kernel density estimation of the density
forecast.
- 'exoProj' : Tolerate missing exogenous variables by projecting
them by a fitted model. Only when the 'condDB'
input is empty!

Options are:

- '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.
- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.
- 'exProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.
- 'exProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.
- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.
- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.
- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example

{'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when `exoProj` is set to 'AR'.

- 'bounds'
: A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps` double matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a 1x1 double or a `nSteps x 1` double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs'
: This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.

- 'foundReplic'
: A struct with size `1 x parameterDraws`. Each element must be on the same format as `obj.solution`. I.e. each element must be the solution of the model given a set of drawn parameters. See the `parameterDraws` method of the `nb_model_generic` class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.

```
- 'seed' : Set simulation seed. Default is 2.0719e+05.
```

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist ↑**

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_exprmodel.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist ↑**

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_exprmodel.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
    nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getCondDB ↑

[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments ↑**

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependent ↑**

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getFiltered ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables. I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_exprmodel.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast** ↑

```
fcstData          = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();
```

```

    end

> 'date'      : A string or a nb_date object with the date of the
                 wanted forecast. E.g. '2012Q1'. The fcstData will
                 be a nb_ts object with size nHor x nVar x nPerc + 1,
                 while fcstPercData will be empty. nPerc will then be
                 the number of percentiles/simualtions. Mean will be at
                 last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'   : This option will return the forecast as a
                 nPeriods + nHor x nVar x nHor nb_ts object. This
                 option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).

```

Optional inputs:

```

> 'horizon'   : The fcstData output will be a nb_ts object with
                 size nRec x nVars. While the fcstPercData output
                 will be a nb_ts object with size nRec x nVars x nSim.
                 You can set the horizon to return by the optional
                 input 'horizon'. See the 'timing' option also.

```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_exprModel.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables ↑**

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

p = getParameters(obj,varargin)

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as

fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

- : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
- : Give 'double' to return the value as a numerical array.
- : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

► **getRecursiveScore ↑**

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **getResidual** ↑

`residual = getResidual(obj)`

Description:

Get residual from a estimated `nb_model_generic` object

Input:

- `obj` : An object of class `nb_model_generic`

Output:

- `residual` : Either a `nb_ts` or a `nb_cs` object with `residual(s)` stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualGraph** ↑

`plotter = getResidualGraph(obj)`

Description:

Get residual graph from the given estimator. The returned will be an object of class `nb_graph`, which you can call the `graphInfoStruct` method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- `obj` : An object of class `nb_model_generic` (or a subclass of this class).

Output:

- `plotter` : An object of class `nb_graph`. Use the `graphInfoStruct` method or the `nb_graphInfoStructGUI` class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of `nb_model_generic` object

Input:

- `obj` : A vector of `nb_model_generic` objects

Output:

- `residualNames` : A cellstr with the unique residual names of all the models

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method `solve`.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getScore ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.

- type : A string with one of the following:
- 'RMSE' : One over root mean squared error
- 'MSE' : One over mean squared error
- 'MAE' : One over mean absolute error
- 'MEAN' : One over mean error
- 'STD' : One over standard error of the forecast error
- 'ESLS' : Exponential of the sum of the log scores
- 'EELS' : Exponential of the mean of the log scores
- 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.

- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution ↑**

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_exprModel.simulatedMoments](#), [nb_exprModel.theoreticalMoments](#)
[nb_exprModel.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth SÃ¶therhagen Paulsen

► **handleMissing** ↑

ret = handleMissing(obj)

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► help ↑

```
helpText = nb_exprModel.help
helpText = nb_exprModel.help(option)
helpText = nb_exprModel.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► initialize ↑

```
obj = initialize(template)
```

Description:

Intialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:**Input:**

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.

- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.
- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_exprmodel.forecast](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [irf](#) ↑

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsg objects.
- 'compare' : Give true if you have a scalar nb_dsg model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.
- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.

```

- 'factor'           : A cell array with the factors to multiply the
                      irf of the individual model variables.
                      I.e. {'var1',100,...} or
                           {'var1','var2'},100,...}

                      If the string starts with a asterisk you will
                      multiply all the variables that contain that
                      string with the given factor.
                      E.g. {'*_GAP',100}

- 'fanPerc'         : This options sets the error band percentiles of the
                      graph, when the 'perc' input is empty. As a 1 x
                      numErrorBand double. E.g. [0.3,0.5,0.7,0.9].
                      Default is 0.68.

- 'foundReplic'     : A struct with size 1 x replic. Each element
                      must be on the same format as obj.solution. I.e.
                      each element must be the solution of the model
                      given a set of drawn parameters. See the
                      parameterDraws method of the nb_model_generic class.

                      Caution: You still need to set 'parameterDraws'
                      to the number of draws you want to do.

- 'irfCompare'      : A struct on the same format as the irfs output from
                      this function with the IRFs to compare to.

- 'levelMethod'      : One of the following:

  > 'cumulative product'          : cumprod(1 + X,1)
  > 'cumulative sum'             : cumsum(X,1)
  > 'cumulative product (log)'    : log(cumprod(1 + X,1))
  > 'cumulative sum (exponential)' : exp(cumsum(X,1))
  > 'cumulative product (%)'      : cumprod(1 + X/100,1)
  > 'cumulative sum (%)'          : cumsum(X/100,1)
  > 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
  > 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
  > '4 period growth (log approx)' : nb_msum(X,3)

- 'method'            : The selected method to create error bands.
                      Default is ''. See help on the method input of the
                      nb_model_generic.parameterDraws method for more
                      this input. An extra option is:

  > 'identDraws' : Uses the draws of the matrix with
                  the map from structural shocks to dependent
                  variables. See nb_var.set_identification. Of
                  course this option only makes sense for VARs
                  identified with sign restrictions.

```

- 'normalize' : A 1 x 3 cell. First element must be the variable name as a string. The second element must be the value to normalize to, as an integer. While the third element is the period to be normalized, if set to inf, it will normalize the max impact period.
 E.g. {'Var',1,2}, {'Var',1,inf}
 Caution: 2 means observation 2 of the IRF, and as the IRF start at period 0, this means that observation 2 is period 1.
- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of irfs, while 'mean' normalize the mean and scale percentiles/other draws accordingly. Default is 'draws'.
 Caution: Setting this to 'mean' will not work for reported variables that is not measured as % deviation from steady-state/mean.
- 'newReplic' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the replic input.
- 'parallel' : Give true if you want to do the irfs in parallel. This option will parallelize over models. Default is false.
- 'parallelL' : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if numel(obj) == 1. Default is false.
- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for nb_dsg objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for nb_dsg objects.

- 'replic' : The number of parameter draws.
 Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.

- 'settings' : Extra graphs settings given to nb_plots function. Must be a cell.

- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.
 For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.

- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.

- 'startingProb' : Either a double or a char (Only for Markov-switching models):

- > scalar : Select the the regime to take the initial transition probabilities from.
- > double : A draws x nRegime or a 1 x nRegime double. draws refer to the number set by the 'draws' input.
- > 'ergodic' : Start from the ergodic transition probabilities. Default for 'irf'.
- > 'random' : Randomize the starting values using the simulated starting points. Default for 'girf'.

- 'startingValues' : Either a double or a char:
 > double : A nVar x 1 double.
 > 'steadystate' : Start from the steady state. If you are dealing with a MS-model or a break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. For MS - models the default is the ergodic mean

(default as long as 'girf' is not selected as 'type'), while for break-point models it is to start from the first regime.

- > 'zero' : Start from zero on all variables.
- > 'random' : Randomize the starting values using the simulated starting points. Default when 'type' set to 'girf'.
- 'states' : Either an integer with the states to produce irf in, or a double with the states to condition on. Must have size periods x 1 in the last case. Applies to both MS - models and break-point models.
- 'type' : 'girf' or 'irf'. (If empty 'irf' will be used)
 - > 'girf' : Generalized impulse response function calculated as the mean difference between shocking the model with a one period shock (1 std) and no shock at all. Use the 'draws' input to set the number of simulations to use to base the calculation on. This type of irfs must be used for non-linear models.
 - > 'irf' : Standard irf for linear models. Calculated by shocking the model with a one period shock (1 std).
- 'variables' : The variables to create impulse responses of. Default is the dependent variables defined by the first model.

Caution: The variables reported by the reporting property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.
- I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.('E_X_NW'). Which will then be a nb_ts object of all the wanted variables.
- Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.
- Caution: Each nb_model_generic object can have different variables and shocks.
- irfsBands : A struct with the shocks as fieldnames. Each field store

a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.
 - > 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
 - > 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast ↑**

ret = isDensityForecast(obj)

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered ↑**

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

