► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters** ↑

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.

- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!

- 'instrument' : A one line char with the name of the instrument. Must be provided!

- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!

- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.

- 'perc' : Error band percentiles. As a 1 x nPerc double.
E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will
be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the
double method on this output to convert it to a double
matrix.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws
(bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see
[nb_bootstrap](#). For bayesian models 'posterior' is the only
option. Default is 'bootstrap' for classical models, while
'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is
1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property
is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterioriors** ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot. Default is 10.
- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
- plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.

Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
                    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [convert ↑](#)

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► [convertEach ↑](#)

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_MODELDATA`

► `createVariables` ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM `nb_modelData` object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.

> third column : Any expression that can be interpreted by the `nb_ts.createShift` method.

> fourth column : Comments

- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name,    input,    shift,    description
  'VAR1_G',    'pcn(VAR1)', 'avg',    'VAR1 growth'
  'VAR2_G',    'pcn(VAR2)', 'avg',    'VAR2 growth'
  'VAR3_G',    'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

[nb_model_generic.transformations](#), [nb_model_generic.reporting](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► dieboldMarianoTest ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_fm.uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **doForecastPerc2Dist ↑**

obj = doForecastPerc2Dist(obj, draws)

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_fm.forecast](#), [nb_fm.forecastPerc2Dist](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

`nb_fm.forecast, nb_distribution.perc2ParamDist`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity** ↑

`obj = doSimulateFromDensity(obj, draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `obj` : A `nb_model_forecast` object.
- `draws` : Number of draws to use for simulation.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_model_generic.forecast, nb_fm.simulateFromDensity`

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass `NB_MODEL_FORECAST`

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_generic` object. The `options.data` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

```

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables.
            'dependent' will return the moment of the dependent
            variables. 'dependent' is default.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or
               not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to
             true.

- 'type' : Either 'covariance' or 'correlation'. Default is
            'correlation'.

- 'startDate' : The start date of the calculations. Default is the start
                date of the options.data property. Only for time-series!
                Must be a string or a nb_date object.

- 'endDate' : The end date of the calculations. Default is the end
               date of the options.data property. Only for time-series!
               Must be a string or a nb_date object.

- 'demean' : true (demean data during estimation of the
              autocovariance matrix), false (do not). Default is true.

```

Output:

```

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.

- varargout{2} : The contemporaneous covariances/correlations, as a nVar
                x nVar nb_cs object or double. The variance is along
                the diagonal. (Will be symmetric)

- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar
                x nVar nb_cs object or double. Along the diagonal is the
                auto-covariance/correlation with the variable itself. In
                the upper triangular part you can find cov(x,y(-i)),
                where x is the variable along the first dimension. In
                the lower triangular part you can find cov(x(-i),y),
                where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find
      cov(x,y(-i)) you can use
      getVariable(varargin{i}, 'y', 'x'),
      while to get cov(x(-i),y) (== cov(x,y(+i))) you
      can use getVariable(varargin{i}, 'x', 'y'). (This
      example only works if the output is of class nb_cs)

```

See also:

[nb_fm.graphCorrelation](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj          = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default

is to open max number of cores available. Only an option if 'parallel' is given.

- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Inherited from superclass NB_MODEL_GENERIC

► **explained** ↑

```
[expl,plotter] = explained(obj)
```

Description:

Get how much of the variation in the data the factors explain.

Caution: Remember that for dynamic factor models the factors are not orthogonal.

Input:

- obj : A scalar nb_factor_model_generic object.

Output:

- expl : A nb_cs object with size nFactors x 1.
- plotter : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to plot it on the screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **forecast** ↑

```
obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for forward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
 - 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
 - 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
 - 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error
- Only for density forecast:
- 'logScore' : Log score
- Can also be a cellstr with the above listed evaluation types.
- Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.
- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
 - 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density

forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.

- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density forecast.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'bins' : The length of the bins og the domain of the density. Either;
 - > [] : The domain will be found. See nb_getDensityPoints (default is that 1000 observations of the density is stored).
 - > integer : The min and max is found but the length of the bins is given by the provided integer.
 - > cell : Must be on the format:
`{'Var1',lowerLimit1,upperLimit1,binsL1;
 'Var2',lowerLimit2,upperLimit2,binsL2;
 ...}`
 - lowerLimit1 : An integer, can be nan, i.e. will be found.
 - upperLimit1 : An integer, can be nan, i.e. will be found.
 - binsL1 : An integer with the length of the bins. Can be nan. I.e. bins length will be adjusted to create a domain of 1000 elements.

Caution : The variables not included will be given

the default domain. No warning will be given if a variable is provided in the cell but not forecast by the model. (This because different models can forecast different variables)

Caution : The `combineForecast` method of the `nb_model_group` class is much faster if the lower limit, upper limit! Or else it must simulate new draws and do kernel density estimation for each model again with the shared domain of all models densities.

- `'startDate'`
 - : The start date of forecast. Must be a string or an object of class `nb_date`. If empty the `estim_end_date + 1` will be used.
 - Caution:** If '`fcstEval`' is not empty this will set the start date of the recursive forecast. Default is to start from the first possible date.
- `'endDate'`
 - : The end date of forecast. Must be a string or an object of class `nb_date`. If empty the `estim_end_date + 1` will be used.
 - Caution:** If '`fcstEval`' is empty this input will have nothing to say.
- `'saveToFile'`
 - : Logical. Save densities and domains to files. One file for each model. Default is `false` (do not).
- `'observables'`
 - : A `cellstr` with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- `'condDB'`
 - : One of the following:
 - > A `nb_ts` object with size `nSteps x nCondVar` with the information to condition on.
If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A `nb_data` object with size `nSteps x nCondVar x nPeriods` with the information to condition on. The `dataNames` property must be set to the start dates of the recursive conditional information. `nPeriods` will be the number of recursive periods.
 - > A `nb_ts` object with size `nSteps x nCondVar x 3` with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given

as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)

> A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is choosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual

to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.

> StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.

Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.

If not provided. Model stds are used.

> Horizon : Anticipated horizon of the shocks/residual. 1 is default.

> Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.

- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned

included the lag variables. Also including exogenous and shocks.

> 'all' : All variables are returned (but not the lags). Including exogenous and shocks.

- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.

> double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.

> 'mean' : Start from the mean of the data observations. Default.

> 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.

> 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)

- 'startingProb' : Either a double or a char:

> [] : If the model is filtered the starting value is calculated on filtered transition probabilities. Otherwise the ergodic mean is used.

> double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.

> 'ergodic' : Start from the ergodic transition probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

- 'states' : Either an integer with the regime to forecast/simulate in, or an object of class nb_ts

with the regimes to condition on. The name of the variable must be 'states'.

Caution: For break-point models this is decided by the dates of the breaks, and cannot be set by this option!

- 'compareToRev' : Which revision to compare to. Default is final revision, i.e. []. Give 5 to get fifth revision. must be an integer. Keep in mind that this number should be larger than the nSteps input.
- 'compareTo' : Sometime you want to evaluate the forecast of one variable against another variable which is not part of the model. E.g. if you use the first release of a variable and want to compare it against the final release. To do this you can give a cellstr with size n x 2, where n is the number of variables to change the the actual observations to test against. {'VAR_1','VAR_FINAL',...}.
- 'estimateDensities' : true or false. true if you want to do a kernel density estimation of the density forecast.
- 'exoProj' : Tolerate missing exogenous variables by projecting them by a fitted model. Only when the 'condDB' input is empty!
 - Options are:
 - '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.
 - 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.
- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the

method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when exoProj is set to 'AR'.

- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matix. For the order of the

variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs' : This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.
- 'seed' : Set simulation seed. Default is 2.0719e+05.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist ↑**

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_fm.forecast](#)

Inherited from superclass NB_MODEL_FORECAST

► forecastPerc2ParamDist ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_fm.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditinal information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments** ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- `obj` : An object of class nb_model_generic.
- `dsgeVar` : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- `'maxIter'` : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- `'tol'` : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- `GammaYY` : A $N \times N$ double with the nonstandardized sample moments of the left-hand variables of the VAR.
- `GammaXX` : A $(C + N*L) \times (C + N*L)$ double with the nonstandardized sample moments of the right-hand variables of the VAR.
- `GammaXY` : A $(C + N*L) \times N$ double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Inherited from superclass NB_MODEL_GENERIC

► **getDependent** ↑

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

dependentNames = getDependentNames(obj)

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)

Written by Kenneth SÃ¶terhagen Paulsen
```

► **getEstimationStartDate ↑**

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getFactors ↑**

```
factors = getFactors(obj)
```

Description:

Get factors from a estimated nb_factor_model_generic object

Input:

- obj : An object of class nb_factor_model_generic

Output:

- factors : A nb_ts object with the estimated factors of the model stored.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **getFiltered ↑**

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_fm.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast ↑**

```
fcstData = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0, -1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.
```

For real-time forecast the vintage at the time is

returned as the historical data, when includeHist is true.

> 'horizon' : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.

If includeHist is true the actual data is added as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!

Caution : If the horizon input is set you will set nHor to one, and the fcstPercData will be non-empty, if density forecast has been produced.

- includeHist : Give true (1) to include history in the output. Only an options for the 'date' and 'horizon' outputType. Default is false (0).

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with size nRec x nVars. While the fcstPercData output will be a nb_ts object with size nRec x nVars x nSim. You can set the horizon to return by the optional input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_fm.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables ↑**

vars = getForecastVariables(obj)

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► getHistory ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getLHSVars ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj,varsIn)
```

Description:

Get all left hand side variables of the model.
For factor models the observable (+ observableFast) are added as well.
The list will be sorted.
Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsg object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getObservables ↑

```
observables = getObservables(obj)
```

Description:

Get observables from a estimated nb_factor_model_generic object

Input:

- obj : An object of class nb_factor_model_generic

Output:

- observables : A nb_ts object with observables of the factor model stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► getOriginalVariables ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► getPIT ↑

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option

is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)

- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

: Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.

: Give 'double' to return the value as a numerical array.

: Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

```
- obj : An object of class nb_model_generic.
```

Optitonal input:

```
- 'draws' : The number of draws to sample from the posterior to base  
the kernel estimation on, if empty all draws are used for  
estimation.
```

Output:

```
- distr : A 1 x numCoeff nb_distribution object.
```

```
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

```
- obj : An object of class nb_model_generic
```

Output:

```
- residual : Either a nb_ts or a nb_cs object with predicted variable(s)  
stored.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_subplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);
plotter.graphSubPlots();
```

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveScore ↑**

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

residual = getResidual(obj)

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph** ↑

plotter = getResidualGraph(obj)

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames ↑**

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,... 
                  rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.

- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution** ↑

```
value = getSolution(obj,type)
```

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_fm.simulatedMoments](#), [nb_fm.theoreticalMoments](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **help** ↑

```
helpText = nb_fm.help  
helpText = nb_fm.help(option)  
helpText = nb_fm.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize** ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **interpretForecast** ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsgc.
- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.

- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_fm.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf ↑**

[irfs, irfsBands, plotter] = irf(obj, varargin)

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgen objects.
- 'compare' : Give true if you have a scalar nb_dsgen model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the

nb_graphSubPlotGUI class to produce the graphs in this case.

- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.

- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.
I.e. {'var1',100,...} or {{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This options sets the error band percentiles of the graph, when the 'perc' input is empty. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

> 'cumulative product'	: cumprod(1 + X,1)
------------------------	--------------------

```

> 'cumulative sum' : cumsum(X,1)
> 'cumulative product (log)' : log(cumprod(1 + X,1))
> 'cumulative sum (exponential)' : exp(cumsum(X,1))
> 'cumulative product (%)' : cumprod(1 + X/100,1)
> 'cumulative sum (%)' : cumsum(X/100,1)
> 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
> 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
> '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
  Default is ''. See help on the method input of the
  nb_model_generic.parameterDraws method for more
  this input. An extra option is:

  > 'identDraws' : Uses the draws of the matrix with
    the map from structural shocks to dependent
    variables. See nb_var.set_identification. Of
    course this option only makes sense for VARs
    identified with sign restrictions.

- 'normalize' : A 1 x 3 cell. First element must be the variable
  name as a string. The second element must be the
  value to normalize to, as an integer. While the
  third element is the period to be normalized, if
  set to inf, it will normalize the max impact
  period.

  E.g. {'Var',1,2}, {'Var',1,inf}

  Caution: 2 means observation 2 of the IRF, and as
  the IRF start at period 0, this means that
  observation 2 is period 1.

- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of
  irfs, while 'mean' normalize the mean and scale
  percentiles/other draws accordingly. Default is
  'draws'.

  Caution: Setting this to 'mean' will not work for
  reported variables that is not measured
  as % deviation from steady-state/mean.

- 'newReplic' : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the replic input.

- 'parallel' : Give true if you want to do the irfs in parallel.
  This option will parallelize over models. Default
  is false.

- 'parallelL' : Give true if you want to do the irfs in parallel.

```

This option will parallelize over parameter simulations. Only an option if `numel(obj) == 1`. Default is false.

- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for `nb_dsg` objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for `nb_dsg` objects.
- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method `nb_var.set_identification` for more.

- 'settings' : Extra graphs settings given to `nb_plots` function. Must be a cell.
- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.

For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.

```

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):

    > scalar      : Select the the regime to take the
                     initial transition probabilities
                     from.

    > double      : A draws x nRegime or a 1 x
                     nRegime double. draws refer to
                     the number set by the 'draws'
                     input.

    > 'ergodic'   : Start from the ergodic transition
                     probabilities. Default for 'irf'.

    > 'random'    : Randomize the starting values
                     using the simulated starting
                     points. Default for 'girf'.

- 'startingValues' : Either a double or a char:

    > double      : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing
                      with a MS-model or a break-point model you can
                      indicate the regime by 'steadystate(regime)'. E.g.
                      to start in regime 1 give; 'steadystate(1)'. For
                      MS - models the default is the ergodic mean
                      (default as long as 'girf' is not selected as
                      'type'), while for break-point models it is to
                      start from the first regime.

    > 'zero'       : Start from zero on all variables.

    > 'random'    : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'       : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'         : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generlized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'  : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

- 'variables'    : The variables to create impulse responses of.
                     Default is the dependent variables defined by the

```

first model.

Caution: The variables reported by the reporting property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.('E_X_NW'). Which will then be a nb_ts object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.

> 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

> 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast** ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency ↑**

ret = isMixedFrequency(obj)

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB ↑**

ret = isNB(obj)

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

ret = isStateSpaceModel(obj)

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

ret = issolved(obj)

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

[bands,plotter] = jointPredictionBands(obj,varargin)

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

```

- 'vars' : A cellstr with the variables to return
the calculated joint prediction bands of.

- 'perc' : Error band percentiles. As a 1 x numErrorBand
double. E.g. [0.3,0.5,0.7,0.9] (default) or
0.9. Cannot be empty!

- 'date' : If recursive forecast has been produced,
you can use this option to choose which of
the recursive forecast to construct the
joint prediction bands of. Default is empty,
i.e. use the last forecast.

- 'method' : Choose between:

    > 'kolsrud' : See Akram et al (2016), Joint
                   prediction bands for
                   macroeconomic risk management

    > 'copula' : Using a copula likelihood approach.

    > 'mostlik' : Group the paths based on how
                   likely they are.

- 'nSteps' : Number of forecasting steps to use when constructing the
error bands. If empty (default) all forecasting steps stored
in the object is used.

```

Output:

```

- JPB : An nb_ts object storing the joint prediction bands.
The percentiles are stored as datasets. See the
dataNames property for which page represent which
percentile.

The data of the nb_ts object has size nSteps x nVars
x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method
to produce the graphs.

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_fm.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

f = mcfRestriction(obj,type,restriction)

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use @(x)f1(x)&&f2(x), where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.

- type : The type of restriction. Either 'irf', 'corr' or 'cov'.

- restriction : Depends on the type input:

> 'irf' : A N x 4 cell, where the elements of each row are:
1. Name of the shock. 'E_X'
2. Name of the variable. 'X'
3. Horizon. E.g. 1 or 1:3.
4. Restriction. E.g. @(x)gt(x,0),
@(x)gt(x,0)||lt(x,1), i.e. a function_handle that takes a scalar double as input and a scalar logical as output.

> 'rirf' : A N x 7 cell, where the elements of each row are:
1. Name of the shock 1. 'E_X'
2. Name of the variable 1. 'X'
3. Horizon of variable 1. E.g. 1.
4. Name of the shock 2. 'E_Y'
5. Name of the variable 2. 'Y'
6. Horizon of variable 2. E.g. 2.

7. Restriction. E.g. $\@(\mathbf{x}, \mathbf{y})\gt(\mathbf{x}, \mathbf{y})$,
 $\@(\mathbf{x}, \mathbf{y})\gt(\mathbf{x}-\mathbf{y}, 0) \mid \lt(\mathbf{x}-\mathbf{y}, 1)$, i.e. a
function_handle that takes a two scalar
double as inputs and a scalar logical
as output.

> 'corr' : A N x 4 cell, where the elements of each
row are:
1. Name of the first variable.
2. Name of the second variable.
3. Number of periods to lag the 2. variable.
4. Same as 4 for 'irf'.

E.g. {'Var1', 'Var1', 1, @(\mathbf{x})\gt(\mathbf{x}, 0.1)}, to
test a restriction on the autocorrelation
at lag for variable 'Var1'.

E.g. {'Var1', 'Var2', 0, @(\mathbf{x})\lt(\mathbf{x}, 0.1)}, to
test a restriction on the contemporaneous
correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. {'Var1', 'Var1', 0, @(\mathbf{x})\lt(\mathbf{x}, 0.1)}, to
test a restriction on the contemporaneous
variance.

> 'ss' : A N x 2 cell, where the elements of each
row are:
1. The expression using any of the
endogenous variables of the model.
2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

[nb_fm.monteCarloFiltering](#), [nb_fm.irf](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mincerZarnowitzTest ↑**

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_fm.uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj, varargin)
[paramD, values, solvingFailed, objAcc] = monteCarloFiltering(obj, varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterDraws ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated

with classical methods.

```

> 'wildBlockBootstrap' : Create artificial data by wild
  overlapping random block length
  bootstrap., and then "draw" parameters
  based on estimation on these data.
  Only an option for models estimated
  with classical methods.

> 'copulaBootstrap'      : Uses a copula approach to draw residual
  that are autocorrelated, Does not handle
  heteroscedasticity. Only an option for
  models estimated with classical methods.

> 'posterior'           : Posterior draws. Only for models
  estimated with bayesian methods.
  Default for models estimated with
  bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
  on this option.

- stable : Give true if you want to discard the parameter draws
  that give rise to an unstable model. Default is false.

```

Optional input:

```

- 'parallel'      : Run in parallel. true or false.

- 'cores'         : Number of cores to use. Default is to use all cores
  available.

- 'newDraws'       : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the draws input.

  Caution: When setting 'parallel' to true on MATLAB
  version later than R2017B this number will
  be the number of new draws, and not the
  factor!!! E.g. set it to 100. If it is given
  as a number less than 1, it will by default
  be set to 100.

- 'initialDraws'  : When drawing parameters this factor decides how many
  many draws that are produced before solving the model.
  Default is 1. I.e. it is equal to draws input. For
  VAR models with underidentification it may be a good
  idea to set this to a value > 1 as you may drop a
  lot of parameters when identification fails. Default
  is 1.

```

Output:

```

- out          : The output depend on the input output:

> 'param'     : Default. A struct with the following fields:

  beta   : A nPar x nEq x draws double with the

```

estimated parameters.

sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:

lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.

R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.

factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

ci = parameterIntervals(obj,alpha)

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

```
- ci      : A nPar x 3 cell matrix.  
Written by Kenneth SÃ¶terhagen Paulsen  
Inherited from superclass NB_MODEL_GENERIC
```

► **plotFactors** ↑

```
plotter = plotFactors(obj,errBands)
```

Description:

Get factors from a estimated nb_factor_model_generic object

Input:

```
- obj      : An object of class nb_factor_model_generic  
- errBands : Give true to add one std bands around the factor estimates.  
             Default is false.
```

Output:

```
- plotter : A nb_graph_ts object to use to plot the factors. Use the  
           graphSubPlots method or the nb_graphSubPlotGUI.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **plotForecast** ↑

```
plotter          = plotForecast(obj)  
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate,...  
                                         increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model
in the vector of nb_model_forecast objects

Input:

```
- obj  : A vector of nb_model_forecast objects  
- type : Type of plot, as a string;  
         > 'default'   : Plot the forcast for the last period of  
                         estimation and ahead. Possibly with density for
```

the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.

> 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.

- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF ↑**

plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...
upperBound,method)

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest** ↑

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,nameValue)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Inherited from superclass NB_MODEL_GENERIC

► **plotPosterioriors ↑**

```
plotter = plotPosterioriors(obj)
plotter = plotPosterioriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.
- Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

printed = printCov(obj)

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results** ↑

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_fm.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations** ↑

obj = removeObservations(obj,numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► set ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition ↑**

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects

- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.

```

- 'endDate'      : End date of the decomposition. As a string. If
                  different models has different frequency this date will
                  be converted.

- 'perc'         : Error band percentiles. As a 1 x numErrorBand double.
                  E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error
                  bands.

- 'method'       : The selected method to create error bands.
                  Default is ''. See help on the method input of the
                  nb_model_generic.parameterDraws method for more
                  this input. An extra option is:

> 'identDraws' : Uses the draws of the matrix with
                  the map from structural shocks to dependent variables.
                  See nb_var.set_identification. Of course this option
                  only makes sense for VARs identified with sign
                  restrictions.

- 'replic'        : The number of simulation for posterior, bootstrap and
                  MC methods. Default is 1. Only used when 'perc' is
                  provided.

Caution: Will not have anything to say for the method
          'identDraws'. See the option 'draws' of the
          method nb_var.set_identification for more.

- 'stabilityTest' : Give true if you want to discard the draws
                  that give rise to an unstable model. Default
                  is false.

- 'parallel'      : Give true if you want to do the shock decomp in
                  parallel. Default is false.

- 'fcstDB'        : An object of class nb_ts with the forecast to
                  decompose. must contain all model variables and
                  shocks/residuals, and must start the period after
                  the estimation/filtering end date or at the
                  estimation/filtering start date. See
                  the nb_model_generic.getForecast method.

- 'type'          : Choose 'updated' or 'smoothed'. 'smoothed' is
                  default.

- 'anticipationStartDate' : Start date of anticipating shocks. As a
                  string. If different models has different
                  frequency this date will be converted.

- 'model2'         : A struct with the solution of the second
                  model to use for decomposition.

- 'secondModelStartDate' : Start date of second model. As a string.
                  If different models has different frequency
                  this date will be converted.

```

Output:

- decomp : A structure of nb_ts objects with the shock

decomposition for each model.

- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

[nb_fm.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulate ↑**

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.

```

> 'all'      : All variables are returned (but not
               the lags). Also including exogenous
               and shocks.

- 'parallel'   : Give true if you want to do the simulations in
                  parallel. I.e. spread models to different threads.
                  Default is false.

- 'parameterDraws' : Number of draws of the parameters. When set to 1
                     it will discard parameter uncertainty. Default is 1.

- 'regime'      : Select the regime you want to simulate. If empty
                  the simulation will switch between regimes. Only
                  an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations.
                  This will have no effect if the states input is
                  providing the full path of regimes. Default is 1.

- 'seed'         : Set simulation seed. Default is 2.0719e+05.

- 'startDate'    : Give the start date of the simulation. If not
                  provided the output will be a nb_data object
                  without a spesific start date (default). If
                  provided the output will be an object of class
                  nb_ts.

Caution : If dealing with break-points or exogenous
           time-varying parameters this input must be
           provided.

- 'startingValues' : Either a double or a char:

    > double       : A 1 x nVar double.

    > 'mean'        : Start from the mean of the data
                      observations. Default for all
                      model except nb_dsgc models.

    > 'steadystate' : Start from the steady state. For
                      now only an option for nb_dsgc
                      models. If you are dealing with a
                      MS-model you can indicate the
                      state by 'steadystate(state)'.
                      E.g. to start in state 1 give;
                      'steadystate(1)'. Default for
                      nb_dsgc models.

    > 'zero'         : Start from zero on all variables
                      (Except for the deterministic
                      exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws
                    that give rise to an unstable model. Default
                    is false.

- 'startingProb'  : Either a double or a char:

```

> double	: A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
> 'ergodic'	: Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```

[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)

```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
 - 'nLags' : Number of lags to compute when 'stacked' is set to true.
 - 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
 - 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
 - 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
 - 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.
- Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
 - 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
 - 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is

true.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
getVariable(varargin{i}, 'y', 'x'),
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

Inherited from superclass NB_MODEL_GENERIC

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_fm object(s).

Input:

- obj : A vector of nb_fm objects.

Output:

- obj : A vector of nb_fm objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_fm.solveNormal(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_fm.solveRecursive(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_fm.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

```
options = nb_fm.template()
options = nb_fm.template(num)
```

Description:

Construct a struct which can be provided to the nb_fm class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► testParameters ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

```
- obj : A scalar solved nb_model_generic object.  
  
- expression : A MATLAB expression as a string. Use parameter names as  
variables. See model.parameters.name.  
  
- method : A string with the method to use. For bootstrap method see  
nb_bootstrap. For bayesian models 'posterior' is the only  
option. Default is 'bootstrap' for classical models, while  
'posterior' is the default for bayesian models.  
  
- draws : Number of draws from the parameter distribution. Default  
is 1000.  
  
- alpha : Confidence level. Default is 0.05.  
  
- type : Type of test:  
    > '=' : Two sided test. expression == 0 (default)  
            For two-sided tests it is assumed that the  
            distribution is symmetric! Use  
            confidence/probability intervals instead.  
    > '>' : One sided test. expression > 0  
    > '<' : One sided test. expression < 0
```

Output:

```
- pval : > 'classical' : P-value of test.  
        > 'bayesian' : Probability of test.  
  
        A 1x1 double.  
  
- ci : A 1 x 2 double with the lower and upper bound of the  
confidence/probability interval of the tested expression.  
  
- dist : A nb_distribution object storing the distribution of the  
tested expression.
```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c] = theoreticalMoments(obj,varargin)
[m,c,ac1] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the

parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
getVariable(varargout{i}, 'y', 'x'),
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.

- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.

```
> {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object  
storing the numerically calculated  
forecast error variances/skewnesses.  
  
- plotter : A nb_graph_ts object which the method graph can be used to  
produce graphs.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_fm.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_fm.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **update ↑**

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition ↑**

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.
Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double.

E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomposition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomposition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

[nb_fm.parameterDraws](#), [nb_varDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

■ nb_fmdyn

Go to: [Properties](#) | [Methods](#)

A class for estimation of dynamic factor models on the form:

$$\begin{aligned} X(t) &= B \cdot W(t) + L \cdot F(t) + \epsilon(t) & (1) \\ \epsilon(t) &= \alpha \cdot \epsilon(t-1) + e(t) & (2) \\ F(t) &= A \cdot F(t-1) + u(t) & (3) \end{aligned}$$

where

- > The data is assumed to have T observations. Some may be missing, and have different frequencies.
- > $X(t)$ is a vector of observed data with size $N \times 1$.
- > $W(t)$ are the exogenous variables of the model, here the constant term will be included. $W(t)$ has size $NE \times 1$.
- > B is a matrix with size $N \times NE$.
- > $F(t)$ is the unobserved factors with size $R \cdot (nLags-1) \times 1$ (see comment on the A matrix), i.e. R is the number of factors to be estimated.
- > L is the factor loadings with size $N \times R \cdot (nLags-1)$. Zero restrictions as in Banbura et al. (2010b) may be applied, and zeros will be added to be consistent with the comment for the matrix A . L may also be adjusted to allow for mixed frequencies, again following the procedure of Banbura et al. (2010b).
- > $e(t) \sim N(0, \Sigma)$ for a diagonal covariance matrix Σ .
- > α is a diagonal matrix of AR(1) parameters of the idiosyncartic component of each variable in X . Optional. If turned off, it is assumed that $\epsilon(t) \sim N(0, \Sigma)$.
- > $u(t) \sim N(0, Q)$, and is the residuals of the VAR model of the factors.
- > A is a matrix with size $R \cdot (nLags-1) \times R \cdot (nLags-1)$, where $nLags$ is the selected number of lags of the VAR of the factors, i.e.

```

F(t) = [f(t), f(t-1), ..., f(t-nLags)].
> Let beta be the full set of parameters to estimate, and zeta(t) the
full set of unobserved state variables the model can be put on the
form

```

$$X(t) = \mu + Z(\beta) * zeta(t) \quad (4)$$

$$zeta(t) = T(\beta) * zeta(t-1) + eta(t) \quad (5)$$

The model can either be estimated using a two step frequentistic algorithm, a bayesian gibbs sampling algorithm or the algorithm suggested by Koop and Korobilis (2014) extended by Schroder and Eraslan (2021) to handle mixed frequency.

1. Follows the two step procedure of Banbura et al. (2010a). First some initial values of the factors has to be estimated by principal components on a balanced datasets of X. Here we use a spline method to fill in the missing values. As this is only used to initialize the algorithm it is not of any more importance than the speed up of the convergence of the estimation algorithm. $\epsilon(t)$ is then estimated from using (1). From there parameters are then initialized with the ols estimator based on the initial values of the factors. The first step of ML algorithm is then to filter/smooth out the $zeta(t)$ given β , and then use the expected maximum likelihood estimator on β given the filtered values of $zeta(t)$. This is done until convergance of the log likelihood. This is the algorithm used when 'estim_method' option is set to 'dfmeml'.
2. In the bayesian setting we have a prior on β . The conditional posterior of $p(zeta|X, \beta)$ and $p(\beta|X, zeta)$ are then known for priors we offer. Here we drop (t) script to mean the full series. As we have the conditional posteriors we can draw from them using the Gibbs sampler as suggested by Carter and Kohn (1994). In practice we can draw from $p(zeta|X, \beta)$ using the kalman smoother given the last draw of β . When doing gibbs sampling you may need to use a burn in face and use thinning to prevent autocorrelated draws from the posterior. For more information on the prior spesification see nb_fmdyn.priorTemplate and nb_fmdyn.setPrior. Bayesian estimation is triggered by calling nb_fmdyn.setPrior, or else the algorithm under 1 is ran. This is the algorithm used when 'estim_method' option is set to 'bdfm'. (Not yet finished!)
3. Koop and Korobilis (2014) extended by Schroder and Eraslan (2021) to handle mixed frequency. See the nb_tvpmsvEstimator package. (Not part of the open source version yet!)

Caution: Some small alteration to the referenced algorithm may have been done in special cases.

Superclasses:

`nb_factor_model_generic, nb_model_generic`

Constructor:

`obj = nb_fmdyn(varargin)`

Optional input:

- See the `set` method for more on the inputs.
`(nb_model_estimate.set)`

Output:

- `obj` : An `nb_fmdyn` object.

See also:

`nb_model_generic, nb_model_estimate.set`
`nb_dfmemlEstimator.estimate, nb_bdfmEstimator.estimate`

Written by Kenneth Sæterhagen Paulsen

Properties:

- `addAutoName`
- `dependent`
- `factors`
- `options`
- `results`
- `addAutoNameIfLocal`
- `endogenous`
- `forecastOutput`
- `parameters`
- `solution`
- `addID`
- `estOptions`
- `name`
- `reporting`
- `transformations`
- `addIDIfLocal`
- `exogenous`
- `observables`

- `userData`

- **`addAutoName`** ↑

Add automatic name (first) to default name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **`addAutoNameIfLocal`** ↑

Add automatic name (first) to local name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **`addID`** ↑

Add identifier to default name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **`addIDIfLocal`** ↑

Add identifier to local name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **factors** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the factors, the tex_name holds the names in the tex format. The number field holds a double with the number of factors. Cannot be set. Model must be estimated

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **observables** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) of the model observation equation, the tex_name holds the names in the tex format. The number field holds a double with the number of variables of the model observation equation. To set it use the set function. E.g. obj = set(obj,'observables',{'Var1','Var2'}); or use the <className>.template() method.

If the model class also supports mixed frequency data, it has two additional fields; frequency and mapping. These fields stores the selected frequency and mapping for each element.

Inherited from superclass NB_FACTOR_MODEL_GENERIC

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.

- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.
As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters** ↑

obj = assignParameters(obj,varargin)

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

```
obj = assignPosteriorDraws(obj,varargin)
```

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames** ↑

```
obj = assignTexNames(obj, names, texNames)
```

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as `_t` is automatically appended to each variable! Use superscripts instead.

Input:

- `obj` : An object of class `nb_model_generic`.
- `names` : A `Nx1` cellstr with the names of the variables and/or parameters of the model.
- `texNames` : A `Nx1` cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- `obj` : A `nb_model_generic` object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its `tex_name` fields. (Also `observables` and `observablesFast` for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **calculate** ↑

```
calc = calculate(obj, varargin)
```

Description:

Do the calculation associated with the object.

Input:

- `obj` : An object array of class `nb_calculate_generic`.
- `'parallel'` : Use this string as one of the optional inputs to run the estimation in parallel.

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- calc : An cell array of class nb_ts, each element stores the calculation results of the corresponding model. An element is empty if the corresponding model is found not to be valid.

See also:

[nb_fmdyn.getCalculated](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsgen.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!
- 'instrument' : A one line char with the name of the instrument. Must be provided!
- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!
- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!
- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.
- 'perc' : Error band percentiles. As a 1 x nPerc double. E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the double method on this output to convert it to a double matrix.

See also:

[nb_fmdyn.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Å;terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

obj = calculateStandardError(obj,method,draws)

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see

`nb_bootstrap`. For bayesian models '`posterior`' is the only option. Default is '`bootstrap`' for classical models, while '`posterior`' is the default for bayesian models.

- `draws` : Number of draws from the parameter distribution. Default is 1000.
- `alpha` : Confidence level. Default is 0.05.

Output:

- `obj` : A scalar `nb_model_generic` object, where the `results` property is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

 - `stdBeta` : Standard deviation of coefficient of the main equation.
 - `tStatBeta` : T-statistic for the coefficient of the main equation.
 - `pValBeta` : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
 - `stdLambda` : Standard deviation of coefficient of the observation equation.
 - `tStatLambda` : T-statistic for the coefficient of the observation equation.
 - `pValLambda` : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- `ci` : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in `beta!` As a $(nCoeff * nEq) + 1 \times 3$ cell array.
- `dist` : Estimated distribution of the coefficients of the main equation. As a $(nCoeff * nEq) \times 1$ `nb_distribution` object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkModel ↑**

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosteriors ↑**

```
[DB,plotter,pAutocorr] = checkPosteriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot. Default is 10.
- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
- plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

`nb_graph_data, nb_graphSubPlotGUI, nb_model_sampling.checkUpdatedPriors`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkReporting** ↑

`obj = checkReporting(obj)`

Description:

Check reporting, and store historical observation of reported variables.

Input:

- `obj` : A NxM `nb_modelData` object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODELDATA`

► **conditionalTheoreticalMoments** ↑

`c = conditionalTheoreticalMoments(obj,varargin)`

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the `theoreticalMoments` method
when the 'stacked' input is set to true.

Caution : For recursivly estimated model only the full sample estimation
results is used.

Input:

- `obj` : An object of class `nb_model_generic`

Optional inputs;

- `'vars'` : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws. Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with

bayesian methods.

Caution : Posterior draws is
already made at the
estimation stage.

- 'nSteps' : Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB           = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...  
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous

restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
          allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.

- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **convert ↑**

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handled correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the

input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

```
> second column : Any expression that can be interpreted  
by the nb_ts.createVariable method.  
  
> third column : Any expression that can be interpreted  
by the nb_ts.createShift method.  
  
> fourth column : Comments  
  
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is  
important that this option is higher than the number of  
forecasting/irf steps, or else the output will be nan!
```

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name, input, shift, description  
'VAR1_G', 'pcn(VAR1)', 'avg', 'VAR1 growth'  
'VAR2_G', 'pcn(VAR2)', 'avg', 'VAR2 growth'  
'VAR3_G', 'pcn(VAR3)', 'avg', 'VAR3 growth'};  
  
model = model.createVariables(expressions)
```

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **detNumFactors ↑**

R = detNumFactors(obj,type)

Description:

Determine the number of factors to use in the factor model. These test are based on PCA on the observed data. If missing observations these are filled in for using nb_dfmmlEstimator.fillInForMissing.

Input:

- type : One of:
 - > 'scree' : Scree plot.
 - > 'expl' : Criteria using that the factors should explain X amount of the variation in the data.
 - > 'trapani' : Uses the test that is implemented in nb_trapaniNFactorTest.
 - > 'bn' : Implements the IC_p1 test of Bai and Ng (2002).
 - > 'horn' : Implements the test proposed by Horn (1965) and developed by Ledesma et al. (2007). Code is written by Lanya Tianhao Cai (2016). This test is only valid if the time series are standardized. See the option 'transformation' of the nb_fmdyn object to apply this.

Optional input:

- 'threshold' : The threshold for the given type of test. Have an impact on the following types
 - > 'expl' : Sets the X value. Default is 0.9.
 - > 'trapani' : Confidence level of test. Default is 0.05.

Output:**See also:**

[nb_trapaniNFactorTest](#)

Written by Kenneth Å!terhagen Paulsen

► dieboldMarianoTest ↑

[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band width selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **doForecastPerc2Dist** ↑

```
obj = doForecastPerc2Dist(obj,draws)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_fmdyn.forecast](#), [nb_fmdyn.forecastPerc2Dist](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist** ↑

```
[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.

- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!

- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity** ↑

obj = doSimulateFromDensity(obj, draws)

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_fmdyn.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_generic object. The options.data property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use

```
getVariable(varargin{i},'y','x'),  
while to get cov(x(-i),y) (== cov(x,y(+i))) you  
can use getVariable(varargin{i},'x','y'). (This  
example only works if the output is of class nb_cs)
```

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind     = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj        = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d,{'MSE'},0,1)
m = evalFcstAtDates(b,d,{'MSE','RMSE'},0,1)
```

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior** ↑

```
logPriorD = nb_model_generic.evaluatePrior(prior,par)
```

Description:

Evaluate the prior at a point in the parameter space.

Input:

```
- prior : See options.prior.  
- par : A nEst x 1 double with the value of the point of evaluation.
```

Output:

```
- logPriorD: The log prior density at the evaluated point.
```

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

► **explainFactors** ↑

```
[dec,plotter] = factorDecomposition(obj)
```

Description:

Decomposition of the factors into contributions from the observables.

Input:

```
- obj : A scalar nb_fmdyn object.
```

Output:

```
- explained : A nb_cs object with size nFactors x nObservables that stores the explained variance of each observable.  
- plotter : A 1 x nFactors nb_graph_cs object array. Use the graph method or the nb_graphMultiGUI class.
```

See also:

[nb_graph_cs](#), [nb_graphMultiGUI](#)

Written by Kenneth Sæterhagen Paulsen

► **explained** ↑

```
[expl,plotter] = explained(obj)
```

Description:

Get how much of the variation in the data the factors explain.

Caution: Remember that for dynamic factor models the factors are not orthogonal.

Input:

- obj : A scalar nb_factor_model_generic object.

Output:

- expl : A nb_cs object with size nFactors x 1.
- plotter : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to plot it on the screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **factorDecomposition ↑**

```
[dec,plotter] = factorDecomposition(obj)
```

Description:

Decomposition of the factors into contributions from the observables.

Input:

- obj : A scalar nb_fmdyn object.

Output:

- dec : A nb_ts object with size T x nObservables x nFactors that stores the decomposition.
- plotter : A nb_graph_ts object. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_graph_ts](#), [nb_graphPagesGUI](#)

Written by Kenneth Sæterhagen Paulsen

► **forecast ↑**

```

obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)

```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for foward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' : - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error
Only for density forecast:
 - 'logScore' : Log score
Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.
- 'estDensity' : The method to estimate the density. As a string. Either:

```

        - 'normal' : Normal density approximation.

        - 'kernel' : Kernel density estimation. Default.

- 'varOfInterest' : A char with the variable to produce the forecast of.
Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!

- 'parallel'      : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.

- 'cores'         : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.

- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.

- 'draws'          : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.

- 'regimeDraws'    : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.

- 'newDraws'        : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.

- 'perc'            : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density forecast.

- 'method'          : The selected method to create density forecast.
Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

- 'bins'             : The length of the bins og the domain of the density.
Either;

> []      : The domain will be found. See

```

nb_getDensityPoints (default is that 1000 observations of the density is stored).

> integer : The min and max is found but the length of the bins is given by the provided integer.

> cell : Must be on the format:

```

{'Var1',lowerLimit1,upperLimit1,binsL1;
 'Var2',lowerLimit2,upperLimit2,binsL2;
 ...}
  
```

- lowerLimit1 : An integer, can be nan, i.e. will be found.

- upperLimit1 : An integer, can be nan, i.e. will be found.

- binsL1 : An integer with the length of the bins. Can be nan. I.e. bins length will be adjusted to create a domain of 1000 elements.

Caution : The variables not included will be given the default domain. No warning will be given if a variable is provided in the cell but not forecast by the model. (This because different models can forecast different variables)

Caution : The combineForecast method of the nb_model_group class is much faster if the lower limit, upper limit! Or else it must simulate new draws and do kernel density estimation for each model again with the shared domain of all models densities.

- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is not empty this will set the start date of the recursive forecast. Default is to start from the first possible date.

- 'endDate' : The end date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is empty this input will have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).

- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be

produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.

Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.

If not provided. Model stds are used.

 - > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
 - > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!
- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only

supported for the nb_var and nb_pitvar classes.

- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.

- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.

- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.

> 'endo' : All the endogenous variables are returned.

> 'fullendo' : All the endogenous variables are returned included the lag variables.

> 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.

> 'all' : All variables are returned (but not the lags). Including exogenous and shocks.

- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.

> double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.

> 'mean' : Start from the mean of the data observations. Default.

> 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.

```

> 'zero'          : Start from zero on all variables
                    (Except for the deterministic
                     exogenous variables)

- 'startingProb' : Either a double or a char:

    > []           : If the model is filtered the
                     starting value is calculated
                     on filtered transition
                     probabilities. Otherwise the
                     ergodic mean is used.

    > double       : A nPeriods x nRegime or a 1 x
                     nRegime double. nPeriods refer to
                     the number of recursive periods to
                     forecast.

    > 'ergodic'    : Start from the ergodic transition
                     probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws
                     that give rise to an unstable model. Default
                     is false.

- 'states'        : Either an integer with the regime to
                     forecast/simulate in, or an object of class nb_ts
                     with the regimes to condition on. The name of the
                     variable must be 'states'.

Caution: For break-point models this is decided by
the dates of the breaks, and cannot be set
by this option!

- 'compareToRev'  : Which revision to compare to. Default is final
revision, i.e. []. Give 5 to get fifth revision.
must be an integer. Keep in mind that this number
should be larger than the nSteps input.

- 'compareTo'     : Sometime you want to evaluate the forecast of one
variable against another variable which is not
part of the model. E.g. if you use the first release
of a variable and want to compare it against the
final release. To do this you can give a cellstr
with size n x 2, where n is the number of variables
to change the the actual observations to test
against. {'VAR_1','VAR_FINAL',...}.

- 'estimateDensities' : true or false. true if you want to do a
kernel density estimation of the density
forecast.

- 'exoProj'        : Tolerate missing exogenous variables by projecting
them by a fitted model. Only when the 'condDB'
input is empty!

Options are:

- ''   : No projection are done. Error will be

```

given if some exogenous variables are not given any conditional information.
 Default.

- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.

- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficent 0.8, while 'exoVar2' with a constant term equal to

0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when `exoProj` is set to 'AR'.

- 'bounds'
: A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps` double matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a 1x1 double or a `nSteps x 1` double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs'
: This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.

- 'foundReplic'
: A struct with size `1 x parameterDraws`. Each element must be on the same format as `obj.solution`. I.e. each element must be the solution of the model given a set of drawn parameters. See the `parameterDraws` method of the `nb_model_generic` class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.

- 'seed'
: Set simulation seed. Default is `2.0719e+05`.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_fmdyn.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► [getActual](#) ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.

```
- solution : See the property solution of the nb_model_generic object.

- vars      : A cellstr with the names of the variables to get the actual
               data of.

- startFcst : The recursive forecasting periods. Either as a double
               with the indecies or a cellstr with the dates.

- nSteps    : Number of forecasting steps. If empty the sample will not
               be split.

- inputs     : A struct with some options passed to the
               nb_forecast.getActual function. Optional.

- nowcast    : Indicate how many periods there has been produced nowcast
               of.
```

Output:

```
- actual : A nSteps x nVars x nPeriods double with the actual data for
           each recursive forecast if nSteps is given, otherwise a nobs
           x nVars double.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getCalculated** ↑

```
calc = getCalculated(obj)
```

Description:

Get calculated series from model.

Input:

```
- obj : A scalar nb_calculate_generic object.
```

Output:

```
- calc : An object of class nb_ts.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_CALCULATE_GENERIC

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provide recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

Inherited from superclass NB_MODEL_GENERIC

► **getDSGEVARPriorMoments** ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by
nb_var.priorTemplate('dsge').

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

[nb_var](#), [nb_var.priorTemplate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependent** ↑

```
dependent = getDependent(obj)
```

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getFactors** ↑

```
factors = getFactors(obj)
```

Description:

Get factors from a estimated nb_factor_model_generic object

Input:

- obj : An object of class nb_factor_model_generic

Output:

- factors : A nb_ts object with the estimated factors of the model stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **getFiltered** ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be $N(0,1)$. Default is false.
- econometricians : Get econometricians view of the filtered variables. I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a $N \times 3$ cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_fmdyn.estimate](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [getForecast](#) ↑

```
fcstData          = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.
- outputType :
 - > 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.
 - The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forcast if produced. (Else it is a empty struct). Each field has the same sizes as the fcstData output.
- > 'graph' : This option can be used to make it easier to plot the recursive densities.
 - The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.
 - The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they is calculated, or else it is a empty struct.

To graph the recursive forecast use this example:

```

fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

```

- > 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simualtions. Mean will be at last page.
- For real-time forecast the vintage at the time is returned as the historical data, when includeHist is true.
- > 'horizon' : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.
 - If includeHist is true the actual data is added as an additional page of the nb_ts object.

```
Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).
```

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with
 size nRec x nVars. While the fcstPercData output
 will be a nb_ts object with size nRec x nVars x nSim.
 You can set the horizon to return by the optional
 input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

[nb_fmdyn.plotForecast](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables ↑**

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.
- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.
The same apply for real-time data.
- notSmoothed : Prevent getting history from smoothed estimates.
- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Åtterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj,varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

```
- obj      : A scalar nb_model_generic object.  
- varsIn : The variables that can be found in the data of the model.  
If empty, they are found at obj.options.data.variables.  
  
Caution: Only used in special cases.
```

Output:

```
- vars : A cellstr array with the variables of the model.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

```
- obj      : A N x M nb_model_forecast object.
```

Output:

```
- names : A N x M cellstr.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)  
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgen object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getObservables ↑

```
observables = getObservables(obj)
```

Description:

Get observables from a estimated nb_factor_model_generic object

Input:

- obj : An object of class nb_factor_model_generic

Output:

- observables : A nb_ts object with observables of the factor model stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► getOriginalVariables ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODELDATA

► getPIT ↑

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)

- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:[nb_calculatePIT](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► getParameterDrawsMethods ↑

```
methods = parameterDraws(obj)
```

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getParameters ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.
- Optional input
 - varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).
 - : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
 - : Give 'double' to return the value as a numerical array.
 - : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [getPosteriorDistributions](#) ↑

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.
- Optitonal input:
 - 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

```
- distr      : A 1 x numCoeff nb_distribution object.  
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.  
  
Written by Kenneth SÃ¶terhagen Paulsen  
  
Inherited from superclass NB_MODEL_GENERIC
```

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

```
- obj : An object of class nb_model_generic
```

Output:

```
- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

```
- obj      : An object of class nb_model_generic (or a subclass of this class).
```

Output:

```
- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.
```

Examples:

```
plotter = getRecursiveEstimationGraph(obj);
plotter.graphSubPlots();
```

See also:

[nb_graph_ts](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveScore** ↑

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

residual = getResidual(obj)

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph** ↑

plotter = getResidualGraph(obj)

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.
- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
                  rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores

- 'MLS' : Mean log score

If the object intput is a vector, the type input can also be a cellstr array wit matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursivly, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

See also:

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution ↑**

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the 'varOfInterest' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the 'observables' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'. Only some specific class of models.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the acl output from SIM or THEO, the fourth input can be the acl output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_fmdyn.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► handleMissing ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

► help ↑

```
helpText = nb_fmdyn.help  
helpText = nb_fmdyn.help(option)  
helpText = nb_fmdyn.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **initialize** ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **interpretForecast** ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores'	: The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB'	: A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model'	: A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps'	: Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer'	: The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset'	: Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel'	: Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters'	: To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsge.
- 'periods'	: The number of periods that you let innovations from the model represented by obj be active.
- 'startDate'	: The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest'	: A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch'	: If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale'	: Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \logFunc$, where logFunc is either the minus

log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.

- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

[nb_fmdyn.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf ↑**

[irfs,irfsBands,plotter] = irf(obj,varargin)

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgen objects.
- 'compare' : Give true if you have a scalar nb_dsgen model and you want to graph the irfs from the different regimes from a NBToolbox solved model against each other. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a

scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the
nb_graphSubPlotGUI class to produce the graphs in
this case.

- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.
- 'draws' : Number of draws for calculating gирf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.
- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.
I.e. {'var1',100,...} or {{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}
- 'fanPerc' : This options sets the error band percentiles of the graph, when the 'perc' input is empty. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'irfCompare' : A struct on the same format as the irfs output from this function with the IRFs to compare to.
- 'levelMethod' : One of the following:
 - > 'cumulative product' : cumprod(1 + X,1)
 - > 'cumulative sum' : cumsum(X,1)
 - > 'cumulative product (log)' : log(cumprod(1 + X,1))
 - > 'cumulative sum (exponential)' : exp(cumsum(X,1))

```

> 'cumulative product (%)' : cumprod(1 + X/100,1)
> 'cumulative sum (%)' : cumsum(X/100,1)
> 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
> 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
> '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
  Default is ''. See help on the method input of the
  nb_model_generic.parameterDraws method for more
  this input. An extra option is:

> 'identDraws' : Uses the draws of the matrix with
  the map from structural shocks to dependent
  variables. See nb_var.set_identification. Of
  course this option only makes sense for VARs
  identified with sign restrictions.

- 'normalize' : A 1 x 3 cell. First element must be the variable
  name as a string. The second element must be the
  value to normalize to, as an integer. While the
  third element is the period to be normalized, if
  set to inf, it will normalize the max impact
  period.

E.g. {'Var',1,2}, {'Var',1,inf}

Caution: 2 means observation 2 of the IRF, and as
the IRF start at period 0, this means that
observation 2 is period 1.

- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of
irfs, while 'mean' normalize the mean and scale
percentiles/other draws accordingly. Default is
'draws'.