```
ret = isMixedFrequency(obj)
```

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

ret = isbayesian(obj)

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► jointPredictionBands ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint prediction bands for macroeconomic risk management
 - > 'copula' : Using a copula likelihood approach.
 - > 'mostlik' : Group the paths based on how likely they are.

- 'nSteps' : Number of forecasting steps to use when constructing the error bands. If empty (default) all forecasting steps stored in the object is used.

Output:

- JPB : An nb_ts object storing the joint prediction bands. The percentiles are stored as datasets. See the dataNames property for which page represent which percentile.

The data of the nb_ts object has size nSteps x nVars x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method to produce the graphs.

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior** ↑

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_exprModel.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x)&&f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. `@(x)gt(x,0), @(x)gt(x,0)||lt(x,1)`, i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. `@(x,y)gt(x,y), @(x,y)gt(x-y,0)||lt(x-y,1)`, i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. `{'Var1','Var1',1,@(x)gt(x,0.1)}`, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. `{'Var1','Var2',0,@(x)lt(x,0.1)}`, to test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.
 - > 'cov' : Same as for 'corr'.

E.g. `{'Var1','Var1',0,@(x)lt(x,0.1)}`, to test a restriction on the contemporaneous

variance.

```
> 'ss'      : A N x 2 cell, where the elements of each
               row are:
               1. The expression using any of the
                  endogenous variables of the model.
               2. Same as 4 for 'irf'.
```

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

[nb_exprModel.monteCarloFiltering](#), [nb_exprmodel.irf](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mincerZarnowitzTest ↑**

```
[test,pval,res] = mincerZarnowitzTest(obj,precision)
```

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_exprModel.uncondForecast](#)

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is specified with some lower and upper bounds. For each draw the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.

```

- 'waitbar'      : true or false. Default is true.

- 'output'       : Either 'double' or 'logical'. Default is 'logical'.

- 'seed'         : Set the seed to use to draw the monte carlo simulated
                    parameter sets. Default is 1. Seed is set back to old
                    state after this method is called!

```

Output:

```

- paramD        : The draws made from the parameter space. As a draws x N
                  double. Use paramD(success,:) to get the accepted
                  draws.

- values         : A N x 1 logical/double. An element is true/not nan if
                  the model where solved and the test function returned
                  a value.

- solvingFailed : A N x 1 logical. An element is true if the model could
                  not be solved.

- objAcc        : A 1 x nAcc vector of nb_model_generic objects
                  representing the accepted models.

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_GENERIC](#)

► **parameterDraws** ↑

```

out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)

```

Description:

Make either posterior draws or bootstrapped draws from the distribution
of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

```

- obj      : An object of a subclass of the nb_model_generic class.

- draws    : Number of draws, as an integer. Default is 1000.

- method   : The selected method to make draws.

> 'asymptotic'          : Draw from the confidence set using

```

the assumption of asymptotic normality.
 See the `nb_mlEstimator.drawParameters`
 for more on this option. Applies to models
 estimated with maximum likelihood.

> 'bootstrap' : Create artificial data to bootstrap
 the estimated parameters. Default
 for models estimated with classical
 methods.

> 'wildBootstrap' : Create artificial data by wild
 bootstrap, and then "draw" paramters
 based on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'blockBootstrap' : Create artificial data by
 non-overlapping block bootstrap,
 and then "draw" paramters based
 on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'mblockBootstrap' : Create artificial data by
 overlapping block bootstrap,
 and then "draw" paramters based
 on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'rblockBootstrap' : Create artificial data by
 overlapping random block length
 bootstrap, and then "draw" paramters
 based on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'wildBlockBootstrap' : Create artificial data by wild
 overlapping random block length
 bootstrap., and then "draw" paramters
 based on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'copulaBootstrap' : Uses a copula approach to draw residual
 that are autocorrelated, Does not handle
 heteroscedasticity. Only an option for
 models estimated with classical methods.

> 'posterior' : Posterior draws. Only for models
 estimated with bayesian methods.
 Default for models estimated with
 bayesian methods.

- `output` : 'param' | 'solution' | 'object'. See output section for more
 on this option.
- `stable` : Give true if you want to discard the parameter draws
 that give rise to an unstable model. Default is false.

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores available.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.
- 'initialDraws' : When drawing parameters this factor decides how many many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
 - > 'param' : Default. A struct with the following fields:
 - beta : A nPar x nEq x draws double with the estimated parameters.
 - sigma : A nEq x nEq x draws double with the estimated covariance matrix.
- For factor models these fields are also returned:
 - lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.
 - R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.
 - factors : Draws of the factors as a T x nFac x draws double.
- > 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

```
> 'object'      : Get the draws as a 1 x draws nb_model_generic object.  
                  Each element will be a model representing a given draw  
                  from the distribution of the parameters. I.e. only one  
                  output!
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► plotForecast ↑

```
plotter          = plotForecast(obj)  
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate,...  
                                         increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model
in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

```
plotter = plotForecastDensity(obj,date,variable)
```

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the

provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF** ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...  
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

```
- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method  
or the nb_graphPagesGUI class to produce the  
graphs.  
    > 'biplot'      : A vector of nb_graph_data objects with size  
equal to the number of pairwise combination of  
the parameters that can be made. Use the  
graph method or the nb_graphMultiGUI class to  
produce the graphs.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest ↑**

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_exprModel.monteCarloFiltering](#), [nb_cucconiTest](#), [nb_smirnovTest](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,valueName)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_exprModel.monteCarloFiltering](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optitonal input:

- `'prior'` : Give this string as an input to compare posterior draws with the prior distributions (if available).
- `'updated'` : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- `'subplot'` : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- `'draws'` : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If `'updated'` is given as input, this will also set the the same options for the updated prior!

Output:

- `plotter` : A $1 \times \text{numCoeff}$ vector of objects of class `nb_graph_data`. Use either the `graph` method or the `nb_graphMultiGUI` class to plot the posteriors on screen.

Caution: If `'subplot'` is given it will return a scalar `nb_graph_data` object. Use the `graphSubPlots` method or the `nb_graphSubPlotGUI` class to plot the posteriors on screen.

[nb_exprModel.getPosteriorDistributions](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotPriors ↑**

`plotter = plotPriors(obj,varargin)`

Description:

Plot priors. Only for bayesian models.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model with a set prior.

Optitonal input:

- `'subplot'` : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- `plotter` : A $1 \times \text{numCoeff}$ vector of objects of class `nb_graph_data`. Use either the `graph` method or the `nb_graphMultiGUI` class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar `nb_graph_data` object is returned. Use the `graphSubPlots` method or the `nb_graphSubPlotGUI` class to plot the priors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **print** ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- `obj` : A vector of `nb_model_estimate` objects.

Output:

- `printed` : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results ↑**

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_exprmodel.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations ↑**

obj = removeObservations(obj, numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

obj = set(obj,varargin)

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition ↑**

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If

different models has different frequency this date will be converted.

- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.
- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

See also:

[nb_exprModel.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulate** ↑

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also

including exogenous and shocks.

> 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.

- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.

- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.

- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.

- 'seed' : Set simulation seed. Default is 2.0719e+05.

- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a specific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:

- > double : A 1 x nVar double.
- > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsge models.
- > 'steadystate' : Start from the steady state. For now only an option for nb_dsge models. If you are dealing with a MS-model you can indicate the state by 'steadystate(state)'. E.g. to start in state 1 give; 'steadystate(1)'. Default for nb_dsge models.
- > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

- 'startingProb' : Either a double or a char:

```

> double      : A nPeriods x nRegime or a 1 x
    nRegime double. nPeriods refer to
    the number of recursive periods to
    forecast.