Caution: Setting this to 'mean' will not work for
reported variables that is not measured
as % deviation from steady-state/mean.

- 'newReplic' : When out of parameter draws, this factor decides how
many new draws are going to be made. Default is 0.1.
I.e. 1/10 of the replic input.

- 'parallel' : Give true if you want to do the irfs in parallel.
This option will parallelize over models. Default
is false.

- 'parallelL' : Give true if you want to do the irfs in parallel.
This option will parallelize over parameter
simulations. Only an option if numel(obj) == 1.
Default is false.

- 'pause' : true or false, Enable or disable pause option
when calculating the irfs. Default is true.

```

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for nb_dsg objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for nb_dsg objects.
- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!
- 'settings' : Extra graphs settings given to nb_plots function. Must be a cell.
- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.

For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.
- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char (Only for Markov-switching models):
 - > scalar : Select the the regime to take the initial transition probabilities from.

```

> double      : A draws x nRegime or a 1 x
    nRegime double. draws refer to
    the number set by the 'draws'
    input.

> 'ergodic'   : Start from the ergodic transition
    probabilities. Default for 'irf'.

> 'random'    : Randomize the starting values
    using the simulated starting
    points. Default for 'girf'.

- 'startingValues' : Either a double or a char:

> double      : A nVar x 1 double.

> 'steadystate' : Start from the steady state. If you are dealing
    with a MS-model or a break-point model you can
    indicate the regime by 'steadystate(regime)'. E.g.
    to start in regime 1 give; 'steadystate(1)'. For
    MS - models the default is the ergodic mean
    (default as long as 'girf' is not selected as
    'type'), while for break-point models it is to
    start from the first regime.

> 'zero'       : Start from zero on all variables.

> 'random'    : Randomize the starting values using the simulated
    starting points. Default when 'type' set to
    'girf'.

- 'states'     : Either an integer with the states to produce irf in,
    or a double with the states to condition on. Must
    have size periods x 1 in the last case. Applies to
    both MS - models and break-point models.

- 'type'        : 'girf' or 'irf'. (If empty 'irf' will be used)

> 'girf'       : Generalized impulse response function
    calculated as the mean difference between
    shocking the model with a one period shock
    (1 std) and no shock at all. Use the 'draws'
    input to set the number of simulations to use
    to base the calculation on. This type of
    irfs must be used for non-linear models.

> 'irf'        : Standard irf for linear models. Calculated by
    shocking the model with a one period shock
    (1 std).

- 'variables'   : The variables to create impulse responses of.
    Default is the dependent variables defined by the
    first model.

    Caution: The variables reported by the reporting
    property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level

```

using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.'(E_X_NW')'. Which will then be a nb_ts object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different variables and shocks.
- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!
- plotter : An object of class nb_graph_ts.
 - > 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
 - > 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast ↑**

ret = isDensityForecast(obj)

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsgc object is filtered or not.

Input:

- obj : An object of class nb_dsgc.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

ret = isMixedFrequency(obj)

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

ret = isNB(obj)

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

```
- ret : A M x N x Q logical. An element is set to true if the model uses  
a NB toolbox solver.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

```
- obj : A scalar nb_model_generic object.
```

Output:

```
- ret : true or false. true if the estimation settings is so that the  
solution to the model is a state-space model.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

```
- obj : A scalar nb_model_estimate object.
```

Output:

```
- ret : true or false. true if the estimation settings is so that the  
model is static.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

ret = issolved(obj)

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

[bands,plotter] = jointPredictionBands(obj,varargin)

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

```

- 'vars' : A cellstr with the variables to return
the calculated joint prediction bands of.

- 'perc' : Error band percentiles. As a 1 x numErrorBand
double. E.g. [0.3,0.5,0.7,0.9] (default) or
0.9. Cannot be empty!

- 'date' : If recursive forecast has been produced,
you can use this option to choose which of
the recursive forecast to construct the
joint prediction bands of. Default is empty,
i.e. use the last forecast.

- 'method' : Choose between:

    > 'kolsrud' : See Akram et al (2016), Joint
                   prediction bands for
                   macroeconomic risk management

    > 'copula' : Using a copula likelihood approach.

    > 'mostlik' : Group the paths based on how
                   likely they are.

- 'nSteps' : Number of forecasting steps to use when constructing the
error bands. If empty (default) all forecasting steps stored
in the object is used.

```

Output:

```

- JPB : An nb_ts object storing the joint prediction bands.
The percentiles are stored as datasets. See the
dataNames property for which page represent which
percentile.

The data of the nb_ts object has size nSteps x nVars
x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method
to produce the graphs.

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_fmdyn.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

f = mcfRestriction(obj,type,restriction)

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use @(x)f1(x)&&f2(x), where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.

- type : The type of restriction. Either 'irf', 'corr' or 'cov'.

- restriction : Depends on the type input:

> 'irf' : A N x 4 cell, where the elements of each row are:
1. Name of the shock. 'E_X'
2. Name of the variable. 'X'
3. Horizon. E.g. 1 or 1:3.
4. Restriction. E.g. @(x)gt(x,0),
@(x)gt(x,0)||lt(x,1), i.e. a function_handle that takes a scalar double as input and a scalar logical as output.

> 'rirf' : A N x 7 cell, where the elements of each row are:
1. Name of the shock 1. 'E_X'
2. Name of the variable 1. 'X'
3. Horizon of variable 1. E.g. 1.
4. Name of the shock 2. 'E_Y'
5. Name of the variable 2. 'Y'
6. Horizon of variable 2. E.g. 2.

7. Restriction. E.g. `@(x,y)gt(x,y),`
`@(x,y)gt(x-y,0)||lt(x-y,1)`, i.e. a
function_handle that takes a two scalar
double as inputs and a scalar logical
as output.

> 'corr' : A N x 4 cell, where the elements of each
row are:
1. Name of the first variable.
2. Name of the second variable.
3. Number of periods to lag the 2. variable.
4. Same as 4 for 'irf'.

E.g. `{'Var1','Var1',1,@(x)gt(x,0.1)}`, to
test a restriction on the autocorrelation
at lag for variable 'Var1'.

E.g. `{'Var1','Var2',0,@(x)lt(x,0.1)}`, to
test a restriction on the contemporaneous
correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. `{'Var1','Var1',0,@(x)lt(x,0.1)}`, to
test a restriction on the contemporaneous
variance.

> 'ss' : A N x 2 cell, where the elements of each
row are:
1. The expression using any of the
endogenous variables of the model.
2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mincerZarnowitzTest ↑**

`[test,pval,res] = mincerZarnowitzTest(obj,precision)`

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering ↑**

```
paramD = monteCarloFiltering(obj, varargin)
[paramD, values, solvingFailed, objAcc] = monteCarloFiltering(obj, varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

See also:

[nb_fmdyn.assignParameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated

with classical methods.

```

> 'wildBlockBootstrap' : Create artificial data by wild
  overlapping random block length
  bootstrap., and then "draw" parameters
  based on estimation on these data.
  Only an option for models estimated
  with classical methods.

> 'copulaBootstrap'      : Uses a copula approach to draw residual
  that are autocorrelated, Does not handle
  heteroscedasticity. Only an option for
  models estimated with classical methods.

> 'posterior'           : Posterior draws. Only for models
  estimated with bayesian methods.
  Default for models estimated with
  bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
  on this option.

- stable : Give true if you want to discard the parameter draws
  that give rise to an unstable model. Default is false.

```

Optional input:

```

- 'parallel'      : Run in parallel. true or false.

- 'cores'         : Number of cores to use. Default is to use all cores
  available.

- 'newDraws'       : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the draws input.

  Caution: When setting 'parallel' to true on MATLAB
  version later than R2017B this number will
  be the number of new draws, and not the
  factor!!! E.g. set it to 100. If it is given
  as a number less than 1, it will by default
  be set to 100.

- 'initialDraws'  : When drawing parameters this factor decides how many
  many draws that are produced before solving the model.
  Default is 1. I.e. it is equal to draws input. For
  VAR models with underidentification it may be a good
  idea to set this to a value > 1 as you may drop a
  lot of parameters when identification fails. Default
  is 1.

```

Output:

```

- out          : The output depend on the input output:

> 'param'     : Default. A struct with the following fields:

  beta   : A nPar x nEq x draws double with the

```

estimated parameters.

sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:

lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.

R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.

factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

ci = parameterIntervals(obj,alpha)

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

```
- ci      : A nPar x 3 cell matrix.  
  
Written by Kenneth SÃ¶terhagen Paulsen  
  
Inherited from superclass NB_MODEL_GENERIC
```

► **plotFactors** ↑

```
plotter = plotFactors(obj,errBands)
```

Description:

Get factors from a estimated nb_factor_model_generic object

Input:

```
- obj      : An object of class nb_factor_model_generic  
  
- errBands : Give true to add one std bands around the factor estimates.  
             Default is false.
```

Output:

```
- plotter : A nb_graph_ts object to use to plot the factors. Use the  
           graphSubPlots method or the nb_graphSubPlotGUI.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **plotForecast** ↑

```
plotter          = plotForecast(obj)  
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate,...  
                                         increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model
in the vector of nb_model_forecast objects

Input:

```
- obj  : A vector of nb_model_forecast objects  
  
- type : Type of plot, as a string;  
  
        > 'default'   : Plot the forcast for the last period of  
                      estimation and ahead. Possibly with density for
```

the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.

> 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.

- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

```
plotter = A nb_graph_data object. Use the graph method to produce the
figure, or the nb_graphPagesGUI class.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF ↑**

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound, ...
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest** ↑

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,nameValue)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_fmdyn.monteCarloFiltering](#)

Written by Kenneth Åtterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [plotPosterioriors](#) ↑

```
plotter = plotPosterioriors(obj)
plotter = plotPosterioriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.
- Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

printed = printCov(obj)

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results ↑**

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_fmdyn.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **priorTemplate ↑**

prior = nb_fmdyn.priorTemplate()
prior = nb_fmdyn.priorTemplate(type)
prior = nb_fmdyn.priorTemplate(type, num)

Description:

Construct a struct which can be given to the method setPrior.

The structure provided the user the possibility to set different prior options.

Input:

- type : A string;

- 'kkse' : This is the prior used in the paper by Koop and Korobilis (2014) extended by Schroder and Eraslan (2021) to handle mixed frequency.

> 'f0VarScale' : Scale factor on the variance of the prior on the initial value of factors. Default is 10. $N(0, f0VarScale \cdot I)$

> 'lambda0VarScale' : Scale factor on the variance of the prior on the initial value of the factor loadings. Default is 1. $N(0, lambdaVarScale \cdot I)$

> 'V0VarScale' : Scale factor on the mean of the prior on the initial value of the measurement equation covariance matrix. Default is 0.1. Dogmatic prior set to $V0VarScale \cdot I$.

> 'Q0VarScale' : Scale factor on the mean of the prior on the initial value of the state equation covariance matrix. Default is 0.1. Dogmatic prior set to $Q0VarScale \cdot I$.

> 'gamma' : Hyperparameter on prior variance of the coefficients of the state equations. On the form $V(i, j) = gamma ./ (ceil(j/options.nFactors).^2)$. Where V is a matrix with size option.nFactors x option.nLags*option.nFactors. Default value is 0.1.

> 'l_1m' : Starting value of: Decay factor for the measurement error variance of the monthly variables. A smaller value puts smaller weight on past observations and thus allows for faster parameter change. A value of 1 implies constant parameters. Default is 0.9.

> 'l_1q' : Starting value of: Decay factor for the measurement error variance of the quarterly variables. A smaller value puts smaller weight on past observations and thus allows for faster parameter change. A value of 1 implies constant parameters. Default is 0.9.

> 'l_2' : Starting value of: Decay factor for the factor error variance. A smaller value puts smaller weight on past observations and thus allows for faster parameter change. A

```

value of 1 implies constant parameters.
Default is 0.9.

> 'l_3'          : Starting value of:
Decay factor for the loadings' error
variance. A smaller value puts smaller
weight on past observations and thus
allows for faster parameter change. A
value of 1 implies constant parameters.
Default is 0.9.

> 'l_4'          : Starting value of:
Decay factor for the factor VAR
parameters' error variance.
A smaller value puts smaller
weight on past observations and thus
allows for faster parameter change. A
value of 1 implies constant parameters.
Default is 0.9.

> 'l_1_endo_update': Controls the endogenous forgetting
factors
1: l_1m and l_1q are time-varying/endogenous
0: l_1m and l_1q are constant/static
Default is 0.

> 'l_2_endo_update': Controls the endogenous forgetting
factors
1: l_2 is time-varying/endogenous
0: l_2 is constant/static
Default is 0.

> 'l_3_endo_update': Controls the endogenous forgetting
factors
1: l_3 is time-varying/endogenous
0: l_3 is constant/static
Default is 0.

> 'l_4_endo_update': Controls the endogenous forgetting
factors
1: l_4 is time-varying/endogenous
0: l_4 is constant/static
Default is 0.

- num  : Number of prior templates to make.

```

Output:

- options : A struct.

See also:

[nb_fmdyn](#)

Written by Kenneth Sæterhagen Paulsen and Maximilian Schräder

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **setBlocks** ↑

obj = setBlocks(obj, blocks)

Description:

Use this function to set zero restriction in the factor loadings. This can be used to only restrict some factors to explain the observables. E.g. in this way we can have one factor that only relates to one class of observables, and in this way we can identify that factor with that specific class.

Input:

- obj : An object of class nb_fmdyn.

- blocks : A nb_cs or double with size N x R, where N is the number of observables and R is the number of factors. Give a nb_cs object to name the factors! Ordering of the nb_cs input is not important, but if given as a double the ordering is given by obj.observables.name. Set a one in the row of the observables that belong to the block of the corresponding column, otherwise 0.

Output:

- obj : An object of class nb_fmdyn, where the blocks field of the options property is set.

See also:

[nb_fmdyn.set](#)

Written by Kenneth Sæterhagen Paulsen

► **setFrequency** ↑

`obj = setFrequency(obj, freq)`

Description:

Set the frequency of the decleared observables of a formulated model.

Supported frequencies:

- 'quarterly' : 4
- 'monthly' : 12

Input:

- `obj` : An object of class `nb_fmdyn`.
- `freq` : A cellstr on the format; `{'Var1',4,'Var2',4}`. There is no need to set the frequency of those variables that has the same frequency as the data (`options.data`)!

Output:

- `obj` : An object of class `nb_fmdyn` where the frequency of a set of variables has been set. See the `observables` properties.

See also:

[nb_fmdyn.setMapping](#)

Written by Kenneth Sæterhagen Paulsen

► **setMapping** ↑

`obj = setMapping(obj, freq)`

Description:

Set the maping of the decleared `nb_fmdyn` of a formulated model. I.e. how to map the higher frequency to lower frequency in the observation equation.

See `setFrequency` for the supported frequencies.

Supported mappings (Examples are given for a monthly and quarterly mixed frequency data):

- 'levelSummed'	:	$Y(q)$	= $Y(m) + Y(m-1) + Y(m-2)$
- 'diffSummed'	:	$Y(q)$	= $Y(m) + 2*Y(m-1) + 3*Y(m-2) + 2*Y(m-3) + Y(m-4)$
- 'levelAverage'	:	$Y(q)$	= $1/3*(Y(m) + Y(m-1) + Y(m-2))$
- 'diffAverage'	:	$Y(q)$	= $1/3*Y(m) + 2/3*Y(m-1) + Y(m-2) + 2/3*Y(m-3) + 1/3*Y(m-4)$
- 'end'	:	$Y(q)$	= $Y(m)$

The default mapping that is used for all series with lower frequency is 'diffAverage'.

Input:

- obj : An object of class nb_fmdyn
- map : A cellstr on the format; {'Var1','levelSummed',...,'Var2','diffSummed'}

Output:

- obj : An object of class nb_mfvar where the mapping of a set of variables has been set. See the dependent and block_exogenous properties.

See also:

[nb_fmdyn.setFrequency](#)

Written by Kenneth Åtterhagen Paulsen

► **setPrior** ↑

obj = setPrior(obj,prior)

Description:

Set priors of a vector of nb_fmdyn objects. The prior input must either be a struct or nb_struct with same size as obj or have size 1.

The provided struct will be added to the property options as the field prior.

See [nb_fmdyn.priorTemplate](#) for the format of the struct.

Input:

- obj : A vector of nb_fmdyn objects
- prior : A struct or nb_struct with either matching numel of obj or size 1. If size is 1 all models gets the same prior settings.

Output:

- obj : A vector of nb_fmdyn objects with the priors set.

See also:

[nb_fmdyn.priorTemplate](#)

Written by Kenneth Sæterhagen Paulsen

► **shock_decomposition ↑**

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will

be converted.

- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. E.g. $[0.3, 0.5, 0.7, 0.9]$. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.
- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulate** ↑

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also

including exogenous and shocks.

> 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.

- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.

- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.

- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.

- 'seed' : Set simulation seed. Default is 2.0719e+05.

- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a specific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:

- > double : A 1 x nVar double.
- > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsge models.
- > 'steadystate' : Start from the steady state. For now only an option for nb_dsge models. If you are dealing with a MS-model you can indicate the state by 'steadystate(state)'. E.g. to start in state 1 give; 'steadystate(1)'. Default for nb_dsge models.
- > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

- 'startingProb' : Either a double or a char:

```

> double      : A nPeriods x nRegime or a 1 x
    nRegime double. nPeriods refer to
    the number of recursive periods to
    forecast.

> 'ergodic'   : Start from the ergodic transition
    probabilities. Default.

```

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```

[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)

```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
 - 'nLags' : Number of lags to compute when 'stacked' is set to true.
 - 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
 - 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
 - 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
 - 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.
- Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
 - 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
 - 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is

true.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_fmdyn object(s).

Input:

- obj : A vector of nb_fmdyn objects.

Output:

- obj : A vector of nb_fmdyn objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

tempSol = nb_fmdyn.solveNormal(results,opt)

Written by Kenneth Sæterhagen Paulsen

► **solveRecursive** ↑

tempSol = nb_fmdyn.solveRecursive(results,opt)

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

obj = solveVector(obj)

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_fmdyn.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template ↑**

```
options = nb_fmdyn.template()
options = nb_fmdyn.template(num)
```

Description:

Construct a struct which can be provided to the nb_fmdyn class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions ↑**

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► testParameters ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

```
- obj : A scalar solved nb_model_generic object.  
  
- expression : A MATLAB expression as a string. Use parameter names as  
variables. See model.parameters.name.  
  
- method : A string with the method to use. For bootstrap method see  
nb_bootstrap. For bayesian models 'posterior' is the only  
option. Default is 'bootstrap' for classical models, while  
'posterior' is the default for bayesian models.  
  
- draws : Number of draws from the parameter distribution. Default  
is 1000.  
  
- alpha : Confidence level. Default is 0.05.  
  
- type : Type of test:  
    > '=' : Two sided test. expression == 0 (default)  
            For two-sided tests it is assumed that the  
            distribution is symmetric! Use  
            confidence/probability intervals instead.  
    > '>' : One sided test. expression > 0  
    > '<' : One sided test. expression < 0
```

Output:

```
- pval : > 'classical' : P-value of test.  
        > 'bayesian' : Probability of test.  
  
        A 1x1 double.  
  
- ci : A 1 x 2 double with the lower and upper bound of the  
confidence/probability interval of the tested expression.  
  
- dist : A nb_distribution object storing the distribution of the  
tested expression.
```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c] = theoreticalMoments(obj,varargin)
[m,c,ac1] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the

parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargout{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

See also:

[nb_fmdyn.graphCorrelation](#), [nb_fmdyn.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **trendAndCycle** ↑

[O,decomp,results] = trendAndCycle(obj,varargin)

Description:

Decompose the observed variables into deterministic, trend, cycle and noise components.

We follow Barigozzi and Luciani (2017) "Common Factors, Trends, and Cycles in Large Datasets".

The decomposition is given by:

```
O_t = Dhat_t                                (Deterministic)
      + G*PHI1*That_t                          (Trend)
      + G*PHI0*Chat_t                          (Cycle)
      + G*PHI0*(Ghat_t - H*Chat_t) + eps_t    (Noise)
```

where O_t is the observed variables, G is the factor loadings and ϵ_{st} is the idiosyncratic components found during estimation. See section 3.3 for a description of the rest of the terms in the equation.

Input:

- 'q' : The number of common shocks. $d=q-m$ will be the number of stationary common shocks.
- 'm' : The number of common trends. Same as $q-d$ in Barigozzi and Luciani (2017).
- 'nLags' : Number of lags to include in equation (20) of Barigozzi and Luciani (2017).

Output:

- O : A $T \times N \times 4$ nb_ts object. T is number of observations, N is number of observed variables. The pages represents deterministic, trend, cycle and noise components respectively.
- decomp : A struct with fields:
 - > That : A $T \times m$ nb_ts object. T is number of observations, m is the number of common trends.
 - > Chat : A $T \times (q-m)$ nb_ts object. T is number of observations, $(q-m)$ is the number of common stationary shocks (cycle).
 - > Ithat : A $T \times (r - q)$ nb_ts object. T is number of observations, m is the number of common noise.
- results : A struct with fields PHI1, PHI0 and H. See equation above.

See also:

[nb_model_generic.estimate](#)

Written by Kenneth Sæterhagen Paulsen

► **uncertaintyDecomposition ↑**

```
[data,plotter] = uncertaintyDecomposition(obj,varargin)
```

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output :

```
- data      : Depend on the 'method' input:  
    > 'percentiles'   : A nHor x (nExo + nRes)*2 x nVars nb_ts  
        object storing the uncertainty  
        decomposition.  
    > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object  
        storing the numerically calculated  
        forecast error variances/skewnesses.  
  
- plotter : A nb_graph_ts object which the method graph can be used to  
    produce graphs.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► uncondForecast ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

```
- obj      : A vector of nb_model_generic objects.  
- nSteps   : Number of forecasting steps. As a 1x1 double. Default is 8.
```

Optional inputs:

- See the nb_model_generic.forecast method

Output:

```
- obj      : A vector of nb_model_generic objects. See the property  
            forecastOutput.
```

See also:

[nb_fmdyn.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► unstruct ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_fmdyn.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **update ↑**

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic

- type : > '' : Only update data. Default
 > 'estimate' : Update data and estimate.
 > 'solve' : Update data, estimate and solve
 > 'forecast' : Update data, estimate, solve and forecast.

- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.

- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.

- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► variance_decomposition ↑

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.

- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomosition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomosition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

[nb_fmdyn.parameterDraws](#), [nb_varDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

■ nb_fmsa

Go to: [Properties](#) | [Methods](#)

A class for estimation and identification of step ahead factor models.

Superclasses:

[nb_factor_model_generic](#), [nb_model_generic](#)

Constructor:

obj = nb_fmsa(varargin)

Optional input:

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : An nb_fmsa object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#)

Properties:

- [addAutoName](#)
- [dependent](#)
- [forecastOutput](#)
- [parameters](#)
- [solution](#)
- [addAutoNameIfLocal](#)
- [endogenous](#)
- [name](#)
- [reporting](#)
- [transformations](#)
- [addID](#)
- [estOptions](#)
- [observables](#)
- [residuals](#)
- [userData](#)
- [addIDIfLocal](#)
- [exogenous](#)
- [options](#)
- [results](#)

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[dependent](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgc models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **[endogenous](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous

variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgen models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **observables** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the variable(s) of the model observation equation, the tex_name holds the names in the tex format. The number field holds a double with the number of variables of the model observation equation. To set it use the set function. E.g. obj = set(obj,'observables',{'Var1','Var2'}); or use the <className>.template() method.

If the model class also supports mixed frequency data, it has two additional fields; frequency and mapping. These fields stores the selected frequency and mapping for each element.

Inherited from superclass NB_FACTOR_MODEL_GENERIC

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t$, $e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t$, $u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation. As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.

- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

Inherited from superclass NB_MODEL_GENERIC

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters** ↑

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.

- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!

- 'instrument' : A one line char with the name of the instrument. Must be provided!

- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!

- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.

- 'perc' : Error band percentiles. As a 1 x nPerc double.
E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will
be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the
double method on this output to convert it to a double
matrix.

See also:

[nb_fmsa.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws
(bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see
[nb_bootstrap](#). For bayesian models 'posterior' is the only
option. Default is 'bootstrap' for classical models, while
'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is
1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property
is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterioriors** ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optional input:

- `'nLags'` : Number of lags to include in the autocorrelation plot. Default is 10.
- `'iter'` : The recursive iteration date. Either as a string or a `nb_date` object. If recursive estimation is done, this input must be provided.

Output:

- `DB` : A `nb_data` object with size `nDraws x numCoeff`.
- `plotter` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.
- `pAutocorr` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.

Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
                    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

[nb_model_forecast.getScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [convert ↑](#)

`obj = convert(obj,freq,method,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convert`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convert`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► [convertEach ↑](#)

`obj = convert(obj,freq,methods,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

► `createVariables` ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM `nb_modelData` object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.

> third column : Any expression that can be interpreted by the `nb_ts.createShift` method.

> fourth column : Comments

- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name,    input,    shift,    description
  'VAR1_G',    'pcn(VAR1)', 'avg',    'VAR1 growth'
  'VAR2_G',    'pcn(VAR2)', 'avg',    'VAR2 growth'
  'VAR3_G',    'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

► dieboldMarianoTest ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

► **doForecastPerc2Dist ↑**

```
obj = doForecastPerc2Dist(obj,draws)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

`nb_fmsa.forecast, nb_distribution.perc2ParamDist`

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity** ↑

`obj = doSimulateFromDensity(obj, draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `obj` : A `nb_model_forecast` object.
- `draws` : Number of draws to use for simulation.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_model_generic.forecast, nb_fmsa.simulateFromDensity`

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass `NB_MODEL_FORECAST`

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_generic` object. The `options.data` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

Inherited from superclass NB_MODEL_GENERIC

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj        = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default

is to open max number of cores available. Only an option if 'parallel' is given.

- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

► **evaluateForecast ↑**

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **explained** ↑

```
[expl,plotter] = explained(obj)
```

Description:

Get how much of the variation in the data the factors explain.

Caution: Remember that for dynamic factor models the factors are not orthogonal.

Input:

- obj : A scalar nb_factor_model_generic object.

Output:

- expl : A nb_cs object with size nFactors x 1.
- plotter : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to plot it on the screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **forecast** ↑

```
obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for forward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
 - 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
 - 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
 - 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error
- Only for density forecast:
- 'logScore' : Log score
- Can also be a cellstr with the above listed evaluation types.
- Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.
- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
 - 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density

forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.

- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density forecast.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'bins' : The length of the bins og the domain of the density. Either;
 - > [] : The domain will be found. See nb_getDensityPoints (default is that 1000 observations of the density is stored).
 - > integer : The min and max is found but the length of the bins is given by the provided integer.
 - > cell : Must be on the format:
`{'Var1',lowerLimit1,upperLimit1,binsL1;
 'Var2',lowerLimit2,upperLimit2,binsL2;
 ...}`
 - lowerLimit1 : An integer, can be nan, i.e. will be found.
 - upperLimit1 : An integer, can be nan, i.e. will be found.
 - binsL1 : An integer with the length of the bins. Can be nan. I.e. bins length will be adjusted to create a domain of 1000 elements.

Caution : The variables not included will be given

the default domain. No warning will be given if a variable is provided in the cell but not forecast by the model. (This because different models can forecast different variables)

Caution : The `combineForecast` method of the `nb_model_group` class is much faster if the lower limit, upper limit! Or else it must simulate new draws and do kernel density estimation for each model again with the shared domain of all models densities.

- `'startDate'`
 - : The start date of forecast. Must be a string or an object of class `nb_date`. If empty the `estim_end_date + 1` will be used.
 - Caution:** If '`fcstEval`' is not empty this will set the start date of the recursive forecast. Default is to start from the first possible date.
- `'endDate'`
 - : The end date of forecast. Must be a string or an object of class `nb_date`. If empty the `estim_end_date + 1` will be used.
 - Caution:** If '`fcstEval`' is empty this input will have nothing to say.
- `'saveToFile'`
 - : Logical. Save densities and domains to files. One file for each model. Default is `false` (do not).
- `'observables'`
 - : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- `'condDB'`
 - : One of the following:
 - > A `nb_ts` object with size `nSteps x nCondVar` with the information to condition on.
If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A `nb_data` object with size `nSteps x nCondVar x nPeriods` with the information to condition on. The `dataNames` property must be set to the start dates of the recursive conditional information. `nPeriods` will be the number of recursive periods.
 - > A `nb_ts` object with size `nSteps x nCondVar x 3` with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given

as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)

> A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is choosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual

to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.

> StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.

Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.

If not provided. Model stds are used.

> Horizon : Anticipated horizon of the shocks/residual. 1 is default.

> Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.

- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned

included the lag variables. Also including exogenous and shocks.

> 'all' : All variables are returned (but not the lags). Including exogenous and shocks.

- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.

> double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.

> 'mean' : Start from the mean of the data observations. Default.

> 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.

> 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)

- 'startingProb' : Either a double or a char:

> [] : If the model is filtered the starting value is calculated on filtered transition probabilities. Otherwise the ergodic mean is used.

> double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.

> 'ergodic' : Start from the ergodic transition probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

- 'states' : Either an integer with the regime to forecast/simulate in, or an object of class nb_ts

with the regimes to condition on. The name of the variable must be 'states'.

Caution: For break-point models this is decided by the dates of the breaks, and cannot be set by this option!

- 'compareToRev' : Which revision to compare to. Default is final revision, i.e. []. Give 5 to get fifth revision. must be an integer. Keep in mind that this number should be larger than the nSteps input.
- 'compareTo' : Sometime you want to evaluate the forecast of one variable against another variable which is not part of the model. E.g. if you use the first release of a variable and want to compare it against the final release. To do this you can give a cellstr with size n x 2, where n is the number of variables to change the the actual observations to test against. {'VAR_1','VAR_FINAL',...}.
- 'estimateDensities' : true or false. true if you want to do a kernel density estimation of the density forecast.
- 'exoProj' : Tolerate missing exogenous variables by projecting them by a fitted model. Only when the 'condDB' input is empty!
 - Options are:
 - '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.
 - 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.
 - Caution :** If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.
 - Caution :** If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.
- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the

method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when exoProj is set to 'AR'.

- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matix. For the order of the

variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs' : This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.
- 'seed' : Set simulation seed. Default is 2.0719e+05.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist ↑**

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_fmsa.forecast](#)

Written by Per Bjarne Bye, Kenneth Åkerhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► forecastPerc2ParamDist ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_fmsa.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst, ...
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditinal information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments** ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Inherited from superclass NB_MODEL_GENERIC

► **getDependent** ↑

```
dependent = getDependent(obj)
```

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)

Written by Kenneth SÃ¶terhagen Paulsen
```

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getFactors** ↑

```
factors = getFactors(obj)
```

Description:

Get factors from a estimated nb_factor_model_generic object

Input:

- obj : An object of class nb_factor_model_generic

Output:

- factors : A nb_ts object with the estimated factors of the model stored.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **getFiltered** ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_fmsa.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast ↑**

```
fcstData = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0, -1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.
```

For real-time forecast the vintage at the time is

returned as the historical data, when includeHist is true.

> 'horizon' : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.

If includeHist is true the actual data is added as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!

Caution : If the horizon input is set you will set nHor to one, and the fcstPercData will be non-empty, if density forecast has been produced.

- includeHist : Give true (1) to include history in the output. Only an options for the 'date' and 'horizon' outputType. Default is false (0).

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with size nRec x nVars. While the fcstPercData output will be a nb_ts object with size nRec x nVars x nSim. You can set the horizon to return by the optional input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_fmsa.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables ↑**

vars = getForecastVariables(obj)

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► getHistory ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getLHSVars ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj,varsIn)
```

Description:

Get all left hand side variables of the model.
For factor models the observable (+ observableFast) are added as well.
The list will be sorted.
Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsg object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getObservables ↑

```
observables = getObservables(obj)
```

Description:

Get observables from a estimated nb_factor_model_generic object

Input:

- obj : An object of class nb_factor_model_generic

Output:

- observables : A nb_ts object with observables of the factor model stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► getOriginalVariables ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► getPIT ↑

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option

is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)

- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

: Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.

: Give 'double' to return the value as a numerical array.

: Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

```
- obj : An object of class nb_model_generic.
```

Optitonal input:

```
- 'draws' : The number of draws to sample from the posterior to base  
the kernel estimation on, if empty all draws are used for  
estimation.
```

Output:

```
- distr : A 1 x numCoeff nb_distribution object.
```

```
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

```
- obj : An object of class nb_model_generic
```

Output:

```
- residual : Either a nb_ts or a nb_cs object with predicted variable(s)  
stored.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_subplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);
plotter.graphSubPlots();
```

See also:

[nb_graph_ts](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveScore ↑**

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

residual = getResidual(obj)

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph** ↑

plotter = getResidualGraph(obj)

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames ↑**

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.

- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution** ↑

```
value = getSolution(obj,type)
```

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_fmsa.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

► **help** ↑

```
helpText = nb_fmsa.help  
helpText = nb_fmsa.help(option)  
helpText = nb_fmsa.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize** ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **interpretForecast** ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsgc.
- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.

- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_fmsa.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf ↑**

[irfs, irfsBands, plotter] = irf(obj, varargin)

Description:

Create impulse responses of the given vector of nb_model_generic objects
Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgen objects.
- 'compare' : Give true if you have a scalar nb_dsgen model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the

nb_graphSubPlotGUI class to produce the graphs in this case.

- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.

- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.
I.e. {'var1',100,...} or
{{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This options sets the error band percentiles of the graph, when the 'perc' input is empty. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from this function with the IRFs to compare to.

- 'levelMethod' : One of the following:
 - > 'cumulative product' : cumprod(1 + X,1)

```

> 'cumulative sum' : cumsum(X,1)
> 'cumulative product (log)' : log(cumprod(1 + X,1))
> 'cumulative sum (exponential)' : exp(cumsum(X,1))
> 'cumulative product (%)' : cumprod(1 + X/100,1)
> 'cumulative sum (%)' : cumsum(X/100,1)
> 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
> 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
> '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
  Default is ''. See help on the method input of the
  nb_model_generic.parameterDraws method for more
  this input. An extra option is:

  > 'identDraws' : Uses the draws of the matrix with
    the map from structural shocks to dependent
    variables. See nb_var.set_identification. Of
    course this option only makes sense for VARs
    identified with sign restrictions.

- 'normalize' : A 1 x 3 cell. First element must be the variable
  name as a string. The second element must be the
  value to normalize to, as an integer. While the
  third element is the period to be normalized, if
  set to inf, it will normalize the max impact
  period.

  E.g. {'Var',1,2}, {'Var',1,inf}

  Caution: 2 means observation 2 of the IRF, and as
  the IRF start at period 0, this means that
  observation 2 is period 1.

- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of
  irfs, while 'mean' normalize the mean and scale
  percentiles/other draws accordingly. Default is
  'draws'.

  Caution: Setting this to 'mean' will not work for
  reported variables that is not measured
  as % deviation from steady-state/mean.

- 'newReplic' : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the replic input.

- 'parallel' : Give true if you want to do the irfs in parallel.
  This option will parallelize over models. Default
  is false.

- 'parallelL' : Give true if you want to do the irfs in parallel.

```

This option will parallelize over parameter simulations. Only an option if `numel(obj) == 1`. Default is false.

- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for `nb_dsg` objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for `nb_dsg` objects.
- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method `nb_var.set_identification` for more.

- 'settings' : Extra graphs settings given to `nb_plots` function. Must be a cell.
- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.

For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.

```

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):

    > scalar      : Select the the regime to take the
                     initial transition probabilities
                     from.

    > double      : A draws x nRegime or a 1 x
                     nRegime double. draws refer to
                     the number set by the 'draws'
                     input.

    > 'ergodic'   : Start from the ergodic transition
                     probabilities. Default for 'irf'.

    > 'random'    : Randomize the starting values
                     using the simulated starting
                     points. Default for 'girf'.

- 'startingValues' : Either a double or a char:

    > double      : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing
                      with a MS-model or a break-point model you can
                      indicate the regime by 'steadystate(regime)'. E.g.
                      to start in regime 1 give; 'steadystate(1)'. For
                      MS - models the default is the ergodic mean
                      (default as long as 'girf' is not selected as
                      'type'), while for break-point models it is to
                      start from the first regime.

    > 'zero'       : Start from zero on all variables.

    > 'random'    : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'       : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'         : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generlized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'  : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

- 'variables'    : The variables to create impulse responses of.
                     Default is the dependent variables defined by the

```

first model.

Caution: The variables reported by the reporting property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.('E_X_NW'). Which will then be a nb_ts object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.

> 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

> 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast** ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency ↑**

ret = isMixedFrequency(obj)

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB ↑**

ret = isNB(obj)

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

ret = isStateSpaceModel(obj)

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

ret = issolved(obj)

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

[bands,plotter] = jointPredictionBands(obj,varargin)

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

```

- 'vars' : A cellstr with the variables to return
the calculated joint prediction bands of.

- 'perc' : Error band percentiles. As a 1 x numErrorBand
double. E.g. [0.3,0.5,0.7,0.9] (default) or
0.9. Cannot be empty!

- 'date' : If recursive forecast has been produced,
you can use this option to choose which of
the recursive forecast to construct the
joint prediction bands of. Default is empty,
i.e. use the last forecast.

- 'method' : Choose between:

    > 'kolsrud' : See Akram et al (2016), Joint
                   prediction bands for
                   macroeconomic risk management

    > 'copula' : Using a copula likelihood approach.

    > 'mostlik' : Group the paths based on how
                   likely they are.

- 'nSteps' : Number of forecasting steps to use when constructing the
error bands. If empty (default) all forecasting steps stored
in the object is used.

```

Output:

```

- JPB : An nb_ts object storing the joint prediction bands.
The percentiles are stored as datasets. See the
dataNames property for which page represent which
percentile.

The data of the nb_ts object has size nSteps x nVars
x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method
to produce the graphs.

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

f = mcfRestriction(obj,type,restriction)

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use @(x)f1(x)&&f2(x), where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.

- type : The type of restriction. Either 'irf', 'corr' or 'cov'.

- restriction : Depends on the type input:

> 'irf' : A N x 4 cell, where the elements of each row are:
1. Name of the shock. 'E_X'
2. Name of the variable. 'X'
3. Horizon. E.g. 1 or 1:3.
4. Restriction. E.g. @(x)gt(x,0),
@(x)gt(x,0)||lt(x,1), i.e. a function_handle that takes a scalar double as input and a scalar logical as output.

> 'rirf' : A N x 7 cell, where the elements of each row are:
1. Name of the shock 1. 'E_X'
2. Name of the variable 1. 'X'
3. Horizon of variable 1. E.g. 1.
4. Name of the shock 2. 'E_Y'
5. Name of the variable 2. 'Y'
6. Horizon of variable 2. E.g. 2.

7. Restriction. E.g. $\@(\mathbf{x}, \mathbf{y})gt(\mathbf{x}, \mathbf{y})$,
 $\@(\mathbf{x}, \mathbf{y})gt(\mathbf{x}-\mathbf{y}, 0) || lt(\mathbf{x}-\mathbf{y}, 1)$, i.e. a
function_handle that takes a two scalar
double as inputs and a scalar logical
as output.

> 'corr' : A N x 4 cell, where the elements of each
row are:
1. Name of the first variable.
2. Name of the second variable.
3. Number of periods to lag the 2. variable.
4. Same as 4 for 'irf'.

E.g. {'Var1', 'Var1', 1, @(\mathbf{x})gt(\mathbf{x}, 0.1)}, to
test a restriction on the autocorrelation
at lag for variable 'Var1'.

E.g. {'Var1', 'Var2', 0, @(\mathbf{x})lt(\mathbf{x}, 0.1)}, to
test a restriction on the contemporaneous
correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. {'Var1', 'Var1', 0, @(\mathbf{x})lt(\mathbf{x}, 0.1)}, to
test a restriction on the contemporaneous
variance.

> 'ss' : A N x 2 cell, where the elements of each
row are:
1. The expression using any of the
endogenous variables of the model.
2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

► **mincerZarnowitzTest ↑**

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj, varargin)
[paramD, values, solvingFailed, objAcc] = monteCarloFiltering(obj, varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterDraws ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated

with classical methods.

```

> 'wildBlockBootstrap' : Create artificial data by wild
  overlapping random block length
  bootstrap., and then "draw" parameters
  based on estimation on these data.
  Only an option for models estimated
  with classical methods.

> 'copulaBootstrap'      : Uses a copula approach to draw residual
  that are autocorrelated, Does not handle
  heteroscedasticity. Only an option for
  models estimated with classical methods.

> 'posterior'           : Posterior draws. Only for models
  estimated with bayesian methods.
  Default for models estimated with
  bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
  on this option.

- stable : Give true if you want to discard the parameter draws
  that give rise to an unstable model. Default is false.

```

Optional input:

```

- 'parallel'      : Run in parallel. true or false.

- 'cores'         : Number of cores to use. Default is to use all cores
  available.

- 'newDraws'       : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the draws input.

  Caution: When setting 'parallel' to true on MATLAB
  version later than R2017B this number will
  be the number of new draws, and not the
  factor!!! E.g. set it to 100. If it is given
  as a number less than 1, it will by default
  be set to 100.

- 'initialDraws'  : When drawing parameters this factor decides how many
  many draws that are produced before solving the model.
  Default is 1. I.e. it is equal to draws input. For
  VAR models with underidentification it may be a good
  idea to set this to a value > 1 as you may drop a
  lot of parameters when identification fails. Default
  is 1.

```

Output:

```

- out          : The output depend on the input output:

> 'param'      : Default. A struct with the following fields:

  beta   : A nPar x nEq x draws double with the

```

estimated parameters.

sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:

lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.

R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.

factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

ci = parameterIntervals(obj,alpha)

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

```
- ci      : A nPar x 3 cell matrix.  
  
Written by Kenneth SÃ¶terhagen Paulsen  
  
Inherited from superclass NB_MODEL_GENERIC
```

► **plotFactors** ↑

```
plotter = plotFactors(obj,errBands)
```

Description:

Get factors from a estimated nb_factor_model_generic object

Input:

```
- obj      : An object of class nb_factor_model_generic  
  
- errBands : Give true to add one std bands around the factor estimates.  
             Default is false.
```

Output:

```
- plotter : A nb_graph_ts object to use to plot the factors. Use the  
           graphSubPlots method or the nb_graphSubPlotGUI.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_FACTOR_MODEL_GENERIC

► **plotForecast** ↑

```
plotter          = plotForecast(obj)  
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate,...  
                                         increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model
in the vector of nb_model_forecast objects

Input:

```
- obj  : A vector of nb_model_forecast objects  
  
- type : Type of plot, as a string;  
  
        > 'default'   : Plot the forcast for the last period of  
                      estimation and ahead. Possibly with density for
```

the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.

> 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.

- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

```
plotter = A nb_graph_data object. Use the graph method to produce the
figure, or the nb_graphPagesGUI class.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF ↑**

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound, ...
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest** ↑

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,nameValue)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_fmsa.monteCarloFiltering](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [plotPosterioriors](#) ↑

```
plotter = plotPosterioriors(obj)
plotter = plotPosterioriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.
- Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)
[nb_fmsa.getPosteriorDistributions](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

printed = printCov(obj)

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results** ↑

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_fmsa.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations** ↑

obj = removeObservations(obj,numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► set ↑

obj = set(obj,varargin)

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition ↑**

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects

- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.

```

- 'endDate'      : End date of the decomposition. As a string. If
                  different models has different frequency this date will
                  be converted.

- 'perc'         : Error band percentiles. As a 1 x numErrorBand double.
                  E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error
                  bands.

- 'method'       : The selected method to create error bands.
                  Default is ''. See help on the method input of the
                  nb_model_generic.parameterDraws method for more
                  this input. An extra option is:

> 'identDraws' : Uses the draws of the matrix with
                  the map from structural shocks to dependent variables.
                  See nb_var.set_identification. Of course this option
                  only makes sense for VARs identified with sign
                  restrictions.

- 'replic'        : The number of simulation for posterior, bootstrap and
                  MC methods. Default is 1. Only used when 'perc' is
                  provided.

Caution: Will not have anything to say for the method
          'identDraws'. See the option 'draws' of the
          method nb_var.set_identification for more.

- 'stabilityTest' : Give true if you want to discard the draws
                  that give rise to an unstable model. Default
                  is false.

- 'parallel'      : Give true if you want to do the shock decomp in
                  parallel. Default is false.

- 'fcstDB'        : An object of class nb_ts with the forecast to
                  decompose. must contain all model variables and
                  shocks/residuals, and must start the period after
                  the estimation/filtering end date or at the
                  estimation/filtering start date. See
                  the nb_model_generic.getForecast method.

- 'type'          : Choose 'updated' or 'smoothed'. 'smoothed' is
                  default.

- 'anticipationStartDate' : Start date of anticipating shocks. As a
                  string. If different models has different
                  frequency this date will be converted.

- 'model2'         : A struct with the solution of the second
                  model to use for decomposition.

- 'secondModelStartDate' : Start date of second model. As a string.
                  If different models has different frequency
                  this date will be converted.

```

Output:

- decomp : A structure of nb_ts objects with the shock

decomposition for each model.

- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

Inherited from superclass NB_MODEL_GENERIC

► **simulate ↑**

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.

```

> 'all'      : All variables are returned (but not
               the lags). Also including exogenous
               and shocks.

- 'parallel'   : Give true if you want to do the simulations in
                  parallel. I.e. spread models to different threads.
                  Default is false.

- 'parameterDraws' : Number of draws of the parameters. When set to 1
                     it will discard parameter uncertainty. Default is 1.

- 'regime'      : Select the regime you want to simulate. If empty
                  the simulation will switch between regimes. Only
                  an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations.
                  This will have no effect if the states input is
                  providing the full path of regimes. Default is 1.

- 'seed'         : Set simulation seed. Default is 2.0719e+05.

- 'startDate'    : Give the start date of the simulation. If not
                  provided the output will be a nb_data object
                  without a spesific start date (default). If
                  provided the output will be an object of class
                  nb_ts.

Caution : If dealing with break-points or exogenous
           time-varying parameters this input must be
           provided.

- 'startingValues' : Either a double or a char:

        > double       : A 1 x nVar double.

        > 'mean'       : Start from the mean of the data
                         observations. Default for all
                         model except nb_dsgc models.

        > 'steadystate' : Start from the steady state. For
                          now only an option for nb_dsgc
                          models. If you are dealing with a
                          MS-model you can indicate the
                          state by 'steadystate(state)'.
                          E.g. to start in state 1 give;
                          'steadystate(1)'. Default for
                          nb_dsgc models.

        > 'zero'        : Start from zero on all variables
                          (Except for the deterministic
                          exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws
                    that give rise to an unstable model. Default
                    is false.

- 'startingProb'  : Either a double or a char:

```

> double	: A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
> 'ergodic'	: Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```

[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)

```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
 - 'nLags' : Number of lags to compute when 'stacked' is set to true.
 - 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
 - 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
 - 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
 - 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.
- Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
 - 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
 - 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is

true.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_fmsa object(s).

Input:

- obj : A vector of nb_fmsa objects.

Output:

- obj : A vector of nb_fmsa objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_fmsa.solveNormal(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_fmsa.solveRecursive(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_fmsa.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template ↑**

```
options = nb_fmsa.template()
options = nb_fmsa.template(num)
```

Description:

Construct a struct which can be provided to the nb_fmsa class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions ↑**

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► testParameters ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

```
- obj : A scalar solved nb_model_generic object.  
  
- expression : A MATLAB expression as a string. Use parameter names as  
variables. See model.parameters.name.  
  
- method : A string with the method to use. For bootstrap method see  
nb_bootstrap. For bayesian models 'posterior' is the only  
option. Default is 'bootstrap' for classical models, while  
'posterior' is the default for bayesian models.  
  
- draws : Number of draws from the parameter distribution. Default  
is 1000.  
  
- alpha : Confidence level. Default is 0.05.  
  
- type : Type of test:  
    > '=' : Two sided test. expression == 0 (default)  
            For two-sided tests it is assumed that the  
            distribution is symmetric! Use  
            confidence/probability intervals instead.  
    > '>' : One sided test. expression > 0  
    > '<' : One sided test. expression < 0
```

Output:

```
- pval : > 'classical' : P-value of test.  
        > 'bayesian' : Probability of test.  
  
        A 1x1 double.  
  
- ci : A 1 x 2 double with the lower and upper bound of the  
confidence/probability interval of the tested expression.  
  
- dist : A nb_distribution object storing the distribution of the  
tested expression.
```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c] = theoreticalMoments(obj,varargin)
[m,c,ac1] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the

parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargout{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.

- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.

```
> {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object  
storing the numerically calculated  
forecast error variances/skewnesses.  
  
- plotter : A nb_graph_ts object which the method graph can be used to  
produce graphs.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_fmsa.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_fmsa.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► [update ↑](#)

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition ↑**

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.
Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double.

E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomposition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomposition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

■ nb_mfvar

Go to: [Properties](#) | [Methods](#)

A class for estimation and identification of mixed frequency VAR models.

Superclasses:

[nb_var](#), [nb_model_generic](#),

Constructor:

```
obj = nb_mfvar(varargin)
```

Optional input:

- See the set method for more on the inputs.
([nb_model_estimate.set](#))

Output:

- obj : A nb_mfvar object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#), [nb_mfvar.template](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [addAutoName](#)
- [block_exogenous](#)
- [exogenous](#)
- [options](#)
- [results](#)
- [addAutoNameIfLocal](#)
- [dependent](#)
- [factors](#)
- [parameters](#)
- [solution](#)
- [addID](#)
- [endogenous](#)
- [forecastOutput](#)
- [reporting](#)
- [transformations](#)
- [addIDIfLocal](#)
- [estOptions](#)
- [name](#)
- [residuals](#)
- [userData](#)

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[block_exogenous](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the block exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of block exogenous variables. To set it use the set function. E.g. obj = set(obj,'block_exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_VAR

- **[dependent](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgen models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **factors** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the factors, the tex_name holds the names in the tex format. The number field holds a double with the number of factors. To set it use the set function. E.g. obj = set(obj,'factors',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_VAR

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this property to be up to date!

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t$, $e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t$, $u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation. As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.

- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

► ABidentification ↑

```
S = nb_var.ABidentification(ident,A,sigma,maxDraws,draws,ask)
```

Description:

Identification of VAR model using combination of zero and sign restrictions. See Binning (2013), "Underidentified SVAR models: A framework for combining short and long-run restrictions with sign-restrictions". Many thanks to him for supplying help!

As a extension to Binning (2013) this code also allow for magnitude restrictions.

Input:

- ident : The identification assumption, as a struct. See set_identification method of the nb_var class for more
- A : Transition matrix
- sigma : Covariance matrix of the VAR residuals.
- maxDraws : The number of maximal rotations when looking for a identification satifying the sign restrictions. Can be set to inf. Default is 10000.

- draws : The number of wanted draws of the matrix of the map from structural shocks to dependent variables (C). Default is one.

Output:

- S : A nb_struct with field W, with the stored map from structural shocks to dependent variables.

Written by Kenneth Å!terhagen Paulsen,
Subfunctions of this code are written by Andrew Binning.

Inherited from superclass NB_VAR

► **appendData ↑**

obj = appendData(obj,DB)

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODELDATA

► **applyLongRunPriors** ↑

```
obj = applyLongRunPriors(obj,H,phi)
```

Description:

Apply priors for the long run as in Giannone et. al (2014).

If the prior field of the options property is not yet assign a prior, a jeffrey prior is used as default.

Caution: Please do not call this method before nb_var.setPrior!

Input:

- obj : A N x M matrix of nb_var objects, with nDep dependent variables.

- phi : Either a nDep x 1 double vector with the prior shrinkage parameter for each equation, or a m x 2 cell. m <= nDep. The format of the cell input must be as follows;

```
{'var1',1;'var2',0.5}
```

If some dependent variables are not assign any parameter the default is 1.

- H : A q x nDep matrix, where q <= nDep. Each row is the cointegration vector to apply on the prior. If q < nDep the null space will be applied to the rest of the rows.

Or it can be a q x 1 cellstr with the cointegration relations. Again q <= nDep, and if q < nDep the null space will be applied to the rest of the rows. Please note that only dependent variables may be applied in the cointegration relations! Example:

```
{'var1 - var2','var3 + var1'}
```

Output:

- obj : A N x M matrix of nb_var objects.

See also:

[nb_mfvar.set](#), [nb_mfvar.setPrior](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_VAR

► **assignParameters** ↑

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.

- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.

- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.

- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.

- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model have been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► assignTexNames ↑

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.
- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsgen.writeTex](#), [nb_dsgen.writePDF](#)

Written by Kenneth Åtterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► calculateMultipliers ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsgen.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!
- 'instrument' : A one line char with the name of the instrument. Must be provided!
- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!
- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.
- 'perc' : Error band percentiles. As a 1 x nPerc double. E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the double method on this output to convert it to a double matrix.

See also:

[nb_mfvar.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.

- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

obj = checkModel(obj)

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterior** ↑

[DB,plotter,pAutocorr] = checkPosterior(obj,varargin)

Description:

Plot posteriors draws in the order they were drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot. Default is 10.

- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.

- plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.

- pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursivly estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the

all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.
Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.

Caution : Posterior draws is already made at the estimation stage.

- 'nSteps' : Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB           = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...  
horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
           allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

Inherited from superclass NB_MODEL_GENERIC

► **constructScoreLowFreq ↑**

```
score = nb_mfvar.constructScoreLowFreq(forecastOutput,type,freq)
[score,start] = nb_mfvar.constructScoreLowFreq(forecastOutput,type,...  
    freq,highPeriod,allPeriods,startDate,endDate,...  
    rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_generic class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- freq : The frequency of the evaluated forecast. Only the variables observed at this frequency are evaluated.
- highPeriod : Give 0 to get the forecast when the data of low and high frequency is balanced, 1 if the high frequency data has one more observation, and so on. Default is 0.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.

- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

► **convert ↑**

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
- > third column : Any expression that can be interpreted by the nb_ts.createShift method.
- > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
  Name,      input,    shift,    description
  'VAR1_G',  'pcn(VAR1)', 'avg',   'VAR1 growth'
  'VAR2_G',  'pcn(VAR2)', 'avg',   'VAR2 growth'
  'VAR3_G',  'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

► **dieboldMarianoTest** ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold–Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.

- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_mfvar.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity ↑**

obj = doSimulateFromDensity(obj,draws)

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_mfvar.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► empiricalMoments ↑

```
[m,c] = empiricalMoments(obj,varargin)
[m,c,ac1] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_generic object. The options.data property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.

- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i},'y','x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i},'x','y')`. (This example only works if the output is of class nb_cs)

Inherited from superclass NB_MODEL_GENERIC

► **eq ↑**

`ret = eq(obj,other)`

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;
ind     = v(1) == v
```

See also:

isequal

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► estimate ↑

```
obj      = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

nb_model_generic, solve

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d,{'MSE'},0,1)
m = evalFcstAtDates(b,d,{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior** ↑

```
logPriorD = nb_model_generic.evaluatePrior(prior,par)
```

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsgc.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **filter** ↑

```
obj = filter(obj,varargin)
```

Description:

Filter the data with the mean parameter estimates. The default is to filter over the estimation sample, but it is possible to adjust the filtering sample by setting 'estim_start_date' and 'estim_end_date'.

Input:

- obj : An object of class nb_mfvar.

Optional input:

- 'waitbar' : Provide this one line char to make a waitbar when looping the method over different models.
- Given to the nb_model_estimate.set metod. See description on relevant options to adjust.

Output:

- obj : An object of class nb_mfvar, where the filtering results are stored in the results property.

See also:

[nb_model_generic.getFiltered](#)

Written by Kenneth Sæterhagen Paulsen

► **forecast** ↑

```
obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for foward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
 - 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
 - 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
 - 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error
- Only for density forecast:
- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.

- 'estDensity' : The method to estimate the density. As a string. Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
- 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density

```

forecast.

- 'method'
  : The selected method to create density forecast.
  Default is ''. See help on the method input of the
  nb_model_generic.parameterDraws method for more
  this input.

- 'bins'
  : The length of the bins og the domain of the density.
  Either;

    > []      : The domain will be found. See
      nb_getDensityPoints (default is that 1000
      observations of the density is stored).

    > integer : The min and max is found but the length
      of the bins is given by the provided
      integer.

    > cell     : Must be on the format:

      {'Var1',lowerLimit1,upperLimit1,binsL1;
       'Var2',lowerLimit2,upperLimit2,binsL2;
       ...}

      - lowerLimit1 : An integer, can be nan,
                     i.e. will be found.

      - upperLimit1 : An integer, can be nan,
                     i.e. will be found.

      - binsL1      : An integer with the
                     length of the bins. Can
                     be nan. I.e. bins length
                     will be adjusted to
                     create a domain of 1000
                     elements.

Caution : The variables not included will be given
          the default domain. No warning will be
          given if a variable is provided in the
          cell but not forecast by the model. (This
          because different models can forecast
          different variables)

Caution : The combineForecast method of the
          nb_model_group class is much faster if the
          lower limit, upper limit! Or else
          it must simulate new draws and do kernel
          density estimation for each model again
          with the shared domain of all models
          densities.

- 'startDate'
  : The start date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

Caution: If 'fcstEval' is not empty this will set
         the start date of the recursive forecast.
         Default is to start from the first possible

```

date.

- 'endDate' : The end date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is empty this input will have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.
If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))
If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided.

I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
 - If not provided. Model stds are used.

```

> Horizon          : Anticipated horizon of the
                     shocks/residual. 1 is default.

> Periods          : The active periods of the
                     shocks/residual. If nan, the
                     shocks/residual is active for
                     all periods. Must be given!

- 'kalmanFilter'   : Set to true to use a Kalman filter to do conditional
                     forecasting (on endogenous variables). Only
                     supported for the nb_var and nb_pitvar classes.

- 'sigma'           : A nCondVar*nSteps x nCondVar*nSteps double with the
                     correlation matrix of the endogenous variables to
                     condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix
of the multivariate distribution to draw the
endogenous variables from. As the endogenous
variables are autocorrelated all variables for all
periods must be drawn at the same time, using this
autocorrelation matrix.

- 'sigmaType'       : Type of correlation calculated. For more on this
                     input see nb_copula.type.

- 'output'          : Either 'endo' (default), 'fullendo' or 'all'. This
                     input indicates which variables to return the
                     simulation of.

    > 'endo'          : All the endogenous variables are
                     returned.

    > 'fullendo'       : All the endogenous variables are
                     returned included the lag variables.

    > 'full'            : All the variables are returned
                     included the lag variables. Also
                     including exogenous and shocks.

    > 'all'             : All variables are returned (but not
                     the lags). Including exogenous and
                     shocks.

- 'startingValues'  : Either a double or a char:

This option is mainly used for making simulations
from a model.

    > double            : A nPeriods x nVar or a 1 x nVar
                     double. nPeriods refer to the
                     number of recursive periods to
                     forecast.

    > 'mean'            : Start from the mean of the data
                     observations. Default.

    > 'steadystate'     : Start from the steady state. For

```

now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.

<ul style="list-style-type: none"> - 'startingProb' : Either a double or a char: 	<ul style="list-style-type: none"> > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
	<ul style="list-style-type: none"> > [] : If the model is filtered the starting value is calculated on filtered transition probabilities. Otherwise the ergodic mean is used.
	<ul style="list-style-type: none"> > double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
	<ul style="list-style-type: none"> > 'ergodic' : Start from the ergodic transition probabilities.
- 'stabilityTest'	: Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'states'	: Either an integer with the regime to forecast/simulate in, or an object of class nb_ts with the regimes to condition on. The name of the variable must be 'states'.
<i>Caution: For break-point models this is decided by the dates of the breaks, and cannot be set by this option!</i>	
- 'compareToRev'	: Which revision to compare to. Default is final revision, i.e. []. Give 5 to get fifth revision. must be an integer. Keep in mind that this number should be larger than the nSteps input.
- 'compareTo'	: Sometime you want to evaluate the forecast of one variable against another variable which is not part of the model. E.g. if you use the first release of a variable and want to compare it against the final release. To do this you can give a cellstr with size n x 2, where n is the number of variables to change the the actual observations to test against. {'VAR_1','VAR_FINAL',...}.

- 'estimateDensities' : true or false. true if you want to do a kernel density estimation of the density forecast.
- 'exoProj' : Tolerate missing exogenous variables by projecting them by a fitted model. Only when the 'condDB' input is empty!
 - Options are:
 - '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.
 - 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR coefficients as well.
- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.
- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan) .

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a $1 \times 2*N$ cell array. N is equal to the number of exogenous variables you extrapolate. An example `{'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}`. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when exoProj is set to 'AR'.

- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1×1 double value or a function handle to a probability distribution to draw from.
 - 'upper' : The upper bound of the selected variable. Either a 1×1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a $nVar \times nSteps$ double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1×1 double or a $nSteps \times 1$ double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs' : This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.
- 'foundReplic' : A struct with size $1 \times \text{parameterDraws}$. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.
- 'seed' : Set simulation seed. Default is 2.0719e+05.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_mfvar.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist ↑**

forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_mfvar.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the `nb_distribution.perc2ParamDist` function.

Input:

- `forecastOutput` : A `forecast` property of the `nb_model_forecast` class where the `forecastOutput.data` stores the forecast of the percentiles.
- `distribution` : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- `draws` : Number of draws to make from the estimated distributions.

Optional input:

- `'optimizer'` : See doc of the optimizer input to the `nb_callOptimizer` function. Default is '`fmincon`'.
- `'optimset'` : See doc of the `opt` input to the `nb_callOptimizer` function.

Output:

- `forecastOutput` : A struct on the same format as the `nb_model_forecast.forecastOutput` property

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
    nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [getActualLowFreq ↑](#)

```
actual = getActualLowFreq(obj,variable,freq,release,dates,nSteps)
```

Description:

Get the actual data of a low frequency variable to for example compare forecast to.

Input:

- obj : An object of class nb_mfvar
- variable : The variable to get the actual data on.
- freq : The low frequency to fetch.

- release : The releaseto return, empty or 0 will return the final (default).
- dates : A 1 x nDates cellstr array with the dates for where to split the history.
- nSteps : The number of steps of each split. Default is 1.

Output:

- actual : A nb_ts object with the wanted release, or if nargin > 3 a nb_data object with size nSteps x nVars x nDates.

Written by Kenneth Sæterhagen Paulsen

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provided recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default

is false.

- `recStart` : An object of class `nb_date` or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if `recursive` is set to true.

Output:

- `condDB` : As a `nb_ts` or `nb_data` object. Can be given as input to the `condDB` option of the `nb_model_generic.forecast` method.
- `obj` : An object of class `nb_model_generic`. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.`data` option may change.

► **getDSGEVARPriorMoments** ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by `nb_var.priorTemplate('dsge')`.

Input:

- `obj` : An object of class `nb_model_generic`.
- `dsgeVar` : A `nb_var` object set up with options for estimation of a DSGE-VAR.

Optional input:

- `'maxIter'` : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- `'tol'` : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

See also:

Inherited from superclass NB_MODEL_GENERIC

► **getDependent** ↑

```
dependent = getDependent(obj)
```

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getFiltered** ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables. I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsgen.filter](#), [nb_mfvar.estimate](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast ↑**

```
fcstData = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.
```

For real-time forecast the vintage at the time is returned as the historical data, when includeHist is true.

> 'horizon' : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.

If includeHist is true the actual data is added as an additional page of the nb_ts object.

```

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).

```

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with
 size nRec x nVars. While the fcstPercData output
 will be a nb_ts object with size nRec x nVars x nSim.
 You can set the horizon to return by the optional
 input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_mfvar.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastLowFreq ↑**

```

[fcstData,fcstDates]           = getForecastLowFreq(obj,freq)
[fcstData,fcstDates,fcstPercData] = getForecastLowFreq(obj,freq,...)
                                 outputType)
[fcstData,fcstDates,fcstPercData] = getForecastLowFreq(obj,freq,...)
                                 outputType,includeHist,variables)

```

Description:

Get the forecast at a low frequency as a nb_ts object.

Caution : In the case that low frequency variables are observed with
 one or more periods of data at a given recursion, these
 variables will be given nan for the number of extra periods of
 data for the given recursion.

Input:

- obj : An object of class nb_mfvar. Must have produced forecast.
- freq : The returned frequency of the forecast. Only the variables observed at this frequency are returned.
- outputType :
 - > 'recursive' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.
- > 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.
- includeHist : Give true (1) to include smoothed estimates of the history in the output. Only an option for the 'date' outputType. Default is false (0).
- variables : The variables to get the forecast of, as a cellstr. When this is given the original frequency of the variables are disregarded

Output:

- fcstData : See the input outputType
- fcstDates : The forecast dates for each variable, in the case that if the outputType is a date. Otherwise the start date of the forecast of all the variables for the given recursion.
- fcstPercData : See the input outputType

See also:

[nb_model_generic.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

► **getForecastVariables ↑**

`vars = getForecastVariables(obj)`

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getFrequency** ↑

```
freq = getFrequency(obj,date)
```

Description:

Get the frequency of the variables of the model.

Input:

- obj : A scalar object of class nb_mfvar.
- date : As the frequency may change for some variable, you can give a date to get the frequency at a given time. Default is to return the end frequency.

Output:

- freq : A 1 x nDep + nBlockExo double with the frequency of each dependent (nDep) and block exogenous variables (nBlockExo).
 - 1 : Yearly
 - 2 : Semi-annually
 - 4 : Quarterly
 - 12 : Monthly
 - 52 : Weekly

[nb_mfvar.setFrequency](#)

Written by Kenneth Sæterhagen Paulsen

► **getFrequencyStatic** ↑

```
[freq,date] = nb_mfvar.getFrequencyStatic(estOptions,dateInd)
```

Description:

Get the frequency of the variables of the model.

See also:

[nb_mfvar.getFrequency](#)

Written by Kenneth Sæterhagen Paulsen

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.
- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.
The same apply for real-time data.
- notSmoothed : Prevent getting history from smoothed estimates.
- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getIdentification** ↑

```
matrix = getIdentification(obj)
```

Description:

Get restrictions on the structural shock matrix, i.e C in the equation below:

$$y(t) = A*y(t-1) + B*x(t) + C*e(t), \text{ where } e(t) \sim N(0, I).$$

Input:

- obj : A identified scalar nb_var object.

Output:

- matrix : nEndo x nEndo cell array.

See also:

[nb_mfvar.set_identification](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_VAR

► [getIdentifiedResidual ↑](#)

```
residual = getIdentifiedResidual(obj)
```

Description:

Get identified residual from a estimated nb_var object

If we have a VAR it can be written as (dropping exogenous variables):

$$y_t = A*y_{t-1} + e_t$$

A identified VAR can be written as:

$$y_t = A*y_{t-1} + C*d_t$$

Therefore the identified residuals/shocks can be found as:

$$d_t = \text{inv}(C)*e_t$$

Caution: Will only return the residual that uses the full sample. I.e. when recursive estimation is done, only the residuals from the last estimation will be returned.

Input:

- obj : An object of class nb_var

Output:

```
- residual : A nb_ts object with the identified residual(s) stored.  
As a nobs x nEq x nIdent. Where nIdent is the number of  
identified C matrices, i.e. when the user have asked to  
identify more than one matrix (underidentification).
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► **getLHSVars** ↑

```
vars = getLHSVars(obj)  
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgen object only the observables are returned!

Input:

```
- obj : A scalar nb_model_generic object.  
- varsIn : The variables that can be found in the data of the model.  
If empty, they are found at obj.options.data.variables.
```

Caution: Only used in special cases.

Output:

```
- vars : A cellstr array with the variables of the model.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given
the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgen object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.

- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT ↑**

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)

- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:[nb_calculatePIT](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► getParameterDrawsMethods ↑

```
methods = parameterDraws(obj)
```

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getParameters ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.
- Optional input
 - varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).
 - : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
 - : Give 'double' to return the value as a numerical array.
 - : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [getPosteriorDistributions](#) ↑

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.
- Optitonal input:
 - 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

```
- distr      : A 1 x numCoeff nb_distribution object.  
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.  
  
Written by Kenneth SÃ¶terhagen Paulsen  
  
Inherited from superclass NB_MODEL_GENERIC
```

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

```
- obj : An object of class nb_model_generic
```

Output:

```
- residual : Either a nb_ts or a nb_cs object with predicted variable(s)  
           stored.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPriorDistributions** ↑

```
[distr,paramNames] = getPriorDistributions(obj)
```

Description:

Get prior distributions of B-VAR model.

Input:

```
- obj      : An object of class nb_var.
```

Output:

```
- distr      : A 1 x numCoeff nb_distribution object.  
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_VAR

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

See also:

[nb_graph_ts](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveScore** ↑

```
score          = getRecursiveScore(obj,type)  
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error

```

        - 'MEAN'   : Mean error
        - 'STD'    : Standard error of the forecast error
        - 'ESLS'   : Exponential of the sum of the log scores
        - 'EELS'   : Exponential of the mean of the log scores
        - 'MLS'    : Mean log score

- dim          : Either 'variables' to get the recursive scores of all
                  the variables forecast by a model (the obj input must
                  be a scalar object), or else the name of the variable
                  to get the score of (must be part of all models!).

- startDate    : The date to begin constructing the score. Can be
                  empty. Either as a string or an object of class
                  nb_date.

- endDate      : The date to end constructiong the score. Can be
                  empty. Either as a string or an object of class
                  nb_date.

- invert        : true | false. Default true. If true it will invert the
                  score for 'RMSE', 'MSE', 'MAE' and 'STD'.

```

Output:

```

- score     : A nb_ts object with size nPeriods x nVars x nHorizon if dim
               equal 'variables', else a nb_ts object with size nPeriods x
               nObj x nHorizon.

- plotter   : A nb_graph_ts object to plot the recursive scores. Use the
               graph method. One figure per horizon!

```

Written by Kenneth Åstrehagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual ↑**

```
residual = getResidual(obj)
```

Description:

Get residual from a estimated nb_model_generic object

Input:

```
- obj : An object of class nb_model_generic
```

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph ↑**

```
plotter = getResidualGraph(obj)
```

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which can you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames ↑**

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

roots = getRoots(obj)

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```

scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  

                  rollingWindow,lambda)

```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
 - type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- If the object input is a vector, the type input can also be a cellstr array with matching length.
- Caution: See comment to the invert input!
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
 - startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
 - endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
 - invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
 - rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the the full history at each recursive step.
 - lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

See also:

► **getScoreLowFreq ↑**

```
scores = getScore(obj,type,freq)
scores = getScore(obj,type,freq,highPeriod,allPeriods,startDate, ...
                  endDate,invert,rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation. Nowcast is not evaluated, in this case see [nb_mfvar.getForecastLowFreq](#)!

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- freq : The frequency of the evaluated forecast. Only the variables observed at this frequency are evaluated.
- highPeriod : Give 0 to get the forecast when the data of low and high frequency is balanced, 1 if the high frequency data has one more observation, and so on. Default is 0.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date. Must be on the frequency of the most

frequent data used.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date. Must be on the frequency of the most frequent data used.
- invert : false or true. Default is false. Default is to report the score so that high value means good model.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

[nb_model_group.combineForecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

► **getSolution ↑**

```
value = getSolution(obj,type)
```

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the 'varOfInterest' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the 'observables' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'. Only some specific class of models.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **grangerCausalityTest** ↑

```
[test,pval,results] = grangerCausalityTest(obj,precision)
```

Description:

Test for granger causality between variables using a joint F-test that all the parameters of the lags of a variable y is zero in the equation where x is the dependent variable. If the hypothesis can be rejected we say that y granger cause x.

Caution: If recursive estimation is done it will anyway only do the test using the parameters estimated over the full sample.

Input:

- obj : A 1 x 1 nb_var object
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : The test statistics. As a nDep x nDep double. The diagonal will return nan.
- pval : The p-value of the test statistics. As a nDep x nDep double. The diagonal will return nan.
- results : A string with the printed results of the test.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► graphCorrelation ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_mfvar.simulatedMoments](#), [nb_mfvar.theoreticalMoments](#)

`nb_mfvar.empiricalMoments`, `nb_graphPagesGUI`, `nb_graph_cs`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **handleCondInfo** ↑

`ret = handleCondInfo(obj)`

Description:

Check if a `nb_model_estimate` object handle conditional info.

Input:

- `obj` : A scalar `nb_model_etimate` object.

Output:

- `ret` : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

► **handleMissing** ↑

`ret = handleMissing(obj)`

Description:

Check if a `nb_model_estimate` object handle missing observations.

Input:

- `obj` : A scalar `nb_model_etimate` object.

Output:

- `ret` : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

► **help** ↑

```
helpText = nb_mfvar.help  
helpText = nb_mfvar.help(option)  
helpText = nb_mfvar.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **identDraws2Solutions** ↑

```
sol = identDraws2Solutions(obj)
```

Description:

This function assumes that you have used the set_identification function with the input 'type' set to 'combination'.

Input:

- obj : An object of class nb_var.

Output:

- sol : A struct storing the solution of the model. Same format as the solution property of the nb_var class.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_VAR

► **initialize** ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:**Input:**

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given,

otherwise this option does not apply.

- 'optimizer'
 - : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset'
 - : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel'
 - : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters'
 - : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.
- 'periods'
 - : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate'
 - : The start date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest'
 - : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch'
 - : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale'
 - : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights'
 - : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_mfvar.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf** ↑

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgc objects.
- 'compare' : Give true if you have a scalar nb_dsgc model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

```

- 'draws' : Number of draws for calculating girf. Default is
           1000. For Markov switching models this will set the
           number of simulated paths of states. For more see
           the 'type' input.

- 'factor' : A cell array with the factors to multiply the
             irf of the individual model variables.
             I.e. {'var1',100,...} or
                  {'var1','var2'},100,...}

If the string starts with a asterisk you will
multiply all the variables that contain that
string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This option sets the error band percentiles of the
               graph, when the 'perc' input is empty. As a 1 x
               numErrorBand double. E.g. [0.3,0.5,0.7,0.9].
               Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element
                  must be on the same format as obj.solution. I.e.
                  each element must be the solution of the model
                  given a set of drawn parameters. See the
                  parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from
                  this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

    > 'cumulative product' : cumprod(1 + X,1)

    > 'cumulative sum' : cumsum(X,1)

    > 'cumulative product (log)' : log(cumprod(1 + X,1))

    > 'cumulative sum (exponential)' : exp(cumsum(X,1))

    > 'cumulative product (%)' : cumprod(1 + X/100,1)

    > 'cumulative sum (%)' : cumsum(X/100,1)

    > 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))

    > 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))

    > '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
             Default is ''. See help on the method input of the
             nb_model_generic.parameterDraws method for more
             this input. An extra option is:

    > 'identDraws' : Uses the draws of the matrix with
                    the map from structural shocks to dependent

```

variables. See `nb_var.set_identification`. Of course this option only makes sense for VARs identified with sign restrictions.

- `'normalize'` : A 1 x 3 cell. First element must be the variable name as a string. The second element must be the value to normalize to, as an integer. While the third element is the period to be normalized, if set to `inf`, it will normalize the max impact period.
E.g. `{'Var',1,2}, {'Var',1,inf}`
Caution: 2 means observation 2 of the IRF, and as the IRF start at period 0, this means that observation 2 is period 1.
- `'normalizeTo'` : 'draws' or 'mean'. 'draws' normalize each draw of irfs, while 'mean' normalize the mean and scale percentiles/other draws accordingly. Default is 'draws'.
Caution: Setting this to 'mean' will not work for reported variables that is not measured as % deviation from steady-state/mean.
- `'newReplic'` : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the replic input.
- `'parallel'` : Give true if you want to do the irfs in parallel. This option will parallelize over models. Default is false.
- `'parallelL'` : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if `numel(obj) == 1`. Default is false.
- `'pause'` : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- `'perc'` : Error band percentiles. As a 1 x `numErrorBand` double. The input must be given as the coverage, and not the percentiles itself. E.g. `[0.3,0.5,0.7,0.9]`. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So `[0.3,0.5,0.7,0.9]` will get the percentiles `[5,15,25,35,65,75,85,95]`, i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- `'periods'` : Number of periods of the impulse responses.
- `'plotSS'` : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for `nb_dsg` objects.

```

- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the
initial steady state. Only an option if 'plotSS'
is set to true. Only for nb_dsg objects.

- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the
method 'identDraws'. See the option
'draws' of the method
nb_var.set_identification for more.

- 'settings' : Extra graphs settings given to nb_plots
function. Must be a cell.

- 'shocks' : Which shocks to create impulse responses of.
Default is the residuals defined by the first model.

For Markov switching or break point models it may
be wanted to only run a IRF when switching the
state. To do so set this option to {'states'}.
You should also set 'startingValues' to
'steadystate(r)', where r is the regime you start
in. For a Markov switching model also set
'startingProb' to the same r. This is only an
option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be
a vector of the same size as 'shocks' input.

- 'stabilityTest' : Give true if you want to discard the draws
that give rise to an unstable model. Default
is false.

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):
    > scalar : Select the the regime to take the
initial transition probabilities
from.

    > double : A draws x nRegime or a 1 x
nRegime double. draws refer to
the number set by the 'draws'
input.

    > 'ergodic' : Start from the ergodic transition
probabilities. Default for 'irf'.

    > 'random' : Randomize the starting values
using the simulated starting
points. Default for 'girf'.

- 'startingValues' : Either a double or a char:
    > double : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing

```

with a MS-model or a break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. For MS - models the default is the ergodic mean (default as long as 'girf' is not selected as 'type'), while for break-point models it is to start from the first regime.

```

> 'zero'          : Start from zero on all variables.

> 'random'        : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'         : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'           : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generalized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'   : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

- 'variables'       : The variables to create impulse responses of.
                     Default is the dependent variables defined by the
                     first model.

Caution: The variables reported by the reporting
          property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level
                     using the method specified by 'levelMethod'.

```

Output:

```

- irfs            : The (central) impulse response function stored in a
                     structure of nb_ts object. Each field stores the the
                     impulse responses of each shock. Where the variables
                     of the nb_ts object is the impulse responses of the
                     wanted endogenous variables.

                     I.e. the impuls responses to the shock 'E_X_NW' is
                     stored in irfs.('E_X_NW'). Which will then be a nb_ts
                     object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the
          responses from each model are saved as
          different datasets (pages) of the nb_ts object.

```

```

Caution: Each nb_model_generic object can have different
variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store
  a nb_ts object with the error bands of all variables. The
  pages of the nb_ts object is the percentiles (from lower
  to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter   : An object of class nb_graph_ts.

  > 'compareShocks' set to false (default)
    Use the graphSubPlots method or the
    nb_graphSubPlotGUI class to produce the graphs.

  > 'compareShocks' set to true
    Use the graphSubPlots method or the
    nb_graphSubPlotGUI class to produce the graphs.

- obj       : If the process has been paused, some temporary output will
  be stored in the object, and if you want to continue at a
  later stage you can take up from this point using this
  returned output. If not paused this output is empty.

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast ↑**

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isIdentified** ↑

```
ret = isIdentified(obj)
```

Description:

Is the nb_var object identified or not.

Input:

- obj : A nb_var object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_VAR

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

ret = isMixedFrequency(obj)

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

ret = isNB(obj)

Description:

This will return true for all objects except nb_dsg objects!

For nb_dsg objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

ret = isStateSpaceModel(obj)

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint prediction bands for macroeconomic risk management
 - > 'copula' : Using a copula likelihood approach.
 - > 'mostlik' : Group the paths based on how likely they are.
- 'nSteps' : Number of forecasting steps to use when constructing the error bands. If empty (default) all forecasting steps stored in the object is used.

Output:

- JPB : An nb_ts object storing the joint prediction bands. The percentiles are stored as datasets. See the dataNames property for which page represent which percentile.

The data of the nb_ts object has size nSteps x nVars x nPerc.
- plotter : A nb_graph_ts object. Use the graphSubPlots method to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior ↑**

posterior = loadPosterior(obj)

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_mfvar.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► mcfRestriction ↑

f = mcfRestriction(obj,type,restriction)

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use @(x)f1(x)&&f2(x), where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.

- type : The type of restriction. Either 'irf', 'corr' or 'cov'.

- restriction : Depends on the type input:

> 'irf' : A N x 4 cell, where the elements of each row are:
1. Name of the shock. 'E_X'
2. Name of the variable. 'X'
3. Horizon. E.g. 1 or 1:3.
4. Restriction. E.g. @(x)gt(x,0),
@(x)gt(x,0)||lt(x,1), i.e. a
function_handle that takes a scalar
double as input and a scalar logical as
output.

> 'rirf' : A N x 7 cell, where the elements of each

```

row are:
1. Name of the shock 1. 'E_X'
2. Name of the variable 1. 'X'
3. Horizon of variable 1. E.g. 1.
4. Name of the shock 2. 'E_Y'
5. Name of the variable 2. 'Y'
6. Horizon of variable 2. E.g. 2.
7. Restriction. E.g. @(x,y)gt(x,y),
@(x,y)gt(x-y,0)||lt(x-y,1), i.e. a
function_handle that takes a two scalar
double as inputs and a scalar logical
as output.

> 'corr' : A N x 4 cell, where the elements of each
row are:
1. Name of the first variable.
2. Name of the second variable.
3. Number of periods to lag the 2. variable.
4. Same as 4 for 'irf'.

E.g. {'Var1','Var1',1,@(x)gt(x,0.1)}, to
test a restriction on the autocorrelation
at lag for variable 'Var1'.

E.g. {'Var1','Var2',0,@(x)lt(x,0.1)}, to
test a restriction on the contemporaneous
correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to
test a restriction on the contemporaneous
variance.

> 'ss' : A N x 2 cell, where the elements of each
row are:
1. The expression using any of the
endogenous variables of the model.
2. Same as 4 for 'irf'.

```

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

[nb_mfvar.monteCarloFiltering](#), [nb_mfvar.irf](#)
[nb_mfvar.theoreticalMoments](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mincerZarnowitzTest** ↑

```
[test,pval,res] = mincerZarnowitzTest(obj,precision)
```

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_mfvar.uncondForecast](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

`nb_mfvar.assignParameters`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► `objective` ↑

```
fval = nb_mfvar.objective(par,indPar,beta,modelInfo,options,y,...  
                           observables)
```

Description:

The objective to minimize when doing estimation of a mixed frequency VAR.

Input:

- `par` : Current vector of the estimated parameters.
- `indPar` : Not needed. Just for generics.
- `beta` : Not needed. Just for generics.
- `model` : Not needed. Just for generics.
- `options` : The `obj.estOptions` property of the `nb_dsg` class.
(After calling `getEstimationOptions`, i.e. calling the `estimate` method.)
- `y` : A `nObservables` x `nPeriods` double with the data to estimate the model on. The data may contain missing observations.
- `z` : A `nExo` x `nPeriods` double with the data of the exogenous variables of the model.
- `observables` : Not needed. Just for generics.

Output:

- `fval` : Value of the objective at the given parameters.

See also:

`nb_mfvar.stateSpace`, `nb_kalmanlikelihood_missing`
`nb_model_generic.estimate`

Written by Kenneth Sæterhagen Paulsen

► `parameterDraws` ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'wildBlockBootstrap' : Create artificial data by wild overlapping random block length

bootstrap., and then "draw" parameters
 based on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'copulaBootstrap' : Uses a copula approach to draw residual
 that are autocorrelated, Does not handle
 heteroscedasticity. Only an option for
 models estimated with classical methods.

> 'posterior' : Posterior draws. Only for models
 estimated with bayesian methods.
 Default for models estimated with
 bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
 on this option.
- stable : Give true if you want to discard the parameter draws
 that give rise to an unstable model. Default is false.

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores available.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the draws input.

 Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.
- 'initialDraws' : When drawing parameters this factor decides how many many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
- > 'param' : Default. A struct with the following fields:
 - beta : A nPar x nEq x draws double with the estimated parameters.
 - sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:

```
lambda   : Estimated coefficients of the observation
            equation. As a nFac x nObservables x draws
            double.

R        : Estimated covariance matrix of the
            observation equation. As a nFac x nFac x
            draws double.

factors  : Draws of the factors as a T x nFac x
            draws double.

> 'solution' : Get the solution of the model for each draw from the
                distribution of parameters. The output will be a struct
                with size 1 x draws. The struct will have the same
                format as the solution property of the underlying
                object. I.e. only one output!

> 'object'   : Get the draws as a 1 x draws nb_model_generic object.
                Each element will be a model representing a given draw
                from the distribution of the parameters. I.e. only one
                output!
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + ( +/- nb_distribution.t_icdf(alpha/2)) * stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotForecast** ↑

```
plotter          = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
                                         increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forcast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity** ↑

```
plotter = plotForecastDensity(obj,date,variable)
```

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

```
plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastLowFreq** ↑

```
plotter = plotForecastLowFreq(obj,freq)
[plotter,plotFunction2Use] = plotForecastLowFreq(obj,freq,type,...)
                           startDate,highPeriod)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_generic objects

Input:

- obj : A vector of nb_mfvar objects.
- freq : The frequency of the forecast to plot. Only the variables observed at this frequency are plotted.
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced. Must be at the high frequency.
- highPeriod : Give 0 to get the forecast when the data of low and high frequency is balanced, 1 if the high frequency data has one more observation, and so on. Default is 0.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

► [plotMCF ↑](#)

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound, ...
                                    upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.

- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

► **plotMCFDistTest ↑**

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo

filtering.

- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues ↑**

plotter = nb_model_generic.plotMCFValues(paramD, params, nameValue)

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optitonal input:

- `'prior'` : Give this string as an input to compare posterior draws with the prior distributions (if available).
- `'updated'` : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- `'subplot'` : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- `'draws'` : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If `'updated'` is given as input, this will also set the the same options for the updated prior!

Output:

- `plotter` : A $1 \times \text{numCoeff}$ vector of objects of class `nb_graph_data`. Use either the `graph` method or the `nb_graphMultiGUI` class to plot the posteriors on screen.

Caution: If `'subplot'` is given it will return a scalar `nb_graph_data` object. Use the `graphSubPlots` method or the `nb_graphSubPlotGUI` class to plot the posteriors on screen.

► **plotPriors** ↑

```
plotter = plotPriors(obj,varargin)
```

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

► **priorTemplate** ↑

```
prior = nb_mfvar.priorTemplate()
prior = nb_mfvar.priorTemplate(type)
prior = nb_mfvar.priorTemplate(type, num)
```

Description:

Construct a struct which can be given to the method setPrior.

The structure provided the user the possibility to set different prior options.

Input:

- type : A string;
 - 'minnesotaMF' : Minnesota type prior options.
 - > 'a_bar_1' : Hyperparameter on own lags. Default is 0.5.
 - > 'a_bar_2' : Hyperparameter on other lags. Default is 0.5.
 - > 'a_bar_3' : Hyperparameter on other lags. Default is 100.
 - > 'ARcoeff' : Hyperparameter on first lag coefficient of each equation. Default is 0.9.
 - > 'coeff' : A N x 2 cell array with specific priors on some coefficients. In the first column you must provide the name of the coefficient, name of dependent + _ + name of rhs variable + lag specifier. E.g. 'Var1_Var1_lag1' or 'Var1_Var2'. In the last example Var2 is an exogenous variable. In the second column you give the prior value, as a scalar double.
 - > 'method' : Sets the method to use to draw from the posterior. Either 'default' (default) or any other string. 'default' uses (a fixed) covariance matrix of the shocks (i.e. the prior). Otherwise it also samples from the posterior distribution of the covariance matrix, as in the same way as in the case of the independent normal wishart (inwishart) prior. The 'burn', 'thin' and 'S_scale' options only applies to this last case.

```

> 'burn'      : How many draws that should be used as burn
in. Default is 500.

> 'thin'      : Every k draws are kept when doing gibbs.
This options sets k. Default is 2. Increase
this option to prevent autocorrelated
draws. See nb_model_generic.checkPosterior
to test for autocorrelated draws.

> 'S_scale'   : Prior scale of sigma, i.e. the covariance
matrix of the residuals. Default is 1.

> 'R_scale'   : Inverse prior scale of R, i.e. the covariance
matrix of the measurement errors. Default is
10. Default is to only used it for high
frequency variables, if series are measured
with more than one frequency. To apply it to
specific variables use a cell array. In the
first column you must provide the name of
dependent variable. E.g. 'Var1'. In the
second column you give the prior value,
as a scalar double. Full example
{'Var1',inf;'Var2',10}. Here you allow for no
measurement error in 'Var1', and some
measurement error in 'Var2'. All variables
not provided when a cell is used, are set to
inf.

The posterior is constructed by dividing the
variance of each series by the scaling
parameters.

> 'mixing'    : Set to 'low' to use the low frequency
observations when forming the prior of the
covariance matrix of the residuals. Only
in use if you have declared variables as
mixing. Default is to use the high frequency
variable ('high').

- 'nwishartMF' : Normal-Wishart prior options.

> 'V_scale'   : Scale of the prior of the variance of the
coefficients. Default is 10.

> 'S_scale'   : Prior scale of sigma, i.e. the covariance
matrix of the residuals. Default is 1.

> 'burn'      : How many draws that should be used as burn
in. Default is 500.

> 'thin'      : Every k draws are kept when doing gibbs.
This options sets k. Default is 2. Increase
this option to prevent autocorrelated
draws. See nb_model_generic.checkPosterior
to test for autocorrelated draws.

> 'R_scale'   : Inverse prior scale of R, i.e. the covariance
matrix of the measurement errors. Default is
10. Default is to only used it for high

```

frequency variables, if series are measured with more than one frequency. To apply it to specific variables use a cell array. In the first column you must provide the name of dependent variable. E.g. 'Var1'. In the second column you give the prior value, as a scalar double. Full example {'Var1',inf;'Var2',10}. Here you allow for no measurement error in 'Var1', and some measurement error in 'Var2'. All variables not provided when a cell is used, are set to inf.

The posterior is constructed by dividing the variance of each series by the scaling parameters.

- 'glpMF' : This is the prior used in the paper by Giannone, Lenza and Primiceri (2014) adapted to the mixed frequency setting. Cannot apply block exogenous variables with this prior.
- > 'ARcoeff' : Hyperparameter on first lag coefficient of each equation. Default is 0.9.
- > 'coeff' : See same options for the 'minnesota' prior.
- > 'lambda' : Hyperparameter that controls the overall tightness of this prior. Default is 0.2.
- > 'Vc' : Hyperparameter on exogenous variables. Default is 1e7.
- > 'S_scale' : Prior scale of prior on sigma. Default is 1, i.e. OLS.
- > 'burn' : How many draws that should be used as burn in. Default is 500.
- > 'thin' : Every k draws are kept when doing gibbs. This option sets k. Default is 2. Increase this option to prevent autocorrelated draws. See nb_model_generic.checkPosterior to test for autocorrelated draws.
- 'inwishartMF' : Independent Normal-Wishart prior options.
 - > 'V_scale' : Scale of the prior of the variance of the coefficients. Default is 10.
 - > 'S_scale' : Prior scale of sigma, i.e. the covariance matrix of the residuals. Default is 1.
 - > 'burn' : How many draws that should be used as burn in. Default is 500.
 - > 'thin' : Every k draws are kept when doing gibbs. This option sets k. Default is 2. Increase this option to prevent autocorrelated

draws. See nb_model_generic.checkPosteriors to test for autocorrelated draws.

> 'R_scale' : Inverse prior scale of R, i.e. the covariance matrix of the measurement errors. Default is 10. Default is to only used it for high frequency variables, if series are measured with more than one frequency. To apply it to specific variables use a cell array. In the first column you must provide the name of dependent variable. E.g. 'Var1'. In the second column you give the prior value, as a scalar double. Full example {'Var1',inf;'Var2',10}. Here you allow for no measurement error in 'Var1', and some measurement error in 'Var2'. All variables not provided when a cell is used, are set to inf.

The posterior is constructed by dividing the variance of each series by the scaling parameters.

- 'kkse' : This is the prior used in the paper by Koop and Korobilis (2014) extended by Schroder and Eraslan (2021) to handle mixed frequency, but adapted to the VAR setting.
- > 'f0VarScale' : Scale factor on the variance of the prior on the initial value of factors. Default is 10. N(0,f0VarScale*I)
- > 'lambda0VarScale' : Scale factor on the variance of the prior on the initial value of the factor loadings. Default is 1. N(0,lambdaVarScale*I). !!Remove!!
- > 'V0VarScale' : Scale factor on the mean of the prior on the initial value of the measurement equation covariance matrix. Default is 0.1. Dogmatic prior set to V0VarScale*I. !!Remove!!
- > 'Q0VarScale' : Scale factor on the mean of the prior on the initial value of the state equation covariance matrix. Default is 0.1. Dogmatic prior set to Q0VarScale*I.
- > 'gamma' : Hyperparameter on prior variance of the coefficients of the state equations. On the form $V(i,j) = \text{gamma} / (\text{ceil}(j/\text{options.nFactors})^2)$. Where V is a matrix with size option.nFactors x option.nLags*option.nFactors. Default value is 0.1.
- > 'l_1m' : Decay factor for the measurement error variance of the monthly variables. A

smaller value puts smaller weight on past observations and thus allows for faster parameter change. A value of 1 implies constant parameters. Default is 1. Do not adjust!

> 'l_1q' : Decay factor for the measurement error variance of the quarterly variables. A smaller value puts smaller weight on past observations and thus allows for faster parameter change. A value of 1 implies constant parameters. Default is 1. Do not adjust!

> 'l_2' : Decay factor for the factor error variance. A smaller value puts smaller weight on past observations and thus allows for faster parameter change. A value of 1 implies constant parameters. Default is 0.9.

> 'l_3' : Decay factor for the loadings' error variance. A smaller value puts smaller weight on past observations and thus allows for faster parameter change. A value of 1 implies constant parameters. Default is 1. Do not adjust!

> 'l_4' : Decay factor for the factor VAR parameters' error variance. A smaller value puts smaller weight on past observations and thus allows for faster parameter change. A value of 1 implies constant parameters. Default is 0.9.

> 'l_1_endo_update': Controls the endogenous forgetting factors
 1: l_1m and l_1q are time-varying/endogenous
 0: l_1m and l_1q are constant/static
 Default is 0. Do not adjust!

> 'l_2_endo_update': Controls the endogenous forgetting factors
 1: l_2 is time-varying/endogenous
 0: l_2 is constant/static
 Default is 0.

> 'l_3_endo_update': Controls the endogenous forgetting factors
 1: l_3 is time-varying/endogenous
 0: l_3 is constant/static
 Default is 0. Do not adjust!

> 'l_4_endo_update': Controls the endogenous forgetting factors
 1: l_4 is time-varying/endogenous
 0: l_4 is constant/static
 Default is 0.

- num : Number of prior templates to make.

Output:

- options : A struct.

See also:

[nb_mfvar](#), [nb_model_generic.checkPosteriors](#)

Written by Kenneth Sæterhagen Paulsen

► **removeObservations** ↑

obj = removeObservations(obj,numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set** ↑

obj = set(obj,varargin)

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **setFrequency** ↑

obj = setFrequency(obj, freq)

Description:

Set the frequency of the decleared dependent and/or block_exogenous variables of a formulated model.

Supported frequencies:

- 'yearly' : 1
- 'quarterly' : 4
- 'monthly' : 12
- 'weekly' : 52

Input:

- obj : An object of class nb_mfvar.
- freq : A cellstr on the format; {'Var1',1,'Var2',4}. There is no need to set the frequency of those variables that has the same frequency as the data (options.data)!

You can also declare that one variable change frequency using the syntax {'Var1',1,'Var2',{4,cDate,12}}. Here date must be a nb_date object or date string on the same frequency as the data property. It is interpreted as the variable 'Var2' has quarterly frequency until and including the date cDate, from there it has monthly frequency. See example NBTOOLBOX\... Examples\Econometrics\MixedFrequency\test_nb_mfvar_changeFreq.m

Output:

- obj : An object of class nb_mfvar where the frequency of a set of variables has been set. See the dependent and block_exogenous properties.

See also:

[nb_mfvar.setMapping](#)

Written by Kenneth Sæterhagen Paulsen

► [setMapping ↑](#)

obj = setMapping(obj,map)

Description:

Set the maping of the decleared dependent and/or block_exogenous variables of a formulated model. I.e. how to map the higher frequency to lower frequency in the observation equation.

See [setFrequency](#) for the supported frequencies.

Supported mappings (Examples are given for a mixed frequency VAR with monthly and quarterly data):

- 'levelSummed' : $Y(q) = Y(m) + Y(m-1) + Y(m-2)$
- 'diffSummed' : $Y(q) = Y(m) + 2*Y(m-1) + 3*Y(m-2) + 2*Y(m-3) + Y(m-4)$
- 'levelAverage' : $Y(q) = 1/3*(Y(m) + Y(m-1) + Y(m-2))$
- 'diffAverage' : $Y(q) = 1/3*Y(m) + 2/3*Y(m-1) + Y(m-2) + 2/3*Y(m-3) + 1/3*Y(m-4)$
- 'end' : $Y(q) = Y(m)$

The default mapping that is used for all series with lower frequency is 'diffAverage'.

Input:

- obj : An object of class nb_mfvar
- map : A cellstr on the format; {'Var1','levelSummed',...
'Var2','diffSummed'}

Output:

- obj : An object of class nb_mfvar where the mapping of a set of variables has been set. See the dependent and block_exogenous properties.

See also:

`nb_mfvar.setFrequency`

Written by Kenneth Sæterhagen Paulsen

► **setMeasurementEqRestriction** ↑

`obj = setMeasurementEqRestriction(obj, restrictions)`

Description:

Add restrictions in the measurement equation of the model on the form;

`restricted = parameters*variables'`

e.g.

`X = [0.5,0.5]*[Y;Z]`

where X is a observed variable, while Y and Z are state variables.
So for a mixed frequency var, X and Y must be included in the state equation. An error is provided if this is not the case!

For the xxxMF priors this information is taken into account, otherwise it will only be used during conditional forecasting, i.e. the measurement restrictions will be appended to the solution after estimation is done.

See `nb_var.priorTemplate` for more on the supported priors.

Input:

- obj : An object of class nb_var
- restrictions : A struct array with fields
 - > 'restricted' : A one line char with the variable to restrict. It must be a dependent variable or block exogenous variable.
 - > 'parameters' : A cellstr with the names of the variables storing the parameters of the

restriction, or a double array. Must have same length as 'variables'.
 > 'variables' : A cellstr with the names of the variables included in the restriction.
 > 'frequency' : Set to the frequency of the observables. This is only important for the mixed frequency VAR model. Give [], if the restriction is on the same frequency as the data. Either 1 (yearly), 4 (quarterly) or 12 (monthly).
 > 'mapping' : Sets the mapping to use for this restricted variable. See the method nb_mfvar.setMapping for more on the mappings to choose from.
 > 'R_scale' : Inverse prior scale of the variance of the measurement error of this restrictions.

The variance of the measurement error is constructed by dividing the variance of each 'restricted' variable by this scaling parameter.

Output:

- obj : An object of class nb_var where the measurement equation restrictions are added.

► **setMixing** ↑

obj = setMixing(obj,mixing)

Description:

Set the mixing of the decleared dependent and/or block_exogenous variables of a formulated model, i.e. if some of the dependent variables represents the same variable, but with different frequencies.

See [setFrequency](#) for the supported frequencies.

Input:

- obj : An object of class nb_mfvar
- mixing : A cellstr on the format; {'Var1_Q','Var1_M',... 'Var2_Q','Var2_M'}. For more see [nb_mfvar.help\('mixing'\)](#).

Output:

- obj : An object of class nb_mfvar where the mixing of a set of variables has been set. See the dependent and block_exogenous properties.

See also:

[nb_mfvar.setFrequency](#)

Written by Kenneth Sæterhagen Paulsen

► **setPrior** ↑

obj = setPrior(obj,prior)

Description:

Set priors of a vector of nb_var objects. The prior input must either be a struct or nb_struct with same size as obj or have size 1.

The provided struct will be added to the property options as the field prior.

See nb_var.priorTemplate for the format of the struct.

Caution : The estim_method field of the option property will automatically be set to 'bvar'.

Caution : Not yet supported for the subclass nb_favar!

Input:

- obj : A vector of nb_var objects
- prior : A struct or nb_struct with either matching numel of obj or size 1. If size is 1 all models gets the same prior settings.

Output:

- obj : A vector of nb_var objects with the priors set.

See also:

[nb_var.priorTemplate](#)

Written by Kenneth Sæterhagen Paulsen

► **set_identification** ↑

```
obj = set_identification(obj,type,varargin)
```

Description:

Identify a VAR model. Either using cholesky restrictions or combinations of sign and zero restrictions (short, mid and long term).

The method solve must be called after adding the identifying restrictions

See Andrew Binning (2013), "Underidentified SVAR models: A framework for combining short and long-run restrictions with sign-restrictions". This code is an adaption of his code to the NBToolbox, except that also magnitude restriction is possible using this code.

Input:

- obj : A vector of nb_var objects, or subclasses of this class.
- type : Either 'cholesky' or 'combination'
- varargin (Optional inputs) :
 - > 'cholesky' :
 - 'ordering' : A cellstr with the ordering of the identification. Default is to use the ordering of the dependent variables of the model. The ordering is so that the first variable is the variable that is only influenced by one shock in period 1, the second variable is the variable that is influenced by two shock in period 1, and so on.
 - Caution : All variables of the VAR must be included in this option.
 - > 'combination' :
 - 'maxDraws' : The number of maximal rotations when looking for a identification satifying the sign restrictions. Can be set to inf. Default is 10000.
 - 'draws' : The number of wanted draws of the matrix of the map from structural shocks to dependent variables (C). Default is one.