> 'ergodic'   : Start from the ergodic transition
    probabilities. Default.

```

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
 - 'nLags' : Number of lags to compute when 'stacked' is set to true.
 - 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
 - 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
 - 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
 - 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.
- Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
 - 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
 - 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is

true.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

► **solutionFunc** ↑

```
yPred = nb_exprModel.solutionFunc(Z,t,E,h,beta,depTransFunc,...  
depLagFunc,exoFuncs,nLags,nExo,locDep,nDep)
```

Description:

The function that is used to forecast a model of class nb_exprModel.

Input:

- Z : A nObs x nVar double with the data of the model.
- t : The period to forecast. t <= nObs.
- E : A nRes x nSteps double with the values on the residuals.
- h : The forecasting step.
- beta : The parameters of the model as a 1 x nDep cell array. Each element contains a nExo(ii) x 1 double with the parameters of equation ii.

Output

- Z : A nObs x nVar double with the data of the model, and where the forecast is been filled in at Z(t,locDep).

See also:

[nb_exprModel.solveRecursive](#)

Written by Kenneth Sæterhagen Paulsen

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_exprModel object(s).

Input:

- obj : A vector of nb_exprModel objects.

Output:

- obj : A vector of nb_exprModel objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal ↑**

```
tempSol = nb_exprModel.solveNormal(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_exprModel.solveRecursive(results,options)
```

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_exprmodel.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

```
options = nb_exprModel.template()
options = nb_exprModel.template(num)
```

Description:

Construct a struct which can be provided to the nb_exprModel class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

```
- num      : Number of models to create.
```

Output:

```
- options : A struct.
```

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

```
- obj      : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
                 {variable, date, test}.

    > variable : The variable(s) to test,
                 as a string or cell array of strings.
```

```

> date      : The date as a string. If a cell array is given, a
   copy of the restriction will be made for every given
   date.

> test      : Restriction test as a function handle. The value(s)
   of the variable(s) in 'variable' at time 'date' are
   passed as arguments. Should return a logical.

```

Output:

- out : A double with the probability

Example:

```

restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...
                {'QSA_URR', 'QSA_DPQ_CP'}, '2014Q1', @(x, y) x < y};
probability = model.testForecastRestrictions(restrictions);

```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as variables. See model.parameters.name.
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.

```

- alpha      : Confidence level. Default is 0.05.

- type       : Type of test:
    > '=' : Two sided test. expression == 0 (default)
            For two-sided tests it is assumed that the
            distribution is symmetric! Use
            confidence/probability intervals instead.
    > '>' : One sided test. expression > 0
    > '<' : One sided test. expression < 0

```

Output:

```

- pval      : > 'classical' : P-value of test.
                > 'bayesian' : Probability of test.

                A 1x1 double.

- ci        : A 1 x 2 double with the lower and upper bound of the
                confidence/probability interval of the tested expression.

- dist      : A nb_distribution object storing the distribution of the
                tested expression.

```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► **theoreticalMoments ↑**

```

[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)

```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation,
autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation
results is used.

Caution : Only supported for models that can be solved in the following
way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.
Can also be a cellstr, with a subset of variables from 'full'.
- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : I the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar

`x` nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find `cov(x,y(-i))`, where `x` is the variable along the first dimension. In the lower triangular part the you can find `cov(x(-i),y)`, where `x` is the variable along the first dimension.

E.g: You have two variables `x` and `y`, then to find `cov(x,y(-i))` you can use `getVariable(varargout{i},'y','x')`, while to get `cov(x(-i),y) (== cov(x,y(+i)))` you can use `getVariable(varargout{i},'x','y')`. (This example only works if the output is of class nb_cs)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

```
[data,plotter] = uncertaintyDecomposition(obj,varargin)
```

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- `obj` : A vector of nb_model_generic objects
- `'compare2'` : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- `'method'` : One of:
 - > `'percentiles'` : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the percentiles of this distribution

```

        (default).

    > 'fev'      : Calculate the forecast error variances
                   contributed by each shock based on the
                   simulated densities of the
                   residuals/shocks of models forecast.

- 'perc'      : At which percentile you want to decompose. Must
                be scalar double. Default is 0.9. Only an options for
                'method' set to 'percentiles'.

- 'packages'  : Cell structure with groups of shocks and
                the names of the groups. If you have not
                listed a shock it will be grouped in a
                group called 'Rest'

        Must be given in the following format:

{'shock_group_name_1',..., 'shock_group_name_N';
 'shock_name_1' ,..., 'shock_name_N' }

Where 'shock_name_x' must be a string with
a shock name or a cellstr array with the
shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If
                different models has different frequency this date will
                be converted.

- 'variables' : The variables to decompose. Default is the
                dependent variables defined by the first model.

```

Output:

```

- data      : Depend on the 'method' input:

    > 'percentiles'   : A nHor x (nExo + nRes)*2 x nVars nb_ts
                        object storing the uncertainty
                        decomposition.

    > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object
                        storing the numerically calculated
                        forecast error variances/skewnesses.

- plotter : A nb_graph_ts object which the method graph can be used to
            produce graphs.

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast ↑**

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_exprmodel.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_exprmodel.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► update ↑

```
obj          = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition** ↑

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.

- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomosition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomosition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

■ **nb_favar**

Go to: [Properties](#) | [Methods](#)

A class for estimation and identification of FA-VAR models.

Superclasses:

`nb_factor_model_generic, nb_var, nb_model_generic`

Constructor:

`obj = nb_favar(varargin)`

Optional input:

- See the `set` method for more on the inputs.
(`nb_model_estimate.set`)

Output:

- `obj` : An `nb_favar` object.

See also:

`nb_model_generic, nb_model_estimate.set`

Written by Kenneth Sæterhagen Paulsen

Properties:

- | | | | |
|--------------------------------|-----------------------------------|-------------------------------|-----------------------------|
| • <code>addAutoName</code> | • <code>addAutoNameIfLocal</code> | • <code>addID</code> | • <code>addIDIfLocal</code> |
| • <code>block_exogenous</code> | • <code>dependent</code> | • <code>endogenous</code> | • <code>estOptions</code> |
| • <code>exogenous</code> | • <code>factors</code> | • <code>forecastOutput</code> | • <code>name</code> |
| • <code>observables</code> | • <code>observablesFast</code> | • <code>options</code> | • <code>parameters</code> |
| • <code>reporting</code> | • <code>residuals</code> | • <code>results</code> | • <code>solution</code> |
| • <code>transformations</code> | • <code>userData</code> | | |

- **`addAutoName`** ↑

Add automatic name (first) to default name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **`addAutoNameIfLocal`** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **block_exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the block exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of block exogenous variables. To set it use the set function. E.g. obj = set(obj,'block_exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_VAR

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **factors** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the factors, the tex_name holds the names in the tex format. The number field holds a double with the number of factors. To set it use the set function. E.g. obj = set(obj,'factors',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_VAR

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **observables** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) of the model observation equation, the tex_name holds the names in the tex format. The number field holds a double with the number of variables of the model observation equation. To set it use the set function. E.g. obj = set(obj,'observables',{'Var1','Var2'}); or use the <className>.template() method.

If the model class also supports mixed frequency data, it has two additional fields; frequency and mapping. These fields stores the selected frequency and mapping for each element.

Inherited from superclass NB_FACTOR_MODEL_GENERIC

- **observablesFast** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) of the model observation equation, the tex_name holds the names in the tex format. The number field holds a double with the number of variables of the model observation equation. To set it use the set function. E.g. obj = set(obj,'observablesFast',...{'Var1','Var2'}); or use the <className>.template() method.

These are the variables that are included in the observation equation, but are not included in the estimation of the factors.

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this property to be up to date!

Caution: For nb_dsg models the residuals and exogenous property

stores the same variables (after the model being solved) !

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only) :

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only) :

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only) :

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.

- observables : A 1 x nobs cellstr with the declared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation. As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- transformations ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

► **ABidentification** ↑