Caution : When it comes to producing IRFs with sign restrictions you have two options. The first is to set 'draws' to a large number, say 1000, and then produce irf for each of those draws. The second approach is to draw parameters using bootstrap, MC methods or from the posterior, and then to make one draw of the C for each draw of the paramters.

```

- 'restrictions' : A nRestriction x 4 cell;
    {Dep,Shock,period,type,value;...}

    > Dep      : The dependent variable to add the
                  restriction to. As a string.

    > Shock    : The name of the identified structural
                  shock. As a string.

    > period   : The period of the restriction, as a
                  double. For on impact set 0 and for
                  cumulative restriction set it to inf.

    Use s:e to add a restriction on the
    cumulative contribution of a shock
    to a variable starting at s and
    ending at e. E.g. 0:10.

    > type     : Either 0 for zero restriction,
                  '+/-' for sign restrictions or
                  '>/<' for magnitude restrictions.

    Or 'none' : If you want to add a
                structural shock with no restriction,
                as you already have exactly
                N-1 shocks.

    > value    : A 1x1 double with the value of the
                  magnitude restriction.

```

Output:

- obj : Identified nb_var objects. See the property field identification of the property solution.

Examples:

See ...\\Econometrics\\test\\test_nb_var

Written by Kenneth Återhagen Paulsen
Subfunctions are written by Andrew Binning 2013

Inherited from superclass NB_VAR

► **shock_decomposition ↑**

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the

method nb_var.set_identification for more.

- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.
- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

[nb_mfvar.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [simulate ↑](#)

out = simulate(obj,nSteps,varargin)

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
 - 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e.

each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.
- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.
- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a spesific start date (default). If provided the output will be an object of class

nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:

> double : A 1 x nVar double.

> 'mean' : Start from the mean of the data observations. Default for all model except nb_dsge models.

> 'steadystate' : Start from the steady state. For now only an option for nb_dsge models. If you are dealing with a MS-model you can indicate the state by 'steadystate(state)'. E.g. to start in state 1 give; 'steadystate(1)'. Default for nb_dsge models.

> 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

- 'startingProb' : Either a double or a char:

> double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.

> 'ergodic' : Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments ↑**

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.
- Optional inputs;
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find

```
cov(x,y(-i)) you can use  
getVariable(varargin{i},'y','x'),  
while to get cov(x(-i),y) (== cov(x,y(+i))) you  
can use getVariable(varargin{i},'x','y'). (This  
example only works if the output is of class nb_cs)
```

► **solve** ↑

```
obj = solve(obj)
```

Description:

Solve estimated model(s) represented by nb_mfvar object(s).

Input:

- obj : A vector of nb_mfvar objects.

Output:

- obj : A vector of nb_mfvar objects, where the solved model(s) is/are stored in the property solution.

See also:

```
tempSol = nb_mfvar.solveRecursive(results,opt,ident)
```

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **stateSpace** ↑

```
[x0,P0,d,H,R,T,c,A,B,Q,G,obs,failed] = nb_mfvar.stateSpace(par,nDep,...  
nLags,nExo,restr,restrVal,measErrInd,...  
H,stabilityTest)
```

Description:

Returns a state-space representation of an MF-VARX(nLags) model.

Observation equation:

$y = d + Hx + Tz + v, \quad v \sim N(0, R)$

State equation:

$x = c + Ax_{-1} + Gz + Bu, \quad u \sim N(0, I)$

Input:

- par : The parameter vector of the VARX model.

Order:

- constant
- exogenous
- lagged endogenous
- residual std
- measurement error std

- nDep : The number of dependent variables of the model.
- nLags : The number of lags of the VAR (of the highest frequency).

Caution : The state-space representation may be bigger due the measurement equation.
- constant : Include constant or not. true or false.
- nExo : Number of exogenous variables included in the model.
- restr : A nDep x nDep*nLags logical matrix. true fro the non-restricted parameters.
- restrVal : Values of the restricted parameters.
- measErrInd : The index of the measurement error std to estimate. If empty no measurement errors are allowed.
- H : The matrix of the measurement equation.
- stabilityTest : Check stability of system. Sets failed to true if model is not stationary. Default is false.

Output:

- x0 : Initial state vector.
- P0 : Initial variance.
- See equation above
- obs : Index of observables in the state vector.
- failed : See stabilityTest input.

See also:

[nb_kalmanlikelihood_missing](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **struct ↑**

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_mfvar.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

```
options = nb_mfvar.template()
options = nb_mfvar.template(num)
```

Description:

Construct a struct which can be provided to the nb_mfvar class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

```

- obj : A nb_model_forecast object with density forecast

- restrictions : Restrictions as a n x 3 cell array,
    {variable, date, test}.

    > variable : The variable(s) to test,
        as a string or cell array of strings.

    > date : The date as a string. If a cell array is given, a
        copy of the restriction will be made for every given
        date.

    > test : Restriction test as a function handle. The value(s)
        of the variable(s) in 'variable' at time 'date' are
        passed as arguments. Should return a logical.

```

Output:

- out : A double with the probability

Example:

```

restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...
    {'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};
probability = model.testForecastRestrictions(restrictions);

```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

```

- obj : A scalar solved nb_model_generic object.

- expression : A MATLAB expression as a string. Use parameter names as
    variables. See model.parameters.name.

```

```

- method      : A string with the method to use. For bootstrap method see
               nb_bootstrap. For bayesian models 'posterior' is the only
               option. Default is 'bootstrap' for classical models, while
               'posterior' is the default for bayesian models.

- draws       : Number of draws from the parameter distribution. Default
               is 1000.

- alpha       : Confidence level. Default is 0.05.

- type        : Type of test:
               > '=' : Two sided test. expression == 0 (default)
               For two-sided tests it is assumed that the
               distribution is symmetric! Use
               confidenc/probabillty intervals instead.
               > '>' : One sided test. expression > 0
               > '<' : One sided test. expression < 0

```

Output:

```

- pval        : > 'classical' : P-value of test.
               > 'bayesian'  : Probabilty of test.

               A 1x1 double.

- ci          : A 1 x 2 double with the lower and upper bound of the
               confidence/probabillty interval of the tested expression.

- dist        : A nb_distribution object storing the distribution of the
               tested expression.

```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► **theoreticalMoments** ↑

```

[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)

```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation,
autocovariance/autocorrelation.

Caution : For recursivly estimated model only the full sample estimation
results is used.

Caution : Only supported for models that can be solved in the following
way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.
- Optional inputs;
- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.
Can also be a cellstr, with a subset of variables from 'full'.
- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargout{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

► uncertaintyDecomposition ↑

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the

percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).

> 'fev'	: Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc'	: At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages'	: Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_mfvar.forecast](#)

Written by Kenneth Åstterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_mfvar.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► [update](#) ↑

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► variance_decomposition ↑

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.
Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
> 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent

variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.

- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomposition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomposition for each model. For each percentiles the output is as decomp.

- `plotter` : A 1 x nModel vector of nb_graph_cs objects. Use the `graph` method or the nb_graphPagesGUI class to produce the graphs.
- `plotterBands`: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the `graphSubPlots` method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

■ nb_midas

Go to: [Properties](#) | [Methods](#)

A class for estimation of MIDAS (MIxed frequency DAta Sampling) models.

$y(tq+hq) = \lambda y(tq) + F(x(tm), x(tm-1), \dots, p) + e$

Where $x(tm)$ are lagged exogenous variables of the model at high frequency, and y is the dependent variable of the model.

Superclasses:

[nb_model_generic](#)

Constructor:

`obj = nb_midas(varargin)`

Optional input:

- See the `set` method for more on the inputs.
([nb_model_estimate.set](#))

Output:

- `obj` : An nb_midas object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#), [nb_midas.help](#), [nb_midas.template](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- | | | | | |
|----------------------------|-----------------------------------|--------------------------|-------------------------------|--------------------------|
| • <code>addAutoName</code> | • <code>addAutoNameIfLocal</code> | • <code>addID</code> | • <code>addIDIfLocal</code> | • <code>dependent</code> |
| • <code>endogenous</code> | • <code>estOptions</code> | • <code>exogenous</code> | • <code>forecastOutput</code> | • <code>name</code> |
| • <code>options</code> | • <code>parameters</code> | • <code>reporting</code> | • <code>residuals</code> | • <code>results</code> |
| • <code>solution</code> | • <code>transformations</code> | • <code>userData</code> | | |

- **addAutoName** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addAutoNameIfLocal** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgc models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input

variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.

- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.

- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.

- F : See the equation above. A nobs x nExo double. (Storing the impact of exogenous terms of the observation equation)

- G : See the equation above. A nobs x nfact double.

- observables : A 1 x nobs cellstr with the declared observable variables.

- R : Variance/covariance matrix of the residuals/shocks of the observation equation. As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.

- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.

- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use;

methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

► **`appendData`** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters ↑**

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.

- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!

- 'instrument' : A one line char with the name of the instrument. Must be provided!

- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!

- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.

- 'perc' : Error band percentiles. As a 1 x nPerc double.
E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will
be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the
double method on this output to convert it to a double
matrix.

See also:

[nb_midas.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws
(bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see
[nb_bootstrap](#). For bayesian models 'posterior' is the only
option. Default is 'bootstrap' for classical models, while
'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is
1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property
is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterioriors** ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optional input:

- `'nLags'` : Number of lags to include in the autocorrelation plot. Default is 10.
- `'iter'` : The recursive iteration date. Either as a string or a `nb_date` object. If recursive estimation is done, this input must be provided.

Output:

- `DB` : A `nb_data` object with size `nDraws x numCoeff`.
- `plotter` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.
- `pAutocorr` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.

Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods. Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
                    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

[nb_model_forecast.getScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [convert ↑](#)

`obj = convert(obj,freq,method,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convert`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convert`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► [convertEach ↑](#)

`obj = convert(obj,freq,methods,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

See also:

[nb_ts.convert](#)

Inherited from superclass `NB_MODELDATA`

► `createVariables` ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM `nb_modelData` object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.

> third column : Any expression that can be interpreted by the `nb_ts.createShift` method.

> fourth column : Comments

- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name,    input,    shift,    description
  'VAR1_G',    'pcn(VAR1)', 'avg',    'VAR1 growth'
  'VAR2_G',    'pcn(VAR2)', 'avg',    'VAR2 growth'
  'VAR3_G',    'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► dieboldMarianoTest ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

► **doForecastPerc2Dist ↑**

```
obj = doForecastPerc2Dist(obj,draws)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

`nb_midas.forecast`, `nb_distribution.perc2ParamDist`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity** ↑

`obj = doSimulateFromDensity(obj, draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `obj` : A `nb_model_forecast` object.
- `draws` : Number of draws to use for simulation.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_model_generic.forecast`, `nb_midas.simulateFromDensity`

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass `NB_MODEL_FORECAST`

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_generic` object. The `options.data` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

See also:

[nb_midas.graphCorrelation](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj          = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default

is to open max number of cores available. Only an option if 'parallel' is given.

- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_model_generic](#), [solve](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecast** ↑

```
obj          = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for forward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters

for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
 - 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.
- If set to empty, all simulations will be returned.
- Caution: 'draws' must be set to produce density forecast.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

```

- 'bins'      : The length of the bins og the domain of the density.
  Either;
    > []       : The domain will be found. See
      nb_getDensityPoints (default is that 1000
      observations of the density is stored).
    > integer   : The min and max is found but the length
      of the bins is given by the provided
      integer.
    > cell       : Must be on the format:
      {'Var1',lowerLimit1,upperLimit1,binsL1;
       'Var2',lowerLimit2,upperLimit2,binsL2;
       ...}
    - lowerLimit1 : An integer, can be nan,
      i.e. will be found.
    - upperLimit1 : An integer, can be nan,
      i.e. will be found.
    - binsL1      : An integer with the
      length of the bins. Can
      be nan. I.e. bins length
      will be adjusted to
      create a domain of 1000
      elements.

  Caution : The variables not included will be given
            the default domain. No warning will be
            given if a variable is provided in the
            cell but not forecast by the model. (This
            because different models can forecast
            different variables)

  Caution : The combineForecast method of the
            nb_model_group class is much faster if the
            lower limit, upper limit! Or else
            it must simulate new draws and do kernel
            density estimation for each model again
            with the shared domain of all models
            densities.

- 'startDate'   : The start date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

  Caution: If 'fcstEval' is not empty this will set
            the start date of the recursive forecast.
            Default is to start from the first possible
            date.

- 'endDate'     : The end date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

  Caution: If 'fcstEval' is empty this input will

```

have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous

variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
If not provided. Model stds are used.
 - > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
 - > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for

all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.
- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime

is not given, you will start in
 the ergodic steady-state for
 MS-model, and in the last regime
 for break-point models.

- 'startingProb' : Either a double or a char:
 > 'zero' : Start from zero on all variables
 (Except for the deterministic
 exogenous variables)

> [] : If the model is filtered the
 starting value is calculated
 on filtered transition
 probabilities. Otherwise the
 ergodic mean is used.

> double : A nPeriods x nRegime or a 1 x
 nRegime double. nPeriods refer to
 the number of recursive periods to
 forecast.

> 'ergodic' : Start from the ergodic transition
 probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws
 that give rise to an unstable model. Default
 is false.

- 'states' : Either an integer with the regime to
 forecast/simulate in, or an object of class nb_ts
 with the regimes to condition on. The name of the
 variable must be 'states'.

Caution: For break-point models this is decided by
 the dates of the breaks, and cannot be set
 by this option!

- 'compareToRev' : Which revision to compare to. Default is final
 revision, i.e. []. Give 5 to get fifth revision.
 must be an integer. Keep in mind that this number
 should be larger than the nSteps input.

- 'compareTo' : Sometime you want to evaluate the forecast of one
 variable against another variable which is not
 part of the model. E.g. if you use the first release
 of a variable and want to compare it against the
 final release. To do this you can give a cellstr
 with size n x 2, where n is the number of variables
 to change the the actual observations to test
 against. {'VAR_1','VAR_FINAL',...}.

- 'estimateDensities' : true or false. true if you want to do a
 kernel density estimation of the density
 forecast.

- 'exoProj' : Tolerate missing exogenous variables by projecting
 them by a fitted model. Only when the 'condDB'
 input is empty!

Options are:

- '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.
- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.
- 'exProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.
- 'exProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.
- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.
- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.
- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example

{'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when `exoProj` is set to 'AR'.

- 'bounds'
: A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps` double matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a 1x1 double or a `nSteps x 1` double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs'
: This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.

- 'foundReplic'
: A struct with size `1 x parameterDraws`. Each element must be on the same format as `obj.solution`. I.e. each element must be the solution of the model given a set of drawn parameters. See the `parameterDraws` method of the `nb_model_generic` class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.

```
- 'seed' : Set simulation seed. Default is 2.0719e+05.
```

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_midas.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_midas.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
    nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getCondDB ↑

[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments ↑**

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Inherited from superclass NB_MODEL_GENERIC

► **getDependent ↑**

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getFiltered ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables. I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_midas.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast** ↑

```
fcstData          = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();
```

```

    end

> 'date'      : A string or a nb_date object with the date of the
                 wanted forecast. E.g. '2012Q1'. The fcstData will
                 be a nb_ts object with size nHor x nVar x nPerc + 1,
                 while fcstPercData will be empty. nPerc will then be
                 the number of percentiles/simualtions. Mean will be at
                 last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'   : This option will return the forecast as a
                 nPeriods + nHor x nVar x nHor nb_ts object. This
                 option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).

```

Optional inputs:

```

> 'horizon'   : The fcstData output will be a nb_ts object with
                 size nRec x nVars. While the fcstPercData output
                 will be a nb_ts object with size nRec x nVars x nSim.
                 You can set the horizon to return by the optional
                 input 'horizon'. See the 'timing' option also.

```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_midas.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► [getForecastVariables ↑](#)

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_midas object, subclass of the nb_model_generic class.
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables is found.
- date : For recursive real-time estimated models the history may change. This will give the correct vintage for a given recursion.
- notSmoothed : Just for generics. Not in use for the nb_midas class.
- type : Just for generics. Not in use for the nb_midas class.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsg object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```

pit                  = getPIT(obj)
[pit,plotter]       = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)

```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

nb_calculatePIT

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

```
methods = parameterDraws(obj)
```

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the

```
parameter values ('struct' is not supported if
numel(obj) > 1).

: Give 'headers' to add model names as headers for each
column of the return cell. Only if numel(obj) > 1.

: Give 'double' to return the value as a numerical array.

: Give 'skipBreaks' to not remove any break-point parameters.
```

Output:

- p : See the type input.

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base
the kernel estimation on, if empty all draws are used for
estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.

- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted ↑**

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph ↑**

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

► **getRecursiveScore** ↑

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

```
residual = getResidual(obj)
```

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph** ↑

```
plotter = getResidualGraph(obj)
```

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);
plotter.graphInfoStruct();
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames** ↑

residualNames = getResidualNames(obj)

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

roots = getRoots(obj)

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursivly estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.
- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
 - type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- If the object input is a vector, the type input can also be a cellstr array with matching length.
- Caution: See comment to the invert input!
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
 - startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
 - endDate : The date to end constructiong the score. Can be

empty. Either as a string or an object of class nb_date.

- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

► **getSolution** ↑

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_midas.simulatedMoments](#), [nb_midas.theoreticalMoments](#)
[nb_midas.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **help ↑**

```
helpText = nb_midas.help
helpText = nb_midas.help(option)
helpText = nb_midas.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize ↑**

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:**Input:**

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given,

otherwise this option does not apply.

- 'optimizer'
 - : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset'
 - : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel'
 - : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters'
 - : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.
- 'periods'
 - : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate'
 - : The start date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest'
 - : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch'
 - : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale'
 - : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights'
 - : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_midas.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf** ↑

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgc objects.
- 'compare' : Give true if you have a scalar nb_dsgc model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

```

- 'draws' : Number of draws for calculating girf. Default is
           1000. For Markov switching models this will set the
           number of simulated paths of states. For more see
           the 'type' input.

- 'factor' : A cell array with the factors to multiply the
             irf of the individual model variables.
             I.e. {'var1',100,...} or
                  {'var1','var2'},100,...}

If the string starts with a asterisk you will
multiply all the variables that contain that
string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This option sets the error band percentiles of the
               graph, when the 'perc' input is empty. As a 1 x
               numErrorBand double. E.g. [0.3,0.5,0.7,0.9].
               Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element
                  must be on the same format as obj.solution. I.e.
                  each element must be the solution of the model
                  given a set of drawn parameters. See the
                  parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from
                  this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

    > 'cumulative product' : cumprod(1 + X,1)

    > 'cumulative sum' : cumsum(X,1)

    > 'cumulative product (log)' : log(cumprod(1 + X,1))

    > 'cumulative sum (exponential)' : exp(cumsum(X,1))

    > 'cumulative product (%)' : cumprod(1 + X/100,1)

    > 'cumulative sum (%)' : cumsum(X/100,1)

    > 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))

    > 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))

    > '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
             Default is ''. See help on the method input of the
             nb_model_generic.parameterDraws method for more
             this input. An extra option is:

    > 'identDraws' : Uses the draws of the matrix with
                    the map from structural shocks to dependent

```

variables. See `nb_var.set_identification`. Of course this option only makes sense for VARs identified with sign restrictions.

- `'normalize'` : A 1 x 3 cell. First element must be the variable name as a string. The second element must be the value to normalize to, as an integer. While the third element is the period to be normalized, if set to `inf`, it will normalize the max impact period.
E.g. `{'Var',1,2}, {'Var',1,inf}`
Caution: 2 means observation 2 of the IRF, and as the IRF start at period 0, this means that observation 2 is period 1.
- `'normalizeTo'` : 'draws' or 'mean'. 'draws' normalize each draw of irfs, while 'mean' normalize the mean and scale percentiles/other draws accordingly. Default is 'draws'.
Caution: Setting this to 'mean' will not work for reported variables that is not measured as % deviation from steady-state/mean.
- `'newReplic'` : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the replic input.
- `'parallel'` : Give true if you want to do the irfs in parallel. This option will parallelize over models. Default is false.
- `'parallelL'` : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if `numel(obj) == 1`. Default is false.
- `'pause'` : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- `'perc'` : Error band percentiles. As a 1 x `numErrorBand` double. The input must be given as the coverage, and not the percentiles itself. E.g. `[0.3,0.5,0.7,0.9]`. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So `[0.3,0.5,0.7,0.9]` will get the percentiles `[5,15,25,35,65,75,85,95]`, i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- `'periods'` : Number of periods of the impulse responses.
- `'plotSS'` : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for `nb_dsg` objects.

```

- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the
initial steady state. Only an option if 'plotSS'
is set to true. Only for nb_dsg objects.

- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the
method 'identDraws'. See the option
'draws' of the method
nb_var.set_identification for more.

- 'settings' : Extra graphs settings given to nb_plots
function. Must be a cell.

- 'shocks' : Which shocks to create impulse responses of.
Default is the residuals defined by the first model.

For Markov switching or break point models it may
be wanted to only run a IRF when switching the
state. To do so set this option to {'states'}.
You should also set 'startingValues' to
'steadystate(r)', where r is the regime you start
in. For a Markov switching model also set
'startingProb' to the same r. This is only an
option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be
a vector of the same size as 'shocks' input.

- 'stabilityTest' : Give true if you want to discard the draws
that give rise to an unstable model. Default
is false.

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):

    > scalar : Select the the regime to take the
initial transition probabilities
from.

    > double : A draws x nRegime or a 1 x
nRegime double. draws refer to
the number set by the 'draws'
input.

    > 'ergodic' : Start from the ergodic transition
probabilities. Default for 'irf'.

    > 'random' : Randomize the starting values
using the simulated starting
points. Default for 'girf'.

- 'startingValues' : Either a double or a char:

    > double : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing

```

with a MS-model or a break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. For MS - models the default is the ergodic mean (default as long as 'girf' is not selected as 'type'), while for break-point models it is to start from the first regime.

```

> 'zero'          : Start from zero on all variables.

> 'random'        : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'         : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'           : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generlized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'   : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

- 'variables'       : The variables to create impulse responses of.
                     Default is the dependent variables defined by the
                     first model.

Caution: The variables reported by the reporting
property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level
                     using the method specified by 'levelMethod'.

```

Output:

```

- irfs      : The (central) impulse response function stored in a
               structure of nb_ts object. Each field stores the the
               impulse responses of each shock. Where the variables
               of the nb_ts object is the impulse responses of the
               wanted endogenous variables.

               I.e. the impuls responses to the shock 'E_X_NW' is
               stored in irfs.('E_X_NW'). Which will then be a nb_ts
               object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the
responses from each model are saved as
different datasets (pages) of the nb_ts object.

```

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.
 - > 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
 - > 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast ↑**

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

```
ret = isMixedFrequency(obj)
```

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic ↑**

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

► **isbayesian ↑**

ret = isbayesian(obj)

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

ret = isestimated(obj)

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

ret = isforecasted(obj)

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint

```
prediction bands for  
macroeconomic risk management  
  
> 'copula' : Using a copula likelihood approach.  
  
> 'mostlik' : Group the paths based on how  
likely they are.  
  
- 'nSteps' : Number of forecasting steps to use when constructing the  
error bands. If empty (default) all forecasting steps stored  
in the object is used.
```

Output:

- JPB : An nb_ts object storing the joint prediction bands.
The percentiles are stored as datasets. See the
dataNames property for which page represent which
percentile.

The data of the nb_ts object has size nSteps x nVars
x nPerc.
- plotter : A nb_graph_ts object. Use the graphSubPlots method
to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend
on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_midas.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use @(x)f1(x)&&f2(x), where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. @(x)gt(x,0), @(x)gt(x,0)||lt(x,1), i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. @(x,y)gt(x,y), @(x,y)gt(x-y,0)||lt(x-y,1), i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. {'Var1','Var1',1,@(x)gt(x,0.1)}, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. {'Var1','Var2',0,@(x)lt(x,0.1)}, to

test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous variance.

> 'ss' : A N x 2 cell, where the elements of each row are:

1. The expression using any of the endogenous variables of the model.
2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mincerZarnowitzTest ↑**

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_midas.uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.

- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

See also:

[function_handle](#), [nb_midas.mcfRestriction](#), [nb_midas.solve](#)
[nb_midas.assignParameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_GENERIC](#)

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj,draws,method,output,stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'wildBlockBootstrap' : Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'copulaBootstrap' : Uses a copula approach to draw residual that are autocorrelated, Does not handle heteroscedasticity. Only an option for models estimated with classical methods.
 - > 'posterior' : Posterior draws. Only for models estimated with bayesian methods.

Default for models estimated with
bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more on this option.
- stable : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores available.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.
- 'initialDraws' : When drawing parameters this factor decides how many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
 - > 'param' : Default. A struct with the following fields:
 - beta : A nPar x nEq x draws double with the estimated parameters.
 - sigma : A nEq x nEq x draws double with the estimated covariance matrix.
- For factor models these fields are also returned:
- lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.
 - R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.
- factors : Draws of the factors as a T x nFac x

```

draws double.

> 'solution' : Get the solution of the model for each draw from the
distribution of parameters. The output will be a struct
with size 1 x draws. The struct will have the same
format as the solution property of the underlying
object. I.e. only one output!

> 'object'   : Get the draws as a 1 x draws nb_model_generic object.
Each element will be a model representing a given draw
from the distribution of the parameters. I.e. only one
output!

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + ( +/- nb_distribution.t_icdf(alpha/2) ) * stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► plotForecast ↑

```

plotter          = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
                                         increment,varargin)

```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► plotMCF ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...  
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot.

'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- `plotter` : > 'allInOne' : A `nb_graph_cs` object. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
 > 'biplot' : A vector of `nb_graph_data` objects with size equal to the number of pairwise combination of the parameters that can be made. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotMCFDistTest ↑**

`plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)`

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `test` : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,valueName)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `nameValue` : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

[nb_midas.monteCarloFiltering](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)
[nb_midas.getPosteriorDistributions](#)

Written by Kenneth Åtterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results ↑**

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_midas.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations ↑**

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties
of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **setFrequency** ↑

obj = setFrequency(obj, freq)

Description:

Set the frequency of the decleared dependent and/or exogenous
variables of a formulated model.

Supported frequencies:

- 'yearly' : 1
- 'quarterly' : 4
- 'monthly' : 12
- 'weekly' : 52

Input:

- obj : An object of class nb_midas.

- freq : A scalar integer with the frequency of the dependent variable,
or a cellstr on the format; {'Var1',1,'Var2',4}. There is no
need to set the frequency of those variables that has the same
frequency as the data (options.data)!

Caution: The frequency of the dependent variable must be greater
or equal to the frequency of the exogenous!

Output:

- obj : An object of class nb_midas where the frequency of a set of
variables has been set. See the dependent and exogenous
properties.

Written by Kenneth Sæterhagen Paulsen

► **shock_decomposition** ↑

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';  
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the

nb_model_generic.parameterDraws method for more this input. An extra option is:

```
> 'identDraws' : Uses the draws of the matrix with  
      the map from structural shocks to dependent variables.  
      See nb_var.set_identification. Of course this option  
      only makes sense for VARs identified with sign  
      restrictions.  
  
- 'replic'          : The number of simulation for posterior, bootstrap and  
      MC methods. Default is 1. Only used when 'perc' is  
      provided.  
  
      Caution: Will not have anything to say for the method  
      'identDraws'. See the option 'draws' of the  
      method nb_var.set_identification for more.  
  
- 'stabilityTest' : Give true if you want to discard the draws  
      that give rise to an unstable model. Default  
      is false.  
  
- 'parallel'        : Give true if you want to do the shock decomp in  
      parallel. Default is false.  
  
- 'fcstDB'          : An object of class nb_ts with the forecast to  
      decompose. must contain all model variables and  
      shocks/residuals, and must start the period after  
      the estimation/filtering end date or at the  
      estimation/filtering start date. See  
      the nb_model_generic.getForecast method.  
  
- 'type'            : Choose 'updated' or 'smoothed'. 'smoothed' is  
      default.  
  
- 'anticipationStartDate' : Start date of anticipating shocks. As a  
      string. If different models has different  
      frequency this date will be converted.  
  
- 'model2'          : A struct with the solution of the second  
      model to use for decomposition.  
  
- 'secondModelStartDate' : Start date of second model. As a string.  
      If different models has different frequency  
      this date will be converted.
```

Output:

- decomp : A structure of nb_ts objects with the shock
 decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty
 bounds of the shock decomposition for each model at each
 percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the
 graph method to produce the graphs or use the
 nb_graphPagesGUI on each element of the graph objects.

`nb_midas.parameterDraws, nb_shockDecomp`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **simulate** ↑

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- `obj` : A vector of `nb_model_generic` objects.
- `nSteps` : Number of simulation steps. As a `1x1 double`. Default is 100.

Optional inputs:

- `'burn'` : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- `'bounds'` : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - `'shock'` : Name of the shock to match the restriction on the bounds of the given variable.
 - `'lower'` : The lower bound of the selected variable. Either a `1x1 double` value or a function handle to a probability distribution to draw from.
 - `'upper'` : The upper bound of the selected variable. Either a `1x1 double` value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps double` matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a `1x1 double` or a `nSteps x 1 double`.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.
- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty

the simulation will switch between regimes. Only an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a specific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:
 - > double : A 1 x nVar double.
 - > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsg models.
 - > 'steadyState' : Start from the steady state. For now only an option for nb_dsg models. If you are dealing with a MS-model you can indicate the state by 'steadyState(state)'. E.g. to start in state 1 give; 'steadyState(1)'. Default for nb_dsg models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char:
 - > double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
 - > 'ergodic' : Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consists of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the

'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.
 Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.
 Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
 Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i},'y','x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i},'x','y'). (This example only works if the output is of class nb_cs)

[nb_midas.graphCorrelation](#), [nb_midas.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_midas object(s).

Input:

- obj : A vector of nb_midas objects.

Output:

- obj : A vector of nb_midas objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_midas.solveNormal(results,opt)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_midas.solveRecursive(results,opt)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_midas.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

```
options = nb_midas.template()
options = nb_midas.template(num)
```

Description:

Construct a struct which can be provided to the nb_midas class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

```

- obj : A nb_model_forecast object with density forecast

- restrictions : Restrictions as a n x 3 cell array,
    {variable, date, test}.

    > variable : The variable(s) to test,
        as a string or cell array of strings.

    > date : The date as a string. If a cell array is given, a
        copy of the restriction will be made for every given
        date.

    > test : Restriction test as a function handle. The value(s)
        of the variable(s) in 'variable' at time 'date' are
        passed as arguments. Should return a logical.

```

Output:

- out : A double with the probability

Example:

```

restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...
    {'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};
probability = model.testForecastRestrictions(restrictions);

```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

```

- obj : A scalar solved nb_model_generic object.

- expression : A MATLAB expression as a string. Use parameter names as
    variables. See model.parameters.name.

```

```

- method      : A string with the method to use. For bootstrap method see
               nb_bootstrap. For bayesian models 'posterior' is the only
               option. Default is 'bootstrap' for classical models, while
               'posterior' is the default for bayesian models.

- draws       : Number of draws from the parameter distribution. Default
               is 1000.

- alpha       : Confidence level. Default is 0.05.

- type        : Type of test:
    > '=' : Two sided test. expression == 0 (default)
            For two-sided tests it is assumed that the
            distribution is symmetric! Use
            confidenc/probabillty intervals instead.
    > '>' : One sided test. expression > 0
    > '<' : One sided test. expression < 0

```

Output:

```

- pval        : > 'classical' : P-value of test.
               > 'bayesian' : Probabilty of test.

               A 1x1 double.

- ci          : A 1 x 2 double with the lower and upper bound of the
               confidence/probabillty interval of the tested expression.

- dist        : A nb_distribution object storing the distribution of the
               tested expression.

```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► **theoreticalMoments** ↑

```

[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)

```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation,
autocovariance/autocorrelation.

Caution : For recursivly estimated model only the full sample estimation
results is used.

Caution : Only supported for models that can be solved in the following
way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.
- Optional inputs;
- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.
Can also be a cellstr, with a subset of variables from 'full'.
- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargout{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

See also:

[nb_midas.graphCorrelation](#), [nb_midas.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition** ↑

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the

percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).

> 'fev'	: Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc'	: At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages'	: Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_midas.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_midas.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► [update ↑](#)

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► variance_decomposition ↑

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.
Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
> 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent

variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.

- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomposition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomposition for each model. For each percentiles the output is as decomp.

- `plotter` : A $1 \times nModel$ vector of `nb_graph_cs` objects. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
- `plotterBands`: A $1 \times nModel$ struct. Each field is a $1 \times nVars$ vector of `nb_graph_cs` objects. Use the `graphSubPlots` method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

■ **nb_model_convert**

Go to: [Properties](#) | [Methods](#)

A class for converting the frequency of `nb_model_forecasts`. This makes it easier to compare or combine forecasts from objects with different frequency.

Superclasses:

`nb_model_forecast`, `nb_model_estimate`

Constructor:

`obj = nb_model_convert(model, varargin)`

Input:

- `model` : An object of class `nb_model_generic` with stored forecasts.

Optional input:

- `'freq'` : The frequency you want to convert to. As integer. Either 1, 2, 4, 12 or 365.
- `'method'` : The method which you would like to use to convert the forecasts with. For more, see the `nb_ts.convert` method.
- `'name'` : To set a name for the object.
- `'interpolatedate'` : Use this to determine if you would like to choose the start of the new period or end of the new period as date as your forecast date. E.g. if you are going from quarterly to monthly and choose `'start'`, then 2010Q2 becomes 2010M4. Either `'start'` or `'end'`, default is `'start'`.

Output:

- obj: An object of class nb_model_convert

Examples:

- nb_model_convert(obj,'freq',12,'method','linear','name','test',...
 'interpolatedate','start')

[nb_model_generic](#)

Written by Tobias Ingebrigtsen

Properties:

- [addAutoName](#)
- [addAutoNameIfLocal](#)
- [addID](#)
- [addIDIfLocal](#)
- [estOptions](#)
- [forecastOutput](#)
- [model](#)
- [name](#)
- [options](#)
- [reporting](#)
- [results](#)
- [transformations](#)

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[estOptions](#)** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **[forecastOutput](#)** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **model** ↑

The nb_model_generic object with the original forecast

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that persevere the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that persevere the time span are supported in expression. You can also call user defined

functions, as long as they take and return a nb_math_ts object.
A nb_math_ts object is just a double with a time dimension!
To get a list of all the methods of the nb_math_ts class use;
`methods('nb_math_ts')`.

Can also be empty.

See also: `nb_ts.createVariable` and `nb_ts.createShift`.

Inherited from superclass `NB_MODELDATA`

- `template`
- `testForecastRestrictions`
- `uncondForecast`
- `unstruct`
- `update`

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **checkModel** ↑

```
obj = checkModel(obj)
```

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_convert.

Output:

- obj : An object of class nb_model_convert.

Written by Kenneth SÃ¶terhagen Paulsen

► checkReporting ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODELDATA

► convert ↑

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertModel** ↑

```
obj = convertModel(obj)
```

Description:

A method for converting the frequency of an nb_model_convert object with forecasts.

Caution: When converting from high frequency to lowe frequency it uses the same information content, as is the case for the last forecast produced, for all recursive periods. This means that if 2000Q2 is the last forecast start date, then it will fetch the forecast from 1999Q2, 1998Q2, etc...

Input:

- obj : An object of class nb_model_convert with stored forecasts.

Output:

- obj : An object of class nb_model_convert with the converted forecasts.

Written by Tobias Ingebrigtsen

► createVariables ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the nb_ts.createVariable method.

> third column : Any expression that can be interpreted by the nb_ts.createShift method.

> fourth column : Comments

- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,    shift,   description
'VAR1_G',   'pcn(VAR1)', 'avg',   'VAR1 growth'
'VAR2_G',   'pcn(VAR2)', 'avg',   'VAR2 growth'
'VAR3_G',   'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **doForecastPerc2Dist** ↑

```
obj = doForecastPerc2Dist(obj, draws)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_convert.forecast](#), [nb_model_convert.forecastPerc2Dist](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist** ↑

```
[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_convert.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity ↑**

obj = doSimulateFromDensity(obj, draws)

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

`nb_model_generic.forecast`, `nb_model_convert.simulateFromDensity`

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass `NB_MODEL_FORECAST`

► **estimate** ↑

```
obj      = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by `nb_model_estimate` object(s).

Input:

- `obj` : A vector of `nb_model_generic` objects.
- `'parallel'` : Use this string as one of the optional inputs to run the estimation in parallel.
- `'cores'` : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if `'parallel'` is given.
- `'remove'` : Give `'remove'` to remove the models that return errors from the `obj` output. This input is not stored to the `forecastOutput` property of the objects.
- `'waitbar'` : Use this string to give a waitbar during estimation. I.e. when looping over models. If `'parallel'` is used this option is not supported!
- `'write'` : Use this option to write errors to a file instead of throwing the error.

Optional input:

- `varargin` : See the the set method.

Output:

- `obj` : A vector of `nb_model_generic` objects, where the estimation results are stored in the property `results`.
- `valid` : A logical with size `nObj` x 1. true at location `ii` if estimation of model `ii` succeeded, otherwise false. If `'write'` is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

nb_model_generic, solve

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d,{'MSE'},0,1)
m = evalFcstAtDates(b,d,{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **forecast** ↑

```
obj = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_convert objects. First the model stored in the model property is forecast then the forecast is converted.

Input:

- obj : A vector of nb_model_convert objects.
- nSteps : See the forecast method of the nb_model_generic class

Optional inputs:

- See the forecast method of the nb_model_generic class

Output:

- obj : A vector of nb_model_convert objects.

Written by Kenneth Sæterhagen Paulsen

► **forecastPerc2Dist ↑**

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_convert.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_convert.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_convert objects

Input:

- obj : A vector of nb_model_convert objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the model. The return value is the estimation start date of the model that is ordered last.

Input:

- obj : An object of class nb_model_convert

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

► **getForecast** ↑

```
fcstData          = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.
```

For real-time forecast the vintage at the time is returned as the historical data, when includeHist is true.

> 'horizon' : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.

If includeHist is true the actual data is added as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!

Caution : If the horizon input is set you will set nHor to one, and the fcstPercData will be non-empty, if density forecast has been produced.

- includeHist : Give true (1) to include history in the output. Only an options for the 'date' and 'horizon' outputType. Default is false (0).

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with size nRec x nVars. While the fcstPercData output will be a nb_ts object with size nRec x nVars x nSim. You can set the horizon to return by the optional input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_model_convert.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables ↑**

vars = getForecastVariables(obj)

Description:

Get the variables that the model forecast.

Input:

```
- obj : An object of class nb_model_forecast.
```

Output:

```
- vars : A cellstr with the variables of the original data source.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory ↑**

```
histData = getHistory(obj,vars)
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data.

Input:

```
- obj : A scalar nb_model_convert object.
- vars : A cellstr with the variables to get. May include
          shocks/residuals. Only the variables found is returned,
          i.e. no error is provided if not all variables is found.
- date : Ignored
- notSmoothed : Ignored
- type : Ignored
```

Output:

```
- histData : A nb_ts object with the historical data.
```

Written by Kenneth SÃ¶terhagen Paulsen

► **getModelNames ↑**

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will
get the PIT from the start date of the recursive forecast and
use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct
the PITs based on the period from the estimation start date
until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► [getRecursiveScore ↑](#)

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► [getResidualNames ↑](#)

residualNames = getResidualNames(obj)

Description:

Get all the unique residual names of a vector of nb_model_convert object

Input:

- obj : A vector of nb_model_convert objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

► getScore ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert, ...
                  rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.

- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

See also:

[nb_model_group.combineForecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **help ↑**

```
helpText = nb_model_convert.help
helpText = nb_model_convert.help(option)
helpText = nb_model_convert.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **isDensityForecast ↑**

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► mincerZarnowitzTest ↑

```
[test,pval,res] = mincerZarnowitzTest(obj,precision)
```

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

Input:

- obj : An object of class nb_model_group. You need to call the combineForecast method first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_model_generic.combineForecast](#)

Written by Kenneth SÃ¶terhagen Paulsen

► plotForecast ↑

```
plotter = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► print ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_convert.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **print_estimation_results** ↑

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_generic.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object

- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **struct ↑**

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_convert.

Output:

- s : A struct representing the nb_model_convert object.

See also:

[nb_model_convert.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

► **template ↑**

```
options = nb_model_convert.template()
options = nb_model_convert.template(num)
```

Description:

Construct a struct which can be provided to the nb_model_convert class constructor.

This structure provided the user the possibility to set different conversion options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast

- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.

> variable : The variable(s) to test,
as a string or cell array of strings.

> date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.

> test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...
                {'QSA_URR', 'QSA_DPQ_CP'}, '2014Q1', @(x, y) x < y};
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_convert objects.

Input:

- obj : A vector of nb_model_convert objects.
- nSteps : See the uncondForecast method of the nb_model_generic class

Optional inputs:

- See the uncondForecast method of the nb_model_generic class

Output:

- obj : A vector of nb_model_convert objects.

See also:

[nb_model_convert.forecast](#)

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

```
obj = nb_model_convert.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_convert class.

Input:

- s : A struct. See nb_model_convert.struct.

Output:

- obj : An object which is a subclass of the nb_model_convert class.

See also:

[nb_model_convert.struct](#)

Written by Kenneth Sæterhagen Paulsen

► **update ↑**

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of the object, and optionally re-estimate, re-solve, forecast the models given the updated data and convert the forecast.

Input:

- obj : A vector of objects of class nb_model_group
- type : > '' : Only update data. Default
> 'estimate' : Update data and estimate.
> 'solve' : Update data, estimate and solve
> 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'.
- groupIndex : A 1 x nLevel double with the group level.

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if estimation or forecasting fails. The models that fail will then be removed when calling methods as compareForecast and aggregateForecast etc. See the valid property.

Output:

- obj : A vector of objects of class nb_model_convert.
- valid : A logical with size 1 x nObj. true at location ii if updating of model group ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

■ nb_model_estimate

Go to: [Properties](#) | [Methods](#)

An abstract superclass for all model objects that can be estimated.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- estOptions • options • reporting • results • transformations

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that pserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **results** ↑

A struct storing all the results of the estimation.

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

Methods:

- [appendData](#)
- [convert](#)
- [createVariables](#)
- [getOriginalVariables](#)
- [handleMissing](#)
- [print](#)
- [removeObservations](#)
- [struct](#)
- [checkReporting](#)
- [convertEach](#)
- [estimate](#)
- [handleCondInfo](#)
- [isStatic](#)
- [print_estimation_results](#)
- [set](#)
- [unstruct](#)

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **checkReporting** ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **convert** ↑

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach ↑**

obj = convert(obj,freq,methods,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables ↑**

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
 - > third column : Any expression that can be interpreted by the nb_ts.createShift method.
 - > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,    shift,   description
'VAR1_G',   'pcn(VAR1)', 'avg',   'VAR1 growth'
'VAR2_G',   'pcn(VAR2)', 'avg',   'VAR2 growth'
'VAR3_G',   'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

[nb_model_generic.transformations](#), [nb_model_generic.reporting](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **estimate** ↑

```
obj          = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **handleCondInfo** ↑

```
ret = handleCondInfo(obj)
```

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

► **print** ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

► **print_estimation_results ↑**

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_generic.print](#)

Written by Kenneth Sæterhagen Paulsen

► **removeObservations ↑**

```
obj = removeObservations(obj, numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► set ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.
Where you can set all fields of some properties
of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_model_estimate.unstruct](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **unstruct** ↑

obj = nb_model_estimate.unstruct(s)

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_model_estimate.struct](#)

Written by Kenneth Sæterhagen Paulsen

■ nb_model_generic

Go to: [Properties](#) | [Methods](#)

An abstract superclass of all model classes that is both estimated and forecasted.

Constructor:

No constructor exist. This class is abstract.

Written by Kenneth Sæterhagen Paulsen

Properties:

- | | | | | |
|---------------|----------------------|-------------|------------------|-------------|
| • addAutoName | • addAutoNameIfLocal | • addID | • addIDIfLocal | • dependent |
| • endogenous | • estOptions | • exogenous | • forecastOutput | • name |
| • options | • parameters | • reporting | • residuals | • results |
| • solution | • transformations | • userData | | |

- **addAutoName** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addAutoNameIfLocal** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **dependent** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t$, $e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t$, $u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.
As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the

model.

- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

Methods:

- appendData
- assignPosteriorDraws

► **appendData** ↑

```
obj = appendData(obj, DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over

the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters ↑**

obj = assignParameters(obj,varargin)

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

► **assignPosteriorDraws** ↑

```
obj = assignPosteriorDraws(obj,varargin)
```

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same

size as `obj.results.sigma`. The draws must come in the third dimension.

- `'lambda'` : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as `obj.results.lambda`. Only for factor models. The draws must come in the third dimension.
- `'R'` : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as `obj.results.R`. Only for factor models. The draws must come in the third dimension.
- `'period'` : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- `obj` : An object of class `nb_model_generic`, where the parameters of the underlying model has been changed. See `solve` to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

► **assignTexNames ↑**

```
obj = assignTexNames(obj, names, texNames)
```

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as `_t` is automatically appended to each variable! Use superscripts instead.

Input:

- `obj` : An object of class `nb_model_generic`.
- `names` : A Nx1 cellstr with the names of the variables and/or parameters of the model.
- `texNames` : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- `obj` : A `nb_model_generic` object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its `tex_name` fields. (Also `observables` and `observablesFast` for factor model.)

See also:

`nb_dsge.writeTex`, `nb_dsge.writePDF`

Written by Kenneth Sæterhagen Paulsen

► **calculateMultipliers** ↑

```
mult = calculateMultipliers(obj,varargin)
```

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is `delta_Y` and `delta_G` not `Y` and `G` of the formula (3)!

Input:

- `obj` : An object of class `nb_dsge`.

Optional input:

- `'variables'` : A cellstr with the variables to produce the multipliers of. Must be provided!
- `'instrument'` : A one line char with the name of the instrument. Must be provided!
- `'rate'` : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!
- `'shocks'` : A cellstr with the shocks to produce the multipliers of. Must be provided!
- `'gross'` : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.
- `'perc'` : Error band percentiles. As a $1 \times nPerc$ double. E.g. $[0.3, 0.5, 0.7, 0.9]$. If empty all the simulation will be returned.
- `rest` : Use the `'replic'` option to produce error bands.

Output:

- `mult` : A $nShocks \times nVars \times nSim$ ($nPerc$) `nb_cs` object. Use the `double` method on this output to convert it to a double matrix.

See also:

[nb_model_generic.irf](#), [nb_calcMultiplier](#)

► **calculateStandardError** ↑

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel

```
density estimator of the parameter  
distribution. Two-sided test against the  
null hypothesis of the parameters being 0.  
  
- ci : Confidence interval/probability interval calculated based on  
a kernel density estimation instead of assuming asymptotic  
normal distribution. Only for the parameter in beta! As a  
(nCoeff * nEq) + 1 x 3 cell array.  
  
- dist : Estimated distribution of the coefficients of the main  
equation. As a (nCoeff * nEq) x 1 nb_distribution object.
```

Written by Kenneth Sæterhagen Paulsen

► **checkModel** ↑

```
obj = checkModel(obj)
```

Description:

Secure that the object is up to date when it comes to the options,
estOptions and results struct properties.

Input:

```
- obj : An object of class nb_model_generic.
```

Output:

```
- obj : An object of class nb_model_generic.
```

Written by Kenneth Sæterhagen Paulsen

► **checkPosteriors** ↑

```
[DB,plotter,pAutocorr] = checkPosteriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they were drawn. This to check for
problems with posterior draws that may be autocorrelated.

Input:

```
- obj : A scalar object of class nb_model_generic. It must represent  
a bayesian model that is estimated.
```

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot.
Default is 10.
- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
 - plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
 - pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- Caution: Only plots the autocorrelation for the first chain
if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **checkReporting** ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments** ↑

c = conditionalTheoreticalMoments(obj,varargin)

Description:

Calculate conditional theoretical moments; I.e.
 (auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
 Equivalent to the output of the theoreticalMoments method
 when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
 results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
 the moment of the dependent variables of the model without
 lag, while full will include all lags as well. 'dependent'
 is default.

Can also be a cellstr, with a subset of variables
 from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
 estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
 E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
 all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.
 Default is ''. See below for what that means.

> 'bootstrap' : Create artificial data to bootstrap
 the estimated parameters. Default
 for models estimated with classical
 methods.

> 'wildBootstrap' : Create artificial data by wild
 bootstrap, and then "draw" parameters
 based on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'blockBootstrap' : Create artificial data by
 non-overlapping block bootstrap,
 and then "draw" parameters based
 on estimation on these data.
 Only an option for models estimated
 with classical methods.

```

> 'mBlockBootstrap'      : Create artificial data by
                           overlapping block bootstrap,
                           and then "draw" parameters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'rBlockBootstrap'      : Create artificial data by
                           overlapping random block length
                           bootstrap, and then "draw" parameters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'wildBlockBootstrap'   : Create artificial data by wild
                           overlapping random block length
                           bootstrap., and then "draw" parameters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'posterior'            : Posterior draws. Only for models
                           estimated with bayesian methods.
                           Default for models estimated with
                           bayesian methods.

                           Caution : Posterior draws is
                           already made at the
                           estimation stage.

- 'nSteps'      : Number of steps ahead. As an integer.

```

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

► **constructCondDB** ↑

```

condDB           = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)

```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.

- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

► **constructScore ↑**

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.

```

        - 'MSE'      : One over mean squared error.
        - 'MAE'      : One over mean absolute error.
        - 'ME'       : Mean error.
        - 'STD'      : One over Standard error of the forecast
                       error.
        - 'ESLS'     : Exponential of the sum of the log scores.
        - 'EELS'     : Exponential of the mean of the log scores.
        - 'MLS'      : Mean log score.

- allPeriods      : true if you want the scores to be calculated for all
                    periods recursively, or else give false, i.e. only
                    calculate the score for the last period. False is
                    default.

- startDate       : The date to begin constructing the score. Can be
                    empty.

- endDate         : The date to end constructing the score. Can be
                    empty.

- nSteps          : Select the number of forecasting steps. Can be
                    empty.

- rollingWindow   : Set it to a number if the combination weights are to
                    be calculated using a rolling window. Default is
                    empty, i.e. to calculate the weights recursively using
                    the full history at each recursive step.

- lambda          : Give the value of the parameter of the exponential
                    decaying weights on past forecast errors when
                    constructing the score. If empty the weights on all
                    past forecast errors are equal.

```

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

► **convert ↑**

`obj = convert(obj,freq,method,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both
the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending
cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach ↑**

obj = convert(obj,freq,methods,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
 - > third column : Any expression that can be interpreted by the nb_ts.createShift method.
 - > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,    shift,    description
'VAR1_G',   'pcn(VAR1)', 'avg',   'VAR1 growth'
'VAR2_G',   'pcn(VAR2)', 'avg',   'VAR2 growth'
'VAR3_G',   'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

► **dieboldMarianoTest** ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method.

Default.

> 'a' : Andrews selection method. AR(1) specification.

- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

► **doForecastPerc2Dist** ↑

obj = doForecastPerc2Dist(obj, draws)

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

► **doForecastPerc2ParamDist** ↑

```
[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity** ↑

```
obj = doSimulateFromDensity(obj,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_model_generic.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **empiricalMoments** ↑

```
[m,c] = empiricalMoments(obj,varargin)
[m,c,ac1] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_generic object. The options.data property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.