```
S = nb_var.ABidentification(ident,A,sigma,maxDraws,draws,ask)
```

Description:

Identification of VAR model using combination of zero and sign restrictions. See Binning (2013), "Underidentified SVAR models: A framework for combining short and long-run restrictions with sign-restrictions". Many thanks to him for supplying help!

As a extension to Binning (2013) this code also allow for magnitude restrictions.

Input:

- ident : The identification assumption, as a struct. See set_identification method of the nb_var class for more
- A : Transition matrix
- sigma : Covariance matrix of the VAR residuals.
- maxDraws : The number of maximal rotations when looking for a identification satifying the sign restrictions. Can be set to inf. Default is 10000.
- draws : The number of wanted draws of the matrix of the map from structural shocks to dependent variables (C). Default is one.

Output:

- S : A nb_struct with field W, with the stored map from structural shocks to dependent variables.

Written by Kenneth Sæterhagen Paulsen,
Subfunctions of this code are written by Andrew Binning.

Inherited from superclass NB_VAR

► **appendData** ↑

obj = appendData(obj, DB)

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **applyLongRunPriors** ↑

```
obj = applyLongRunPriors(obj,H,phi)
```

Description:

Apply priors for the long run as in Giannone et. al (2014).

If the prior field of the options property is not yet assign a prior, a jeffrey prior is used as default.

Caution: Please do not call this method before nb_var.setPrior!

Input:

- obj : A N x M matrix of nb_var objects, with nDep dependent variables.

- phi : Either a nDep x 1 double vector with the prior shrinkage parameter for each equation, or a m x 2 cell. m <= nDep. The format of the cell input must be as follows;

```
{'var1',1;'var2',0.5}
```

If some dependent variables are not assign any parameter the default is 1.

- H : A q x nDep matrix, where q <= nDep. Each row is the cointegration vector to apply on the prior. If q < nDep the null space will be applied to the rest of the rows.

Or it can be a q x 1 cellstr with the cointegration relations. Again q <= nDep, and if q < nDep the null space will be applied to the rest of the rows. Please note that only dependent variables may be applied in the cointegration relations! Example:

```
{'var1 - var2','var3 + var1'}
```

Output:

- obj : A N x M matrix of nb_var objects.

See also:

[nb_favar.set](#), [nb_favar.setPrior](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► **assignParameters ↑**

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model have been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames** ↑

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.
- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj, varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!
- 'instrument' : A one line char with the name of the instrument. Must be provided!
- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!
- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.
- 'perc' : Error band percentiles. As a 1 x nPerc double. E.g. [0.3, 0.5, 0.7, 0.9]. If empty all the simulation will be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the double method on this output to convert it to a double matrix.

[nb_favar.inf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

obj = calculateStandardError(obj,method,draws)

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.

- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterior** ↑

```
[DB,plotter,pAutocorr] = checkPosterior(obj,varargin)
```

Description:

Plot posteriors draws in the order they were drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot. Default is 10.
- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
- plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursivly estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the

all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.
Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.

Caution : Posterior draws is already made at the estimation stage.

- 'nSteps' : Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB           = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...  
horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
           allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **convert ↑**

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach ↑**

obj = convert(obj,freq,methods,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables ↑**

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

```
> second column : Any expression that can be interpreted
by the nb_ts.createVariable method.
```

```

> third column : Any expression that can be interpreted
    by the nb_ts.createShift method.

> fourth column : Comments

- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is
    important that this option is higher than the number of
    forecasting/irf steps, or else the output will be nan!

```

Output:

- obj : The NxM object itself added the model variables. The
 expressions input is stored in the property
 transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending.
 Use the graphInfoStruct method or the nb_graphInfoStruct
 class to produce the graph.

Examples:

```

expressions = {%
  Name,      input,    shift,    description
'VAR1_G',   'pcn(VAR1)', 'avg',   'VAR1 growth'
'VAR2_G',   'pcn(VAR2)', 'avg',   'VAR2 growth'
'VAR3_G',   'pcn(VAR3)', 'avg',   'VAR3 growth'};
model = model.createVariables(expressions)

```

See also:

Inherited from superclass NB_MODELDATA

► **dieboldMarianoTest ↑**

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band width selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

```
[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_favar.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity** ↑

obj = doSimulateFromDensity(obj, draws)

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_favar.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_generic object. The options.data property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic
- Optional inputs;
- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
 - 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
 - 'nLags' : Number of lags to compute when 'stacked' is set to true.
 - 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
 - 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
 - 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
 - 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
 - varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
 - varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part you can find cov(x(-i),y), where x is the variable along the first dimension.
- E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
getVariable(varargin{i}, 'y', 'x'),
while to get cov(x(-i),y) (== cov(x,y(+i))) you

can use `getVariable(varargin{i},'x','y')`. (This example only works if the output is of class nb_cs)

See also:

[nb_favar.graphCorrelation](#)

Inherited from superclass NB_MODEL_GENERIC

► [eq](#) ↑

`ret = eq(obj,other)`

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- `obj` : A nb_model_generic object either with same size as others, or equal to 1.
- `others` : A nb_model_generic model with `dim == 3` or less

Output:

- `ret` : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind     = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [estimate](#) ↑

```
obj        = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d,{'MSE'},0,1)
m = evalFcstAtDates(b,d,{'MSE','RMSE'},0,1)
```

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior** ↑

```
logPriorD = nb_model_generic.evaluatePrior(prior,par)
```

Description:

Evaluate the prior at a point in the parameter space.

Input:

```
- prior : See options.prior.  
- par : A nEst x 1 double with the value of the point of evaluation.
```

Output:

```
- logPriorD: The log prior density at the evaluated point.
```

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [explained ↑](#)

```
[expl,plotter] = explained(obj)
```

Description:

Get how much of the variation in the data the factors explain.

Caution: Remember that for dynamic factor models the factors are not orthogonal.

Input:

```
- obj : A scalar nb_factor_model_generic object.
```

Output:

```
- expl : A nb_cs object with size nFactors x 1.  
- plotter : A nb_graph_cs object. Use the graph method or the  
nb_graphPagesGUI class to plot it on the screen.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► [forecast ↑](#)

```
obj = forecast(obj,nSteps,varargin)  
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for foward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
- 'varOfInterest' : A char with the variable to produce the forecast of.

Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!

- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.
- If set to empty, all simulations will be returned.
- Caution:** 'draws' must be set to produce density forecast.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'bins' : The length of the bins og the domain of the density. Either;
 - > [] : The domain will be found. See nb_getDensityPoints (default is that 1000 observations of the density is stored).
 - > integer : The min and max is found but the length of the bins is given by the provided integer.

```

> cell      : Must be on the format:

{'Var1',lowerLimit1,upperLimit1,binsL1;
 'Var2',lowerLimit2,upperLimit2,binsL2;
 ...
}

- lowerLimit1 : An integer, can be nan,
  i.e. will be found.

- upperLimit1 : An integer, can be nan,
  i.e. will be found.

- binsL1      : An integer with the
  length of the bins. Can
  be nan. I.e. bins length
  will be adjusted to
  create a domain of 1000
  elements.

Caution : The variables not included will be given
the default domain. No warning will be
given if a variable is provided in the
cell but not forecast by the model. (This
because different models can forecast
different variables)

Caution : The combineForecast method of the
nb_model_group class is much faster if the
lower limit, upper limit! Or else
it must simulate new draws and do kernel
density estimation for each model again
with the shared domain of all models
densities.

- 'startDate'   : The start date of forecast. Must be a string or an
object of class nb_date. If empty the estim_end_date
+ 1 will be used.

Caution: If 'fcstEval' is not empty this will set
the start date of the recursive forecast.
Default is to start from the first possible
date.

- 'endDate'     : The end date of forecast. Must be a string or an
object of class nb_date. If empty the estim_end_date
+ 1 will be used.

Caution: If 'fcstEval' is empty this input will
have nothing to say.

- 'saveToFile'   : Logical. Save densities and domains to files. One
file for each model. Default is false (do not).

- 'observables'  : A cellstr with the observables you want the
forecast of. Only for factor models. Will be
discared for all other types of models.

- 'condDB'       : One of the following:

```

> A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.

> A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.

> A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)

> A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is choosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with

uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.

- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
 - If not provided. Model stds are used.
 - > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
 - > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!
- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogneous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.

- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:
 This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
- 'startingProb' : Either a double or a char:

```

> [ ]           : If the model is filtered the
                  starting value is calculated
                  on filtered transition
                  probabilities. Otherwise the
                  ergodic mean is used.

> double       : A nPeriods x nRegime or a 1 x
                  nRegime double. nPeriods refer to
                  the number of recursive periods to
                  forecast.

> 'ergodic'    : Start from the ergodic transition
                  probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws
                    that give rise to an unstable model. Default
                    is false.

- 'states'      : Either an integer with the regime to
                    forecast/simulate in, or an object of class nb_ts
                    with the regimes to condition on. The name of the
                    variable must be 'states'.

Caution: For break-point models this is decided by
          the dates of the breaks, and cannot be set
          by this option!

- 'compareToRev' : Which revision to compare to. Default is final
                   revision, i.e. []. Give 5 to get fifth revision.
                   must be an integer. Keep in mind that this number
                   should be larger than the nSteps input.

- 'compareTo'   : Sometime you want to evaluate the forecast of one
                   variable against another variable which is not
                   part of the model. E.g. if you use the first release
                   of a variable and want to compare it against the
                   final release. To do this you can give a cellstr
                   with size n x 2, where n is the number of variables
                   to change the the actual observations to test
                   against. {'VAR_1','VAR_FINAL',...}.

- 'estimateDensities' : true or false. true if you want to do a
                      kernel density estimation of the density
                      forecast.

- 'exoProj'      : Tolerate missing exogenous variables by projecting
                   them by a fitted model. Only when the 'condDB'
                   input is empty!

Options are:

- ''   : No projection are done. Error will be
         given if some exogenous variables are
         not given any conditional information.
         Default.

- 'ar' : The exogenous variables will be fitted by
         a univaiate AR model with the lag length

```

chosen with a 'aicc' criterion.

Caution : If density forecast are produced
the AR estimates will be
bootstrapped, and the exogenous
variables will be re-sampled
based on the bootstrapped values.

Caution : If forecast are being produced
recursively with recursively
estimated parameters, the
forecast/bootstrapping of the
exogenous variables will be done
based on recursively estimated AR
coefficients as well.

- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.
- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummy variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when exoProj is set to 'AR'.

- 'bounds' : A struct. Each fieldname must be the name of the

variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs' : This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.
 - 'seed' : Set simulation seed. Default is 2.0719e+05.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so

in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist ↑**

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_favar.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist ↑**

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_favar.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► getActual ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.

- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.

- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments ↑**

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by `nb_var.priorTemplate('dsge')`.

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependent** ↑

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

dependentNames = getDependentNames(obj)

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

outOpt = getEstimationOptions(obj)

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

start = getEstimationStartDate(obj)

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getFactors** ↑

factors = getFactors(obj)

Description:

```
Get factors from a estimated nb_factor_model_generic object
```

Input:

- obj : An object of class nb_factor_model_generic

Output:

- factors : A nb_ts object with the estimated factors of the model stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **getFiltered ↑**

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables. I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_favar.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast** ↑

```
fcstData           = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```

fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date'      : A string or a nb_date object with the date of the
                  wanted forecast. E.g. '2012Q1'. The fcstData will
                  be a nb_ts object with size nHor x nVar x nPerc + 1,
                  while fcstPercData will be empty. nPerc will then be
                  the number of percentiles/simualtions. Mean will be at
                  last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'   : This option will return the forecast as a
                  nPeriods + nHor x nVar x nHor nb_ts object. This
                  option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
                options for the 'date' and 'horizon' outputType.
                Default is false (0).

```

Optional inputs:

```

> 'horizon'   : The fcstData output will be a nb_ts object with
                  size nRec x nVars. While the fcstPercData output
                  will be a nb_ts object with size nRec x nVars x nSim.
                  You can set the horizon to return by the optional
                  input 'horizon'. See the 'timing' option also.

```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

[nb_favar.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables** ↑

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.
- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.
- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getIdentification ↑

```
matrix = getIdentification(obj)
```

Description:

Get restrictions on the structural shock matrix, i.e C in the equation below:

$y(t) = A*y(t-1) + B*x(t) + C*e(t)$, where $e(t) \sim N(0, I)$.

Input:

- obj : A identified scalar nb_var object.

Output:

- matrix : nEndo x nEndo cell array.

See also:

[nb_favar.set_identification](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► getIdentifiedResidual ↑

```
residual = getIdentifiedResidual(obj)
```

Description:

Get identified residual from a estimated nb_var object

If we have a VAR it can be written as (dropping exogenous variables):

$y_t = A*y_{t-1} + e_t$

A identified VAR can be written as:

$y_t = A*y_{t-1} + C*d_t$

Therefore the identified residuals/shocks can be found as:
d_t = inv(C)*e_t

Caution: Will only return the residual that uses the full sample. I.e.
when recursive estimation is done, only the residuals from the
last estimation will be returned.

Input:

- obj : An object of class nb_var

Output:

- residual : A nb_ts object with the identified residual(s) stored.
As a nobs x nEq x nIdent. Where nIdent is the number of
identified C matrices, i.e. when the user have asked to
identify more than one matrix (underidentification).

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► **getLHSVars ↑**

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgen object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgen object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.

- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getObservables** ↑

```
observables = getObservables(obj)
```

Description:

Get observables from a estimated nb_factor_model_generic object

Input:

- obj : An object of class nb_factor_model_generic

Output:

- observables : A nb_ts object with observables of the factor model stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

```
methods = parameterDraws(obj)
```

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.
- Optional input
 - varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).
 - : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
 - : Give 'double' to return the value as a numerical array.
 - : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

parameters

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions** ↑

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPriorDistributions** ↑

[distr,paramNames] = getPriorDistributions(obj)

Description:

Get prior distributions of B-VAR model.

Input:

- obj : An object of class nb_var.

Output:

- distr : A 1 x numCoeff nb_distribution object.

- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► **getRecursiveEstimationGraph** ↑

plotter = getRecursiveEstimationGraph(obj)

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- `plotter` : An object of class `nb_graph_ts`. Use the `graphSubPlots` method or the `nb_subplotGUI` class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);
plotter.graphSubPlots();
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getRecursiveScore ↑**

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- `obj` : A vector of `nb_model_forecast` objects.
- `type` : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- `dim` : Either 'variables' to get the recursive scores of all the variables forecast by a model (the `obj` input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- `startDate` : The date to begin constructing the score. Can be empty. Either as a string or an object of class `nb_date`.
- `endDate` : The date to end constructiong the score. Can be empty. Either as a string or an object of class `nb_date`.
- `invert` : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

residual = getResidual(obj)

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph** ↑

plotter = getResidualGraph(obj)

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.
- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
                  rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores

- 'MLS' : Mean log score

If the object intput is a vector, the type input can also be a cellstr array wit matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursivly, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution ↑**

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList ↑**

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **grangerCausalityTest ↑**

```
[test,pval,results] = grangerCausalityTest(obj,precision)
```

Description:

Test for granger causality between variables using a joint F-test that all the parameters of the lags of a variable y is zero in the equation where x is the dependent variable. If the hypothesis can be rejected we say that y granger cause x.