```
- 'demean'      : true (demean data during estimation of the  
autocovariance matrix), false (do not). Default is true.
```

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

See also:

[nb_model_generic.graphCorrelation](#)

Written by Kenneth Sæterhagen Paulsen

► [eq](#) ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sense they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind     = v(1) == v
```

See also:

`isequal`

Written by Kenneth Sæterhagen Paulsen

► **estimate** ↑

```
obj      = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by `nb_model_estimate` object(s).

Input:

- `obj` : A vector of `nb_model_generic` objects.
- `'parallel'` : Use this string as one of the optional inputs to run the estimation in parallel.
- `'cores'` : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if `'parallel'` is given.
- `'remove'` : Give `'remove'` to remove the models that return errors from the `obj` output. This input is not stored to the `forecastOutput` property of the objects.
- `'waitbar'` : Use this string to give a waitbar during estimation. I.e. when looping over models. If `'parallel'` is used this option is not supported!
- `'write'` : Use this option to write errors to a file instead of throwing the error.

Optional input:

- `varargin` : See the the `set` method.

Output:

- `obj` : A vector of `nb_model_generic` objects, where the estimation results are stored in the property `results`.
- `valid` : A logical with size `nObj` x 1. true at location `ii` if estimation of model `ii` succeeded, otherwise false. If `'write'` is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_ESTIMATE`

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
    quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- `obj` : A `nb_model_generic` or `nb_model_group` object containing forecasts.
- `dates` : A cellstring containing the dates that the forecast should be evaluated at. Can also be a `nb_date` object.
- `type` : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- `density` : Set true if you have a density forecast.
- `quart` : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- `evaluation` : A `nb_data` object with the evaluation scores for each observation and variable.
- `errorDates` : Since it is not always the case that all of the dates are being used, `errorDates` returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d,{'MSE'},0,1)
m = evalFcstAtDates(b,d,{'MSE','RMSE'},0,1)
```

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior** ↑

```
logPriorD = nb_model_generic.evaluatePrior(prior,par)
```

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

► **forecast** ↑

```
obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for foward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' : - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
- 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states

input is providing the full path of regimes. Default is 1.

- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density forecast.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'bins' : The length of the bins og the domain of the density. Either;
 - > [] : The domain will be found. See nb_getDensityPoints (default is that 1000 observations of the density is stored).
 - > integer : The min and max is found but the length of the bins is given by the provided integer.
 - > cell : Must be on the format:
 - {'Var1',lowerLimit1,upperLimit1,binsL1; 'Var2',lowerLimit2,upperLimit2,binsL2; ...}
 - lowerLimit1 : An integer, can be nan, i.e. will be found.
 - upperLimit1 : An integer, can be nan, i.e. will be found.
 - binsL1 : An integer with the length of the bins. Can be nan. I.e. bins length will be adjusted to create a domain of 1000 elements.

Caution : The variables not included will be given the default domain. No warning will be

given if a variable is provided in the cell but not forecast by the model. (This because different models can forecast different variables)

Caution : The combineForecast method of the nb_model_group class is much faster if the lower limit, upper limit! Or else it must simulate new draws and do kernel density estimation for each model again with the shared domain of all models densities.

- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is not empty this will set the start date of the recursive forecast. Default is to start from the first possible date.

- 'endDate' : The end date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is empty this input will have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).

- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.

- 'condDB' : One of the following:

> A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.

> A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.

> A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also

possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)

> A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is choosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the

conditional information. If an shock/residual is not included here, it means that it is not activated.

> StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.

Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.

If not provided. Model stds are used.

> Horizon : Anticipated horizon of the shocks/residual. 1 is default.

> Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.

- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.

- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.

- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.

> 'endo' : All the endogenous variables are returned.

> 'fullendo' : All the endogenous variables are returned included the lag variables.

> 'full' : All the variables are returned included the lag variables. Also

including exogenous and shocks.

> 'all' : All variables are returned (but not the lags). Including exogenous and shocks.

- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.

> double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.

> 'mean' : Start from the mean of the data observations. Default.

> 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.

> 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)

- 'startingProb' : Either a double or a char:

> [] : If the model is filtered the starting value is calculated on filtered transition probabilities. Otherwise the ergodic mean is used.

> double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.

> 'ergodic' : Start from the ergodic transition probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

- 'states' : Either an integer with the regime to forecast/simulate in, or an object of class nb_ts with the regimes to condition on. The name of the

variable must be 'states'.

Caution: For break-point models this is decided by the dates of the breaks, and cannot be set by this option!

- 'compareToRev' : Which revision to compare to. Default is final revision, i.e. []. Give 5 to get fifth revision. must be an integer. Keep in mind that this number should be larger than the nSteps input.
 - 'compareTo' : Sometime you want to evaluate the forecast of one variable against another variable which is not part of the model. E.g. if you use the first release of a variable and want to compare it against the final release. To do this you can give a cellstr with size n x 2, where n is the number of variables to change the the actual observations to test against. {'VAR_1','VAR_FINAL',...}.
 - 'estimateDensities' : true or false. true if you want to do a kernel density estimation of the density forecast.
 - 'exoProj' : Tolerate missing exogenous variables by projecting them by a fitted model. Only when the 'condDB' input is empty!
- Options are:
- '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.
 - 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.
- Caution :** If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.
- Caution :** If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.
- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1,'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when exoProj is set to 'AR'.

- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matix. For the order of the variables see; obj.solution.endo. The

value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs' : This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.
- 'seed' : Set simulation seed. Default is 2.0719e+05.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_model_generic.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

► **forecastPerc2Dist ↑**

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► forecastPerc2ParamDist ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provide recursive conditional information.

Caution : If the dataset is of type real-time, this function interprets the endDate input as the estimation end date for the last recursion. It also assumes that each vintage gives rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

See also:

[nb_modelData.createVariables](#), [nb_model_generic.forecast](#)

► **getDSGEVARPriorMoments** ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by
nb_var.priorTemplate('dsge').

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

See also:

[nb_var](#), [nb_var.priorTemplate](#)

Written by Kenneth Sæterhagen Paulsen

► **getDependent** ↑

```
dependent = getDependent(obj)
```

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

```
- obj : An object of class nb_model_generic
```

Output:

```
- start : An object of class nb_date.
```

Written by Kenneth Sæterhagen Paulsen

► **getFiltered ↑**

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

```
- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.
```

Optional input:

```
- 'reporting' : Either 'stored' or a N x 3 cell array on the format
of the reporting property. If 'stored' it will use
the reporting property stored in the object. If that
is empty, no reporting is done. Default is not to do
any reporting.
```

Output:

```
- data : A nb_ts object with size nobs x nvars included the filtered
variables.
```

See also:

[nb_dsge.filter](#), [nb_model_generic.estimate](#)

► **getForecast** ↑

```
fcstData           = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
```

```

        fcstPerc = fcstPercData.(fields{ii});
        plotter = nb_graph_ts(fcstMean);
        plotter.set('fanDatasets',fcstPerc);
        plotter.graph();

    end

> 'date'      : A string or a nb_date object with the date of the
                  wanted forecast. E.g. '2012Q1'. The fcstData will
                  be a nb_ts object with size nHor x nVar x nPerc + 1,
                  while fcstPercData will be empty. nPerc will then be
                  the number of percentiles/simualtions. Mean will be at
                  last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'   : This option will return the forecast as a
                  nPeriods + nHor x nVar x nHor nb_ts object. This
                  option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
                options for the 'date' and 'horizon' outputType.
                Default is false (0).

```

Optional inputs:

```

> 'horizon'   : The fcstData output will be a nb_ts object with
                  size nRec x nVars. While the fcstPercData output
                  will be a nb_ts object with size nRec x nVars x nSim.
                  You can set the horizon to return by the optional
                  input 'horizon'. See the 'timing' option also.

```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_model_generic.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables** ↑

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.

- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgen object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)

- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

```
methods = parameterDraws(obj)
```

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sætherhagen Paulsen

► **getParameters** ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).
- : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
- : Give 'double' to return the value as a numerical array.
- : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

parameters

Written by Kenneth Sæterhagen Paulsen

► **getPosteriorDistributions** ↑

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

See also:

[nb_graph_ts](#)

► **getRecursiveScore** ↑

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

```
residual = getResidual(obj)
```

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

► **getResidualGraph** ↑

```
plotter = getResidualGraph(obj)
```

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.
- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth SÃ¶therhagen Paulsen

► getScore ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...,
                  rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object intput is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

See also:

[nb_model_group.combineForecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution** ↑

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_model_generic.simulatedMoments](#), [nb_model_generic.theoreticalMoments](#)
[nb_model_generic.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth Sætherhagen Paulsen

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

ret = handleMissing(obj)

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► initialize ↑

```
obj = initialize(template)
```

Description:

Intialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be intialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth SÃ¶terhagen Paulsen

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsgc.
- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the

- variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \logFunc$, where \logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
 - 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

► **irf ↑**

[irfs, irfsBands, plotter] = irf(obj, varargin)

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgen objects.
- 'compare' : Give true if you have a scalar nb_dsgen model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.

- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.
I.e. {'var1',100,...} or {{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This options sets the error band percentiles of the graph, when the 'perc' input is empty. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

```

> 'cumulative product' : cumprod(1 + X,1)
> 'cumulative sum' : cumsum(X,1)
> 'cumulative product (log)' : log(cumprod(1 + X,1))
> 'cumulative sum (exponential)' : exp(cumsum(X,1))
> 'cumulative product (%)' : cumprod(1 + X/100,1)
> 'cumulative sum (%)' : cumsum(X/100,1)
> 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
> 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
> '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
  Default is ''. See help on the method input of the
  nb_model_generic.parameterDraws method for more
  this input. An extra option is:

    > 'identDraws' : Uses the draws of the matrix with
      the map from structural shocks to dependent
      variables. See nb_var.set_identification. Of
      course this option only makes sense for VARs
      identified with sign restrictions.

- 'normalize' : A 1 x 3 cell. First element must be the variable
  name as a string. The second element must be the
  value to normalize to, as an integer. While the
  third element is the period to be normalized, if
  set to inf, it will normalize the max impact
  period.

  E.g. {'Var',1,2}, {'Var',1,inf}

  Caution: 2 means observation 2 of the IRF, and as
  the IRF start at period 0, this means that
  observation 2 is period 1.

- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of
  irfs, while 'mean' normalize the mean and scale
  percentiles/other draws accordingly. Default is
  'draws'.

  Caution: Setting this to 'mean' will not work for
  reported variables that is not measured
  as % deviation from steady-state/mean.

- 'newReplic' : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the replic input.

- 'parallel' : Give true if you want to do the irfs in parallel.
  This option will parallelize over models. Default
  is false.

```

- 'parallelL' : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if numel(obj) == 1. Default is false.
- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for nb_dsg objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for nb_dsg objects.
- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'settings' : Extra graphs settings given to nb_plots function. Must be a cell.
- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.

For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.
- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.

```

- 'startingProb'      : Either a double or a char (Only for Markov-switching
models):

    > scalar           : Select the the regime to take the
                           initial transition probabilities
                           from.

    > double            : A draws x nRegime or a 1 x
                           nRegime double. draws refer to
                           the number set by the 'draws'
                           input.

    > 'ergodic'         : Start from the ergodic transition
                           probabilities. Default for 'irf'.

    > 'random'          : Randomize the starting values
                           using the simulated starting
                           points. Default for 'girf'.

- 'startingValues'   : Either a double or a char:

    > double            : A nVar x 1 double.

    > 'steadystate'     : Start from the steady state. If you are dealing
                           with a MS-model or a break-point model you can
                           indicate the regime by 'steadystate(regime)'. E.g.
                           to start in regime 1 give; 'steadystate(1)'. For
                           MS - models the default is the ergodic mean
                           (default as long as 'girf' is not selected as
                           'type'), while for break-point models it is to
                           start from the first regime.

    > 'zero'             : Start from zero on all variables.

    > 'random'           : Randomize the starting values using the simulated
                           starting points. Default when 'type' set to
                           'girf'.

- 'states'            : Either an integer with the states to produce irf in,
                           or a double with the states to condition on. Must
                           have size periods x 1 in the last case. Applies to
                           both MS - models and break-point models.

- 'type'               : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf'             : Generlized impulse response function
                           calculated as the mean difference between
                           shocking the model with a one period shock
                           (1 std) and no shock at all. Use the 'draws'
                           input to set the number of simulations to use
                           to base the calculation on. This type of
                           irfs must be used for non-linear models.

    > 'irf'                : Standard irf for linear models. Calculated by
                           shocking the model with a one period shock
                           (1 std).

- 'variables'          : The variables to create impulse responses of.

```

Default is the dependent variables defined by the first model.

Caution: The variables reported by the reporting property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.('E_X_NW'). Which will then be a nb_ts object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.

> 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

> 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.

- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

► **isDensityForecast** ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► **isMixedFrequency** ↑

ret = isMixedFrequency(obj)

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

► **isNB** ↑

ret = isNB(obj)

Description:

This will return true for all objects except nb_dsgc objects!

For nb_dsgc objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth SÃ¶terhagen Paulsen

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth SÃ¶terhagen Paulsen

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

ret = issolved(obj)

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► **jointPredictionBands** ↑

[bands,plotter] = jointPredictionBands(obj,varargin)

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

```

- 'vars'      : A cellstr with the variables to return
                 the calculated joint prediction bands of.

- 'perc'      : Error band percentiles. As a 1 x numErrorBand
                 double. E.g. [0.3,0.5,0.7,0.9] (default) or
                 0.9. Cannot be empty!

- 'date'      : If recursive forecast has been produced,
                 you can use this option to choose which of
                 the recursive forecast to construct the
                 joint prediction bands of. Default is empty,
                 i.e. use the last forecast.

- 'method'    : Choose between:
                 > 'kolsrud' : See Akram et al (2016), Joint
                               prediction bands for
                               macroeconomic risk management
                 > 'copula'   : Using a copula likelihood approach.
                 > 'mostlik' : Group the paths based on how
                               likely they are.

- 'nSteps'    : Number of forecasting steps to use when constructing the
                 error bands. If empty (default) all forecasting steps stored
                 in the object is used.

```

Output:

```

- JPB        : An nb_ts object storing the joint prediction bands.
                 The percentiles are stored as datasets. See the
                 dataNames property for which page represent which
                 percentile.

The data of the nb_ts object has size nSteps x nVars
x nPerc.

- plotter    : A nb_graph_ts object. Use the graphSubPlots method
                 to produce the graphs.

```

Written by Kenneth Sætherhagen Paulsen

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

```
- obj       : An object of class nb_model_generic.
```

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_model_generic.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

► **mcfRestriction** ↑

f = mcfRestriction(obj,type,restriction)

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use @(x)f1(x)&&f2(x), where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. @(x)gt(x,0),
@(x)gt(x,0)||lt(x,1), i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. @(x,y)gt(x,y),
@(x,y)gt(x-y,0)||lt(x-y,1), i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.

as output.

> 'corr' : A N x 4 cell, where the elements of each row are:

1. Name of the first variable.
2. Name of the second variable.
3. Number of periods to lag the 2. variable.
4. Same as 4 for 'irf'.

E.g. {'Var1','Var1',1,@(x)gt(x,0.1)}, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. {'Var1','Var2',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous variance.

> 'ss' : A N x 2 cell, where the elements of each row are:

1. The expression using any of the endogenous variables of the model.
2. Same as 4 for 'irf'.

Output:

- f : A function handle that can be used as an input to the monteCarloFiltering method.

See also:

[nb_model_generic.theoreticalMoments](#)

Written by Kenneth Sæterhagen Paulsen

► **mincerZarnowitzTest ↑**

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_model_generic.uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

► monteCarloFiltering ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to

```

'double'. Return true if the model fit a certain
criteria.

- 'method'      : The method used to draw the monte carlo simulated
                  parameters. See the method input to the nb_monteCarloSim
                  function for the supported values. Default is 'latin'.

- 'parallel'    : Give true to run the MCF in parallel. Default is false.

- 'parameters' : A 1 x N cellstr with the parameter names to be drawn
                  from. Must be part of model, and must be provided!

- 'lowerBound'  : A 1 x N double with the lower bound on the parameters of
                  interest.

- 'upperBound'  : A 1 x N double with the upper bound on the parameters of
                  interest.

- 'waitbar'     : true or false. Default is true.

- 'output'      : Either 'double' or 'logical'. Default is 'logical'.

- 'seed'         : Set the seed to use to draw the monte carlo simulated
                  parameter sets. Default is 1. Seed is set back to old
                  state after this method is called!

```

Output:

```

- paramD        : The draws made from the parameter space. As a draws x N
                  double. Use paramD(success,:) to get the accepted
                  draws.

- values         : A N x 1 logical/double. An element is true/not nan if
                  the model where solved and the test function returned
                  a value.

- solvingFailed : A N x 1 logical. An element is true if the model could
                  not be solved.

- objAcc        : A 1 x nAcc vector of nb_model_generic objects
                  representing the accepted models.

```

See also:

[function_handle](#), [nb_model_generic.mcfRestriction](#), [nb_model_generic.solve](#)
[nb_model_generic.assignParameters](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **parameterDraws** ↑

```

out = parameterDraws(obj)
out = parameterDraws(obj,draws,method,output,stable)

```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'wildBlockBootstrap' : Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.

```

> 'copulaBootstrap'      : Uses a copula approach to draw residual
                           that are autocorrelated, Does not handle
                           heteroscedasticity. Only an option for
                           models estimated with classical methods.

> 'posterior'           : Posterior draws. Only for models
                           estimated with bayesian methods.
                           Default for models estimated with
                           bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
on this option.

- stable : Give true if you want to discard the parameter draws
that give rise to an unstable model. Default is false.

```

Optional input:

```

- 'parallel'      : Run in parallel. true or false.

- 'cores'          : Number of cores to use. Default is to use all cores
available.

- 'newDraws'       : When out of parameter draws, this factor decides how
many new draws are going to be made. Default is 0.1.
I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB
version later than R2017B this number will
be the number of new draws, and not the
factor!!! E.g. set it to 100. If it is given
as a number less than 1, it will by default
be set to 100.

- 'initialDraws'  : When drawing parameters this factor decides how many
many draws that are produced before solving the model.
Default is 1. I.e. it is equal to draws input. For
VAR models with underidentification it may be a good
idea to set this to a value > 1 as you may drop a
lot of parameters when identification fails. Default
is 1.

```

Output:

```

- out      : The output depend on the input output:

> 'param'   : Default. A struct with the following fields:

beta    : A nPar x nEq x draws double with the
estimated parameters.

sigma   : A nEq x nEq x draws double with the
estimated covariance matrix.

For factor models these fields are also returned:

lambda  : Estimated coefficients of the observation

```

equation. As a nFac x nObservables x draws double.

R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.

factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Sæterhagen Paulsen

► parameterIntervals ↑

ci = parameterIntervals(obj,alpha)

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

$\text{beta} + (+/-\text{nb_distribution.t_icdf}(\alpha/2)) * \text{stdBeta}$.

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

► plotForecast ↑

```

plotter          = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
                                         increment,varargin)

```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity** ↑

```
plotter = plotForecastDensity(obj,date,variable)
```

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

```
plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF** ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...  
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of

interest.

- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_model_generic.monteCarloFiltering](#)

Written by Kenneth Sæterhagen Paulsen

► **plotMCFDistTest ↑**

plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size $1 \times N$. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

`nb_model_generic.monteCarloFiltering`, `nb_cucconiTest`, `nb_smirnovTest`

Written by Kenneth SÃ¶terhagen Paulsen

► **plotMCFValues** ↑

`plotter = nb_model_generic.plotMCFValues(paramD, params, nameValue)`

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- `paramD` : A $\text{draws} \times N$ double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A $1 \times N$ cellstr with the names of the parameters.
- `values` : A $\text{draws} \times 1$ double with the values of the monte carlo filtering.
- `nameValue` : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size $1 \times N$. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

`nb_model_generic.monteCarloFiltering`

Written by Kenneth SÃ¶terhagen Paulsen

► **plotPosteriors** ↑

```
plotter = plotPosterior(obj)
plotter = plotPosterior(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)
[nb_model_generic.getPosteriorDistributions](#)

Written by Kenneth Sætherhagen Paulsen

► **plotPriors ↑**

```
plotter = plotPriors(obj,varargin)
```

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optional input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)

Written by Kenneth Sætherhagen Paulsen

► **print ↑**

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sætherhagen Paulsen

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

► **print_estimation_results** ↑

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_generic.print](#)

Written by Kenneth Sæterhagen Paulsen

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition ↑**

[decomp, decompBand, plotter] = shock_decomposition(obj, varargin)

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects

- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

Caution: Two special identifiers can be used;

'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.

- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.
- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

See also:

[nb_model_generic.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

► **simulate ↑**

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting

values of the simulation. Default is 0.

- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
 - 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be

discared for all other types of models.

- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.
- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.
- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a spesific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.
- 'startingValues' : Either a double or a char:
 - > double : A 1 x nVar double.
 - > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsg models.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsg models. If you are dealing with a MS-model you can indicate the

```

state by 'steadyState(state)'.
E.g. to start in state 1 give;
'stadyState(1)'. Default for
nb_dsgc models.

> 'zero'      : Start from zero on all variables
                  (Except for the deterministic
                   exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws
                     that give rise to an unstable model. Default
                     is false.

- 'startingProb' : Either a double or a char:

    > double       : A nPeriods x nRegime or a 1 x
                      nRegime double. nPeriods refer to
                      the number of recursive periods to
                      forecast.

    > 'ergodic'    : Start from the ergodic transition
                      probabilities. Default.

```

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

► **simulateFromDensity ↑**

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass [NB_MODEL_FORECAST](#)

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- `obj` : An object of class `nb_model_generic`.
- Optional inputs;
- `'output'` : Either '`nb_cs`' or '`double`'. Default is '`nb_cs`'.
- `'stacked'` : If the output should be stacked in one matrix or not. true or false. Default is false.
- `'nLags'` : Number of lags to compute when '`stacked`' is set to true.
- `'vars'` : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- `'type'` : Either '`covariance`' or '`correlation`'. Default is '`correlation`'.
- `'draws'` : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- `'pDraws'` : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- `'perc'` : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: '`pDraws`' or '`draws`' must be set to a number > 1.
- `'nSteps'` : Number of simulation steps. As a 1×1 double. Default is 100.

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Default is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
 - varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
 - varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.
- E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

See also:

[nb_model_generic.graphCorrelation](#), [nb_model_generic.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

`obj = solveVector(obj)`

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_model_generic.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **testForecastRestrictions** ↑

probability = testForecastRestrictions(model, restrictions)

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
- > variable : The variable(s) to test,
as a string or cell array of strings.
- > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
- > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► testParameters ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or
posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as

```

variables. See model.parameters.name.

- method      : A string with the method to use. For bootstrap method see
                nb_bootstrap. For bayesian models 'posterior' is the only
                option. Default is 'bootstrap' for classical models, while
                'posterior' is the default for bayesian models.

- draws       : Number of draws from the parameter distribution. Default
                is 1000.

- alpha       : Confidence level. Default is 0.05.

- type        : Type of test:
                > '=' : Two sided test. expression == 0 (default)
                        For two-sided tests it is assumed that the
                        distribution is symmetric! Use
                        confidenc/probabillty intervals instead.
                > '>' : One sided test. expression > 0
                > '<' : One sided test. expression < 0

```

Output:

```

- pval        : > 'classical' : P-value of test.
                > 'bayesian'   : Probabilty of test.

                A 1x1 double.

- ci          : A 1 x 2 double with the lower and upper bound of the
                confidence/probabillty interval of the tested expression.

- dist        : A nb_distribution object storing the distribution of the
                tested expression.

```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

► **theoreticalMoments ↑**

```
[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation,
autocovariance/autocorrelation.

Caution : For recursivly estimated model only the full sample estimation
results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargout{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

See also:

[nb_model_generic.graphCorrelation](#), [nb_model_generic.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

► **uncertaintyDecomposition** ↑

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of

each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).

> 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.

- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.

- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd', 'fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth SÃ¶therhagen Paulsen

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_model_generic](#).struct

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **update** ↑

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failles. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if

estimation or forecasting of model is succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Åkerhagen Paulsen

► **variance_decomposition ↑**

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.

```

- 'output'      : Either 'closest2median' (default) or 'median'.
                  > 'closest2median' : The median is represented by the
                           model(s) that are closest to the
                           actual median.
                  > 'median'       : The median represented by the
                           numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc'
           is nonempty.

- 'parallel'    : Give true if you want to do the forecast in parallel.
                   Default is false.

- 'regime'      : Select the regime to do the FEVD of. Only for Markov-
                   switching model. If empty the ergodic mean will be
                   used.

- 'foundReplic' : A struct with size 1 x replic. Each element
                   must be on the same format as obj.solution. I.e.
                   each element must be the solution of the model
                   given a set of drawn parameters.

- 'stabilityTest' : Give true if you want to discard the draws
                     that give rise to an unstable model. Default
                     is false.

- 'packages'     : Cell matrix with groups of shocks and
                   the names of the groups. If you have not
                   listed a shock it will be grouped in a
                   group called 'Rest'

Must be given in the following format:

{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}

Where 'shock_name_x' must be a string with
a shock name or a cellstr array with the
shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

```

Output:

- decomp : A structure of nb_ts objects with the variance
 decomosition for each model. (If simulated it will store
 the median or closest to median dependent on the 'output'
 option)
- decompBands : A structure of structs with the percentiles
 of the variance decomosition for each model. For each
 percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the
 graph method or the nb_graphPagesGUI class to produce
 the graphs.

- `plotterBands`: A $1 \times nModel$ struct. Each field is a $1 \times nVars$ vector of `nb_graph_cs` objects. Use the `graphSubPlots` method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

[nb_model_generic.parameterDraws](#), [nb_varDecomp](#)

Written by Kenneth Sæterhagen Paulsen

■ **nb_model_group**

Go to: [Properties](#) | [Methods](#)

A class for combining models or model groups for forecast, irfs and so on.

Constructor:

```
obj = nb_model_group(models)
```

Input:

- `models` : Either a vector of `nb_model_generic` or `nb_model_group` objects or a cell array with a combination of them.

Output:

- `obj` : A `nb_model_group` object

Examples:

See also:

[nb_model_generic](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- `addAutoName`
- `addAutoNameIfLocal`
- `addID`
- `addIDIfLocal`
- `forecastOutput`
- `models`
- `name`
- `valid`

- **addAutoName ↑**

Add automatic name (first) to default name in `getName`. Default is false.

Inherited from superclass `NB_MODEL_NAME`

- **addAutoNameIfLocal ↑**

Add automatic name (first) to local name in `getName`. Default is false.

Inherited from superclass `NB_MODEL_NAME`

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **models** ↑

A cell array of nb_model_generic and nb_model_group objects

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **valid** ↑

A logical array of same dimension as models. If an element is false that means that a error occured during estimation or forecasting for the corresponding model/model group.

Methods:

- aggregateForecast
- checkModel

- simulateFromDensity
- storeModelsToPath
- struct
- testForecastRestrictions
- uncondForecast
- unstruct
- update

► **aggregateForecast** ↑

```
obj = aggregateForecast(obj,varargin)
```

Description:

Aggregate forecast of subcomponents of a series.

Caution: The model with the shortest forecast horizon will set the forecast horizon of the aggregated series.

Caution: A intersection of the dates from which the recursive forecast is made will be done.

Caution: If type is set to 'density' consistent paths are sampled from the marginal using a copula with an empirically estimated autocorrelation matrix.

Input:

- obj : An object of class nb_model_group

Optional Inputs:

- 'startDate' : Start date of the aggregation of forecast. I.e. the start date of which the weights are constructed. Default is to use the first shared forecast date. Must be given as a string or a nb_date object.
- 'endDate' : End date of the aggregation of forecast. I.e. the end date of which the weights are constructed. Default is to use the last shared forecast date. Must be given as a string or a nb_date object.
- 'nSteps' : The number of steps ahead forecast. The default is to take the minimum over the selected models.
- 'density' : Give 1 (true) if you want to evaluate and produce density forecast. Default is not (0 or false).

Caution: If the 'method' option is set to 'copula' the selected variables must be stationary.
- 'method' : Either:
 - > 'copula' : Use a copula to draw consistent draws from each marginal distribution. Default.
 - > 'perfectcorr' : Make the assumption that the aggregated variables are perfectly correlated, and we can therefore just sum over the distribution using the chosen weights.
- 'condLags' : Number of lags included in the calculation of the (auto)correlation matrix used when 'density' is set to true and 'method' is set to 'copula'. I.e. the number of periods to "condition on". This option should only be used if the forecast densities to be aggregated are not condition on information up until the time of the forecast. This is not the normal case, so default is 0.
- 'nLags' : Max number autocorrelation to include in the stacked autocorrelation matrix. Default is 5. If 0, only contemporaneous correlations are used. Only an option when 'density' is set to true and 'method' is set to 'copula'. If empty the full set of autocorrelations are used.
- 'weights' : The aggregation weights. As a 1 x nModels double, or a T x nModels nb_ts object (time-varying weights). Default is equal weights.

```

- 'newVar'           : A string with the name of the aggregate series.

- 'variables'       : A cellstr with same length as obj.models. These are
                      the variables from the different models to aggregate.
                      Default is to take the first variables from the
                      forecastOutput.variables list.

- 'draws'            : Number of draws from the marginal distributions of
                      the disaggregated models to base the new aggregated
                      density forecast on. Default is 1000.

- 'fcstEval'         : See the forecast method of the nb_model_generic
                      class.

- 'perc'              : Error band percentiles. As a 1 x numErrorBand
                      double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.9.
                      Can be empty, i.e. no percentiles are reported, and
                      all simulation are stored.

- 'parallel'          : When numel(obj) > 1 you may run the process in
                      parallel. true or false.

Caution: Cannot be provided if numel(obj) == 1.

- 'cores'             : Number of cores to use when the process is ran in
                      parallel. As a positive integer.

Caution: Cannot be provided if numel(obj) == 1.

- 'saveToFile'        : Logical. Save densities and domains to files. One
                      file for each model. Default is false (do not).

- 'recursive'         : Calculate the correlation matrix recursively when
                      aggregating density forecast using the 'copula'
                      method. true or false. Default is false.

- 'rollingWindow'     : If the correlation matrix should be calculated
                      recursively with a rolling window. Default is [], i.e.
                      to use the full sample to calculate the correlation
                      matrix.

- 'waitbar'            : true or false. Default is true. Not in parallel
                      session.

- 'weightsMethod'      : Either 'actual', 'end', 'ar' or 'var'. This options
                      sets the way weights are recursively extrapolated
                      when the 'weights' is set ot an object of class
                      nb_ts. See the 'method' input to the
                      recursiveExtrapolate method of the nb_ts class for
                      more on this option.

- 'sigmaMethod'        : Either 'var' or 'correlation'. If set to 'var'
                      the autocorrelation matrix is estimated using the
                      theoretical conditional moments of the forecast
                      from a VAR. If 'correlation' the autocorrelation
                      matrix is estimated based on the emprirical data
                      only. 'correlation' is default.

```

Output:

- obj : A nb_model_group object storing the aggregated forecast.

See also:

[nb_model_group.combineForecast](#)

Written by Kenneth Sæterhagen Paulsen

► **checkModel** ↑

```
obj = checkModel(obj)
```

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_group.

Output:

- obj : An object of class nb_model_group.

Written by Kenneth Sæterhagen Paulsen

► **combineForecast** ↑

```
obj = combineForecast(obj,varargin)
[obj,weights,plotter] = combineForecast(obj,varargin)
```

Description:

Combine density or point forecast.

Input:

- obj : An object of class nb_model_group

Optional inputs:

- 'startDate' : Start date of the combination of forecast. I.e. the start date of which the weights are constructed. Default is to use the first shared forecast date. Must be given as a string or a nb_date object.
- 'endDate' : End date of the combination of forecast. I.e. the end date of which the weights are constructed. Default is to use the last shared forecast date. Must be given as a string or a nb_date object.
- 'nSteps' : The number of steps ahead forecast. The default is to take the minimum over the selected models.
- 'type' :
 - : A string with one of the following:
 - 'MSE' : Mean squared error
 - 'RMSE' : Root mean squared errors
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'equal' : Use equal weights
- 'draws' : Number of draws from the combine density. Default is 1000.
- 'density' :
 - : Give 1 (true) if you want to evaluate and produce density forecast. Default is not (0 or false).
 - Caution: If you set this option to false the mean forecast is used to construct the point forecast from model which has produced density forecast.
- 'perc' :
 - : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.9. Can be empty, i.e. no percentiles are reported. Only an option when 'density' is set to true.
- 'allPeriods' :
 - : Give 1 (true) if you want to construct (density) forecast for all recursive forecast (which may have been produced by the models stored in this object). Default is 0 (false), i.e. only to produce forecast for the last period.
- 'optimizeOpt' :
 - : Give 1 (true), if you want to use optimized weights, instead of weights based on the formula;
 - w(i) = score(i)/sum(score)
 - Caution : Not yet finished!!!
- 'fcstEval' :
 - : See the forecast method of the nb_model_generic class.
- 'varOfInterest' :
 - : As a string or a cellstr. Use this option if you want to combine forecast for one or more variables.
- 'check' :
 - : Give true (1) to check that the domain is the same for all models. If they are not we need to simulate "new" densities at a shared domain (using 1000 bins). This could take a lot of time! To prevent this

use the 'bins' option of the forecast method of the nb_model_generic. Default is false (The error may be hard to interpret if the domain is conflicting). This may also lead to more severe density estimation errors!

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'rollingWindow' : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- 'parallel' : Set to true to run forecast combination in parallel.
- 'lambda' : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- obj : An object of class nb_model_group where the combined forecast is saved in the property forecastOutput
- weights : A struct. Where each field store the weights at forecast horizon h. Each field consist of a nDates x nModel x nVar_nb_ts object.
- plotter : A 1 x h nb_graph_ts object, which you can call the graph method on to produce a graph of the weights over the recursive periods if allPeriods is set to true.

Written by Kenneth Sætherhagen Paulsen

► **doForecastPerc2Dist ↑**

obj = doForecastPerc2Dist(obj, draws)

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_group.forecast](#), [nb_model_group.forecastPerc2Dist](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist** ↑

```
[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the `nb_distribution.perc2ParamDist` function.

Input:

- `obj` : A `nb_model_forecast` object.
- `distribution` : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- `draws` : Number of draws to make from the estimated distributions.

Optional input:

- `'optimizer'` : See doc of the optimizer input to the `nb_callOptimizer` function. Default is '`fmincon`'.
- `'optimset'` : See doc of the `opt` input to the `nb_callOptimizer` function.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

[nb_model_group.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity** ↑

```
obj = doSimulateFromDensity(obj,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_model_group.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **empiricalMoments ↑**

```
[m,c]          = empiricalMoments(obj,varargin)
[m,c,ac1]      = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]  = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_group object. The options.data property of the models property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_group
- Optional inputs;
- 'vars' : A cellstr with the wanted variables.
 - 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

```
- 'nLags'      : Number of lags to compute when 'stacked' is set to true.  
- 'type'       : Either 'covariance' or 'correlation'. Default is 'correlation'.  
- 'startDate'  : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.  
- 'endDate'    : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.  
- 'demean'     : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.
```

Output:

```
- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
```

Written by Kenneth Sæterhagen Paulsen

► **estimate** ↑

```
obj = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_group object(s).

Input:

```
- obj : A vector of nb_model_group objects.
```

Optional input:

```
- varargin : See the the estimate method of the nb_model_generic class.
```

Output:

```
- obj : A vector of nb_model_group objects, where the estimation results are stored in the property results.
```

See also:

[nb_model_generic](#)

Written by Kenneth Sæterhagen Paulsen

► evalFcstAtDates ↑

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)  
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast** ↑

obj = evaluateForecast(obj,varargin)

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **forecast** ↑

obj = forecast(obj,nSteps,varargin)

Description:

Produced conditional point and density forecast of nb_model_group objects. Use the combineForecast method to produce the combined density or point forecast.

Input:

- obj : A vector of nb_model_group objects.
- nSteps : See the forecast method of the nb_model_generic class

Optional inputs:

- See the forecast method of the nb_model_generic class

Output:

- obj : A vector of nb_model_group objects. See the property forecastOutput of each model stored in the models property of the nb_model_group object.

Written by Kenneth Sæterhagen Paulsen

► forecastPerc2Dist ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_group.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_group.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_group.getActual(models,vars,startFcst,nSteps,inputs)
```

Description:

Get actual data to compare against the forecast.

Input:

- models : See the property models of the nb_model_group class.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_group objects

Input:

- obj : A vector of nb_model_group objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the model group. The return value is the estimation start date of the model that is ordered last.

Input:

- obj : An object of class nb_model_group

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

► getForecast ↑

```
fcstData           = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast output on the nb_ts format object.

Input:

- obj : An object of class nb_model_group. Must have produced forecast.
- outputType :
 - > 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.
 - The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.
 - > 'graph' : This option can be used to make it easier to plot the recursive densities.
 - The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.
 - The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are.

calculated, or else it is a empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the
wanted forecast. E.g. '2012Q1'. The fcstData will
be a nb_ts object with size nHor x nVar x nPerc + 1,
while fcstPercData will be empty. nPerc will then be
the number of percentiles/simualtions. Mean will be at
last page.
```

For real-time forecast the vintage at the time is returned as the historical data, when includeHist is true.

- includeHist : Give true (1) to include history in the output. Only an options for the 'date' outputType. Default is false (0).

Optional inputs:

```
> 'horizon' : The fcstData output will be a nb_ts object with
size nRec x nVars. While the fcstPercData output
will be a nb_ts object with size nRec x nVars x nSim.
You can set the horizon to return by the optional
input 'horizon'. See the 'timing' option also.
```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_model_group.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

► **getForecastVariables ↑**

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_group object
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.
- date : For recursively estimated models, the residual vary with the date of recursion, so by this option you can get the residual of a given recursion.
The same apply for real-time data.
- notSmoothed : Prevent getting history from smoothed estimates.
- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth SÃ¶terhagen Paulsen

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getPIT ↑**

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

[nb_calculatePIT](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getRecursiveScore ↑**

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidualNames ↑**

residualNames = getResidualNames(obj)

Description:

Get all the unique residual names of a vector of nb_model_group object

Input:

- obj : A vector of nb_model_group objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...)
                    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when

constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **irf ↑**

[irfs,irfsBands,plotter] = irf(obj,varargin)

Description:

Produce IRFs of the model(s) represented by nb_model_group object.

Input:

- obj : A nb_model_group object.

Optional input:

- varargin : See the the irf method of the nb_model_generic class.

Output:

- [irfs,irfsBands,plotter] : See the the irf method of the nb_model_generic class.

See also:

[nb_model_generic](#)

Written by Kenneth Sæterhagen Paulsen

► **isDensityForecast ↑**

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **loadModelsFromPath** ↑

```
obj = nb_model_group.loadModelsFromPath(pathName)
```

Description:

Load models saved to separate .mat files stored in a folder to a model group object. The models must be stored as nb_model_generic or nb_model_group objects.

Input:

```
- pathName : Full path name of the folder the model files are stored.  
As a string.
```

Output:

```
- obj : An object of class nb_model_group
```

Written by Kenneth SÃ¶terhagen Paulsen

► **mincerZarnowitzTest ↑**

```
[test,pval,res] = mincerZarnowitzTest(obj,precision)
```

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

Input:

```
- obj : An object of class nb_model_group. You need to call the  
combineForecast method first!  
  
- precision : The precision of the printed result. As a string. Default  
is '%8.6f'.
```

Output:

```
- test : A nb_ts object with the test statistic. As a  
nHor x nModel x nVar nb_ts object.  
  
- pval : A nb_ts object with the p-values of the test. As a  
nHor x nModel x nVar nb_ts object.  
  
- res : A char with the printout of the test.
```

See also:

[nb_model_generic.combineForecast](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **plotForecast ↑**

```
plotter = plotForecast(obj)  
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate,...  
increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► removeObservationsOfGroup ↑

obj = removeObservationsOfGroup(obj, numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_model_group or nb_model_selection_group object.
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_model_group or nb_model_selection_group object.

See also:

`nb_model_selection_group.removeObservations`

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

`obj = set(obj,varargin)`

Description:

Sets the properties of the nb_model_group objects.

Input:

- `obj` : A vector of nb_model_group objects.

Optional input:

If number of inputs equals 1:

- `varargin{1}` : A structure of fields to be set.

Else:

- `varargin` : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object.

Output:

- `obj` : A vector of nb_model_group objects.

Written by Kenneth Sæterhagen Paulsen

► **simulateFromDensity** ↑

`obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `forecastOutput` : A forecast property of the nb_model_forecast class where the `forecastOutput.evaluation` stores the kernel density estimate.

- `draws` : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **storeModelsToPath** ↑

storeModelsToPath(obj, pathName)

Description:

Save the different models of the nb_model_group object to seperate .mat files to a given folder.

Input:

- obj : An object of class nb_model_group
- pathName : Full path name of the folder the model files should be stored. As a string. Must be ended with a '\'.

Written by Kenneth Sæterhagen Paulsen

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_group.

Output:

- s : A struct representing the nb_model_group object.

See also:

nb_model_group.unstruct

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_group objects. Use the combineForecast method to produce the combined density or point forecast.

Input:

- obj : A vector of nb_model_group objects.
- nSteps : See the uncondForecast method of the nb_model_generic class

Optional inputs:

- See the uncondForecast method of the nb_model_generic class

Output:

- obj : A vector of nb_model_group objects. See the property forecastOutput of each model stored in the models property of the nb_model_group object.

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

obj = nb_model_group.unstruct(s)

Description:

Convert a struct to an object which is a subclass of the nb_model_group class.

Input:

- s : A struct. See nb_model_group.struct.

Output:

- obj : An object which is a subclass of the nb_model_group class.

See also:

[nb_model_group.struct](#)

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model group, and optionally re-estimate, re-solve and forecast the models given the updated data

Input:

- obj : A vector of objects of class nb_model_group
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'.
- groupIndex : A 1 x nLevel double with the group level.

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if estimation or forecasting failes. The models that failes will then be removed when calling methods as compareForecast and aggregateForecast etc. See the valid property.

Output:

- obj : A vector of objects of class nb_model_group.
- valid : A logical with size 1 x nObj. true at location ii if updating of model group ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

■ nb_model_recursive_detrending

Go to: [Properties](#) | [Methods](#)

Do recursive de-trending of a model and produce recursive forecast based on this recursive detrending. The resulting object can be used by nb_model_group as a normal nb_model_generic object.

Constructor:

```
- obj = nb_model_recursive_detrending(model,varargin)

Input:

- model : An object of a subclass of the nb_model_generic class.

Optional input:

- See the set method for more on the inputs.
  (nb_model_recursive_detrending.set)

Output:

- obj : An object of class nb_model_recursive_detrending.
```

- [userData](#)

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[forecastOutput](#)** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **model** ↑

The underlying model to use for forecasting. As a subclass of the nb_model_generic class.

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that persevere the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **results** ↑

A struct storing all the results of the estimation.

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F + G*P_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

```
X_t = G*Z_t + Y_t
```

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors (exogenous variable in the case of ARIMA models).
- F : See the equation above. A nobs x 1 double.
(Storing the constant terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.
As a nobs x nobs double.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

- **transformations** [↑](#)

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; `methods('nb_math_ts')`.

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** [↑](#)

Adds the possibility to add user data. Can be of any type

► **appendData ↑**

```
obj = appendData(obj, DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► checkModel ↑

obj = checkModel(obj)

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_recursive_detrending.

Output:

- obj : An object of class nb_model_recursive_detrending.

Written by Kenneth Sæterhagen Paulsen

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables

Input:

- obj : A scalar nb_model_recursive_detrending object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

► **convert** ↑

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A 1x1 nb_model_recursive_detrending object
- expressions : A N x 4 x nPeriods cell matrix of how to transform input data to model variables recursively. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
- > third column : Any expression that can be interpreted by the nb_ts.createShift method.
- > fourth column : Comments

The third dimension of this input refers to the number of recursive period you want to estimate or forecast your model. This allow for time-varying detrending, as for example real-time hp-filtering.

Caution : The size of the third dimension must be equal to recursive period given by the recursive_start_date and recursive_end_date options.

- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A 1 x nPeriods vector of nb_graph_ts object with a graph with the detrending of each recursive period. Use the graphInfoStruct method to produce the graph of each object. Do not call it on the hole vector!!

Examples:

```
expressions = {%
    Name,      input,      shift,      description
    'QSA_DPQ_YMN',   'log(QSA_YMN)',   {'hpfilter',1600}, '',
    'QSA_DPQ_PCPIJAE', 'log(QSA_DPQ_PCPIJAE)', {'hpfilter',1600}, '',
    'QSA_DPQ_CP',     'log(QSA_DPQ_CP)',   {'hpfilter',1600}, ''};

modelRec = modelRec.createVariables(expressions)
```

[nb_model_recursive_detrending.reporting](#)

► **doForecastPerc2Dist** ↑

```
obj = doForecastPerc2Dist(obj,draws)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_recursive_detrending.forecast](#), [nb_model_recursive_detrending.forecastPerc2Dist](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist** ↑

```
[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_recursive_detrending.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity ↑**

obj = doSimulateFromDensity(obj, draws)

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_model_recursive_detrending.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **empiricalMoments ↑**

```
[m,c] = empiricalMoments(obj,varargin)
[m,c,ac1] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_group object. The options.data property of the model property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_recursive_detrending.

Optional inputs;

- 'vars' : A cellstr with the wanted variables.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

► **estimate ↑**

```
obj = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_recursive_detrending object(s).

Caution: If the underlying model is of class nb_dsg, only recursive filtering is done with the call to this function!

Input:

- obj : A vector of nb_model_recursive_detrending objects.

Optional input:

- Optional inputs given to the nb_dsg.filter method, if the model property is of class nb_dsg. Otherwise it has no effect.

Caution : The 'endDate' inputs to the filter method will be overwritten!

Output:

- obj : A vector of nb_model_recursive_detrending objects, where the estimation results are stored in the property results.

Written by Kenneth Sæterhagen Paulsen

► evalFcstAtDates ↑

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:

```

- 'RMSE'   : Root mean squared error
- 'MSE'    : Mean squared error
- 'MAE'    : Mean absolute error
- 'MEAN'   : Mean error
- 'STD'    : Standard error of the forecast error
- 'ESLS'   : Exponential of the sum of the log scores
- 'EELS'   : Exponential of the mean of the log scores
- 'MLS'    : Mean log score

- density : Set true if you have a density forecast.

- quart   : Set true if you want to compare the quarterly forecasts. This
            option automatically detects and uses the quarterly estimates
            when evaluating.

```

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **forecast** ↑

obj = forecast(obj,nSteps,varargin)

Description:

Produced recursive conditional point and density forecast of nb_model_recursive_detrending objects.

Input:

- obj : A vector of nb_model_recursive_detrending objects.
- nSteps : See the forecast method of the nb_model_generic class

Optional inputs:

- See the forecast method of the nb_model_generic class

Output:

- obj : A vector of nb_model_recursive_detrending objects. See the property forecastOutput.

Written by Kenneth Sæterhagen Paulsen

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_recursive_detrending.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist ↑**

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_recursive_detrending.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åstrøm Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getDependent ↑**

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_recursive_detrending object.

Caution: Only returned for the last period of the recursive estimation.

Input:

- obj : An object of class nb_model_recursive_detrending

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Åstrøm Paulsen

► **getDependentNames ↑**

dependentNames = getDependentNames(obj)

Description:

Get all the unique dependent variables names of a vector of nb_model_recursive_detrending objects

Input:

- obj : A vector of nb_model_recursive_detrending objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

► getEstimationStartDate ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_recursive_detrending

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

► getFiltered ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_recursive_detrending
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.

- normalize : Normalize the shock to be $N(0,1)$. Default is false.
- econometricians : Get econometricians view of the filtered variables. I.e. the filtered variables of each regime multiplied by the regime probabilities.

Output:

- data : A nb_ts object with size nobs x nvars x nPeriods included the filtered variables.

See also:

[nb_model_recursive_detrending.estimate](#)

Written by Kenneth Åkerhagen Paulsen

► **getForecast ↑**

```
fcstData           = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.
- outputType :
 - > 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.
 - The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.
- > 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date'      : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.

For real-time forecast the vintage at the time is returned as the historical data, when includeHist is true.

> 'horizon'   : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.

If includeHist is true the actual data is added as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor to one, and the fcstPercData will be non-empty, if density forecast has been produced.

- includeHist : Give true (1) to include history in the output. Only an options for the 'date' and 'horizon' outputType. Default is false (0).
```

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with size nRec x nVars. While the fcstPercData output will be a nb_ts object with size nRec x nVars x nSim. You can set the horizon to return by the optional input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_model_recursive_detrending.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables** ↑

vars = getForecastVariables(obj)

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

histData = getHistory(obj,vars,date)

Description:

Get historical data

Input:

- obj : A scalar nb_model_recursive_detrending object
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables is found.

- date : For recursively detrended and estimated models, the residual and data vary with the date of recursion, so by this option you can get the residual of a given recursion.

The same apply for real-time data.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)

- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

```
- pit      : A nb_data object with size nPeriods x nHor x nVars  
- plotter : A nb_graph_data object. please use the graph method, if you  
want to plot it.  
- pitTest : Test for a uniformly distributed PITs using a Pearson  
chi-squared test. As a 2 x nHor x nVar nb_cs object.
```

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getPosteriorDistributions** ↑

```
[distr,paramNames] = getPosteriorDistributions(obj)
```

Description:

Get posterior distributions of model.

Input:

```
- obj      : An object of class nb_model_recursive_detrending.
```

Output:

```
- distr      : A nPeriods x numCoeff nb_distribution object.  
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.
```

Written by Kenneth Sæterhagen Paulsen

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_recursive_detrending object

Caution: Only returned for the last period of the recursive estimation.

Input:

- obj : An object of class nb_model_recursive_detrending

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

► **getRecursiveEstimationGraph ↑**

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_recursive_detrending.

Output:

- plotter : An object of class nb_graph.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);
plotter.graphSubPlots();
```

See also:

[nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

► **getRecursivePeriods ↑**

```
periods          = getRecursivePeriods(obj)
[periods,dates,obj] = getRecursivePeriods(obj)
```

Description:

Get the number of recursive periods to be looped.

Input:

- obj : An object of class nb_model_recursive_detrending.

Output:

- periods : The number of recursive periods, as a scalar double.
- obj : An object of class nb_model_recursive_detrending where the options property is updated with the corrected fields 'recursive_start_date'.

Written by Kenneth Sæterhagen Paulsen

► getRecursiveScore ↑

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

```
residual = getResidual(obj)
```

Description:

Get residual from a estimated nb_model_recursive_detrending object

Input:

- obj : An object of class nb_model_recursive_detrending

Output:

- residual : Either a nb_ts object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

► **getResidualGraph** ↑

```
plotter = getResidualGraph(obj)
```

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_recursive_detrending.

Output:

- plotter : An object of class nb_graph.