Caution: If recursive estimation is done it will anyway only do the test using the parameters estimated over the full sample.

Input:

- obj : A 1 x 1 nb_var object
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : The test statistics. As a nDep x nDep double. The diagonal will return nan.
- pval : The p-value of the test statistics. As a nDep x nDep double. The diagonal will return nan.
- results : A string with the printed results of the test.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_VAR

► graphCorrelation ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against emprirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from

`nb_model_generic.simulatedMoments` (SIM) or
`nb_model_generic.theoreticalMoments` (THEO), the second input must be
the c output from `nb_model_generic.empiricalMoments` (EMP), the third
input can be the ac1 output from SIM or THEO, the fourth input can be
the ac1 output from EMP, and so on.

Caution : The inputs must be given as `nb_cs` objects.

Caution : Inputs must come in pairs.

Output:

- `plotter` : An object of class `nb_graph_cs`. Use the `graph` method or the `nb_graphPagesGUI` class.

See also:

`nb_favar.simulatedMoments`, `nb_favar.theoreticalMoments`
`nb_favar.empiricalMoments`, `nb_graphPagesGUI`, `nb_graph_cs`

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **handleCondInfo** ↑

`ret = handleCondInfo(obj)`

Description:

Check if a `nb_model_estimate` object handle conditional info.

Input:

- `obj` : A scalar `nb_model_estimate` object.

Output:

- `ret` : true or false. true if the estimation settings is so that the
model handle conditional info.

Written by Kenneth SÃ¶terhagen Paulsen

► **handleMissing** ↑

`ret = handleMissing(obj)`

Description:

```
Check if a nb_model_estimate object handle missing observations.
```

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

► **help** ↑

```
helpText = nb_favar.help  
helpText = nb_favar.help(option)  
helpText = nb_favar.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **identDraws2Solutions** ↑

```
sol = identDraws2Solutions(obj)
```

Description:

This function assumes that you have used the set_identification function with the input 'type' set to 'combination'.

Input:

- obj : An object of class nb_var.

Output:

- sol : A struct storing the solution of the model. Same format as the solution property of the nb_var class.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_VAR

► initialize ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsgc.
- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.

- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_favar.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf ↑**

[irfs, irfsBands, plotter] = irf(obj, varargin)

Description:

Create impulse responses of the given vector of nb_model_generic objects
Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgen objects.
- 'compare' : Give true if you have a scalar nb_dsgen model and you want to graph the irfs from the different regimes from a NBToolbox solved model against each other. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the

nb_graphSubPlotGUI class to produce the graphs in this case.

- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.

- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.
I.e. {'var1',100,...} or
{{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This options sets the error band percentiles of the graph, when the 'perc' input is empty. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from this function with the IRFs to compare to.

- 'levelMethod' : One of the following:
 - > 'cumulative product' : cumprod(1 + X,1)

```

> 'cumulative sum' : cumsum(X,1)
> 'cumulative product (log)' : log(cumprod(1 + X,1))
> 'cumulative sum (exponential)' : exp(cumsum(X,1))
> 'cumulative product (%)' : cumprod(1 + X/100,1)
> 'cumulative sum (%)' : cumsum(X/100,1)
> 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
> 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
> '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
  Default is ''. See help on the method input of the
  nb_model_generic.parameterDraws method for more
  this input. An extra option is:

  > 'identDraws' : Uses the draws of the matrix with
    the map from structural shocks to dependent
    variables. See nb_var.set_identification. Of
    course this option only makes sense for VARs
    identified with sign restrictions.

- 'normalize' : A 1 x 3 cell. First element must be the variable
  name as a string. The second element must be the
  value to normalize to, as an integer. While the
  third element is the period to be normalized, if
  set to inf, it will normalize the max impact
  period.

  E.g. {'Var',1,2}, {'Var',1,inf}

  Caution: 2 means observation 2 of the IRF, and as
  the IRF start at period 0, this means that
  observation 2 is period 1.

- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of
  irfs, while 'mean' normalize the mean and scale
  percentiles/other draws accordingly. Default is
  'draws'.

  Caution: Setting this to 'mean' will not work for
  reported variables that is not measured
  as % deviation from steady-state/mean.

- 'newReplic' : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the replic input.

- 'parallel' : Give true if you want to do the irfs in parallel.
  This option will parallelize over models. Default
  is false.

- 'parallelL' : Give true if you want to do the irfs in parallel.

```

This option will parallelize over parameter simulations. Only an option if `numel(obj) == 1`. Default is false.

- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for `nb_dsg` objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for `nb_dsg` objects.
- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method `nb_var.set_identification` for more.

- 'settings' : Extra graphs settings given to `nb_plots` function. Must be a cell.
- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.

For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.

```

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):

    > scalar      : Select the the regime to take the
                     initial transition probabilities
                     from.

    > double      : A draws x nRegime or a 1 x
                     nRegime double. draws refer to
                     the number set by the 'draws'
                     input.

    > 'ergodic'   : Start from the ergodic transition
                     probabilities. Default for 'irf'.

    > 'random'    : Randomize the starting values
                     using the simulated starting
                     points. Default for 'girf'.

- 'startingValues' : Either a double or a char:

    > double      : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing
                      with a MS-model or a break-point model you can
                      indicate the regime by 'steadystate(regime)'. E.g.
                      to start in regime 1 give; 'steadystate(1)'. For
                      MS - models the default is the ergodic mean
                      (default as long as 'girf' is not selected as
                      'type'), while for break-point models it is to
                      start from the first regime.

    > 'zero'       : Start from zero on all variables.

    > 'random'    : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'       : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'         : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generlized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'  : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

- 'variables'    : The variables to create impulse responses of.
                     Default is the dependent variables defined by the

```

first model.

Caution: The variables reported by the reporting property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.('E_X_NW'). Which will then be a nb_ts object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.

> 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

> 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast** ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isIdentified** ↑

```
ret = isIdentified(obj)
```

Description:

Is the nb_var object identified or not.

Input:

- obj : A nb_var object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► **isMS** ↑

ret = isMS(obj)

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

ret = isMixedFrequency(obj)

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

ret = isNB(obj)

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

ret = isStateSpaceModel(obj)

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted ↑**

ret = isforecasted(obj)

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved ↑**

ret = issolved(obj)

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► jointPredictionBands ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint prediction bands for macroeconomic risk management
 - > 'copula' : Using a copula likelihood approach.
 - > 'mostlik' : Group the paths based on how likely they are.
- 'nSteps' : Number of forecasting steps to use when constructing the error bands. If empty (default) all forecasting steps stored in the object is used.

Output:

- JPB : An nb_ts object storing the joint prediction bands. The percentiles are stored as datasets. See the

dataNames property for which page represent which percentile.

The data of the nb_ts object has size nSteps x nVars x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior** ↑

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x)&&f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. @(x)gt(x,0), @(x)gt(x,0)||lt(x,1), i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. @(x,y)gt(x,y), @(x,y)gt(x-y,0)||lt(x-y,1), i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. {'Var1','Var1',1,@(x)gt(x,0.1)}, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. {'Var1','Var2',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.
 - > 'cov' : Same as for 'corr'.

E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous variance.
 - > 'ss' : A N x 2 cell, where the elements of each row are:
 1. The expression using any of the endogenous variables of the model.
 2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [mincerZarnowitzTest](#) ↑

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

Inherited from superclass NB_MODEL_GENERIC

► monteCarloFiltering ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj,draws,method,output,stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.

```

> 'wildBootstrap'      : Create artificial data by wild
                           bootstrap, and then "draw" paramters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'blockBootstrap'    : Create artificial data by
                           non-overlapping block bootstrap,
                           and then "draw" paramters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'mblockBootstrap'   : Create artificial data by
                           overlapping block bootstrap,
                           and then "draw" paramters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'rblockBootstrap'   : Create artificial data by
                           overlapping random block length
                           bootstrap, and then "draw" paramters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'wildBlockBootstrap': Create artificial data by wild
                           overlapping random block length
                           bootstrap., and then "draw" paramters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'copulaBootstrap'   : Uses a copula approach to draw residual
                           that are autocorrelated, Does not handle
                           heteroscedasticity. Only an option for
                           models estimated with classical methods.

> 'posterior'         : Posterior draws. Only for models
                           estimated with bayesian methods.
                           Default for models estimated with
                           bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
  on this option.

- stable : Give true if you want to discard the parameter draws
  that give rise to an unstable model. Default is false.

```

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores
 available.
- 'newDraws' : When out of parameter draws, this factor decides how

many new draws are going to be made. Default is 0.1.
I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.

- 'initialDraws' : When drawing parameters this factor decides how many many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
> 'param' : Default. A struct with the following fields:
 beta : A nPar x nEq x draws double with the estimated parameters.
 sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:
 lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.
 R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.
 factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► plotFactors ↑

```
plotter = plotFactors(obj,errBands)
```

Description:

Get factors from a estimated nb_factor_model_generic object

Input:

- obj : An object of class nb_factor_model_generic
- errBands : Give true to add one std bands around the factor estimates.
Default is false.

Output:

- plotter : A nb_graph_ts object to use to plot the factors. Use the graphSubPlots method or the nb_graphSubPlotGUI.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **plotForecast** ↑

```
plotter          = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
                                         increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forcast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity** ↑

```
plotter = plotForecastDensity(obj,date,variable)
```

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

```
plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF** ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...  
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.

- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest ↑**

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo

filtering.

- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues ↑**

plotter = nb_model_generic.plotMCFValues(paramD, params, nameValue)

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optitonal input:

- `'prior'` : Give this string as an input to compare posterior draws with the prior distributions (if available).
- `'updated'` : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- `'subplot'` : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- `'draws'` : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If `'updated'` is given as input, this will also set the the same options for the updated prior!

Output:

- `plotter` : A $1 \times \text{numCoeff}$ vector of objects of class `nb_graph_data`. Use either the `graph` method or the `nb_graphMultiGUI` class to plot the posteriors on screen.

Caution: If `'subplot'` is given it will return a scalar `nb_graph_data` object. Use the `graphSubPlots` method or the `nb_graphSubPlotGUI` class to plot the posteriors on screen.

See also:

`nb_graph_data`, `nb_graphMultiGUI`, `nb_graphSubPlotGUI`
`nb_favar.getPosteriorDistributions`

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotPriors** ↑

```
plotter = plotPriors(obj,varargin)
```

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov ↑**

printed = printCov(obj)

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results ↑**

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_favar.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **priorTemplate ↑**

```
prior = nb_favar.priorTemplate()  
prior = nb_favar.priorTemplate(type)  
prior = nb_favar.priorTemplate(type, num)
```

Description:

Not yet finished!!

Construct a struct which can be given to the method setPrior.

The structure provided the user the possibility to set different prior options.

Input:

- type : A string;
- num : Number of prior templates to make.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **removeObservations ↑**

```
obj = removeObservations(obj, numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

obj = set(obj,varargin)

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **setMeasurementEqRestriction** ↑

```
obj = setMeasurementEqRestriction(obj, restrictions)
```

Description:

Add restrictions in the measurement equation of the model on the form;

```
restricted = parameters*variables'
```

e.g.

```
X = [0.5,0.5]*[Y;Z]
```

where X is a observed variable, while Y and Z are state variables.
So for a mixed frequency var, X and Y must be included in the state
equation. An error is provided if this is not the case!

For the xxxMF priors this information is taken into account, otherwise
it will only be used during conditional forecasting, i.e. the measurement
restrictions will be appended to the solution after estimation is done.

See [nb_var.priorTemplate](#) for more on the supported priors.

Input:

- obj : An object of class nb_var
- restrictions : A struct array with fields
 - > 'restricted' : A one line char with the variable to restrict. It must be a dependent variable or block exogenous variable.
 - > 'parameters' : A cellstr with the names of the variables storing the parameters of the restriction, or a double array. Must have same length as 'variables'.
 - > 'variables' : A cellstr with the names of the variables included in the restriction.
 - > 'frequency' : Set to the frequency of the observables. This is only important for the mixed frequency VAR model. Give [], if the restriction is on the same frequency as the data. Either 1 (yearly), 4 (quarterly) or 12 (monthly).
 - > 'mapping' : Sets the mapping to use for this restricted variable. See the method [nb_mfvar.setMapping](#) for more on the

mappings to choose from.
> 'R_scale' : Inverse prior scale of the variance
of the measurement error of this
restrictions.

The variance of the measurement error
is constructed by dividing the
variance of each 'restricted' variable
by this scaling parameter.

Output:

- obj : An object of class nb_var where the measurement equation restrictions are added.

See also:

[nb_favar.template](#), [nb_bVarEstimator.applyMeasurementEqRestriction](#)
[nb_favar.priorTemplate](#), [nb_mfvar.setMapping](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► **setPrior** ↑

obj = setPrior(obj,prior)

Description:

Set priors of a vector of nb_var objects. The prior input must either be a struct or nb_struct with same size as obj or have size 1.

The provided struct will be added to the property options as the field prior.

See [nb_var.priorTemplate](#) for the format of the struct.

Caution : The estim_method field of the option property will automatically be set to 'bvar'.

Caution : Not yet supported for the subclass nb_favar!

Input:

- obj : A vector of nb_var objects
- prior : A struct or nb_struct with either matching numel of obj or size 1. If size is 1 all models gets the same prior settings.

Output:

- obj : A vector of nb_var objects with the priors set.

See also:

[nb_favar.priorTemplate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► **set_identification** ↑

```
obj = set_identification(obj,type,varargin)
```

Description:

Identify a VAR model. Either using cholesky restrictions or combinations of sign and zero restrictions (short, mid and long term).

The method solve must be called after adding the identifying restrictions

See Andrew Binning (2013), "Underidentified SVAR models: A framework for combining short and long-run restrictions with sign-restrictions". This code is an adaption of his code to the NBToolbox, except that also magnitude restriction is possible using this code.

Input:

- obj : A vector of nb_var objects, or subclasses of this class.
- type : Either 'cholesky' or 'combination'
- varargin (Optional inputs) :
 - > 'cholesky' :
 - 'ordering' : A cellstr with the ordering of the identification. Default is to use the ordering of the dependent variables of the model. The ordering is so that the first variable is the variable that is only influenced by one shock in period 1, the second variable is the variable that is influenced by two shock in period 1, and so on.
 - Caution : All variables of the VAR must be included in this option.
 - > 'combination' :
 - 'maxDraws' : The number of maximal rotations when looking for a identification satifying the sign restrictions. Can be set to inf. Default is 10000.
 - 'draws' : The number of wanted draws of the matrix of the map from structural shocks to dependent variables (C). Default is one.