Examples:

```
plotter = getResidualGraph(obj);
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sætherhagen Paulsen

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_recursive_detrending objects.

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sætherhagen Paulsen

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_recursive_detrending objects.

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.
- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert, ...
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object intput is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Inherited from superclass NB_MODEL_FORECAST

► **help ↑**

```
helpText = nb_model_recursive_detrending.help
helpText = nb_model_recursive_detrending.help(option)
helpText = nb_model_recursive_detrending.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► isDensityForecast ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► isFiltered ↑

```
ret = isFiltered(obj)
ret = isFiltered(obj,tested)
```

Description:

Test if a nb_model_recursive_detrending object is filtered or not.

Input:

- obj : An object of class nb_model_recursive_detrending.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_recursive_detrending object a Markov switching model or not.

Input:

- obj : A nb_model_recursive_detrending object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_recursive_detrending object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_recursive_detrending object empty (not estimated) or not.

Input:

- obj : A nb_model_recursive_detrending object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sætherhagen Paulsen

► plotForecast ↑

```
plotter          = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
                                         increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.

- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity** ↑

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_recursive_detrending objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_recursive_detrending.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

► **print_estimation_results ↑**

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_recursive_detrending objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_recursive_detrending.print](#)

Written by Kenneth Sæterhagen Paulsen

► **removeObservations ↑**

obj = removeObservations(obj,numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

obj = set(obj,varargin)

Description:

Sets the properties of the nb_model_recursive_detrending objects.

Input:

- obj : A vector of nb_model_recursive_detrending objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object.

Output:

- obj : A vector of nb_model_recursive_detrending objects.

Written by Kenneth Sæterhagen Paulsen

► **simulateFromDensity ↑**

obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **solve** ↑

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_model_recursive_detrending object(s).

Input:

- obj : A vector of nb_model_recursive_detrending objects.

Output:

- obj : A vector of nb_model_recursive_detrending objects, where the solved model(s) is/are stored in the property solution.

Written by Kenneth Sæterhagen Paulsen

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_recursive_detrending.

Output:

- s : A struct representing the nb_model_recursive_detrending object.

See also:

[nb_model_group.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

► **template** ↑

```
options = nb_model_recursive_detrending.template()
options = nb_model_recursive_detrending.template(num)
```

Description:

Construct a struct which can be provided to the nb_model_recursive_detrending class constructor.

This structure provided the user the possibility to set different options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

See also:

[nb_model_recursive_detrending](#)

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_C_P'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **uncondForecast ↑**

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_group objects. Use the combineForecast method to produce the combined density or point forecast.

Input:

- obj : A vector of nb_model_recursive_detrending objects.
- nSteps : See the uncondForecast method of the nb_model_generic class

Optional inputs:

- See the uncondForecast method of the nb_model_generic class

Output:

- obj : A vector of nb_model_recursive_detrending objects. See the property forecastOutput.

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

```
obj = nb_model_recursive_detrending.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_recursive_detrending class.

Input:

- s : A struct. See nb_model_recursive_detrending.struct.

Output:

- obj : An object of the nb_model_recursive_detrending class.

See also:

[nb_model_recursive_detrending.struct](#)

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model group, and optionally re-estimate, re-solve and forecast the models given the updated data

Input:

- obj : A vector of objects of class nb_model_recursive_detrending
- type : > '' : Only update data. Default
> 'estimate' : Update data and estimate.
> 'solve' : Update data, estimate and solve
> 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'.
- groupIndex : A 1 x nLevel double with the group level.

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if estimation or forecasting failes. The models that failes will then be removed when calling methods as compareForecast and aggregateForecast etc. See the valid property.

Output:

- obj : A vector of objects of class nb_model_recursive_detrending.
- valid : A logical with size 1 x nObj. true at location ii if updating of model group ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

■ nb_model_selection_group

Go to: [Properties](#) | [Methods](#)

A class for doing model selection.

Superclasses:

nb_model_group, nb_modelData

Constructor:

```
obj = nb_model_selection_group(models)
```

Input:

- models : A 1 x N vector of nb_model_generic object.

Output:

- obj : An object of class nb_model_selection_group

Examples:

See also:

[nb_model_group](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- addAutoName
- addAutoNameIfLocal
- addID
- addIDIfLocal
- forecastOutput
- models
- name
- options
- reporting
- transformations
- valid

- **addAutoName** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addAutoNameIfLocal** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addID** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **addIDIfLocal** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **models** ↑

A cell array of nb_model_generic and nb_model_group objects

Inherited from superclass NB_MODEL_GROUP

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **valid** ↑

A logical array of same dimension as models. If an element is false that means that an error occurred during estimation or forecasting for the corresponding model/model group.

Inherited from superclass NB_MODEL_GROUP

► **aggregateForecast ↑**

```
obj = aggregateForecast(obj,varargin)
```

Description:

Aggregate forecast of subcomponents of a series.

Caution: The model with the shortest forecast horizon will set the forecast horizon of the aggregated series.

Caution: A intersection of the dates from which the recursive forecast is made will be done.

Caution: If type is set to 'density' consistent paths are sampled from the marginal using a copula with an empirically estimated autocorrelation matrix.

Input:

- obj : An object of class nb_model_group

Optional Inputs:

- 'startDate' : Start date of the aggregation of forecast. I.e. the start date of which the weights are constructed. Default is to use the first shared forecast date. Must be given as a string or a nb_date object.

- 'endDate' : End date of the aggregation of forecast. I.e. the end date of which the weights are constructed. Default is to use the last shared forecast date. Must be given as a string or a nb_date object.

- 'nSteps' : The number of steps ahead forecast. The default is to take the minimum over the selected models.

- 'density' : Give 1 (true) if you want to evaluate and produce density forecast. Default is not (0 or false).

Caution: If the 'method' option is set to 'copula' the selected variables must be stationary.

Caution: If you set this option to false the mean forecast is used to construct the point forecast from model which has produced density forecast.

- 'method' : Either:

> 'copula' : Use a copula to draw consistent draws from each marginal distribution. Default.

> 'perfectcorr' : Make the assumption that the aggregated variables are perfectly correlated, and we can therefore just sum over the distribution using the chosen weights.

- 'condLags' : Number of lags included in the calcualtion of the (auto)correlation matrix used when 'density' is set to true and 'method' is set to 'copula'. I.e. the

number of periods to "condition on". This option should only be used if the forecast densities to be aggregated are not condition on information up until the time of the forecast. This is not the normal case, so default is 0.

- 'nLags' : Max number autocorrelation to include in the stacked autocorrelation matrix. Default is 5. If 0, only contemporaneous correlations are used. Only an option when 'density' is set to true and 'method' is set to 'copula'. If empty the full set of autocorrelations are used.
- 'weights' : The aggregation weights. As a 1 x nModels double, or a T x nModels nb_ts object (time-varying weights). Default is equal weights.
- 'newVar' : A string with the name of the aggregate series.
- 'variables' : A cellstr with same length as obj.models. These are the variables from the different models to aggregate. Default is to take the first variables from the forecastOutput.variables list.
- 'draws' : Number of draws from the marginal distributions of the disaggregated models to base the new aggregated density forecast on. Default is 1000.
- 'fcstEval' : See the forecast method of the nb_model_generic class.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.9. Can be empty, i.e. no percentiles are reported, and all simulation are stored.
- 'parallel' : When numel(obj) > 1 you may run the process in parallel. true or false.
 Caution: Cannot be provided if numel(obj) == 1.
- 'cores' : Number of cores to use when the process is ran in parallel. As a positive integer.
 Caution: Cannot be provided if numel(obj) == 1.
- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'recursive' : Calculate the correlation matrix recursively when aggregating density forecast using the 'copula' method. true or false. Default is false.
- 'rollingWindow' : If the correlation matrix should be calculated recursively with a rolling window. Default is [], i.e. to use the full sample to calculate the correlation matrix.
- 'waitbar' : true or false. Default is true. Not in parallel

session.

- 'weightsMethod' : Either 'actual', 'end', 'ar' or 'var'. This option sets the way weights are recursively extrapolated when the 'weights' is set to an object of class nb_ts. See the 'method' input to the recursiveExtrapolate method of the nb_ts class for more on this option.
- 'sigmaMethod' : Either 'var' or 'correlation'. If set to 'var' the autocorrelation matrix is estimated using the theoretical conditional moments of the forecast from a VAR. If 'correlation' the autocorrelation matrix is estimated based on the empirical data only. 'correlation' is default.

Output:

- obj : A nb_model_group object storing the aggregated forecast.

See also:

[nb_model_selection_group.combineForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **appendData** ↑

obj = appendData(obj,DB)

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **checkModel** ↑

obj = checkModel(obj)

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_group.

Output:

- obj : An object of class nb_model_group.

Written by Kenneth Sæterhagen Paulsen

► **checkReporting** ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **combineForecast** ↑

```
obj = combineForecast(obj,varargin)
[obj,weights,plotter] = combineForecast(obj,varargin)
```

Description:

Combine density or point forecast.

Input:

- obj : An object of class nb_model_group

Optional inputs:

- 'startDate' : Start date of the combination of forecast. I.e. the start date of which the weights are constructed. Default is to use the first shared forecast date. Must be given as a string or a nb_date object.
- 'endDate' : End date of the combination of forecast. I.e. the end date of which the weights are constructed. Default is to use the last shared forecast date. Must be given as a string or a nb_date object.
- 'nSteps' : The number of steps ahead forecast. The default is to take the minimum over the selected models.
- 'type' : A string with one of the following:
 - 'MSE' : Mean squared error
 - 'RMSE' : Root mean squared errors
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'equal' : Use equal weights
- 'draws' : Number of draws from the combine density. Default is 1000.
- 'density' : Give 1 (true) if you want to evaluate and produce density forecast. Default is not (0 or false).

Caution: If you set this option to false the mean forecast is used to construct the point forecast from model which has produced density forecast.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.9. Can be empty, i.e. no percentiles are reported. Only an option when 'density' is set to true.
- 'allPeriods' : Give 1 (true) if you want to construct (density) forecast for all recursive forecast (which may have been produced by the models stored in this object). Default is 0 (false), i.e. only to produce forecast for the last period.
- 'optimizeOpt' : Give 1 (true), if you want to use optimized weights, instead of weights based on the formula;

```

w(i) = score(i)/sum(score)

Caution : Not yet finished!!!

- 'fcstEval'      : See the forecast method of the nb_model_generic
                      class.

- 'varOfInterest' : As a string or a cellstr. Use this option if you want
                      to combine forecast for one or more variables.

- 'check'          : Give true (1) to check that the domain is the same
                      for all models. If they are not we need to simulate
                      "new" densities at a shared domain (using 1000
                      bins). This could take a lot of time! To prevent this
                      use the 'bins' option of the forecast method
                      of the nb_model_generic. Default is false (The error
                      may be hard to interpret if the domain is
                      conflicting). This may also lead to more
                      severe density estimation errors!

- 'saveToFile'    : Logical. Save densities and domains to files. One
                      file for each model. Default is false (do not).

- 'rollingWindow' : Set it to a number if the combination weights are to
                      be calculated using a rolling window. Default is
                      empty, i.e. to calculate the weights recursively using
                      the full history at each recursive step.

- 'parallel'       : Set to true to run forecast combination in parallel.

- 'lambda'         : Give the value of the parameter of the exponential
                      decaying weights on past forecast errors when
                      constructing the score. If empty the weights on all
                      past forecast errors are equal.

```

Output:

- obj : An object of class nb_model_group where the combined
 forecast is saved in the property forecastOutput
- weights : A struct. Where each field store the weights at forecast
 horizon h. Each feild consist of a nDates x nModel x nVar
 nb_ts object.
- plotter : A 1 x h nb_graph_ts object, which you can call the graph
 method on to produce a graph of the weights over the
 recursive periods if allPeriods is set to true.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **convert ↑**

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach ↑**

obj = convert(obj,freq,methods,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables ↑**

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
 - > third column : Any expression that can be interpreted by the nb_ts.createShift method.
 - > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,    shift,   description
'VAR1_G',   'pcn(VAR1)', 'avg',   'VAR1 growth'
'VAR2_G',   'pcn(VAR2)', 'avg',   'VAR2 growth'
'VAR3_G',   'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

► **doForecastPerc2Dist** ↑

```
obj = doForecastPerc2Dist(obj, draws)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_selection_group.forecast](#), [nb_model_selection_group.forecastPerc2Dist](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist** ↑

```
[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_selection_group.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity ↑**

obj = doSimulateFromDensity(obj, draws)

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

`nb_model_generic.forecast`, `nb_model_selection_group.simulateFromDensity`

Written by Per Bjarne Bye and Atle Loneland

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_group` object. The `options.data` property of the `models` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- `obj` : An object of class `nb_model_group`

Optional inputs;

- `'vars'` : A cellstr with the wanted variables.
- `'output'` : Either `'nb_cs'` or `'double'`. Default is `'nb_cs'`.
- `'stacked'` : If the output should be stacked in one matrix or not. true or false. Default is false.
- `'nLags'` : Number of lags to compute when `'stacked'` is set to true.
- `'type'` : Either `'covariance'` or `'correlation'`. Default is `'correlation'`.
- `'startDate'` : The start date of the calculations. Default is the start date of the `options.data` property. Only for time-series! Must be a string or a `nb_date` object.
- `'endDate'` : The end date of the calculations. Default is the end date of the `options.data` property. Only for time-series! Must be a string or a `nb_date` object.
- `'demean'` : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **estimate** ↑

obj = estimate(obj,varargin)

Description:

Estimate the model(s) represented by nb_model_group object(s).

Input:

- obj : A vector of nb_model_group objects.

Optional input:

- varargin : See the the estimate method of the nb_model_generic class.

Output:

- obj : A vector of nb_model_group objects, where the estimation results are stored in the property results.

See also:

[nb_model_generic](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **evalFcstAtDates** ↑

[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...
quart)

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► forecast ↑

obj = forecast(obj,nSteps,varargin)

Description:

Produced conditional point and density forecast of nb_model_group objects. Use the combineForecast method to produce the combined density or point forecast.

Input:

- obj : A vector of nb_model_group objects.
- nSteps : See the forecast method of the nb_model_generic class

Optional inputs:

- See the forecast method of the nb_model_generic class

Output:

- obj : A vector of nb_model_group objects. See the property forecastOutput of each model stored in the models property of the nb_model_group object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_selection_group.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_selection_group.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► [getActual](#) ↑

```
actual = nb_model_group.getActual(models, vars, startFcst, nSteps, inputs)
```

Description:

Get actual data to compare against the forecast.

Input:

- models : See the property models of the nb_model_group class.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► getDependentNames ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_group objects

Input:

- obj : A vector of nb_model_group objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► getEstimationStartDate ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the model group. The return value is the estimation start date of the model that is ordered last.

Input:

- obj : An object of class nb_model_group

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **getForecast** ↑

```
fcstData          = getForecast (obj)
[fcstData,fcstPercData] = getForecast (obj,outputType)
[fcstData,fcstPercData] = getForecast (obj,outputType,includeHist,varargin)
```

Description:

Get the forecast output on the nb_ts format object.

Input:

- obj : An object of class nb_model_group. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is a empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they is calculated, or else it is a empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1,
```

while fcstPercData will be empty. nPerc will then be the number of percentiles/simualtions. Mean will be at last page.

For real-time forecast the vintage at the time is returned as the historical data, when includeHist is true.

- includeHist : Give true (1) to include history in the output. Only an options for the 'date' outputType. Default is false (0).

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with size nRec x nVars. While the fcstPercData output will be a nb_ts object with size nRec x nVars x nSim. You can set the horizon to return by the optional input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_model_selection_group.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **getForecastVariables ↑**

vars = getForecastVariables(obj)

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_group object
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.
- date : For recursively estimated models, the residual vary with the date of recursion, so by this option you can get the residual of a given recursion.
The same apply for real-time data.
- notSmoothed : Prevent getting history from smoothed estimates.
- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will
get the PIT from the start date of the recursive forecast and
use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct
the PITs based on the period from the estimation start date
until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a

nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getRecursiveScore ↑**

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:

```

        - 'RMSE'   : Root mean squared error
        - 'MSE'    : Mean squared error
        - 'MAE'    : Mean absolute error
        - 'MEAN'   : Mean error
        - 'STD'    : Standard error of the forecast error
        - 'ESLS'   : Exponential of the sum of the log scores
        - 'EELS'   : Exponential of the mean of the log scores
        - 'MLS'    : Mean log score

- dim          : Either 'variables' to get the recursive scores of all
                  the variables forecast by a model (the obj input must
                  be a scalar object), or else the name of the variable
                  to get the score of (must be part of all models!).

- startDate    : The date to begin constructing the score. Can be
                  empty. Either as a string or an object of class
                  nb_date.

- endDate      : The date to end constructiong the score. Can be
                  empty. Either as a string or an object of class
                  nb_date.

- invert        : true | false. Default true. If true it will invert the
                  score for 'RMSE', 'MSE', 'MAE' and 'STD'.

```

Output:

```

- score     : A nb_ts object with size nPeriods x nVars x nHorizon if dim
               equal 'variables', else a nb_ts object with size nPeriods x
               nObj x nHorizon.

- plotter   : A nb_graph_ts object to plot the recursive scores. Use the
               graph method. One figure per horizon!

```

See also:

[nb_model_generic.forecast](#), [nb_model_generic.constructScore](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidualNames ↑**

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_group object

Input:

```
- obj         : A vector of nb_model_group objects
```

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert, ...
                  rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log scoreIf the object input is a vector, the type input can also be a cellstr array with matching length.
- Caution: See comment to the invert input!
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give

NOT inverted root mean squared error!

- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

► **help ↑**

```
helpText = nb_model_selection_group.help
helpText = nb_model_selection_group.help(option)
helpText = nb_model_selection_group.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **irf** ↑

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Produce IRFs of the model(s) represented by nb_model_group object.

Input:

- obj : A nb_model_group object.

Optional input:

- varargin : See the the irf method of the nb_model_generic class.

Output:

- [irfs,irfsBands,plotter] : See the the irf method of the nb_model_generic class.

See also:

[nb_model_generic](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **isDensityForecast** ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **loadModelsFromPath** ↑

```
obj = nb_model_group.loadModelsFromPath(pathName)
```

Description:

Load models saved to separate .mat files stored in a folder to a model group object. The models must be stored as nb_model_generic or nb_model_group objects.

Input:

- pathName : Full path name of the folder the model files are stored.
As a string.

Output:

- obj : An object of class nb_model_group

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **mincerZarnowitzTest** ↑

```
[test,pval,res] = mincerZarnowitzTest(obj,precision)
```

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

Input:

- obj : An object of class nb_model_group. You need to call the combineForecast method first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

► [modelSelection ↑](#)

```
modelGroup = modelSelection(obj);
[modelGroup,plotter] = modelSelection(obj);
[modelGroup,plotter,errorReport] = modelSelection(obj)
```

Description:

Select models based on their forecasting properties.

- 'class' == 'nb_var':

This function will test combinations of the variables in the data and with different lag length.

This code is inspired by a script made by Martin Blomhoff Holm,
Norges Bank 03/06/2014

- 'class' == 'nb_arima'

This function will test combinations of AR and MA terms.

Caution: This code will not produce the final combined forecast,
use the combineForecast method of nb_model_group class on the output to produce these forecast.

Output:

- modelGroup : A cell array with size 1xM, with the best models at different horizons. See the 'nHor' option.
Caution : If the 'setUpOnly' option is set to true this output is a 1 x num vector of nb_var models.
- plotter : A graph showing the most selected variables in the final selection of models. Shown in a histogram. Use the graph method on the returned object to plot it on the screen. An object of class nb_graph_cs.

[nb_model_group.combineForecast](#), [nb_getCombinations](#)

Written by Kenneth Sæterhagen Paulsen

► [plotForecast ↑](#)

```
plotter = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity** ↑

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **removeObservationsOfGroup** ↑

```
obj = removeObservationsOfGroup(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_model_group or nb_model_selection_group object.
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_model_group or nb_model_selection_group object.

See also:

`nb_model_selection_group.removeObservations`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **set ↑**

`obj = set(obj,varargin)`

Description:

Sets the properties of the nb_model_selection_group objects.

Input:

- `obj` : A vector of nb_model_selection_group objects.

Optional input:

If number of inputs equals 1:

- `varargin{1}` : A structure of fields to be set.

Else:

- `varargin` : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object.

Output:

- `obj` : A vector of nb_model_selection_group objects.

Written by Henrik Halvorsen Hortemo

► **simulateFromDensity ↑**

`obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)`

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **storeModelsToPath ↑**

storeModelsToPath(obj, pathName)

Description:

Save the different models of the nb_model_group object to seperate .mat files to a given folder.

Input:

- obj : An object of class nb_model_group
- pathName : Full path name of the folder the model files should be stored. As a string. Must be ended with a '\'.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **struct ↑**

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_group.

Output:

- s : A struct representing the nb_model_group object.

See also:

[nb_model_selection_group.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **template** ↑

```
options = nb_model_selection_group.template(num)
```

Description:

Construct a struct which can be provided to the nb_model_selection_group class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

See also:

[nb_model_generic](#)

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

```

- obj : A nb_model_forecast object with density forecast

- restrictions : Restrictions as a n x 3 cell array,
    {variable, date, test}.

    > variable : The variable(s) to test,
        as a string or cell array of strings.

    > date : The date as a string. If a cell array is given, a
        copy of the restriction will be made for every given
        date.

    > test : Restriction test as a function handle. The value(s)
        of the variable(s) in 'variable' at time 'date' are
        passed as arguments. Should return a logical.

```

Output:

- out : A double with the probability

Example:

```

restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...
    {'QSA_URR', 'QSA_DPO_C_P'}, '2014Q1', @(x, y) x < y};
probability = model.testForecastRestrictions(restrictions);

```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **uncondForecast ↑**

obj = uncondForecast(obj,nSteps,varargin)

Description:

Produced unconditional point and density forecast of nb_model_group objects. Use the combineForecast method to produce the combined density or point forecast.

Input:

```

- obj : A vector of nb_model_group objects.

- nSteps : See the uncondForecast method of the nb_model_generic class

```

Optional inputs:

- See the uncondForecast method of the nb_model_generic class

Output:

- obj : A vector of nb_model_group objects. See the property forecastOutput of each model stored in the models property of the nb_model_group object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **unstruct** ↑

obj = nb_model_group.unstruct(s)

Description:

Convert a struct to an object which is a subclass of the nb_model_group class.

Input:

- s : A struct. See nb_model_group.struct.

Output:

- obj : An object which is a subclass of the nb_model_group class.

See also:

[nb_model_selection_group.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

► **update** ↑

obj = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)

Description:

Update data of model group, and optionally re-estimate, re-solve and forecast the models given the updated data

Input:

- obj : A vector of objects of class nb_model_group
- type : > '' : Only update data. Default
> 'estimate' : Update data and estimate.
> 'solve' : Update data, estimate and solve

```

        > 'forecast' : Update data, estimate, solve and forecast.

- warningOn    : 'on' or 'off'. If 'on' only warnings are given while
                  the data source is updated, else an error will be given.
                  Default is 'on'. Set it to 'off', if the 'write' option
                  is used.

- inGUI        : 'on' or 'off'. Indicate if the update command is called
                  in the GUI or not. Default is 'off'.

- groupIndex   : A 1 x nLevel double with the group level.

```

Optional input:

```

- 'write'      : Give this string as one of the optional inputs to write
                  an error file if estimation or forecasting failes. The
                  models that failes will then be removed when calling
                  methods as compareForecast and aggregateForecast etc.
                  See the valid property.

```

Output:

```

- obj       : A vector of objects of class nb_model_group.

- valid    : A logical with size 1 x nObj. true at location ii if
              updating of model group ii succeeded, otherwise false. If
              'write' is not used an error will be thrown instead, so in
              this case this output will be true for all models.

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GROUP

■ nb_nonLinearEq

Go to: [Properties](#) | [Methods](#)

A class for estimation of single non-linear equation models.

Superclasses:

nb_model_generic

Constructor:

```
obj = nb_nonLinearEq(varargin)
```

Optional input:

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : An nb_nonLinearEq object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#), [nb_nonLinearEq.template](#)
[nb_nonLinearEq.help](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- [addAutoName](#)
- [dependent](#)
- [forecastOutput](#)
- [parser](#)
- [solution](#)
- [addAutoNameIfLocal](#)
- [endogenous](#)
- [name](#)
- [reporting](#)
- [transformations](#)
- [addID](#)
- [estOptions](#)
- [options](#)
- [residuals](#)
- [userData](#)
- [addIDIfLocal](#)
- [exogenous](#)
- [parameters](#)
- [results](#)

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[dependent](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgen models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **[endogenous](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsgen models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **parser** ↑

This property will store the info on the model, such as equations etc, otherwise it will be empty.

Caution: If you are dealing with an object of class nb_dsg, this property will be empty, if the DSGE model is parsed with RISE or Dynare.

Inherited from superclass NB_MODEL_PARSE

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

```
O_t = F*X_t + G*Y_t + u_t, u ~ N(0,R)
```

Observation equation (ARIMA models only):

```
X_t = G*Z_t + Y_t
```

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.
As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres)

indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

► **`addConstraints`** ↑

```
obj = addConstraints(obj,constraints)
```

Description:

Add (more) constraints to the parameters during estimation. The constraints can only include parameters (and numbers).

Input:

- obj : An object of class nb_dsg or nb_nonLinearEq.
- constraints : A N x M char array or a N x 1 (or 1 x N) cellstr array.
Each element will be counted as a new constraint.

Output:

- obj : An object of class nb_dsg or nb_nonLinearEq.

See also:

[nb_dsg.parse](#), [nb_nonLinearEq.parse](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_PARSE

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters ↑**

obj = assignParameters(obj,varargin)

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- `obj` : An object of class `nb_model_generic`, where the parameters of the underlying model has been changed. See `solve` to get the solution of the model with the updated parameters.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **assignPosteriorDraws** ↑

`obj = assignPosteriorDraws(obj,varargin)`

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- `'param'` : The names of the assign parameters. As a `cellstr` vector.
- `'value'` : The values of the assign parameters. As a double `nParam x nReg x nDraws` vector.

> Optional number of input pairs:

- `'beta'` : Assign all the posterior draws of the parameters of the main equation. Must be of same size as `obj.results.beta`. The draws must come in the third dimension.
- `'sigma'` : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as `obj.results.sigma`. The draws must come in the third dimension.
- `'lambda'` : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as `obj.results.lambda`. Only for factor models. The draws must come in the third dimension.
- `'R'` : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as `obj.results.R`. Only for factor models. The draws must come in the third dimension.
- `'period'` : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► assignTexNames ↑

```
obj = assignTexNames(obj, names, texNames)
```

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as $_t$ is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.
- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► calculateMultipliers ↑

```
mult = calculateMultipliers(obj, varargin)
```

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!
- 'instrument' : A one line char with the name of the instrument. Must be provided!
- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!
- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!
- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.
- 'perc' : Error band percentiles. As a 1 x nPerc double. E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the double method on this output to convert it to a double matrix.

See also:

[nb_nonlineareq.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Åtterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

obj = calculateStandardError(obj,method,draws)

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):
 - stdBeta : Standard deviation of coefficient of the main equation.
 - tStatBeta : T-statistic for the coefficient of the main equation.
 - pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
 - stdLambda : Standard deviation of coefficient of the observation equation.
 - tStatLambda : T-statistic for the coefficient of the observation equation.
 - pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

```
obj = checkModel(obj)
```

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosteriors** ↑

```
[DB,plotter,pAutocorr] = checkPosteriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot. Default is 10.
- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
 - plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
 - pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkReporting** ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments** ↑

c = conditionalTheoreticalMoments(obj,varargin)

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic
- Optional inputs;
- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.
 - 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
 - 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'draws' must be set to a number > 1.
 - 'method' : The selected method to make the parameter draws. Default is ''. See below for what that means.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mBlockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" paramters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rBlockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" paramters based on estimation on these data.

```

Only an option for models estimated
with classical methods.

> 'wildBlockBootstrap' : Create artificial data by wild
overlapping random block length
bootstrap., and then "draw" parameters
based on estimation on these data.
Only an option for models estimated
with classical methods.

> 'posterior'          : Posterior draws. Only for models
estimated with bayesian methods.
Default for models estimated with
bayesian methods.

Caution : Posterior draws is
already made at the
estimation stage.

- 'nSteps'      : Number of steps ahead. As an integer.

```

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constraints ↑**

```
[C,Ceq] = nb_model_parse.constraints(pars,constrFuncEq,constrFuncIneq,
varargin)
```

Description:

Function that will be converted into a function handle during estimation when parameter constraints are added.

Input:

- pars : The current values of the parameters.
- constrFuncEq : A function handle, which is constructed in nb_model_parse.constraints2func, that evaluate the equality constraints on the parameters.
- constrFuncIneq : A function handle, which is constructed in nb_model_parse.constraints2func, that evaluate the inequality constraints on the parameters.

Output:

- C : The value of the evaluated inequality constraints. Parameter values are feasible as long as all(C <= 0).
- Ceq : The value of the evaluated equality constraints. Parameter values are feasible as long as all(abs(Ceq) < eps), for some small eps.

See also:

[nb_nonlineareq.constraints2func](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_PARSE

► **constructCondDB** ↑

```
condDB           = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s)

to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...  
    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.

- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

Inherited from superclass NB_MODEL_GENERIC

► **convert ↑**

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach** ↑

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the

input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
 - > third column : Any expression that can be interpreted by the nb_ts.createShift method.
 - > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name, input, shift, description
  'VAR1_G', 'pcn(VAR1)', 'avg', 'VAR1 growth'
  'VAR2_G', 'pcn(VAR2)', 'avg', 'VAR2 growth'
  'VAR3_G', 'pcn(VAR3)', 'avg', 'VAR3 growth'};

model = model.createVariables(expressions)
```

Written by Kenneth Åtterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **dieboldMarianoTest ↑**

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.

- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!

- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_nonlineareq.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity ↑**

obj = doSimulateFromDensity(obj, draws)

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_nonLinearEq.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **empiricalMoments ↑**

```
[m,c] = empiricalMoments(obj,varargin)
[m,c,ac1] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_generic object. The options.data property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part you can find cov(x,y(-i)),

where `x` is the variable along the first dimension. In the lower triangular part the you can find `cov(x(-i),y)`, where `x` is the variable along the first dimension.

E.g: You have two variables `x` and `y`, then to find `cov(x,y(-i))` you can use `getVariable(varargin{i},'y','x')`, while to get `cov(x(-i),y) (== cov(x,y(+i)))` you can use `getVariable(varargin{i},'x','y')`. (This example only works if the output is of class `nb_cs`)

See also:

[nb_nonLinearEq](#)[graphCorrelation](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **eq ↑**

`ret = eq(obj,other)`

Description:

Test if `nb_model_generic` objects are equal. In the sens they have the same properties.

Input:

- `obj` : A `nb_model_generic` object either with same size as others, or equal to 1.
- `others` : A `nb_model_generic` model with `dim == 3` or less

Output:

- `ret` : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind      = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **estimate** ↑

```
obj          = estimate(obj,varargin)
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► evalFcstAtDates ↑

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)  
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

► **evaluateForecast** ↑

obj = evaluateForecast(obj,varargin)

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.

- 'fcstEval' : See the documentation of the same input in the forecast method.

- 'compareToRev' : See the documentation of the same input in the forecast method.

- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior** ↑

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsg.e.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► forecast ↑

```
obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for foward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' : - '' : No forecast evaluation. Default
- 'se' : Square error forecast evaluations.
- 'abs' : Absolute forecast error
- 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
- 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states

input is providing the full path of regimes. Default is 1.

- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density forecast.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'bins' : The length of the bins og the domain of the density. Either;
 - > [] : The domain will be found. See nb_getDensityPoints (default is that 1000 observations of the density is stored).
 - > integer : The min and max is found but the length of the bins is given by the provided integer.
 - > cell : Must be on the format:
 - {'Var1',lowerLimit1,upperLimit1,binsL1; 'Var2',lowerLimit2,upperLimit2,binsL2; ...}
 - lowerLimit1 : An integer, can be nan, i.e. will be found.
 - upperLimit1 : An integer, can be nan, i.e. will be found.
 - binsL1 : An integer with the length of the bins. Can be nan. I.e. bins length will be adjusted to create a domain of 1000 elements.

Caution : The variables not included will be given the default domain. No warning will be

given if a variable is provided in the cell but not forecast by the model. (This because different models can forecast different variables)

Caution : The combineForecast method of the nb_model_group class is much faster if the lower limit, upper limit! Or else it must simulate new draws and do kernel density estimation for each model again with the shared domain of all models densities.

- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is not empty this will set the start date of the recursive forecast. Default is to start from the first possible date.

- 'endDate' : The end date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used.

Caution: If 'fcstEval' is empty this input will have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).

- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.

- 'condDB' : One of the following:

> A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.

> A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.

> A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also

possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)

> A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is choosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the

conditional information. If an shock/residual is not included here, it means that it is not activated.

> StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.

Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.

If not provided. Model stds are used.

> Horizon : Anticipated horizon of the shocks/residual. 1 is default.

> Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.

- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.

- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.

- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.

> 'endo' : All the endogenous variables are returned.

> 'fullendo' : All the endogenous variables are returned included the lag variables.

> 'full' : All the variables are returned included the lag variables. Also

including exogenous and shocks.

> 'all' : All variables are returned (but not the lags). Including exogenous and shocks.

- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.

> double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.

> 'mean' : Start from the mean of the data observations. Default.

> 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.

> 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)

- 'startingProb' : Either a double or a char:

> [] : If the model is filtered the starting value is calculated on filtered transition probabilities. Otherwise the ergodic mean is used.

> double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.

> 'ergodic' : Start from the ergodic transition probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

- 'states' : Either an integer with the regime to forecast/simulate in, or an object of class nb_ts with the regimes to condition on. The name of the

variable must be 'states'.

Caution: For break-point models this is decided by the dates of the breaks, and cannot be set by this option!

- 'compareToRev' : Which revision to compare to. Default is final revision, i.e. []. Give 5 to get fifth revision. must be an integer. Keep in mind that this number should be larger than the nSteps input.
 - 'compareTo' : Sometime you want to evaluate the forecast of one variable against another variable which is not part of the model. E.g. if you use the first release of a variable and want to compare it against the final release. To do this you can give a cellstr with size $n \times 2$, where n is the number of variables to change the the actual observations to test against. {'VAR_1','VAR_FINAL',...}.
 - 'estimateDensities' : true or false. true if you want to do a kernel density estimation of the density forecast.
 - 'exoProj' : Tolerate missing exogenous variables by projecting them by a fitted model. Only when the 'condDB' input is empty!
- Options are:
- '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.
 - 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.
- Caution :** If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.
- Caution :** If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.
- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1,'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when exoProj is set to 'AR'.

- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matix. For the order of the variables see; obj.solution.endo. The

value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs' : This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.
- 'seed' : Set simulation seed. Default is 2.0719e+05.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_nonLinearEq.parameterDraws](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist ↑**

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_nonlineareq.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► forecastPerc2ParamDist ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_nonlineareq.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst, ...
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditinal information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments** ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Inherited from superclass NB_MODEL_GENERIC

► **getDependent** ↑

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

dependentNames = getDependentNames(obj)

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)

Written by Kenneth SÃ¶terhagen Paulsen
```

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

```
- obj : An object of class nb_model_generic
```

Output:

```
- start : An object of class nb_date.
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getFiltered** ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

```
- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.
```

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsgf.filter](#), [nb_nonlineareq.estimate](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast ↑**

```
fcstData           = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.
- outputType :
 - > 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

```

> 'graph'      : This option can be used to make it easier to plot the
                  recursive densities.

The fcstData output is a struct where the fields
are the recursive forecast periods. Each field has size
nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields
are the recursive forecast periods. Each field has size
nHor x nVars x nPerc. Storing the
percentiles/simulations of the forecast if they is
calculated, or else it is a empty struct.

To graph the recursive forecast use this example:

fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date'       : A string or a nb_date object with the date of the
                  wanted forecast. E.g. '2012Q1'. The fcstData will
                  be a nb_ts object with size nHor x nVar x nPerc + 1,
                  while fcstPercData will be empty. nPerc will then be
                  the number of percentiles/simualtions. Mean will be at
                  last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'    : This option will return the forecast as a
                  nPeriods + nHor x nVar x nHor nb_ts object. This
                  option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
                  options for the 'date' and 'horizon' outputType.
                  Default is false (0).

```

Optional inputs:

```

> 'horizon'    : The fcstData output will be a nb_ts object with
                  size nRec x nVars. While the fcstPercData output
                  will be a nb_ts object with size nRec x nVars x nSim.

```

You can set the horizon to return by the optional input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_nonLinearEq.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables** ↑

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.
- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.
The same apply for real-time data.
- notSmoothed : Prevent getting history from smoothed estimates.
- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getLHSVars ↑**

```
vars = getLHSVars(obj)
vars = getLHSVars(obj,varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgen object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgen object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.

- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit           = getPIT(obj)
[pit,plotter] = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.

- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the

start date of the data stored in the model object.

- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods ↑**

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

p = getParameters(obj,varargin)

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

: Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.

: Give 'double' to return the value as a numerical array.

: Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions** ↑

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.

- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_subplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [getRecursiveScore ↑](#)

```
score          = getRecursiveScore(obj,type)  
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores

```

        - 'MLS'      : Mean log score

- dim          : Either 'variables' to get the recursive scores of all
                  the variables forecast by a model (the obj input must
                  be a scalar object), or else the name of the variable
                  to get the score of (must be part of all models!).

- startDate    : The date to begin constructing the score. Can be
                  empty. Either as a string or an object of class
                  nb_date.

- endDate      : The date to end constructiong the score. Can be
                  empty. Either as a string or an object of class
                  nb_date.

- invert        : true | false. Default true. If true it will invert the
                  score for 'RMSE', 'MSE', 'MAE' and 'STD'.

```

Output:

```

- score       : A nb_ts object with size nPeriods x nVars x nHorizon if dim
                  equal 'variables', else a nb_ts object with size nPeriods x
                  nObj x nHorizon.

- plotter     : A nb_graph_ts object to plot the recursive scores. Use the
                  graph method. One figure per horizon!

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual ↑**

```
residual = getResidual(obj)
```

Description:

Get residual from a estimated nb_model_generic object

Input:

```
- obj : An object of class nb_model_generic
```

Output:

```
- residual : Either a nb_ts or a nb_cs object with residual(s) stored.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph** ↑

```
plotter = getResidualGraph(obj)
```

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

roots = getRoots(obj)

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if

allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution** ↑

```
value = getSolution(obj,type)
```

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast. These are the variables that may be given to the 'varOfInterest' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'.
- observables : A cellstr with the observables the model may forecast. These are the observables that may be given to the 'observables' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation ↑**

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

`nb_nonLinearEq.empiricalMoments`, `nb_graphPagesGUI`, `nb_graph_cs`

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **handleCondInfo** ↑

`ret = handleCondInfo(obj)`

Description:

Check if a `nb_model_estimate` object handle conditional info.

Input:

- `obj` : A scalar `nb_model_estimate` object.

Output:

- `ret` : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass `NB_MODEL_ESTIMATE`

► **handleMissing** ↑

`ret = handleMissing(obj)`

Description:

Check if a `nb_model_estimate` object handle missing observations.

Input:

- `obj` : A scalar `nb_model_estimate` object.

Output:

- `ret` : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass `NB_MODEL_ESTIMATE`

► **help** ↑

```
helpText = nb_nonLinearEq.help  
helpText = nb_nonLinearEq.help(option)  
helpText = nb_nonLinearEq.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **initialize** ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **interpretForecast** ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.
- 'periods' : The number of periods that you let innovations from

the model represented by obj be active.

- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_nonlineareq.forecast](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [irf](#) ↑

[irfs,irfsBands,plotter] = irf(obj,varargin)

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsg objects.
- 'compare' : Give true if you have a scalar nb_dsg model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.
- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.
- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.

I.e. {'var1',100,...} or
{{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}
- 'fanPerc' : This options sets the error band percentiles of the graph, when the 'perc' input is empty. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.

```

- 'foundReplic'      : A struct with size 1 x replic. Each element
                      must be on the same format as obj.solution. I.e.
                      each element must be the solution of the model
                      given a set of drawn parameters. See the
                      parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

- 'irfCompare'       : A struct on the same format as the irfs output from
                      this function with the IRFs to compare to.

- 'levelMethod'       : One of the following:

  > 'cumulative product'           : cumprod(1 + X,1)
  > 'cumulative sum'              : cumsum(X,1)
  > 'cumulative product (log)'     : log(cumprod(1 + X,1))
  > 'cumulative sum (exponential)' : exp(cumsum(X,1))
  > 'cumulative product (%)'       : cumprod(1 + X/100,1)
  > 'cumulative sum (%)'          : cumsum(X/100,1)
  > 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
  > 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
  > '4 period growth (log approx)' : nb_msum(X,3)

- 'method'             : The selected method to create error bands.
                      Default is ''. See help on the method input of the
                      nb_model_generic.parameterDraws method for more
                      this input. An extra option is:

  > 'identDraws' : Uses the draws of the matrix with
                  the map from structural shocks to dependent
                  variables. See nb_var.set_identification. Of
                  course this option only makes sense for VARs
                  identified with sign restrictions.

- 'normalize'          : A 1 x 3 cell. First element must be the variable
                      name as a string. The second element must be the
                      value to normalize to, as an integer. While the
                      third element is the period to be normalized, if
                      set to inf, it will normalize the max impact
                      period.

E.g. {'Var',1,2}, {'Var',1,inf}

Caution: 2 means observation 2 of the IRF, and as
          the IRF start at period 0, this means that
          observation 2 is period 1.

- 'normalizeTo'        : 'draws' or 'mean'. 'draws' normalize each draw of
                      irfs, while 'mean' normalize the mean and scale
                      percentiles/other draws accordingly. Default is

```

```

'draws'.

Caution: Setting this to 'mean' will not work for
reported variables that is not measured
as % deviation from steady-state/mean.

- 'newReplic'
  : When out of parameter draws, this factor decides how
many new draws are going to be made. Default is 0.1.
I.e. 1/10 of the replic input.

- 'parallel'
  : Give true if you want to do the irfs in parallel.
This option will parallelize over models. Default
is false.

- 'parallelL'
  : Give true if you want to do the irfs in parallel.
This option will parallelize over parameter
simulations. Only an option if numel(obj) == 1.
Default is false.

- 'pause'
  : true or false, Enable or disable pause option
when calculating the irfs. Default is true.

- 'perc'
  : Error band percentiles. As a 1 x numErrorBand
double. The input must be given as the coverage, and
not the percentiles itself. E.g. [0.3,0.5,0.7,0.9].
0.3 means to return the two percentiles 35 and 65,
which will cover 30% of the distribution around the
median. So [0.3,0.5,0.7,0.9] will get the
percentiles [5,15,25,35,65,75,85,95], i.e. this
will restrict the percentiles to be symmetric. If
empty (default) all the simulation will be returned.
(The graph will give percentiles specified by the
'fanPerc' input (0.68).)

- 'periods'
  : Number of periods of the impulse responses.

- 'plotSS'
  : Set to true to plot the steady-state in the IRF
graphs. Default is false. Only for nb_dsg objects.

- 'plotDevInitSS'
  : Set to true to plot the IRFs as deviation from the
initial steady state. Only an option if 'plotSS'
is set to true. Only for nb_dsg objects.

- 'replic'
  : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the
method 'identDraws'. See the option
'draws' of the method
nb_var.set_identification for more.

- 'settings'
  : Extra graphs settings given to nb_plots
function. Must be a cell.

- 'shocks'
  : Which shocks to create impulse responses of.
Default is the residuals defined by the first model.

For Markov switching or break point models it may

```

be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char (Only for Markov-switching models):
 - > scalar : Select the the regime to take the initial transition probabilities from.
 - > double : A draws x nRegime or a 1 x nRegime double. draws refer to the number set by the 'draws' input.
 - > 'ergodic' : Start from the ergodic transition probabilities. Default for 'irf'.
 - > 'random' : Randomize the starting values using the simulated starting points. Default for 'girf'.
- 'startingValues' : Either a double or a char:
 - > double : A nVar x 1 double.
 - > 'steadystate' : Start from the steady state. If you are dealing with a MS-model or a break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. For MS - models the default is the ergodic mean (default as long as 'girf' is not selected as 'type'), while for break-point models it is to start from the first regime.
 - > 'zero' : Start from zero on all variables.
 - > 'random' : Randomize the starting values using the simulated starting points. Default when 'type' set to 'girf'.
- 'states' : Either an integer with the states to produce irf in, or a double with the states to condition on. Must have size periods x 1 in the last case. Applies to both MS - models and break-point models.
- 'type' : 'girf' or 'irf'. (If empty 'irf' will be used)

```

> 'girf' : Generalized impulse response function
           calculated as the mean difference between
           shocking the model with a one period shock
           (1 std) and no shock at all. Use the 'draws'
           input to set the number of simulations to use
           to base the calculation on. This type of
           irfs must be used for non-linear models.

> 'irf'   : Standard irf for linear models. Calculated by
           shocking the model with a one period shock
           (1 std).

- 'variables'      : The variables to create impulse responses of.
                      Default is the dependent variables defined by the
                      first model.

Caution: The variables reported by the reporting
          property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level
                      using the method specified by 'levelMethod'.

```

Output:

```

- irfs      : The (central) impulse response function stored in a
               structure of nb_ts object. Each field stores the the
               impulse responses of each shock. Where the variables
               of the nb_ts object is the impulse responses of the
               wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is
      stored in irfs.'(E_X_NW')'. Which will then be a nb_ts
      object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the
          responses from each model are saved as
          different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different
          variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store
               a nb_ts object with the error bands of all variables. The
               pages of the nb_ts object is the percentiles (from lower
               to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter   : An object of class nb_graph_ts.

> 'compareShocks' set to false (default)
    Use the graphSubPlots method or the
    nb_graphSubPlotGUI class to produce the graphs.

> 'compareShocks' set to true
    Use the graphSubPlots method or the
    nb_graphSubPlotGUI class to produce the graphs.

```

- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast** ↑

ret = isDensityForecast(obj)

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

ret = isFiltered(obj)

Description:

Test if a nb_dsgc object is filtered or not.

Input:

- obj : An object of class nb_dsgc.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

ret = isMS(obj)

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

ret = isMixedFrequency(obj)

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsg objects!

For nb_dsg objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

ret = isbayesian(obj)

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

ret = isestimated(obj)

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

ret = isforecasted(obj)

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

ret = issolved(obj)

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► jointPredictionBands ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint prediction bands for macroeconomic risk management
 - > 'copula' : Using a copula likelihood approach.
 - > 'mostlik' : Group the paths based on how likely they are.
- 'nSteps' : Number of forecasting steps to use when constructing the error bands. If empty (default) all forecasting steps stored in the object is used.

Output:

- JPB : An nb_ts object storing the joint prediction bands. The percentiles are stored as datasets. See the dataNames property for which page represent which percentile.

The data of the nb_ts object has size nSteps x nVars x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior** ↑

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_nonLinearEq.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x)&&f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.

- type : The type of restriction. Either 'irf', 'corr' or 'cov'.

- restriction : Depends on the type input:

```

> 'irf'      : A N x 4 cell, where the elements of each
               row are:
               1. Name of the shock. 'E_X'
               2. Name of the variable. 'X'
               3. Horizon. E.g. 1 or 1:3.
               4. Restriction. E.g. @(x)gt(x,0),
                  @(x)gt(x,0)||lt(x,1), i.e. a
                  function_handle that takes a scalar
                  double as input and a scalar logical as
                  output.

> 'rirf'     : A N x 7 cell, where the elements of each
               row are:
               1. Name of the shock 1. 'E_X'
               2. Name of the variable 1. 'X'
               3. Horizon of variable 1. E.g. 1.
               4. Name of the shock 2. 'E_Y'
               5. Name of the variable 2. 'Y'
               6. Horizon of variable 2. E.g. 2.
               7. Restriction. E.g. @(x,y)gt(x,y),
                  @(x,y)gt(x-y,0)||lt(x-y,1), i.e. a
                  function_handle that takes a two scalar
                  double as inputs and a scalar logical
                  as output.

> 'corr'     : A N x 4 cell, where the elements of each
               row are:
               1. Name of the first variable.
               2. Name of the second variable.
               3. Number of periods to lag the 2. variable.
               4. Same as 4 for 'irf'.

               E.g. {'Var1','Var1',1,@(x)gt(x,0.1)}, to
               test a restriction on the autocorrelation
               at lag for variable 'Var1'.

               E.g. {'Var1','Var2',0,@(x)lt(x,0.1)}, to
               test a restriction on the contemporaneous
               correlation between 'Var1' and 'Var2'.

> 'cov'       : Same as for 'corr'.

               E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to
               test a restriction on the contemporaneous
               variance.

> 'ss'        : A N x 2 cell, where the elements of each
               row are:
               1. The expression using any of the
                  endogenous variables of the model.
               2. Same as 4 for 'irf'.

```

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

`nb_nonLinearEq.theoreticalMoments`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **mincerZarnowitzTest ↑**

`[test,pval,res] = mincerZarnowitzTest(obj,precision)`

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- `obj` : An object of class `nb_model_generic`. You need to call one of the forecasting functions first!
- `precision` : The precision of the printed result. As a string. Default is '`%8.6f`'.

Output:

- `test` : A `nb_ts` object with the test statistic. As a `nHor x nModel x nVar nb_ts` object.
- `pval` : A `nb_ts` object with the p-values of the test. As a `nHor x nModel x nVar nb_ts` object.
- `res` : A char with the printout of the test.

See also:

`nb_nonLinearEq.uncondForecast`

► **monteCarloFiltering ↑**

```
paramD           = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if

the model where solved and the test function returned a value.

- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.

```

> 'blockBootstrap'      : Create artificial data by
                           non-overlapping block bootstrap,
                           and then "draw" parameters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'mblockBootstrap'    : Create artificial data by
                           overlapping block bootstrap,
                           and then "draw" parameters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'rblockBootstrap'    : Create artificial data by
                           overlapping random block length
                           bootstrap, and then "draw" parameters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'wildBlockBootstrap' : Create artificial data by wild
                           overlapping random block length
                           bootstrap., and then "draw" parameters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'copulaBootstrap'    : Uses a copula approach to draw residual
                           that are autocorrelated, Does not handle
                           heteroscedasticity. Only an option for
                           models estimated with classical methods.

> 'posterior'          : Posterior draws. Only for models
                           estimated with bayesian methods.
                           Default for models estimated with
                           bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
  on this option.

- stable : Give true if you want to discard the parameter draws
  that give rise to an unstable model. Default is false.

```

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores
 available.
- 'newDraws' : When out of parameter draws, this factor decides how
 many new draws are going to be made. Default is 0.1.
 I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given

as a number less than 1, it will by default be set to 100.

- 'initialDraws' : When drawing parameters this factor decides how many many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:

> 'param' : Default. A struct with the following fields:

 beta : A nPar x nEq x draws double with the estimated parameters.

 sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:

 lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.