Caution : When it comes to producing IRFs with sign restrictions you have two options. The first is to set 'draws' to a large number, say 1000, and then produce irf for each of those draws. The second approach is to draw parameters using bootstrap, MC methods or from the posterior, and then to make one draw of the C for each draw of the paramters.

```

- 'restrictions' : A nRestriction x 4 cell;
  {Dep,Shock,period,type,value;...}

  > Dep      : The dependent variable to add the restriction to. As a string.

  > Shock    : The name of the identified structural shock. As a string.

  > period   : The period of the restriction, as a double. For on impact set 0 and for cumulative restriction set it to inf.

  Use s:e to add a restriction on the cumulative contribution of a shock to a variable starting at s and ending at e. E.g. 0:10.

  > type     : Either 0 for zero restriction, '+/' '-' for sign restrictions or '>'/'<' for magnitude restrictions.

  Or 'none' : If you want to add a structural shock with no restriction, as you already have exactly identified N-1 shocks.

  > value    : A 1x1 double with the value of the magnitude restriction.
  
```

Output:

- obj : Identified nb_var objects. See the property field identification of the property solution.

Examples:

See ...\\Econometrics\\test\\test_nb_var

Written by Kenneth Sæterhagen Paulsen
Subfunctions are written by Andrew Binning 2013

Inherited from superclass NB_VAR

► shock_decomposition ↑

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';  
'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more

this input. An extra option is:

```
> 'identDraws' : Uses the draws of the matrix with  
      the map from structural shocks to dependent variables.  
See nb_var.set_identification. Of course this option  
only makes sense for VARs identified with sign  
restrictions.
```

- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.

- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.

- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.

- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.

- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.

- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.

- 'model2' : A struct with the solution of the second model to use for decomposition.

- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

See also:

`nb_favar.parameterDraws, nb_shockDecomp`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **simulate** ↑

`out = simulate(obj,nSteps,varargin)`

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- `obj` : A vector of `nb_model_generic` objects.
- `nSteps` : Number of simulation steps. As a `1x1 double`. Default is 100.

Optional inputs:

- `'burn'` : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- `'bounds'` : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - `'shock'` : Name of the shock to match the restriction on the bounds of the given variable.
 - `'lower'` : The lower bound of the selected variable. Either a `1x1 double` value or a function handle to a probability distribution to draw from.
 - `'upper'` : The upper bound of the selected variable. Either a `1x1 double` value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps double` matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a `1x1 double` or a `nSteps x 1 double`.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
- 'output' :
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.
- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty

the simulation will switch between regimes. Only an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a specific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:
 - > double : A 1 x nVar double.
 - > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsg models.
 - > 'steadyState' : Start from the steady state. For now only an option for nb_dsg models. If you are dealing with a MS-model you can indicate the state by 'steadyState(state)'. E.g. to start in state 1 give; 'steadyState(1)'. Default for nb_dsg models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char:
 - > double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
 - > 'ergodic' : Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consists of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the

'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i},'y','x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i},'x','y'). (This example only works if the output is of class nb_cs)

[nb_favar.graphCorrelation](#), [nb_favar.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_favar object(s).

Input:

- obj : A vector of nb_favar objects.

Output:

- obj : A vector of nb_favar objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_favar.solveNormal(results,opt,ident)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_favar.solveRecursive(results,opt,ident)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **stateSpace** ↑

```
[x0,P0,d,H,R,T,c,A,B,Q,G,obs,failed] = nb_var.stateSpace(par,nDep,...  
nLags,nExo,restr,restrVal,stabilityTest)
```

Description:

Returns a state-space representation of an VARX(nLags) model.

Observation equation:

y = d + Hx + Tz + v

State equation:

x = c + Ax_1 + Gz + Bu

Input:

- par : The parameter vector of the VARX model.
 - Order:
 - constant
 - exogenous
 - lagged endogenous
 - residual std
- nDep : The number of dependent variables of the model.
- nLags : the number of lags of the VAR.
- constant : Include constant or not. true or false.
- nExo : Number of exogenous variables included in the model.
- restr : A nDep x nDep*nLags logical matrix. true for the non-restricted parameters.
- restrVal : Values of the restricted parameters.
- stabilityTest : Check stability of system. Sets failed to true if model is not stationary. Default is false.

Output:

- x0 : Initial state vector.
- P0 : Initial variance.
- See equation above
- obs : Index of observables in the state vector.
- failed : See stabilityTest input.

Examples:**See also:**

[nb_kalmanlikelihood](#), [nb_kalmanlikelihood_missing](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► struct ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_favar.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

```
options = nb_favar.template()
options = nb_favar.template(num)
```

Description:

Construct a struct which can be provided to the nb_favar class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
- > variable : The variable(s) to test,
as a string or cell array of strings.
- > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
- > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► testParameters ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or
posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as

```

variables. See model.parameters.name.

- method      : A string with the method to use. For bootstrap method see
                nb_bootstrap. For bayesian models 'posterior' is the only
                option. Default is 'bootstrap' for classical models, while
                'posterior' is the default for bayesian models.

- draws       : Number of draws from the parameter distribution. Default
                is 1000.

- alpha       : Confidence level. Default is 0.05.

- type        : Type of test:
                > '=' : Two sided test. expression == 0 (default)
                        For two-sided tests it is assumed that the
                        distribution is symmetric! Use
                        confidenc/probabillty intervals instead.
                > '>' : One sided test. expression > 0
                > '<' : One sided test. expression < 0

```

Output:

```

- pval        : > 'classical' : P-value of test.
                > 'bayesian'   : Probabilty of test.

                A 1x1 double.

- ci          : A 1 x 2 double with the lower and upper bound of the
                confidence/probabillty interval of the tested expression.

- dist        : A nb_distribution object storing the distribution of the
                tested expression.

```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► **theoreticalMoments** ↑

```
[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation,
autocovariance/autocorrelation.

Caution : For recursivly estimated model only the full sample estimation
results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
getVariable(varargout{i}, 'y', 'x'),
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

[nb_favar.graphCorrelation](#), [nb_favar.parameterDraws](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► uncertaintyDecomposition ↑

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of

interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).

- > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_favar.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_favar.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **update** ↑

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type : > '' : Only update data. Default
> 'estimate' : Update data and estimate.
> 'solve' : Update data, estimate and solve
> 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► variance_decomposition ↑

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with

the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.

- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.
- Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomposition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomposition for each model. For each percentiles the output is as decomp.

- `plotter` : A $1 \times nModel$ vector of `nb_graph_cs` objects. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
- `plotterBands`: A $1 \times nModel$ struct. Each field is a $1 \times nVars$ vector of `nb_graph_cs` objects. Use the `graphSubPlots` method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

■ `nb_fm`

Go to: [Properties](#) | [Methods](#)

A class for estimation single equation factor model.

```
y_t = beta*F_t + beta0*X_t + e_t
```

Superclasses:

`nb_factor_model_generic`, `nb_model_generic`

Constructor:

```
obj = nb_fm(varargin)
```

Optional input:

- See the `set` method for more on the inputs.
(`nb_model_estimate.set`)

Output:

- `obj` : An `nb_fm` object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- | | | | |
|-------------------------------|-----------------------------------|----------------------------|-----------------------------|
| • <code>addAutoName</code> | • <code>addAutoNameIfLocal</code> | • <code>addID</code> | • <code>addIDIfLocal</code> |
| • <code>dependent</code> | • <code>endogenous</code> | • <code>estOptions</code> | • <code>exogenous</code> |
| • <code>forecastOutput</code> | • <code>name</code> | • <code>observables</code> | • <code>options</code> |
| • <code>parameters</code> | • <code>reporting</code> | • <code>residuals</code> | • <code>results</code> |
| • <code>solution</code> | • <code>transformations</code> | • <code>userData</code> | |

- **addAutoName** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addAutoNameIfLocal** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgc models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **observables** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) of the model observation equation, the tex_name holds the names in the tex format. The number field holds a double with the number of variables of the model observation equation. To set it use the set function. E.g. obj = set(obj,'observables',{'Var1','Var2'}); or use the <className>.template() method.

If the model class also supports mixed frequency data, it has two additional fields; frequency and mapping. These fields stores the selected frequency and mapping for each element.

Inherited from superclass NB_FACTOR_MODEL_GENERIC

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this property to be up to date!

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.

- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.
As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type