 R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.

 factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **parameterIntervals** ↑

ci = parameterIntervals(obj,alpha)

Description:

```
Get confidence intervals (classic) or probability intervals (bayesian).
```

```
Confidence intervals are constructed as:
```

```
beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.
```

```
Probability intervals are constructed as the per
```

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **parse** ↑

```
obj = nb_nonLinearEq.parse(filename,varargin)
```

Description:

Parse model file on the .nb format.

Input:

- filename : A string with the name of the model file with extension .nb.

Optional inputs:

- 'macroProcessor' : See nb_nonLinearEq.help('macroProcessor').
- 'macroVars' : See nb_nonLinearEq.help('macroVars').
- 'silent' : See nb_nonLinearEq.help('silent').

Output:

- obj : An object of class nb_nonLinearEq.

See also:

[nb_nonLinearEq.template](#), [nb_nonLinearEq.help](#)

Written by Kenneth Sæterhagen Paulsen

► **parseTempParameters** ↑

```
out = nb_model_parse.parseTempParameters(eqs,verbose)
```

Description:

Parse terms starting with #, and substitute out for where these terms are used.

Input:

- eqs : A N x 1 cellstr with the equations of the model.
- verbose : Set to true to print resulting equations.

Output:

- out : A N x 1 cellstr with the parsed equations of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_PARSE

► **plotForecast** ↑

```
plotter = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.

- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity** ↑

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

```
plotter = A nb_graph_data object. Use the graph method to produce the
figure, or the nb_graphPagesGUI class.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► plotMCF ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound, ...
                                     upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest** ↑

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,nameValue)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPosterioriors ↑**

```
plotter = plotPosterioriors(obj)
plotter = plotPosterioriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

► [plotPriors](#) ↑

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results** ↑

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_nonlineareq.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

```
- obj      : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA
```

► **set ↑**

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

```
- obj : A vector of nb_model_estimate objects.
```

Optional input:

If number of inputs equals 1:

```
- varargin{1} : A structure of fields to be set. See the
               template method of each model class for more.
```

Else:

```
- varargin     : ...,'inputName', inputValue,... arguments.
```

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

```
- obj : A vector of nb_model_estimate objects.
```

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition** ↑

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';  
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the

nb_model_generic.parameterDraws method for more this input. An extra option is:

```
> 'identDraws' : Uses the draws of the matrix with  
      the map from structural shocks to dependent variables.  
      See nb_var.set_identification. Of course this option  
      only makes sense for VARs identified with sign  
      restrictions.  
  
- 'replic'          : The number of simulation for posterior, bootstrap and  
      MC methods. Default is 1. Only used when 'perc' is  
      provided.  
  
      Caution: Will not have anything to say for the method  
      'identDraws'. See the option 'draws' of the  
      method nb_var.set_identification for more.  
  
- 'stabilityTest' : Give true if you want to discard the draws  
      that give rise to an unstable model. Default  
      is false.  
  
- 'parallel'        : Give true if you want to do the shock decomp in  
      parallel. Default is false.  
  
- 'fcstDB'          : An object of class nb_ts with the forecast to  
      decompose. must contain all model variables and  
      shocks/residuals, and must start the period after  
      the estimation/filtering end date or at the  
      estimation/filtering start date. See  
      the nb_model_generic.getForecast method.  
  
- 'type'            : Choose 'updated' or 'smoothed'. 'smoothed' is  
      default.  
  
- 'anticipationStartDate' : Start date of anticipating shocks. As a  
      string. If different models has different  
      frequency this date will be converted.  
  
- 'model2'          : A struct with the solution of the second  
      model to use for decomposition.  
  
- 'secondModelStartDate' : Start date of second model. As a string.  
      If different models has different frequency  
      this date will be converted.
```

Output:

- decomp : A structure of nb_ts objects with the shock
 decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty
 bounds of the shock decomposition for each model at each
 percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the
 graph method to produce the graphs or use the
 nb_graphPagesGUI on each element of the graph objects.

`nb_nonLinearEq.parameterDraws, nb_shockDecomp`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **simulate** ↑

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- `obj` : A vector of `nb_model_generic` objects.
- `nSteps` : Number of simulation steps. As a `1x1 double`. Default is 100.

Optional inputs:

- `'burn'` : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- `'bounds'` : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - `'shock'` : Name of the shock to match the restriction on the bounds of the given variable.
 - `'lower'` : The lower bound of the selected variable. Either a `1x1 double` value or a function handle to a probability distribution to draw from.
 - `'upper'` : The upper bound of the selected variable. Either a `1x1 double` value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps double` matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a `1x1 double` or a `nSteps x 1 double`.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
- 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.
- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty

the simulation will switch between regimes. Only an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a specific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:
 - > double : A 1 x nVar double.
 - > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsg models.
 - > 'steadyState' : Start from the steady state. For now only an option for nb_dsg models. If you are dealing with a MS-model you can indicate the state by 'steadyState(state)'. E.g. to start in state 1 give; 'steadyState(1)'. Default for nb_dsg models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char:
 - > double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
 - > 'ergodic' : Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consists of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the

'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```
[m,c]           = simulatedMoments(obj,varargin)
[m,c,ac1]       = simulatedMoments(obj,varargin)
[m,c,ac1,ac2]   = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i},'y','x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i},'x','y'). (This example only works if the output is of class nb_cs)

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_nonlineareq.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

```
options = nb_nonLinearEq.template()
options = nb_nonLinearEq.template(num)
```

Description:

Construct a struct which can be provided to the nb_nonLinearEq class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► testParameters ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

```
- obj : A scalar solved nb_model_generic object.  
  
- expression : A MATLAB expression as a string. Use parameter names as  
variables. See model.parameters.name.  
  
- method : A string with the method to use. For bootstrap method see  
nb_bootstrap. For bayesian models 'posterior' is the only  
option. Default is 'bootstrap' for classical models, while  
'posterior' is the default for bayesian models.  
  
- draws : Number of draws from the parameter distribution. Default  
is 1000.  
  
- alpha : Confidence level. Default is 0.05.  
  
- type : Type of test:  
    > '=' : Two sided test. expression == 0 (default)  
            For two-sided tests it is assumed that the  
            distribution is symmetric! Use  
            confidence/probability intervals instead.  
    > '>' : One sided test. expression > 0  
    > '<' : One sided test. expression < 0
```

Output:

```
- pval : > 'classical' : P-value of test.  
        > 'bayesian' : Probability of test.  
  
        A 1x1 double.  
  
- ci : A 1 x 2 double with the lower and upper bound of the  
confidence/probability interval of the tested expression.  
  
- dist : A nb_distribution object storing the distribution of the  
tested expression.
```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c] = theoreticalMoments(obj,varargin)
[m,c,ac1] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2] = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the

parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargout{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.

- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.

```
> {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object  
    storing the numerically calculated  
    forecast error variances/skewnesses.  
  
- plotter : A nb_graph_ts object which the method graph can be used to  
    produce graphs.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_nonlineareq.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_nonlineareq.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **update ↑**

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition ↑**

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.
Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double.

E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomposition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomposition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

[nb_nonLinearEq.parameterDraws](#), [nb_varDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

■ nb_rw

Go to: [Properties](#) | [Methods](#)

A class for estimation of random walk models.

Superclasses:

nb_model_generic

Constructor:

```
obj = nb_rw(varargin)
```

Optional input:

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : An nb_rw object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- | | | | | |
|-------------------------------|--------------------------------------|-----------------------------|----------------------------------|-----------------------------|
| • addAutoName | • addAutoNameIfLocal | • addID | • addIDIfLocal | • dependent |
| • endogenous | • estOptions | • exogenous | • forecastOutput | • name |
| • options | • parameters | • reporting | • residuals | • results |
| • solution | • transformations | • userData | | |

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[dependent](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsge models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **[endogenous](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that persevere the time span

are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.

- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double. (Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation. As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is

for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

► **`appendData`** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters ↑**

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.

- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!

- 'instrument' : A one line char with the name of the instrument. Must be provided!

- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!

- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.

- 'perc' : Error band percentiles. As a 1 x nPerc double.
E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will
be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the
double method on this output to convert it to a double
matrix.

See also:

[nb_rw.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws
(bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see
[nb_bootstrap](#). For bayesian models 'posterior' is the only
option. Default is 'bootstrap' for classical models, while
'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is
1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property
is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterioriors** ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optional input:

- `'nLags'` : Number of lags to include in the autocorrelation plot. Default is 10.
- `'iter'` : The recursive iteration date. Either as a string or a `nb_date` object. If recursive estimation is done, this input must be provided.

Output:

- `DB` : A `nb_data` object with size `nDraws x numCoeff`.
- `plotter` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.
- `pAutocorr` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.

Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
                    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

► [convert ↑](#)

`obj = convert(obj,freq,method,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convert`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convert`.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► [convertEach ↑](#)

`obj = convert(obj,freq,methods,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

See also:

[nb_ts.convert](#)

Inherited from superclass `NB_MODELDATA`

► `createVariables` ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM `nb_modelData` object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.

> third column : Any expression that can be interpreted by the `nb_ts.createShift` method.

> fourth column : Comments

- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name,    input,    shift,    description
  'VAR1_G',    'pcn(VAR1)', 'avg',    'VAR1 growth'
  'VAR2_G',    'pcn(VAR2)', 'avg',    'VAR2 growth'
  'VAR3_G',    'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► dieboldMarianoTest ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_FORECAST

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

`nb_rw.forecast, nb_distribution.perc2ParamDist`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity** ↑

`obj = doSimulateFromDensity(obj, draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `obj` : A `nb_model_forecast` object.
- `draws` : Number of draws to use for simulation.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_model_generic.forecast, nb_rw.simulateFromDensity`

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass `NB_MODEL_FORECAST`

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_generic` object. The `options.data` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- `obj` : An object of class `nb_model_generic`

Optional inputs;

- `'vars'` : Either `'dependent'` or a cellstr with the wanted variables. `'dependent'` will return the moment of the dependent variables. `'dependent'` is default.
- `'output'` : Either `'nb_cs'` or `'double'`. Default is `'nb_cs'`.
- `'stacked'` : If the output should be stacked in one matrix or not. true or false. Default is false.
- `'nLags'` : Number of lags to compute when `'stacked'` is set to true.
- `'type'` : Either `'covariance'` or `'correlation'`. Default is `'correlation'`.
- `'startDate'` : The start date of the calculations. Default is the start date of the `options.data` property. Only for time-series! Must be a string or a `nb_date` object.
- `'endDate'` : The end date of the calculations. Default is the end date of the `options.data` property. Only for time-series! Must be a string or a `nb_date` object.
- `'demean'` : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- `varargout{1}` : The mean, as a $1 \times nVar$ `nb_cs` object or double.
- `varargout{2}` : The contemporaneous covariances/correlations, as a $nVar \times nVar$ `nb_cs` object or double. The variance is along the diagonal. (Will be symmetric)
- `varargout{i}` : $X > 2$. The auto-covariances/correlations, as a $nVar \times nVar$ `nb_cs` object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part you can find `cov(x,y(-i))`, where `x` is the variable along the first dimension. In the lower triangular part you can find `cov(x(-i),y)`, where `x` is the variable along the first dimension.

E.g: You have two variables `x` and `y`, then to find `cov(x,y(-i))` you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get `cov(x(-i),y)` ($\approx \text{cov}(x,y(+i))$) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class `nb_cs`)

See also:

[nb_rw.graphCorrelation](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj        = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default

is to open max number of cores available. Only an option if 'parallel' is given.

- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast ↑**

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecast** ↑

```
obj          = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for forward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters

for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
 - 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.
- If set to empty, all simulations will be returned.
- Caution: 'draws' must be set to produce density forecast.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

```

- 'bins'          : The length of the bins og the domain of the density.
                    Either;
                      > []      : The domain will be found. See
                        nb_getDensityPoints (default is that 1000
                        observations of the density is stored).
                      > integer : The min and max is found but the length
                        of the bins is given by the provided
                        integer.
                      > cell     : Must be on the format:
                        {'Var1',lowerLimit1,upperLimit1,binsL1;
                         'Var2',lowerLimit2,upperLimit2,binsL2;
                         ...}
                      - lowerLimit1 : An integer, can be nan,
                        i.e. will be found.
                      - upperLimit1 : An integer, can be nan,
                        i.e. will be found.
                      - binsL1      : An integer with the
                        length of the bins. Can
                        be nan. I.e. bins length
                        will be adjusted to
                        create a domain of 1000
                        elements.

Caution : The variables not included will be given
           the default domain. No warning will be
           given if a variable is provided in the
           cell but not forecast by the model. (This
           because different models can forecast
           different variables)

Caution : The combineForecast method of the
           nb_model_group class is much faster if the
           lower limit, upper limit! Or else
           it must simulate new draws and do kernel
           density estimation for each model again
           with the shared domain of all models
           densities.

- 'startDate'    : The start date of forecast. Must be a string or an
                    object of class nb_date. If empty the estim_end_date
                    + 1 will be used.

Caution: If 'fcstEval' is not empty this will set
         the start date of the recursive forecast.
         Default is to start from the first possible
         date.

- 'endDate'      : The end date of forecast. Must be a string or an
                    object of class nb_date. If empty the estim_end_date
                    + 1 will be used.

Caution: If 'fcstEval' is empty this input will

```

have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous

variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
If not provided. Model stds are used.
- > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
- > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for

all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.
- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime

is not given, you will start in
the ergodic steady-state for
MS-model, and in the last regime
for break-point models.

- 'startingProb' : Either a double or a char:

- > [] : If the model is filtered the starting value is calculated on filtered transition probabilities. Otherwise the ergodic mean is used.
- > double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
- > 'ergodic' : Start from the ergodic transition probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

- 'states' : Either an integer with the regime to forecast/simulate in, or an object of class nb_ts with the regimes to condition on. The name of the variable must be 'states'.

Caution: For break-point models this is decided by the dates of the breaks, and cannot be set by this option!

- 'compareToRev' : Which revision to compare to. Default is final revision, i.e. []. Give 5 to get fifth revision. must be an integer. Keep in mind that this number should be larger than the nSteps input.

- 'compareTo' : Sometime you want to evaluate the forecast of one variable against another variable which is not part of the model. E.g. if you use the first release of a variable and want to compare it against the final release. To do this you can give a cellstr with size n x 2, where n is the number of variables to change the the actual observations to test against. {'VAR_1','VAR_FINAL',...}.

- 'estimateDensities' : true or false. true if you want to do a kernel density estimation of the density forecast.

- 'exoProj' : Tolerate missing exogenous variables by projecting them by a fitted model. Only when the 'condDB' input is empty!

Options are:

- '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.

- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.

- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example

{'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when `exoProj` is set to 'AR'.

- 'bounds'
: A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps` double matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a 1x1 double or a `nSteps x 1` double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs'
: This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.

- 'foundReplic'
: A struct with size `1 x parameterDraws`. Each element must be on the same format as `obj.solution`. I.e. each element must be the solution of the model given a set of drawn parameters. See the `parameterDraws` method of the `nb_model_generic` class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.

```
- 'seed' : Set simulation seed. Default is 2.0719e+05.
```

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_rw.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_rw.forecast](#), [nb_distribution.perc2ParamDist](#)

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
    nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getCondDB ↑

[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments ↑**

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Inherited from superclass NB_MODEL_GENERIC

► **getDependent ↑**

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getFiltered ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be $N(0,1)$. Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a $N \times 3$ cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs \times nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_rw.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast** ↑

```
fcstData           = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();
```

```

    end

> 'date'      : A string or a nb_date object with the date of the
                 wanted forecast. E.g. '2012Q1'. The fcstData will
                 be a nb_ts object with size nHor x nVar x nPerc + 1,
                 while fcstPercData will be empty. nPerc will then be
                 the number of percentiles/simualtions. Mean will be at
                 last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'   : This option will return the forecast as a
                 nPeriods + nHor x nVar x nHor nb_ts object. This
                 option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).

```

Optional inputs:

```

> 'horizon'   : The fcstData output will be a nb_ts object with
                 size nRec x nVars. While the fcstPercData output
                 will be a nb_ts object with size nRec x nVars x nSim.
                 You can set the horizon to return by the optional
                 input 'horizon'. See the 'timing' option also.

```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_rw.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► [getForecastVariables ↑](#)

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

p = getParameters(obj,varargin)

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as

fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

- : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
- : Give 'double' to return the value as a numerical array.
- : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

► **getRecursiveScore** ↑

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

Inherited from superclass `NB_MODEL_FORECAST`

► **getResidual** ↑

`residual = getResidual(obj)`

Description:

Get residual from a estimated `nb_model_generic` object

Input:

- `obj` : An object of class `nb_model_generic`

Output:

- `residual` : Either a `nb_ts` or a `nb_cs` object with `residual(s)` stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualGraph** ↑

`plotter = getResidualGraph(obj)`

Description:

Get residual graph from the given estimator. The returned will be an object of class `nb_graph`, which you can call the `graphInfoStruct` method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- `obj` : An object of class `nb_model_generic` (or a subclass of this class).

Output:

- `plotter` : An object of class `nb_graph`. Use the `graphInfoStruct` method or the `nb_graphInfoStructGUI` class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of `nb_model_generic` object

Input:

- `obj` : A vector of `nb_model_generic` objects

Output:

- `residualNames` : A cellstr with the unique residual names of all the models

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method `solve`.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getScore ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.

- type : A string with one of the following:
- 'RMSE' : One over root mean squared error
- 'MSE' : One over mean squared error
- 'MAE' : One over mean absolute error
- 'MEAN' : One over mean error
- 'STD' : One over standard error of the forecast error
- 'ESLS' : Exponential of the sum of the log scores
- 'EELS' : Exponential of the mean of the log scores
- 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.

- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution ↑**

```
value = getSolution(obj,type)
```

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_rw.simulatedMoments](#), [nb_rw.theoreticalMoments](#)
[nb_rw.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **help ↑**

```
helpText = nb_rw.help
helpText = nb_rw.help(option)
helpText = nb_rw.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize ↑**

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:**Input:**

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given,

otherwise this option does not apply.

- 'optimizer'
 - : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset'
 - : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel'
 - : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters'
 - : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.
- 'periods'
 - : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate'
 - : The start date of forecast. Must be a string or an object of class nb_date. If empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest'
 - : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch'
 - : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale'
 - : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights'
 - : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_rw.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf** ↑

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgc objects.
- 'compare' : Give true if you have a scalar nb_dsgc model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

```

- 'draws' : Number of draws for calculating girf. Default is
           1000. For Markov switching models this will set the
           number of simulated paths of states. For more see
           the 'type' input.

- 'factor' : A cell array with the factors to multiply the
             irf of the individual model variables.
             I.e. {'var1',100,...} or
                  {'var1','var2'},100,...}

If the string starts with a asterisk you will
multiply all the variables that contain that
string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This option sets the error band percentiles of the
               graph, when the 'perc' input is empty. As a 1 x
               numErrorBand double. E.g. [0.3,0.5,0.7,0.9].
               Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element
                  must be on the same format as obj.solution. I.e.
                  each element must be the solution of the model
                  given a set of drawn parameters. See the
                  parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from
                  this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

    > 'cumulative product' : cumprod(1 + X,1)

    > 'cumulative sum' : cumsum(X,1)

    > 'cumulative product (log)' : log(cumprod(1 + X,1))

    > 'cumulative sum (exponential)' : exp(cumsum(X,1))

    > 'cumulative product (%)' : cumprod(1 + X/100,1)

    > 'cumulative sum (%)' : cumsum(X/100,1)

    > 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))

    > 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))

    > '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
             Default is ''. See help on the method input of the
             nb_model_generic.parameterDraws method for more
             this input. An extra option is:

    > 'identDraws' : Uses the draws of the matrix with
                    the map from structural shocks to dependent

```

variables. See `nb_var.set_identification`. Of course this option only makes sense for VARs identified with sign restrictions.

- `'normalize'` : A 1 x 3 cell. First element must be the variable name as a string. The second element must be the value to normalize to, as an integer. While the third element is the period to be normalized, if set to `inf`, it will normalize the max impact period.
E.g. `{'Var',1,2}, {'Var',1,inf}`
Caution: 2 means observation 2 of the IRF, and as the IRF start at period 0, this means that observation 2 is period 1.
- `'normalizeTo'` : 'draws' or 'mean'. 'draws' normalize each draw of irfs, while 'mean' normalize the mean and scale percentiles/other draws accordingly. Default is 'draws'.
Caution: Setting this to 'mean' will not work for reported variables that is not measured as % deviation from steady-state/mean.
- `'newReplic'` : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the replic input.
- `'parallel'` : Give true if you want to do the irfs in parallel. This option will parallelize over models. Default is false.
- `'parallelL'` : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if `numel(obj) == 1`. Default is false.
- `'pause'` : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- `'perc'` : Error band percentiles. As a 1 x `numErrorBand` double. The input must be given as the coverage, and not the percentiles itself. E.g. `[0.3,0.5,0.7,0.9]`. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So `[0.3,0.5,0.7,0.9]` will get the percentiles `[5,15,25,35,65,75,85,95]`, i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- `'periods'` : Number of periods of the impulse responses.
- `'plotSS'` : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for `nb_dsg` objects.

```

- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the
initial steady state. Only an option if 'plotSS'
is set to true. Only for nb_dsg objects.

- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the
method 'identDraws'. See the option
'draws' of the method
nb_var.set_identification for more.

- 'settings' : Extra graphs settings given to nb_plots
function. Must be a cell.

- 'shocks' : Which shocks to create impulse responses of.
Default is the residuals defined by the first model.

For Markov switching or break point models it may
be wanted to only run a IRF when switching the
state. To do so set this option to {'states'}.
You should also set 'startingValues' to
'steadystate(r)', where r is the regime you start
in. For a Markov switching model also set
'startingProb' to the same r. This is only an
option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be
a vector of the same size as 'shocks' input.

- 'stabilityTest' : Give true if you want to discard the draws
that give rise to an unstable model. Default
is false.

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):
    > scalar : Select the the regime to take the
initial transition probabilities
from.

    > double : A draws x nRegime or a 1 x
nRegime double. draws refer to
the number set by the 'draws'
input.

    > 'ergodic' : Start from the ergodic transition
probabilities. Default for 'irf'.

    > 'random' : Randomize the starting values
using the simulated starting
points. Default for 'girf'.

- 'startingValues' : Either a double or a char:
    > double : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing

```

with a MS-model or a break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. For MS - models the default is the ergodic mean (default as long as 'girf' is not selected as 'type'), while for break-point models it is to start from the first regime.

```

> 'zero'          : Start from zero on all variables.

> 'random'        : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'         : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'           : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generlized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'   : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

- 'variables'       : The variables to create impulse responses of.
                     Default is the dependent variables defined by the
                     first model.

Caution: The variables reported by the reporting
          property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level
                     using the method specified by 'levelMethod'.

```

Output:

```

- irfs      : The (central) impulse response function stored in a
               structure of nb_ts object. Each field stores the the
               impulse responses of each shock. Where the variables
               of the nb_ts object is the impulse responses of the
               wanted endogenous variables.

               I.e. the impuls responses to the shock 'E_X_NW' is
               stored in irfs.('E_X_NW'). Which will then be a nb_ts
               object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the
          responses from each model are saved as
          different datasets (pages) of the nb_ts object.

```

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.
 - > 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
 - > 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast ↑**

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

```
ret = isMixedFrequency(obj)
```

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

ret = isbayesian(obj)

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► isestimated ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► isforecasted ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint

```

prediction bands for
macroeconomic risk management

> 'copula' : Using a copula likelihood approach.

> 'mostlik' : Group the paths based on how
likely they are.

- 'nSteps' : Number of forecasting steps to use when constructing the
error bands. If empty (default) all forecasting steps stored
in the object is used.

```

Output:

- JPB : An nb_ts object storing the joint prediction bands.
The percentiles are stored as datasets. See the
dataNames property for which page represent which
percentile.

- The data of the nb_ts object has size nSteps x nVars
x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method
to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend
on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_rw.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x)&&f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. `@(x)gt(x,0), @(x)gt(x,0)||lt(x,1)`, i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. `@(x,y)gt(x,y), @(x,y)gt(x-y,0)||lt(x-y,1)`, i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. `{'Var1','Var1',1,@(x)gt(x,0.1)}`, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. `{'Var1','Var2',0,@(x)lt(x,0.1)}`, to

test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous variance.

> 'ss' : A N x 2 cell, where the elements of each row are:

1. The expression using any of the endogenous variables of the model.
2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mincerZarnowitzTest** ↑

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_rw.uncondForecast](#)

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.

- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

See also:

function_handle, nb_rw.mcfRestriction, nb_rw.solve
[nb_rw.assignParameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'wildBlockBootstrap' : Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'copulaBootstrap' : Uses a copula approach to draw residual that are autocorrelated, Does not handle heteroscedasticity. Only an option for models estimated with classical methods.
 - > 'posterior' : Posterior draws. Only for models estimated with bayesian methods.

Default for models estimated with
bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more on this option.
- stable : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores available.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.
- 'initialDraws' : When drawing parameters this factor decides how many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
 - > 'param' : Default. A struct with the following fields:
 - beta : A nPar x nEq x draws double with the estimated parameters.
 - sigma : A nEq x nEq x draws double with the estimated covariance matrix.
- For factor models these fields are also returned:
- lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.
 - R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.
- factors : Draws of the factors as a T x nFac x

```

draws double.

> 'solution' : Get the solution of the model for each draw from the
distribution of parameters. The output will be a struct
with size 1 x draws. The struct will have the same
format as the solution property of the underlying
object. I.e. only one output!

> 'object'   : Get the draws as a 1 x draws nb_model_generic object.
Each element will be a model representing a given draw
from the distribution of the parameters. I.e. only one
output!

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + ( +/- nb_distribution.t_icdf(alpha/2) ) * stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► plotForecast ↑

```

plotter          = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
                                         increment,varargin)

```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► plotMCF ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...  
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot.

'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- `plotter` : > 'allInOne' : A `nb_graph_cs` object. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
 > 'biplot' : A vector of `nb_graph_data` objects with size equal to the number of pairwise combination of the parameters that can be made. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

Inherited from superclass `NB_MODEL_GENERIC`

► **plotMCFDistTest ↑**

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `test` : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

[nb_rw.monteCarloFiltering](#), [nb_cucconiTest](#), [nb_smirnovTest](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,valueName)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `nameValue` : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results ↑**

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_rw.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations ↑**

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties
of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition ↑**

[decomp, decompBand, plotter] = shock_decomposition(obj, varargin)

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : A vector of nb_model_generic objects

- 'packages' : Cell matrix with groups of shocks and
the names of the groups. If you have not
listed a shock it will be grouped in a
group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';  
'shock_name_1' , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with
a shock name or a cellstr array with the
shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

Caution: Two special identifiers can be used;
'Initial Conditions' and 'Steady-state'. The
first represent the impact of all shocks that
hit the system before the decomposition/
estimation started. The second summarizes the
impact of steady-state changes on the system,

i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. E.g. [0.3, 0.5, 0.7, 0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sence for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.

- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

See also:

[nb_rw.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulate ↑**

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be

a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the

simulation of.

- > 'endo' : All the endogenous variables are returned.
- > 'fullendo' : All the endogenous variables are returned included the lag variables.
- > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
- > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.

- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.
- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a spesific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:

- > double : A 1 x nVar double.
- > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsge models.
- > 'steadyState' : Start from the steady state. For now only an option for nb_dsge models. If you are dealing with a MS-model you can indicate the state by 'steadyState(state)'. E.g. to start in state 1 give; 'steadyState(1)'. Default for nb_dsge models.

```

> 'zero'           : Start from zero on all variables
                      (Except for the deterministic
                      exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws
                     that give rise to an unstable model. Default
                     is false.

- 'startingProb'  : Either a double or a char:

    > double        : A nPeriods x nRegime or a 1 x
                      nRegime double. nPeriods refer to
                      the number of recursive periods to
                      forecast.

    > 'ergodic'     : Start from the ergodic transition
                      probabilities. Default.

```

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity ↑**

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- `obj` : An object of class nb_model_generic.
- Optional inputs;
- `'output'` : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- `'stacked'` : If the output should be stacked in one matrix or not. true or false. Default is false.
- `'nLags'` : Number of lags to compute when 'stacked' is set to true.
- `'vars'` : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- `'type'` : Either 'covariance' or 'correlation'. Default is 'correlation'.
- `'draws'` : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- `'pDraws'` : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- `'perc'` : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: 'pDraws' or 'draws' must be set to a number > 1.
- `'nSteps'` : Number of simulation steps. As a 1x1 double. Default is 100.
- `'burn'` : The number of periods to remove at start of the simulations. This is to randomize the starting

values of the simulation. Default is 0.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Default is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
 - varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
 - varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.
- E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

See also:

[nb_rw.graphCorrelation](#), [nb_rw.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [solve ↑](#)

`obj = solve(obj)`

Description:

Solve estimated model(s) represented by nb_rw object(s).

Input:

- obj : A vector of nb_rw objects.

Output:

- obj : A vector of nb_rw objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth Sæterhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_rw.solveNormal(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveRW** ↑

```
tempSol = nb_rw.solveRW(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_rw.solveRecursive(results,opt)
```

Written by Kenneth Sæterhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_rw.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

options = nb_rw.template()

Description:

Construct a struct which can be provided to the nb_rw class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► testForecastRestrictions ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast

- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.

> variable : The variable(s) to test,
as a string or cell array of strings.

> date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.

> test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as variables. See model.parameters.name.
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.
- type : Type of test:
 - > '=' : Two sided test. expression == 0 (default)
For two-sided tests it is assumed that the distribution is symmetric! Use confidenc/probabillty intervals instead.
 - > '>' : One sided test. expression > 0
 - > '<' : One sided test. expression < 0

Output:

- pval : > 'classical' : P-value of test.
> 'bayesian' : Probabilty of test.

A 1x1 double.
- ci : A 1 x 2 double with the lower and upper bound of the confidence/probabillty interval of the tested expression.
- dist : A nb_distribution object storing the distribution of the tested expression.

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is

```

        'correlation'.

- 'pDraws'      : Number of parameter draws. Default is 1. I.e. to use
                  the estimate parameters.

- 'perc'        : Error band percentiles. As a 1 x numErrorBand double.
                  E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
                  all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method'       : The selected method to create confidenc/probability
                  bands. Default is ''. See help on the method input of
                  the nb_model_generic.parameterDraws method for more
                  this input.

- 'foundReplic'  : A struct with size 1 x pDraws. Each element
                  must be on the same format as obj.solution. I.e.
                  each element must be the solution of the model
                  given a set of drawn parameters. See the
                  parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

```

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar
 x nVar nb_cs object or double. The variance is along
 the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar
 x nVar nb_cs object or double. Along the diagonal is the
 auto-covariance/correlation with the variable itself. In
 the upper triangular part the you can find cov(x,y(-i)),
 where x is the variable along the first dimension. In
 the lower triangular part the you can find cov(x(-i),y),
 where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find
 cov(x,y(-i)) you can use
 getVariable(varargout{i}, 'y', 'x'),
 while to get cov(x(-i),y) (== cov(x,y(+i))) you
 can use getVariable(varargout{i}, 'x', 'y'). (This
 example only works if the output is of class nb_cs)

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

```
[data,plotter] = uncertaintyDecomposition(obj,varargin)
```

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

obj = uncondForecast(obj,nSteps,varargin)

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_rw.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [unstruct](#) ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_rw.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► [update](#) ↑

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type : > '' : Only update data. Default
 > 'estimate' : Update data and estimate.
 > 'solve' : Update data, estimate and solve
 > 'forecast' : Update data, estimate, solve and forecast.

- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition ↑**

```
[decomp, decompBands, plotter, plotterBands] = ...
    variance_decomposition(obj, varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8, inf].

- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sence for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and

the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomosition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomosition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

[nb_rw.parameterDraws](#), [nb_varDecomp](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

■ nb_sa

Go to: [Properties](#) | [Methods](#)

A class for estimation of step ahead (indicator) models. I.e. model on the form

$$y(t+h) = c + b*x(t) + e$$

Where $x(t)$ are exogenous variables of the model, and y is the dependent variable of the model.

Superclasses:

`nb_model_generic`

Constructor:

`obj = nb_sa(varargin)`

Optional input:

- See the `set` method for more on the inputs.
`(nb_model_estimate.set)`

Output:

- `obj` : An `nb_sa` object.

See also:

`nb_model_generic`, `nb_model_estimate.set`, `nb_sa.help`, `nb_sa.template`

Written by Kenneth Sætherhagen Paulsen

Properties:

- | | | | | |
|----------------------------|-----------------------------------|--------------------------|-------------------------------|--------------------------|
| • <code>addAutoName</code> | • <code>addAutoNameIfLocal</code> | • <code>addID</code> | • <code>addIDIfLocal</code> | • <code>dependent</code> |
| • <code>endogenous</code> | • <code>estOptions</code> | • <code>exogenous</code> | • <code>forecastOutput</code> | • <code>name</code> |
| • <code>options</code> | • <code>parameters</code> | • <code>reporting</code> | • <code>residuals</code> | • <code>results</code> |
| • <code>solution</code> | • <code>transformations</code> | • <code>userData</code> | | |

- **`addAutoName`** ↑

Add automatic name (first) to default name in `getName`. Default is false.

Inherited from superclass `NB_MODEL_NAME`

- **`addAutoNameIfLocal`** ↑

Add automatic name (first) to local name in `getName`. Default is false.

Inherited from superclass `NB_MODEL_NAME`

- **`addID`** ↑

Add identifier to default name in `getName`. Default is false.

Inherited from superclass `NB_MODEL_NAME`

- **`addIDIfLocal`** ↑

Add identifier to local name in `getName`. Default is false.

Inherited from superclass `NB_MODEL_NAME`

- **`dependent`** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this property to be up to date!

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t$, $e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t$, $u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation. As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.

- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

► **appendData ↑**

```
obj = appendData(obj, DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► assignParameters ↑

obj = assignParameters(obj,varargin)

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

```

> Two input pairs:
  - 'param' : The names of the assign parameters. As a cellstr vector.
  - 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:
  - 'beta'   : Assign all the estimated parameters of the main equation.
                Must be of same size as obj.results.beta.

  - 'sigma'  : Assign all the estimated parameters of the covariance
                matrix of the main equation. Must be of same size as
                obj.results.sigma.

  - 'lambda' : Assign all the estimated parameters of the observation
                equation. Must be of same size as obj.results.lambda. Only
                for factor models.

  - 'R'      : Assign all the estimated parameters of the covariance
                matrix of the observation equation. Must be of same size
                as obj.results.R. Only for factor models.

```

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

```
obj = assignPosteriorDraws(obj,varargin)
```

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

```

> Two input pairs:
  - 'param' : The names of the assign parameters. As a cellstr vector.
  - 'value' : The values of the assign parameters. As a double nParam x
              nReg x nDraws vector.

> Optional number of input pairs:

```

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.
- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!
- 'instrument' : A one line char with the name of the instrument. Must be provided!
- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!
- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!
- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.
- 'perc' : Error band percentiles. As a 1 x nPerc double. E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the double method on this output to convert it to a double matrix.

See also:

[nb_sa.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

obj = calculateStandardError(obj,method,draws)

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see [nb_bootstrap](#). For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter

distribution. Two-sided test against the null hypothesis of the parameters being 0.

- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► checkModel ↑

```
obj = checkModel(obj)
```

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► checkPosteriors ↑

```
[DB,plotter,pAutocorr] = checkPosteriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they were drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot. Default is 10.
- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
 - plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
 - pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkReporting** ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments** ↑

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.

Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.
Default is ''. See below for what that means.

> 'bootstrap' : Create artificial data to bootstrap
the estimated parameters. Default
for models estimated with classical
methods.

> 'wildBootstrap' : Create artificial data by wild
bootstrap, and then "draw" parameters
based on estimation on these data.
Only an option for models estimated

with classical methods.

> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...  
            horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type, ...
                                         allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

► [convert ↑](#)

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► **convertEach ↑**

```
obj = convert(obj,freq,methods,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of `nb_ts.convertEach`.

See also:

[nb_ts.convert](#)

► **createVariables ↑**

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM nb_modelData object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.
 - > third column : Any expression that can be interpreted by the `nb_ts.createShift` method.
 - > fourth column : Comments
- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- `obj` : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- `plotter` : A NxM nb_graph_ts object with a graph with the de-trending. Use the `graphInfoStruct` method or the `nb_graphInfoStruct` class to produce the graph.

Examples:

```
expressions = {%
  Name,    input,    shift,    description
'VAR1_G',  'pcn(VAR1)', 'avg',   'VAR1 growth'
'VAR2_G',  'pcn(VAR2)', 'avg',   'VAR2 growth'
'VAR3_G',  'pcn(VAR3)', 'avg',   'VAR3 growth'};

model = model.createVariables(expressions)
```

► **dieboldMarianoTest ↑**

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string.

```

Default is '%8.6f'.

- 'bandWidth'      : The selected band width of the frequency zero
                      spectrum estimation. Default is to use a automatic
                      selection criterion. See the 'bandWithCrit' input.
                      Must be set to an integer greater then 0.

- 'bandWithCrit'   : Band width selection criterion. Either:

    > 'nw'    : Newey-West selection method.
                  Default.

    > 'a'     : Andrews selection method. AR(1)
                  specification.

- 'multivariate'  : Set to true to do the multivariate test, i.e. test
                      for equal panel forecast. Default is to test each
                      variable separately.

```

Output:

- test : A nb_ts object with the test statistic. As a
 nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a
 nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

► **doForecastPerc2ParamDist** ↑

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_sa.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **doSimulateFromDensity** ↑

```
obj = doSimulateFromDensity(obj,draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_sa.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **empiricalMoments ↑**

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_generic object. The options.data property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.
 E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

See also:

[nb_sa.graphCorrelation](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [eq ↑](#)

ret = eq(obj,other)

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj      = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this

option is not supported!

- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

See also:

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also being in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:

```

- 'RMSE'   : Root mean squared error
- 'MSE'    : Mean squared error
- 'MAE'    : Mean absolute error
- 'MEAN'   : Mean error
- 'STD'    : Standard error of the forecast error
- 'ESLS'   : Exponential of the sum of the log scores
- 'EELS'   : Exponential of the mean of the log scores
- 'MLS'    : Mean log score

- density : Set true if you have a density forecast.

- quart   : Set true if you want to compare the quarterly forecasts. This
            option automatically detects and uses the quarterly estimates
            when evaluating.

```

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

See also:

[nb_evalForecastfromFame](#)

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior** ↑

```
logPriorD = nb_model_generic.evaluatePrior(prior,par)
```

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecast** ↑

```
obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for foward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
 - 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
 - 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
 - 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error
- Only for density forecast:
- 'logScore' : Log score
- Can also be a cellstr with the above listed evaluation types.
- Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.
- 'estDensity' : The method to estimate the density. As a string.
Either:

- 'normal' : Normal density approximation.
- 'kernel' : Kernel density estimation. Default.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
- 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density forecast.

- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'bins' : The length of the bins og the domain of the density. Either;
 - > [] : The domain will be found. See

```

nb_getDensityPoints (default is that 1000
observations of the density is stored).

> integer : The min and max is found but the length
of the bins is given by the provided
integer.

> cell      : Must be on the format:

{'Var1',lowerLimit1,upperLimit1,binsL1;
 'Var2',lowerLimit2,upperLimit2,binsL2;
 ...}

- lowerLimit1 : An integer, can be nan,
i.e. will be found.

- upperLimit1 : An integer, can be nan,
i.e. will be found.

- binsL1      : An integer with the
length of the bins. Can
be nan. I.e. bins length
will be adjusted to
create a domain of 1000
elements.

Caution : The variables not included will be given
the default domain. No warning will be
given if a variable is provided in the
cell but not forecast by the model. (This
because different models can forecast
different variables)

Caution : The combineForecast method of the
nb_model_group class is much faster if the
lower limit, upper limit! Or else
it must simulate new draws and do kernel
density estimation for each model again
with the shared domain of all models
densities.

- 'startDate'   : The start date of forecast. Must be a string or an
object of class nb_date. If empty the estim_end_date
+ 1 will be used.

Caution: If 'fcstEval' is not empty this will set
the start date of the recursive forecast.
Default is to start from the first possible
date.

- 'endDate'     : The end date of forecast. Must be a string or an
object of class nb_date. If empty the estim_end_date
+ 1 will be used.

Caution: If 'fcstEval' is empty this input will
have nothing to say.

- 'saveToFile'   : Logical. Save densities and domains to files. One
file for each model. Default is false (do not).

```

- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be

produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain initial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.

Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.

If not provided. Model stds are used.

 - > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
 - > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!
- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only

supported for the nb_var and nb_pitvar classes.

- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.
 This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.
- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:
 This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.

```

> 'zero'           : Start from zero on all variables
                     (Except for the deterministic
                     exogenous variables)

- 'startingProb' : Either a double or a char:

    > []            : If the model is filtered the
                     starting value is calculated
                     on filtered transition
                     probabilities. Otherwise the
                     ergodic mean is used.

    > double        : A nPeriods x nRegime or a 1 x
                     nRegime double. nPeriods refer to
                     the number of recursive periods to
                     forecast.

    > 'ergodic'     : Start from the ergodic transition
                     probabilities.

- 'stabilityTest' : Give true if you want to discard the parameter draws
                     that give rise to an unstable model. Default
                     is false.

- 'states'        : Either an integer with the regime to
                     forecast/simulate in, or an object of class nb_ts
                     with the regimes to condition on. The name of the
                     variable must be 'states'.

Caution: For break-point models this is decided by
          the dates of the breaks, and cannot be set
          by this option!

- 'compareToRev'  : Which revision to compare to. Default is final
                     revision, i.e. []. Give 5 to get fifth revision.
                     must be an integer. Keep in mind that this number
                     should be larger than the nSteps input.

- 'compareTo'     : Sometime you want to evaluate the forecast of one
                     variable against another variable which is not
                     part of the model. E.g. if you use the first release
                     of a variable and want to compare it against the
                     final release. To do this you can give a cellstr
                     with size n x 2, where n is the number of variables
                     to change the the actual observations to test
                     against. {'VAR_1','VAR_FINAL',...}.

- 'estimateDensities' : true or false. true if you want to do a
                      kernel density estimation of the density
                      forecast.

- 'exoProj'        : Tolerate missing exogenous variables by projecting
                     them by a fitted model. Only when the 'condDB'
                     input is empty!

Options are:

- ''   : No projection are done. Error will be

```

given if some exogenous variables are not given any conditional information.
 Default.

- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.

- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficent 0.8, while 'exoVar2' with a constant term equal to

0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when `exoProj` is set to 'AR'.

- 'bounds'
: A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps` double matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a 1x1 double or a `nSteps x 1` double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs'
: This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.

- 'foundReplic'
: A struct with size `1 x parameterDraws`. Each element must be on the same format as `obj.solution`. I.e. each element must be the solution of the model given a set of drawn parameters. See the `parameterDraws` method of the `nb_model_generic` class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.

- 'seed'
: Set simulation seed. Default is `2.0719e+05`.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_sa.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_sa.forecast](#), [nb_distribution.perc2ParamDist](#)

Inherited from superclass NB_MODEL_FORECAST

► [getActual](#) ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.

- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getCondDB ↑**

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if

recursive estimation is done. See description for a note on real-time estimation.

- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments** ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by `nb_var.priorTemplate('dsge')`.

Input:

- obj : An object of class nb_model_generic.
- dsgeVar : A nb_var object set up with options for estimation of a DSGE-VAR.

Optional input:

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependent** ↑

dependent = getDependent(obj)

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getFiltered** ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_sa.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast ↑**

```
fcstData = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0, -1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.
```

For real-time forecast the vintage at the time is

returned as the historical data, when includeHist is true.

> 'horizon' : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.

If includeHist is true the actual data is added as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!

Caution : If the horizon input is set you will set nHor to one, and the fcstPercData will be non-empty, if density forecast has been produced.

- includeHist : Give true (1) to include history in the output. Only an options for the 'date' and 'horizon' outputType. Default is false (0).

Optional inputs:

> 'horizon' : The fcstData output will be a nb_ts object with size nRec x nVars. While the fcstPercData output will be a nb_ts object with size nRec x nVars x nSim. You can set the horizon to return by the optional input 'horizon'. See the 'timing' option also.

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_sa.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables ↑**

vars = getForecastVariables(obj)

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► getHistory ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getLHSVars ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj,varsIn)
```

Description:

Get all left hand side variables of the model.
For factor models the observable (+ observableFast) are added as well.
The list will be sorted.
Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

names = getModelNames(obj)

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgen object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getOriginalVariables ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► getPIT ↑

```
pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

```
methods = parameterDraws(obj)
```

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.
- Optional input
 - varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).
 - : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
 - : Give 'double' to return the value as a numerical array.
 - : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

► **getPosteriorDistributions** ↑

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph ↑**

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);
plotter.graphSubPlots();
```

► **getRecursiveScore ↑**

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual ↑**

residual = getResidual(obj)

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph ↑**

plotter = getResidualGraph(obj)

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

[nb_graph](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursivly estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.
- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report

the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!

- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution** ↑

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast. These are the variables that may be given to the 'varOfInterest' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'.
- observables : A cellstr with the observables the model may forecast. These are the observables that may be given to the 'observables' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'. Only some specific class of models.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation ↑**

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or

`nb_model_generic.theoreticalMoments` (`THEO`), the second input must be the `c` output from `nb_model_generic.empiricalMoments` (`EMP`), the third input can be the `ac1` output from `SIM` or `THEO`, the fourth input can be the `ac1` output from `EMP`, and so on.

Caution : The inputs must be given as `nb_cs` objects.

Caution : Inputs must come in pairs.

Output:

- `plotter` : An object of class `nb_graph_cs`. Use the `graph` method or the `nb_graphPagesGUI` class.

See also:

`nb_sa.simulatedMoments`, `nb_sa.theoreticalMoments`
`nb_sa.empiricalMoments`, `nb_graphPagesGUI`, `nb_graph_cs`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **handleCondInfo** ↑

`ret = handleCondInfo(obj)`

Description:

Check if a `nb_model_estimate` object handle conditional info.

Input:

- `obj` : A scalar `nb_model_etimate` object.

Output:

- `ret` : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_ESTIMATE`

► **handleMissing** ↑

`ret = handleMissing(obj)`

Description:

```
Check if a nb_model_estimate object handle missing observations.
```

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

► **help** ↑

```
helpText = nb_sa.help
helpText = nb_sa.help(option)
helpText = nb_sa.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize** ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:**Input:**

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.

- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.
- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

See also:

[nb_sa.forecast](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [irf ↑](#)

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsg objects.
- 'compare' : Give true if you have a scalar nb_dsg model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.
- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.
- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.

```

- 'factor'           : A cell array with the factors to multiply the
                      irf of the individual model variables.
                      I.e. {'var1',100,...} or
                           {'var1','var2'},100,...}

                      If the string starts with a asterisk you will
                      multiply all the variables that contain that
                      string with the given factor.
                      E.g. {'*_GAP',100}

- 'fanPerc'         : This options sets the error band percentiles of the
                      graph, when the 'perc' input is empty. As a 1 x
                      numErrorBand double. E.g. [0.3,0.5,0.7,0.9].
                      Default is 0.68.

- 'foundReplic'     : A struct with size 1 x replic. Each element
                      must be on the same format as obj.solution. I.e.
                      each element must be the solution of the model
                      given a set of drawn parameters. See the
                      parameterDraws method of the nb_model_generic class.

                      Caution: You still need to set 'parameterDraws'
                      to the number of draws you want to do.

- 'irfCompare'      : A struct on the same format as the irfs output from
                      this function with the IRFs to compare to.

- 'levelMethod'      : One of the following:

  > 'cumulative product'          : cumprod(1 + X,1)
  > 'cumulative sum'             : cumsum(X,1)
  > 'cumulative product (log)'    : log(cumprod(1 + X,1))
  > 'cumulative sum (exponential)' : exp(cumsum(X,1))
  > 'cumulative product (%)'       : cumprod(1 + X/100,1)
  > 'cumulative sum (%)'          : cumsum(X/100,1)
  > 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
  > 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
  > '4 period growth (log approx)' : nb_msum(X,3)

- 'method'            : The selected method to create error bands.
                      Default is ''. See help on the method input of the
                      nb_model_generic.parameterDraws method for more
                      this input. An extra option is:

  > 'identDraws' : Uses the draws of the matrix with
                  the map from structural shocks to dependent
                  variables. See nb_var.set_identification. Of
                  course this option only makes sense for VARs
                  identified with sign restrictions.

```

- 'normalize' : A 1 x 3 cell. First element must be the variable name as a string. The second element must be the value to normalize to, as an integer. While the third element is the period to be normalized, if set to inf, it will normalize the max impact period.
 E.g. {'Var',1,2}, {'Var',1,inf}
 Caution: 2 means observation 2 of the IRF, and as the IRF start at period 0, this means that observation 2 is period 1.
- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of irfs, while 'mean' normalize the mean and scale percentiles/other draws accordingly. Default is 'draws'.
 Caution: Setting this to 'mean' will not work for reported variables that is not measured as % deviation from steady-state/mean.
- 'newReplic' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the replic input.
- 'parallel' : Give true if you want to do the irfs in parallel. This option will parallelize over models. Default is false.
- 'parallelL' : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if numel(obj) == 1. Default is false.
- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for nb_dsg objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for nb_dsg objects.

- 'replic' : The number of parameter draws.
 Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.

- 'settings' : Extra graphs settings given to nb_plots function. Must be a cell.

- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.
 For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.

- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.

- 'startingProb' : Either a double or a char (Only for Markov-switching models):

- > scalar : Select the the regime to take the initial transition probabilities from.
- > double : A draws x nRegime or a 1 x nRegime double. draws refer to the number set by the 'draws' input.
- > 'ergodic' : Start from the ergodic transition probabilities. Default for 'irf'.
- > 'random' : Randomize the starting values using the simulated starting points. Default for 'girf'.

- 'startingValues' : Either a double or a char:
 > double : A nVar x 1 double.
 > 'steadystate' : Start from the steady state. If you are dealing with a MS-model or a break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. For MS - models the default is the ergodic mean

(default as long as 'girf' is not selected as 'type'), while for break-point models it is to start from the first regime.

- > 'zero' : Start from zero on all variables.
- > 'random' : Randomize the starting values using the simulated starting points. Default when 'type' set to 'girf'.
- 'states' : Either an integer with the states to produce irf in, or a double with the states to condition on. Must have size periods x 1 in the last case. Applies to both MS - models and break-point models.
- 'type' : 'girf' or 'irf'. (If empty 'irf' will be used)
 - > 'girf' : Generalized impulse response function calculated as the mean difference between shocking the model with a one period shock (1 std) and no shock at all. Use the 'draws' input to set the number of simulations to use to base the calculation on. This type of irfs must be used for non-linear models.
 - > 'irf' : Standard irf for linear models. Calculated by shocking the model with a one period shock (1 std).
- 'variables' : The variables to create impulse responses of. Default is the dependent variables defined by the first model.

Caution: The variables reported by the reporting property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.
- I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.('E_X_NW'). Which will then be a nb_ts object of all the wanted variables.
- Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.
- Caution: Each nb_model_generic object can have different variables and shocks.
- irfsBands : A struct with the shocks as fieldnames. Each field store

a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.
 - > 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
 - > 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast ↑**

ret = isDensityForecast(obj)

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered ↑**

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

```
ret = isMixedFrequency(obj)
```

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

► **isbayesian** ↑

ret = isbayesian(obj)

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted** ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► jointPredictionBands ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint prediction bands for macroeconomic risk management
 - > 'copula' : Using a copula likelihood approach.
 - > 'mostlik' : Group the paths based on how likely they are.

- 'nSteps' : Number of forecasting steps to use when constructing the error bands. If empty (default) all forecasting steps stored in the object is used.

Output:

- JPB : An nb_ts object storing the joint prediction bands. The percentiles are stored as datasets. See the dataNames property for which page represent which percentile.

The data of the nb_ts object has size nSteps x nVars x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method to produce the graphs.

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior** ↑

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_sa.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x)&&f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. `@(x)gt(x,0), @(x)gt(x,0)||lt(x,1)`, i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. `@(x,y)gt(x,y), @(x,y)gt(x-y,0)||lt(x-y,1)`, i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. `{'Var1','Var1',1,@(x)gt(x,0.1)}`, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. `{'Var1','Var2',0,@(x)lt(x,0.1)}`, to test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.
 - > 'cov' : Same as for 'corr'.

E.g. `{'Var1','Var1',0,@(x)lt(x,0.1)}`, to test a restriction on the contemporaneous

variance.

```
> 'ss'      : A N x 2 cell, where the elements of each
               row are:
               1. The expression using any of the
                  endogenous variables of the model.
               2. Same as 4 for 'irf'.
```

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mincerZarnowitzTest ↑**

```
[test,pval,res] = mincerZarnowitzTest(obj,precision)
```

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_sa.uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is specified with some lower and upper bounds. For each draw the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.

```

- 'waitbar'      : true or false. Default is true.

- 'output'       : Either 'double' or 'logical'. Default is 'logical'.

- 'seed'         : Set the seed to use to draw the monte carlo simulated
                    parameter sets. Default is 1. Seed is set back to old
                    state after this method is called!

```

Output:

```

- paramD        : The draws made from the parameter space. As a draws x N
                  double. Use paramD(success,:) to get the accepted
                  draws.

- values         : A N x 1 logical/double. An element is true/not nan if
                  the model where solved and the test function returned
                  a value.

- solvingFailed : A N x 1 logical. An element is true if the model could
                  not be solved.

- objAcc        : A 1 x nAcc vector of nb_model_generic objects
                  representing the accepted models.

```

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass [NB_MODEL_GENERIC](#)

► **parameterDraws** ↑

```

out = parameterDraws(obj)
out = parameterDraws(obj, draws, method, output, stable)

```

Description:

Make either posterior draws or bootstrapped draws from the distribution
of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

```

- obj      : An object of a subclass of the nb_model_generic class.

- draws    : Number of draws, as an integer. Default is 1000.

- method   : The selected method to make draws.

> 'asymptotic'          : Draw from the confidence set using

```

the assumption of asymptotic normality.
 See the `nb_mlEstimator.drawParameters`
 for more on this option. Applies to models
 estimated with maximum likelihood.

> 'bootstrap' : Create artificial data to bootstrap
 the estimated parameters. Default
 for models estimated with classical
 methods.

> 'wildBootstrap' : Create artificial data by wild
 bootstrap, and then "draw" paramters
 based on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'blockBootstrap' : Create artificial data by
 non-overlapping block bootstrap,
 and then "draw" paramters based
 on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'mblockBootstrap' : Create artificial data by
 overlapping block bootstrap,
 and then "draw" paramters based
 on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'rblockBootstrap' : Create artificial data by
 overlapping random block length
 bootstrap, and then "draw" paramters
 based on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'wildBlockBootstrap' : Create artificial data by wild
 overlapping random block length
 bootstrap., and then "draw" paramters
 based on estimation on these data.
 Only an option for models estimated
 with classical methods.

> 'copulaBootstrap' : Uses a copula approach to draw residual
 that are autocorrelated, Does not handle
 heteroscedasticity. Only an option for
 models estimated with classical methods.

> 'posterior' : Posterior draws. Only for models
 estimated with bayesian methods.
 Default for models estimated with
 bayesian methods.

- `output` : 'param' | 'solution' | 'object'. See output section for more
 on this option.
- `stable` : Give true if you want to discard the parameter draws
 that give rise to an unstable model. Default is false.

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores available.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.
- 'initialDraws' : When drawing parameters this factor decides how many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
 - > 'param' : Default. A struct with the following fields:
 - beta : A nPar x nEq x draws double with the estimated parameters.
 - sigma : A nEq x nEq x draws double with the estimated covariance matrix.
- For factor models these fields are also returned:
 - lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.
 - R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.
 - factors : Draws of the factors as a T x nFac x draws double.
- > 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

```
> 'object'      : Get the draws as a 1 x draws nb_model_generic object.  
                  Each element will be a model representing a given draw  
                  from the distribution of the parameters. I.e. only one  
                  output!
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► plotForecast ↑

```
plotter          = plotForecast(obj)  
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate,...  
                                         increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model
in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

```
plotter = plotForecastDensity(obj,date,variable)
```

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the

provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF** ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...  
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

```
- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method  
or the nb_graphPagesGUI class to produce the  
graphs.  
> 'biplot' : A vector of nb_graph_data objects with size  
equal to the number of pairwise combination of  
the parameters that can be made. Use the  
graph method or the nb_graphMultiGUI class to  
produce the graphs.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest ↑**

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_sa.monteCarloFiltering](#), [nb_cuconiTest](#), [nb_smirnovTest](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,valueName)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_sa.monteCarloFiltering](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)
[nb_sa.getPosteriorDistributions](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

printed = printCov(obj)

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results ↑**

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_sa.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations ↑**

obj = removeObservations(obj, numPer)

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

obj = set(obj,varargin)

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition ↑**

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1','...','shock_group_name_N';  
 'shock_name_1' ,..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If

different models has different frequency this date will be converted.

- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.
- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

See also:

[nb_sa.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulate ↑**

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
 - 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also

including exogenous and shocks.

- > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.
- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.
- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a specific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:
 - > double : A 1 x nVar double.
 - > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsge models.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsge models. If you are dealing with a MS-model you can indicate the state by 'steadystate(state)'. E.g. to start in state 1 give; 'steadystate(1)'. Default for nb_dsge models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char:

```

> double      : A nPeriods x nRegime or a 1 x
    nRegime double. nPeriods refer to
    the number of recursive periods to
    forecast.

> 'ergodic'   : Start from the ergodic transition
    probabilities. Default.

```

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity** ↑

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```

[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)

```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
 - 'nLags' : Number of lags to compute when 'stacked' is set to true.
 - 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
 - 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
 - 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
 - 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.
- Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
 - 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
 - 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Defualt is

true.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

[nb_sa.graphCorrelation](#), [nb_sa.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_sa object(s).

Input:

- obj : A vector of nb_sa objects.

Output:

- obj : A vector of nb_sa objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_sa.solveNormal(results,opt)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **solveRecursive** ↑

```
tempSol = nb_sa.solveRecursive(results,opt)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_sa.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template ↑**

```
options = nb_sa.template()
options = nb_sa.template(num)
```

Description:

Construct a struct which can be provided to the nb_sa class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions ↑**

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► testParameters ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic
is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as variables. See model.parameters.name.
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.
- type : Type of test:
 - > '=' : Two sided test. expression == 0 (default)
For two-sided tests it is assumed that the distribution is symmetric! Use confidenc/probabillity intervals instead.
 - > '>' : One sided test. expression > 0
 - > '<' : One sided test. expression < 0

Output:

- pval : > 'classical' : P-value of test.
> 'bayesian' : Probabilty of test.

A 1x1 double.
- ci : A 1 x 2 double with the lower and upper bound of the confidence/probabillty interval of the tested expression.
- dist : A nb_distribution object storing the distribution of the tested expression.

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the

parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
getVariable(varargout{i}, 'y', 'x'),
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

See also:

[nb_sa.graphCorrelation](#), [nb_sa.parameterDraws](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.

- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1' , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.

```
> {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object  
storing the numerically calculated  
forecast error variances/skewnesses.  
  
- plotter : A nb_graph_ts object which the method graph can be used to  
produce graphs.
```

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_sa.forecast](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_sa.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **update ↑**

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition ↑**

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.
Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double.

E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomposition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomposition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

■ nb_singleEq

Go to: [Properties](#) | [Methods](#)

A class for estimation of single equation models.

Superclasses:

nb_model_generic

Constructor:

obj = nb_singleEq(varargin)

Optional input:

- See the set method for more on the inputs.
(nb_model_estimate.set)

Output:

- obj : An nb_singleEq object.

See also:

[nb_model_generic](#), [nb_model_estimate.set](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- | | | | | |
|-------------------------------|--------------------------------------|-----------------------------|----------------------------------|-----------------------------|
| • addAutoName | • addAutoNameIfLocal | • addID | • addIDIfLocal | • dependent |
| • endogenous | • estOptions | • exogenous | • forecastOutput | • name |
| • options | • parameters | • reporting | • residuals | • results |
| • solution | • transformations | • userData | | |

- **[addAutoName](#)** ↑

Add automatic name (first) to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addAutoNameIfLocal](#)** ↑

Add automatic name (first) to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addID](#)** ↑

Add identifier to default name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[addIDIfLocal](#)** ↑

Add identifier to local name in getName. Default is false.

Inherited from superclass NB_MODEL_NAME

- **[dependent](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsge models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **[endogenous](#)** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** ↑

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** ↑

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** ↑

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** ↑

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that persevere the time span

are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsgc models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.

- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double. (Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation. As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is

for comments.

All methods of the nb_math_ts class that preserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

Inherited from superclass NB_MODEL_GENERIC

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **assignParameters** ↑

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta' : Assign all the estimated parameters of the main equation. Must be of same size as obj.results.beta.
- 'sigma' : Assign all the estimated parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma.
- 'lambda' : Assign all the estimated parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models.
- 'R' : Assign all the estimated parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj,varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.
- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.

- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

mult = calculateMultipliers(obj,varargin)

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!

- 'instrument' : A one line char with the name of the instrument. Must be provided!

- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!

- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!

- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.

- 'perc' : Error band percentiles. As a 1 x nPerc double.
E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the double method on this output to convert it to a double matrix.

See also:

[nb_singleeq.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError ↑**

```
obj = calculateStandardError(obj,method,draws)
```

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see [nb_bootstrap](#). For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property is updated with the bootstrapped standard errors.

Extra outputs (all based on bootstrapped draws):

- stdBeta : Standard deviation of coefficient of the main equation.
- tStatBeta : T-statistic for the coefficient of the main equation.
- pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- stdLambda : Standard deviation of coefficient of the observation equation.
- tStatLambda : T-statistic for the coefficient of the observation equation.
- pValLambda : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
- ci : Confidence interval/probability interval calculated based on a kernel density estimation instead of assuming asymptotic normal distribution. Only for the parameter in beta! As a (nCoeff * nEq) + 1 x 3 cell array.
- dist : Estimated distribution of the coefficients of the main equation. As a (nCoeff * nEq) x 1 nb_distribution object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

`obj = checkModel(obj)`

Description:

Secure that the object is up to date when it comes to the options, estOptions and results struct properties.

Input:

- obj : An object of class nb_model_generic.

Output:

- obj : An object of class nb_model_generic.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosterioriors** ↑

```
[DB,plotter,pAutocorr] = checkPosterioriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they where drawn. This to check for problems with posterior draws that may be autocorrelated.

Input:

- `obj` : A scalar object of class `nb_model_generic`. It must represent a bayesian model that is estimated.

Optional input:

- `'nLags'` : Number of lags to include in the autocorrelation plot. Default is 10.
- `'iter'` : The recursive iteration date. Either as a string or a `nb_date` object. If recursive estimation is done, this input must be provided.

Output:

- `DB` : A `nb_data` object with size `nDraws x numCoeff`.
- `plotter` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.
- `pAutocorr` : A `nb_graph_data` object. Use the `graphSubPlots` or the `nb_graphSubPlotGUI` class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **checkReporting** ↑

```
obj = checkReporting(obj)
```

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **conditionalTheoreticalMoments ↑**

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.

Default is ''. See below for what that means.

> 'bootstrap'	: Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
> 'wildBootstrap'	: Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'blockBootstrap'	: Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'mBlockBootstrap'	: Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'rBlockBootstrap'	: Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'wildBlockBootstrap'	: Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
> 'posterior'	: Posterior draws. Only for models estimated with bayesian methods. Default for models estimated with bayesian methods.
	Caution : Posterior draws is already made at the estimation stage.
- 'nSteps'	: Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...)
                           horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructScore** ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type,...)
                    allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

See also:

[nb_model_forecast.getScore](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [convert ↑](#)

`obj = convert(obj,freq,method,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_MODELDATA

► [convertEach ↑](#)

`obj = convert(obj,freq,methods,varargin)`

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of `nb_ts.convertEach`.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to `options.data` and not the `dataOrig` property.

Output:

- See the documentation of `nb_ts.convertEach`.

► `createVariables` ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- `obj` : A NxM `nb_modelData` object
- `expressions` : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the `nb_ts.createVariable` method.

> third column : Any expression that can be interpreted by the `nb_ts.createShift` method.

> fourth column : Comments

- `fcstHorizon` : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = { % Name,    input,    shift,    description
  'VAR1_G',    'pcn(VAR1)', 'avg',    'VAR1 growth'
  'VAR2_G',    'pcn(VAR2)', 'avg',    'VAR2 growth'
  'VAR3_G',    'pcn(VAR3)', 'avg',    'VAR3 growth'};

model = model.createVariables(expressions)
```

► dieboldMarianoTest ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.
- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band with selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

► **doForecastPerc2Dist ↑**

```
obj = doForecastPerc2Dist(obj,draws)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- obj : A nb_model_forecast object.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_singleeq.forecast](#), [nb_singleEq.forecastPerc2Dist](#)

► **doForecastPerc2ParamDist ↑**

[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- obj : A nb_model_forecast object.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity** ↑

`obj = doSimulateFromDensity(obj, draws)`

Description:

Simulates from the estimated kernel density.

Input:

- `obj` : A `nb_model_forecast` object.
- `draws` : Number of draws to use for simulation.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_model_generic.forecast`, `nb_singleEq.simulateFromDensity`

► **empiricalMoments** ↑

```
[m,c]           = empiricalMoments(obj,varargin)
[m,c,ac1]       = empiricalMoments(obj,varargin)
[m,c,ac1,ac2]   = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the `nb_model_generic` object. The `options.data` property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

Inherited from superclass NB_MODEL_GENERIC

► **eq** ↑

```
ret = eq(obj,other)
```

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind    = v(1) == v
```

See also:

[isequal](#)

Inherited from superclass NB_MODEL_GENERIC

► **estimate** ↑

```
obj        = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default

is to open max number of cores available. Only an option if 'parallel' is given.

- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

[nb_model_generic](#), [solve](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- density : Set true if you have a density forecast.
- quart : Set true if you want to compare the quarterly forecasts. This option automatically detects and uses the quarterly estimates when evaluating.

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

Inherited from superclass NB_MODEL_FORECAST

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evalaute forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

See also:

[nb_model_generic.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **evaluatePrior ↑**

logPriorD = nb_model_generic.evaluatePrior(prior,par)

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecast** ↑

```
obj          = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only for forward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
- 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error

Only for density forecast:

- 'logScore' : Log score

Can also be a cellstr with the above listed evaluation types.

Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters

for the whole sample.

- 'estDensity' : The method to estimate the density. As a string.
Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
 - 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false.
 - 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
 - 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1, i.e. only produce point forecast.
 - 'regimeDraws' : Number of drawn regime paths when doing density forecast. This will have no effect if the states input is providing the full path of regimes. Default is 1.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. Default is 0.9.
- If set to empty, all simulations will be returned.
- Caution: 'draws' must be set to produce density forecast.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.

```

- 'bins'          : The length of the bins og the domain of the density.
                    Either;
                      > []      : The domain will be found. See
                        nb_getDensityPoints (default is that 1000
                        observations of the density is stored).
                      > integer : The min and max is found but the length
                        of the bins is given by the provided
                        integer.
                      > cell     : Must be on the format:
                        {'Var1',lowerLimit1,upperLimit1,binsL1;
                         'Var2',lowerLimit2,upperLimit2,binsL2;
                         ...}
                      - lowerLimit1 : An integer, can be nan,
                        i.e. will be found.
                      - upperLimit1 : An integer, can be nan,
                        i.e. will be found.
                      - binsL1      : An integer with the
                        length of the bins. Can
                        be nan. I.e. bins length
                        will be adjusted to
                        create a domain of 1000
                        elements.

Caution : The variables not included will be given
           the default domain. No warning will be
           given if a variable is provided in the
           cell but not forecast by the model. (This
           because different models can forecast
           different variables)

Caution : The combineForecast method of the
           nb_model_group class is much faster if the
           lower limit, upper limit! Or else
           it must simulate new draws and do kernel
           density estimation for each model again
           with the shared domain of all models
           densities.

- 'startDate'    : The start date of forecast. Must be a string or an
                    object of class nb_date. If empty the estim_end_date
                    + 1 will be used.

Caution: If 'fcstEval' is not empty this will set
         the start date of the recursive forecast.
         Default is to start from the first possible
         date.

- 'endDate'      : The end date of forecast. Must be a string or an
                    object of class nb_date. If empty the estim_end_date
                    + 1 will be used.

Caution: If 'fcstEval' is empty this input will

```

have nothing to say.

- 'saveToFile' : Logical. Save densities and domains to files. One file for each model. Default is false (do not).
- 'observables' : A cellstr with the observables you want the forecast of. Only for factor models. Will be discarded for all other types of models.
- 'condDB' : One of the following:
 - > A nb_ts object with size nSteps x nCondVar with the information to condition on.

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.
 - > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
 - > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
 - > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous

variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is chosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.
- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
If not provided. Model stds are used.
 - > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
 - > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for

all periods. Must be given!

- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogenous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogenous variables are autocorrelated all variables for all periods must be drawn at the same time, using this autocorrelation matrix.
- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:

This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime

is not given, you will start in
the ergodic steady-state for
MS-model, and in the last regime
for break-point models.

- 'startingProb' : Either a double or a char:
 - > 'zero' : Start from zero on all variables
(Except for the deterministic
exogenous variables)
 - > [] : If the model is filtered the
starting value is calculated
on filtered transition
probabilities. Otherwise the
ergodic mean is used.
 - > double : A nPeriods x nRegime or a 1 x
nRegime double. nPeriods refer to
the number of recursive periods to
forecast.
 - > 'ergodic' : Start from the ergodic transition
probabilities.
- 'stabilityTest' : Give true if you want to discard the parameter draws
that give rise to an unstable model. Default
is false.
- 'states' : Either an integer with the regime to
forecast/simulate in, or an object of class nb_ts
with the regimes to condition on. The name of the
variable must be 'states'.

Caution: For break-point models this is decided by
the dates of the breaks, and cannot be set
by this option!

- 'compareToRev' : Which revision to compare to. Default is final
revision, i.e. []. Give 5 to get fifth revision.
must be an integer. Keep in mind that this number
should be larger than the nSteps input.
- 'compareTo' : Sometime you want to evaluate the forecast of one
variable against another variable which is not
part of the model. E.g. if you use the first release
of a variable and want to compare it against the
final release. To do this you can give a cellstr
with size n x 2, where n is the number of variables
to change the the actual observations to test
against. {'VAR_1','VAR_FINAL',...}.
- 'estimateDensities' : true or false. true if you want to do a
kernel density estimation of the density
forecast.
- 'exoProj' : Tolerate missing exogenous variables by projecting
them by a fitted model. Only when the 'condDB'
input is empty!

Options are:

- '' : No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.

- 'ar' : The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.

Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are beeing produced recursivly with recursivly estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursivly estimated AR cofficients as well.

- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assign to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummie variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example

{'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when `exoProj` is set to 'AR'.

- 'bounds'
: A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a `nVar x nSteps` double matrix. For the order of the variables see; `obj.solution.endo`. The value return by the function must be either a 1x1 double or a `nSteps x 1` double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs'
: This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.

- 'foundReplic'
: A struct with size `1 x parameterDraws`. Each element must be on the same format as `obj.solution`. I.e. each element must be the solution of the model given a set of drawn parameters. See the `parameterDraws` method of the `nb_model_generic` class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.

```
- 'seed' : Set simulation seed. Default is 2.0719e+05.
```

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_singleeq.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_singleeq.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
    nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.
- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getCondDB ↑

[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provied recursive conditional information.

Caution : If the dataset is of type real-time, this function interpret the endDate input as the estimation end date for the last recursion. It also assumes that each vintage give rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default is false.
- recStart : An object of class nb_date or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if recursive is set to true.

Output:

- condDB : As a nb_ts or nb_data object. Can be given as input to the condDB option of the nb_model_generic.forecast method.
- obj : An object of class nb_model_generic. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the options.data option may change.

► **getDSGEVARPriorMoments ↑**

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by [nb_var.priorTemplate\('dsge'\)](#).

Input:

- `obj` : An object of class `nb_model_generic`.
- `dsgeVar` : A `nb_var` object set up with options for estimation of a DSGE-VAR.

Optional input:

- `'maxIter'` : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- `'tol'` : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- `GammaYY` : A $N \times N$ double with the nonstandardized sample moments of the left-hand variables of the VAR.
- `GammaXX` : A $(C + N*L) \times (C + N*L)$ double with the nonstandardized sample moments of the right-hand variables of the VAR.
- `GammaXY` : A $(C + N*L) \times N$ double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getDependent ↑**

`dependent = getDependent(obj)`

Description:

Get dependent variables from a estimated `nb_model_generic` object

Input:

- `obj` : An object of class `nb_model_generic`

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getEstimationOptions** ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► **getEstimationStartDate** ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getFiltered ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be $N(0,1)$. Default is false.
- econometricians : Get econometricians view of the filtered variables.
I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a $N \times 3$ cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs \times nvars included the filtered variables.

See also:

[nb_dsge.filter](#), [nb_singleeq.estimate](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast** ↑

```
fcstData          = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();
```

```

    end

> 'date'      : A string or a nb_date object with the date of the
                 wanted forecast. E.g. '2012Q1'. The fcstData will
                 be a nb_ts object with size nHor x nVar x nPerc + 1,
                 while fcstPercData will be empty. nPerc will then be
                 the number of percentiles/simualtions. Mean will be at
                 last page.

For real-time forecast the vintage at the time is
returned as the historical data, when includeHist
is true.

> 'horizon'   : This option will return the forecast as a
                 nPeriods + nHor x nVar x nHor nb_ts object. This
                 option will only return the mean forecast.

If includeHist is true the actual data is added
as an additional page of the nb_ts object.

Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).

```

Optional inputs:

```

> 'horizon'   : The fcstData output will be a nb_ts object with
                 size nRec x nVars. While the fcstPercData output
                 will be a nb_ts object with size nRec x nVars x nSim.
                 You can set the horizon to return by the optional
                 input 'horizon'. See the 'timing' option also.

```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_singleEq.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► [getForecastVariables ↑](#)

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object

- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.

- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.

The same apply for real-time data.

- notSmoothed : Prevent getting history from smoothed estimates.

- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

```
names = getModelNames(obj)
```

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```
pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)
```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produced it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

[nb_calculatePIT](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

methods = parameterDraws(obj)

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

p = getParameters(obj,varargin)

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as

fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the parameter values ('struct' is not supported if numel(obj) > 1).

- : Give 'headers' to add model names as headers for each column of the return cell. Only if numel(obj) > 1.
- : Give 'double' to return the value as a numerical array.
- : Give 'skipBreaks' to not remove any break-point parameters.

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted** ↑

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

See also:

[nb_graph_ts](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRecursiveScore** ↑

```
score          = getRecursiveScore(obj,type)
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_FORECAST`

► **getResidual** ↑

`residual = getResidual(obj)`

Description:

Get residual from a estimated `nb_model_generic` object

Input:

- `obj` : An object of class `nb_model_generic`

Output:

- `residual` : Either a `nb_ts` or a `nb_cs` object with `residual(s)` stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getResidualGraph** ↑

`plotter = getResidualGraph(obj)`

Description:

Get residual graph from the given estimator. The returned will be an object of class `nb_graph`, which you can call the `graphInfoStruct` method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- `obj` : An object of class `nb_model_generic` (or a subclass of this class).

Output:

- `plotter` : An object of class `nb_graph`. Use the `graphInfoStruct` method or the `nb_graphInfoStructGUI` class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

See also:

► **getResidualNames** ↑

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of `nb_model_generic` object

Input:

- `obj` : A vector of `nb_model_generic` objects

Output:

- `residualNames` : A cellstr with the unique residual names of all the models

Written by Kenneth Åström Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method `solve`.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getScore ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,...  
    rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.

- type : A string with one of the following:
- 'RMSE' : One over root mean squared error
- 'MSE' : One over mean squared error
- 'MAE' : One over mean absolute error
- 'MEAN' : One over mean error
- 'STD' : One over standard error of the forecast error
- 'ESLS' : Exponential of the sum of the log scores
- 'EELS' : Exponential of the mean of the log scores
- 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.

- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursivly using the the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Inherited from superclass NB_MODEL_FORECAST

► **getSolution ↑**

value = getSolution(obj,type)

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the 'varOfInterest' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the 'observables' input to the forecast method of the nb_model_generic forecast, when the 'output' input is set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **graphCorrelation** ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the ac1 output from SIM or THEO, the fourth input can be the ac1 output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_singleEq.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_estimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **help ↑**

```
helpText = nb_singleEq.help  
helpText = nb_singleEq.help(option)  
helpText = nb_singleEq.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize ↑**

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► interpretForecast ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:**Input:**

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given,

otherwise this option does not apply.

- 'optimizer'
 - : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset'
 - : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel'
 - : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters'
 - : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsg.
- 'periods'
 - : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate'
 - : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest'
 - : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch'
 - : If the 'model' input is given these are the variables that are matched, otherwise these are taken from the 'fcstDB' option.
- 'scale'
 - : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights'
 - : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

[nb_singleeq.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf** ↑

```
[irfs,irfsBands,plotter] = irf(obj,varargin)
```

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgc objects.

- 'compare' : Give true if you have a scalar nb_dsgc model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.

- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

```

- 'draws' : Number of draws for calculating girf. Default is
           1000. For Markov switching models this will set the
           number of simulated paths of states. For more see
           the 'type' input.

- 'factor' : A cell array with the factors to multiply the
             irf of the individual model variables.
             I.e. {'var1',100,...} or
                  {'var1','var2'},100,...}

If the string starts with a asterisk you will
multiply all the variables that contain that
string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This option sets the error band percentiles of the
               graph, when the 'perc' input is empty. As a 1 x
               numErrorBand double. E.g. [0.3,0.5,0.7,0.9].
               Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element
                  must be on the same format as obj.solution. I.e.
                  each element must be the solution of the model
                  given a set of drawn parameters. See the
                  parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from
                  this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

    > 'cumulative product' : cumprod(1 + X,1)

    > 'cumulative sum' : cumsum(X,1)

    > 'cumulative product (log)' : log(cumprod(1 + X,1))

    > 'cumulative sum (exponential)' : exp(cumsum(X,1))

    > 'cumulative product (%)' : cumprod(1 + X/100,1)

    > 'cumulative sum (%)' : cumsum(X/100,1)

    > 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))

    > 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))

    > '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
             Default is ''. See help on the method input of the
             nb_model_generic.parameterDraws method for more
             this input. An extra option is:

    > 'identDraws' : Uses the draws of the matrix with
                    the map from structural shocks to dependent

```

variables. See `nb_var.set_identification`. Of course this option only makes sense for VARs identified with sign restrictions.

- `'normalize'` : A 1 x 3 cell. First element must be the variable name as a string. The second element must be the value to normalize to, as an integer. While the third element is the period to be normalized, if set to `inf`, it will normalize the max impact period.
E.g. `{'Var',1,2}, {'Var',1,inf}`
Caution: 2 means observation 2 of the IRF, and as the IRF start at period 0, this means that observation 2 is period 1.
- `'normalizeTo'` : `'draws'` or `'mean'`. `'draws'` normalize each draw of irfs, while `'mean'` normalize the mean and scale percentiles/other draws accordingly. Default is `'draws'`.
Caution: Setting this to `'mean'` will not work for reported variables that is not measured as % deviation from steady-state/mean.
- `'newReplic'` : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the replic input.
- `'parallel'` : Give true if you want to do the irfs in parallel. This option will parallelize over models. Default is false.
- `'parallelL'` : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if `numel(obj) == 1`. Default is false.
- `'pause'` : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- `'perc'` : Error band percentiles. As a 1 x `numErrorBand` double. The input must be given as the coverage, and not the percentiles itself. E.g. `[0.3,0.5,0.7,0.9]`. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So `[0.3,0.5,0.7,0.9]` will get the percentiles `[5,15,25,35,65,75,85,95]`, i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the `'fanPerc'` input (0.68).)
- `'periods'` : Number of periods of the impulse responses.
- `'plotSS'` : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for `nb_dsg` objects.

```

- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the
initial steady state. Only an option if 'plotSS'
is set to true. Only for nb_dsg objects.

- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the
method 'identDraws'. See the option
'draws' of the method
nb_var.set_identification for more.

- 'settings' : Extra graphs settings given to nb_plots
function. Must be a cell.

- 'shocks' : Which shocks to create impulse responses of.
Default is the residuals defined by the first model.

For Markov switching or break point models it may
be wanted to only run a IRF when switching the
state. To do so set this option to {'states'}.
You should also set 'startingValues' to
'steadystate(r)', where r is the regime you start
in. For a Markov switching model also set
'startingProb' to the same r. This is only an
option if 'type' is set to 'irf'.

- 'sign' : Sign of the impulse. Either 1 or -1. Can also be
a vector of the same size as 'shocks' input.

- 'stabilityTest' : Give true if you want to discard the draws
that give rise to an unstable model. Default
is false.

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):

    > scalar : Select the the regime to take the
initial transition probabilities
from.

    > double : A draws x nRegime or a 1 x
nRegime double. draws refer to
the number set by the 'draws'
input.

    > 'ergodic' : Start from the ergodic transition
probabilities. Default for 'irf'.

    > 'random' : Randomize the starting values
using the simulated starting
points. Default for 'girf'.

- 'startingValues' : Either a double or a char:

    > double : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing

```

with a MS-model or a break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. For MS - models the default is the ergodic mean (default as long as 'girf' is not selected as 'type'), while for break-point models it is to start from the first regime.

```

> 'zero'          : Start from zero on all variables.

> 'random'        : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'         : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'           : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generlized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'   : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

- 'variables'       : The variables to create impulse responses of.
                     Default is the dependent variables defined by the
                     first model.

Caution: The variables reported by the reporting
          property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level
                     using the method specified by 'levelMethod'.

```

Output:

```

- irfs      : The (central) impulse response function stored in a
               structure of nb_ts object. Each field stores the the
               impulse responses of each shock. Where the variables
               of the nb_ts object is the impulse responses of the
               wanted endogenous variables.

               I.e. the impuls responses to the shock 'E_X_NW' is
               stored in irfs.('E_X_NW'). Which will then be a nb_ts
               object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the
          responses from each model are saved as
          different datasets (pages) of the nb_ts object.

```

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.
 - > 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
 - > 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast ↑**

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsg object is filtered or not.

Input:

- obj : An object of class nb_dsg.
- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMS** ↑

```
ret = isMS(obj)
```

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

```
ret = isMixedFrequency(obj)
```

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isNB** ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStateSpaceModel** ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

ret = isStatic(obj)

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

ret = isbayesian(obj)

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► isestimated ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► isforecasted ↑

```
ret = isforecasted(obj)
```

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved** ↑

```
ret = issolved(obj)
```

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **jointPredictionBands** ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint

```
prediction bands for  
macroeconomic risk management  
  
> 'copula' : Using a copula likelihood approach.  
  
> 'mostlik' : Group the paths based on how  
likely they are.  
  
- 'nSteps' : Number of forecasting steps to use when constructing the  
error bands. If empty (default) all forecasting steps stored  
in the object is used.
```

Output:

- JPB : An nb_ts object storing the joint prediction bands.
The percentiles are stored as datasets. See the
dataNames property for which page represent which
percentile.

The data of the nb_ts object has size nSteps x nVars
x nPerc.
- plotter : A nb_graph_ts object. Use the graphSubPlots method
to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior ↑**

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend
on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_singleEq.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x)&&f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. `@(x)gt(x,0), @(x)gt(x,0)||lt(x,1)`, i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. `@(x,y)gt(x,y), @(x,y)gt(x-y,0)||lt(x-y,1)`, i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. {'Var1','Var1',1,`@(x)gt(x,0.1)`}, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. {'Var1','Var2',0,`@(x)lt(x,0.1)`}, to

test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.

> 'cov' : Same as for 'corr'.

E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous variance.

> 'ss' : A N x 2 cell, where the elements of each row are:

1. The expression using any of the endogenous variables of the model.
2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

[nb_singleEq.theoreticalMoments](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **mincerZarnowitzTest** ↑

`[test,pval,res] = mincerZarnowitzTest(obj,precision)`

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class `nb_model_generic`. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '`%8.6f`'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

Inherited from superclass NB_MODEL_GENERIC

► **monteCarloFiltering** ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.

- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

See also:

[nb_singleEq.assignParameters](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass [NB_MODEL_GENERIC](#)

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj,draws,method,output,stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.
 - > 'wildBootstrap' : Create artificial data by wild bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'blockBootstrap' : Create artificial data by non-overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'mblockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'rblockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'wildBlockBootstrap' : Create artificial data by wild overlapping random block length bootstrap., and then "draw" parameters based on estimation on these data. Only an option for models estimated with classical methods.
 - > 'copulaBootstrap' : Uses a copula approach to draw residual that are autocorrelated, Does not handle heteroscedasticity. Only an option for models estimated with classical methods.
 - > 'posterior' : Posterior draws. Only for models estimated with bayesian methods.

Default for models estimated with
bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more on this option.
- stable : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores available.
- 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.
- 'initialDraws' : When drawing parameters this factor decides how many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
 - > 'param' : Default. A struct with the following fields:
 - beta : A nPar x nEq x draws double with the estimated parameters.
 - sigma : A nEq x nEq x draws double with the estimated covariance matrix.
- For factor models these fields are also returned:
- lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.
 - R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.
- factors : Draws of the factors as a T x nFac x

```

draws double.

> 'solution' : Get the solution of the model for each draw from the
distribution of parameters. The output will be a struct
with size 1 x draws. The struct will have the same
format as the solution property of the underlying
object. I.e. only one output!

> 'object'   : Get the draws as a 1 x draws nb_model_generic object.
Each element will be a model representing a given draw
from the distribution of the parameters. I.e. only one
output!

```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + ( +/- nb_distribution.t_icdf(alpha/2)) * stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► plotForecast ↑

```

plotter          = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
                                         increment,varargin)

```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.
 - > 'hairyplot' : Plot the recursive point forecast in the same graph as the actual data.
- startDate : A string with the start date of the forecast to plot. As a string or an object of class nb_date. Only an option when type is 'default'. Default is to plot the latest forecast produced.
- increment : Number of periods between the hairs when doing a hairy-plot. Default is 1.

Optional input:

- 'type' : If the history is of some variables are filtered, you can use this input to choose to plot the smoothed or updated estimates of the filtered variables. Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- plotter : An object of class nb_graph. Use the graphSubPlots method or the nb_graphSubPlotGUI class.
- plotFunction2Use : A string with the name of the method to call on the plotter object to produce the graphs.

See also:

[nb_model_generic.uncondForecast](#), [nb_model_generic.forecast](#)

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity ↑**

plotter = plotForecastDensity(obj,date,variable)

Description:

Plot the density forecast at a given date for a given variable. It will be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the provided date. See the dataNames property of the DB property of the returned plotter object. If the model has produced nowcast the names will 'horizon0' (a variable lag one period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► plotMCF ↑

```
plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...  
upperBound,method)
```

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot.

'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- `plotter` : > 'allInOne' : A `nb_graph_cs` object. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
 > 'biplot' : A vector of `nb_graph_data` objects with size equal to the number of pairwise combination of the parameters that can be made. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotMCFDistTest ↑**

`plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)`

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `test` : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

See also:

[nb_singleEq.monteCarloFiltering](#), [nb_cucconiTest](#), [nb_smirnovTest](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,valueName)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- `paramD` : A draws x N double with the parameter draws. E.g. use `paramD(success,:)` from the output of the `monteCarloFiltering` method. N is the number of parameters.
- `params` : A 1 x N cellstr with the names of the parameters.
- `values` : A draws x 1 double with the values of the monte carlo filtering.
- `nameValue` : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- `plotter` : A vector of `nb_graph_data` objects with size 1 x N. Use the `graph` method or the `nb_graphMultiGUI` class to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

► **plotPosteriors** ↑

```
plotter = plotPosteriors(obj)
plotter = plotPosteriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).
- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.

Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)
[nb_singleEq.getPosteriorDistributions](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

See also:

[nb_graph_data](#), [nb_graphMultiGUI](#), [nb_graphSubPlotGUI](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

printed = print(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results ↑**

```
printed = print_estimation_results(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_singleeq.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **removeObservations ↑**

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set ↑**

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties
of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

See also:

[nb_model_generic](#), [nb_judgemental_forecast](#), [nb_model_convert](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **shock_decomposition ↑**

[decomp, decompBand, plotter] = shock_decomposition(obj, varargin)

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : A vector of nb_model_generic objects

- 'packages' : Cell matrix with groups of shocks and
the names of the groups. If you have not
listed a shock it will be grouped in a
group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';  
'shock_name_1' , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with
a shock name or a cellstr array with the
shock names. E.g 'E_X_NW' or {'E_X_NW', 'E_Y_NW'}.

Caution: Two special identifiers can be used;
'Initial Conditions' and 'Steady-state'. The
first represent the impact of all shocks that
hit the system before the decomposition/
estimation started. The second summarizes the
impact of steady-state changes on the system,

i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a $1 \times \text{numErrorBand}$ double. E.g. [0.3, 0.5, 0.7, 0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sence for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.

- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string. If different models has different frequency this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

See also:

[nb_singleEq.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulate ↑**

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be

a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given variable.
- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the

simulation of.

- > 'endo' : All the endogenous variables are returned.
- > 'fullendo' : All the endogenous variables are returned included the lag variables.
- > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
- > 'all' : All variables are returned (but not the lags). Also including exogenous and shocks.

- 'parallel' : Give true if you want to do the simulations in parallel. I.e. spread models to different threads. Default is false.
- 'parameterDraws' : Number of draws of the parameters. When set to 1 it will discard parameter uncertainty. Default is 1.
- 'regime' : Select the regime you want to simulate. If empty the simulation will switch between regimes. Only an option for Markov switching models.
- 'regimeDraws' : Number of drawn regime paths when doing simulations. This will have no effect if the states input is providing the full path of regimes. Default is 1.
- 'seed' : Set simulation seed. Default is 2.0719e+05.
- 'startDate' : Give the start date of the simulation. If not provided the output will be a nb_data object without a spesific start date (default). If provided the output will be an object of class nb_ts.

Caution : If dealing with break-points or exogenous time-varying parameters this input must be provided.

- 'startingValues' : Either a double or a char:

- > double : A 1 x nVar double.
- > 'mean' : Start from the mean of the data observations. Default for all model except nb_dsge models.
- > 'steadyState' : Start from the steady state. For now only an option for nb_dsge models. If you are dealing with a MS-model you can indicate the state by 'steadyState(state)'. E.g. to start in state 1 give; 'steadyState(1)'. Default for nb_dsge models.

```

> 'zero'           : Start from zero on all variables
                      (Except for the deterministic
                      exogenous variables)

- 'stabilityTest' : Give true if you want to discard the parameter draws
                     that give rise to an unstable model. Default
                     is false.

- 'startingProb'  : Either a double or a char:

    > double        : A nPeriods x nRegime or a 1 x
                      nRegime double. nPeriods refer to
                      the number of recursive periods to
                      forecast.

    > 'ergodic'     : Start from the ergodic transition
                      probabilities. Default.

```

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity ↑**

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **simulatedMoments** ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- `obj` : An object of class nb_model_generic.
- Optional inputs;
- `'output'` : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- `'stacked'` : If the output should be stacked in one matrix or not. true or false. Default is false.
- `'nLags'` : Number of lags to compute when 'stacked' is set to true.
- `'vars'` : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- `'type'` : Either 'covariance' or 'correlation'. Default is 'correlation'.
- `'draws'` : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- `'pDraws'` : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- `'perc'` : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: 'pDraws' or 'draws' must be set to a number > 1.
- `'nSteps'` : Number of simulation steps. As a 1x1 double. Default is 100.
- `'burn'` : The number of periods to remove at start of the simulations. This is to randomize the starting

values of the simulation. Default is 0.

- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Default is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
 - varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
 - varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.
- E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
`getVariable(varargin{i}, 'y', 'x')`,
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use `getVariable(varargin{i}, 'x', 'y')`. (This example only works if the output is of class nb_cs)

► **solve ↑**

`obj = solve(obj)`

Description:

Solve estimated model(s) represented by nb_singleEq object(s).

Input:

- obj : A vector of nb_singleEq objects.

Output:

- obj : A vector of nb_singleEq objects, where the solved model(s) is/are stored in the property solution.

See also:

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_singleEq.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

```
options = nb_singleEq.template()
options = nb_singleEq.template(num)
```

Description:

Construct a struct which can be provided to the nb_singleEq class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

Written by Kenneth Sæterhagen Paulsen

► **testForecastRestrictions** ↑

```
probability = testForecastRestrictions(model, restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

```

- obj : A nb_model_forecast object with density forecast

- restrictions : Restrictions as a n x 3 cell array,
    {variable, date, test}.

    > variable : The variable(s) to test,
        as a string or cell array of strings.

    > date : The date as a string. If a cell array is given, a
        copy of the restriction will be made for every given
        date.

    > test : Restriction test as a function handle. The value(s)
        of the variable(s) in 'variable' at time 'date' are
        passed as arguments. Should return a logical.

```

Output:

- out : A double with the probability

Example:

```

restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...
    {'QSA_URR', 'QSA_DPO_CP'}, '2014Q1', @(x, y) x < y};
probability = model.testForecastRestrictions(restrictions);

```

See also nb_testForecastRestrictions

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

```

- obj : A scalar solved nb_model_generic object.

- expression : A MATLAB expression as a string. Use parameter names as
    variables. See model.parameters.name.

```

```

- method      : A string with the method to use. For bootstrap method see
               nb_bootstrap. For bayesian models 'posterior' is the only
               option. Default is 'bootstrap' for classical models, while
               'posterior' is the default for bayesian models.

- draws       : Number of draws from the parameter distribution. Default
               is 1000.

- alpha       : Confidence level. Default is 0.05.

- type        : Type of test:
               > '=' : Two sided test. expression == 0 (default)
               For two-sided tests it is assumed that the
               distribution is symmetric! Use
               confidenc/probabillty intervals instead.
               > '>' : One sided test. expression > 0
               > '<' : One sided test. expression < 0

```

Output:

```

- pval        : > 'classical' : P-value of test.
               > 'bayesian'  : Probabilty of test.

               A 1x1 double.

- ci          : A 1 x 2 double with the lower and upper bound of the
               confidence/probabillty interval of the tested expression.

- dist        : A nb_distribution object storing the distribution of the
               tested expression.

```

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► **theoreticalMoments** ↑

```

[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)

```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation,
autocovariance/autocorrelation.

Caution : For recursivly estimated model only the full sample estimation
results is used.

Caution : Only supported for models that can be solved in the following
way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.
- Optional inputs;
- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.
Can also be a cellstr, with a subset of variables from 'full'.
- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.
- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the all draws.

Caution: 'pDraws' must be set to a number > 1.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargout{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargout{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition** ↑

[data,plotter] = uncertaintyDecomposition(obj,varargin)

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the

percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).

> 'fev'	: Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc'	: At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages'	: Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1', ..., 'shock_group_name_N';
 'shock_name_1'      , ..., 'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

```
obj = uncondForecast(obj,nSteps,varargin)
```

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_singleeq.forecast](#)

Written by Kenneth Åstterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **unstruct** ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_singleeq struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► [update ↑](#)

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type :
 - > '' : Only update data. Default
 - > 'estimate' : Update data and estimate.
 - > 'solve' : Update data, estimate and solve
 - > 'forecast' : Update data, estimate, solve and forecast.
- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► variance_decomposition ↑

```
[decomp,decompBands,plotter,plotterBands] = ...
    variance_decomposition(obj,varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8,inf].
- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.
Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidence/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
> 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent

variables. See nb_var.set_identification. Of course this option only makes sense for VARs identified with sign restrictions.

- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1' ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output :

- decomp : A structure of nb_ts objects with the variance decomposition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomposition for each model. For each percentiles the output is as decomp.

- `plotter` : A $1 \times nModel$ vector of `nb_graph_cs` objects. Use the `graph` method or the `nb_graphPagesGUI` class to produce the graphs.
- `plotterBands`: A $1 \times nModel$ struct. Each field is a $1 \times nVars$ vector of `nb_graph_cs` objects. Use the `graphSubPlots` method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

[nb_singleEq.parameterDraws](#), [nb_varDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_MODEL_GENERIC`

■ `nb_var`

Go to: [Properties](#) | [Methods](#)

A class for estimation and identification of VAR models.

OLS estimated VAR models uses the package `nb_olsEstimator`, while if you select the maximum likelihood estimator the `nb_mlEstimator` package is used.

The bayesian VARs are estimated using code that are based on code from a paper by Koop and Korobilis (2009), Bayesian Multivariate Time Series Methods for Empirical Macroeconomics. These code are extended to handle block exogenous variables, priors for the long run, and missing observations. See the `nb_bVarEstimator` package for the implementation.

The code of the identification algorithm is based on code provided by Andrew Binning, see paper Binning (2013), "Underidentified SVAR models: A framework for combining short and long-run restrictions with sign-restrictions". See the method `nb_var.ABidentification` for the implementation. We extend Binning (2013) to also allow for magnitude restrictions.

Superclasses:

`nb_model_generic`

Constructor:

```
obj = nb_var(varargin)
```

Optional input:

- See the `set` method for more on the inputs.
(`nb_model_estimate.set`)

Output:

- `obj` : An `nb_var` object.

- `transformations`
- `estOptions`
- `name`
- `residuals`
- `userData`

- **`addAutoName`** ↑

Add automatic name (first) to default name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **`addAutoNameIfLocal`** ↑

Add automatic name (first) to local name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **`addID`** ↑

Add identifier to default name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **`addIDIfLocal`** ↑

Add identifier to local name in `getName`. Default is `false`.

Inherited from superclass `NB_MODEL_NAME`

- **`block_exogenous`** ↑

A struct with the fields `name`, `tex_name` and `number`. The `name` field holds a cellstr with the names of all the block exogenous variables, the `tex_name` holds the names in the tex format. The `number` field holds a double with the number of block exogenous variables. To set it use the `set` function. E.g. `obj = set(obj,'block_exogenous',{'Var1','Var2'})`; or use the `<className>.template()` method.

- **`dependent`** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the dependent variables, the tex_name holds the names in the tex format. The number field holds a double with the number of dependent variables. To set it use the set function. E.g. obj = set(obj,'dependent',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models this property stores the variables declared as endogenous in the model file, and will be the same as the endogenous property.

Inherited from superclass NB_MODEL_GENERIC

- **endogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the endogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of endogenous variables. To set it use the set function. E.g. obj = set(obj,'endogenous',{'Var1','Var2'}); or use the <className>.template() method.

Inherited from superclass NB_MODEL_GENERIC

- **estOptions** ↑

A struct with estimation options. Output from the estimator function. E.g. nb_olsEstimator.estimate.

Inherited from superclass NB_MODEL_ESTIMATE

- **exogenous** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the exogenous variables, the tex_name holds the names in the tex format. The number field holds a double with the number of exogenous variables. To set it use the set function. E.g. obj = set(obj,'exogenous',{'Var1','Var2'}); or use the <className>.template() method.

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **factors** ↑

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the factors, the tex_name holds the names in the tex format. The number field holds a double with the number of factors. To set it use the set function. E.g. obj = set(obj,'factors',{'Var1','Var2'}); or use the <className>.template() method.

- **forecastOutput** ↑

A struct with forecast output

Inherited from superclass NB_MODEL_FORECAST

- **name** [↑](#)

Name of model. If not assign a name a generic name will be provided. See the implementation of nb_model_name.createName for different subclasses.

Inherited from superclass NB_MODEL_NAME

- **options** [↑](#)

A struct storing all the options to set for the model object of interest. Use the static <className>.help method to get help on each field of the options structure.

Inherited from superclass NB_MODEL_OPTIONS

- **parameters** [↑](#)

A struct with the parameter names of the model stored at the field name, and the parameter value stored at the field value. See also the getParameters method.

Inherited from superclass NB_MODEL_GENERIC

- **reporting** [↑](#)

A N x 3 cell matrix of how to transform model variables to reported variables. First column is the reported variable name, while the second column is the expression to convert the model variable to reported variable. The last column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: During reporting, 20 periods of history of the input variables are appended to the forecast.

Can also be empty.

See also: nb_ts.checkExpressions.

Inherited from superclass NB_MODELDATA

- **residuals** [↑](#)

A struct with the fields name, tex_name and number. The name field holds a cellstr with the names of all the residuals, the tex_name holds the names in the tex format. The number field holds a double with the number of residuals. Cannot be set. Model must be solved for this proeprty to be up to date!

Caution: For nb_dsg models the residuals and exogenous property stores the same variables (after the model being solved)!

Inherited from superclass NB_MODEL_GENERIC

- **results** ↑

A struct storing all the results of the estimation.

Inherited from superclass NB_MODEL_ESTIMATE

- **solution** ↑

A struct storing the companion form of the model.

$Y_t = A*Y_{t-1} + B*X_t + C*e_t, e \sim N(0, vcv)$

Observation equation (Factor models only):

$O_t = F*X_t + G*Y_t + u_t, u \sim N(0, R)$

Observation equation (ARIMA models only):

$X_t = G*Z_t + Y_t$

Fields:

- A : See the equation above. A nendo x nendo double.
- B : See the equation above. A nendo x nexo double.
- C : See the equation above. A nendo x nres double.
- endo : A 1 x nendo cellstr with the decleared endogenous variables.
- exo : A 1 x nexo cellstr with the decleared exogenous variables.
- res : A 1 x nres cellstr with the decleared residuals/shocks.
- vcv : Variance/covariance matrix of the residuals/shocks. As a nres x nres double.
- class : The name of the model class.

Factor models and ARIMA models (only):

- factors : A 1 x nfact cellstr with the estimated factors and/or exogenous variables of the measurement equation.
- F : See the equation above. A nobs x nExo double.
(Storing the impact of exogenous terms of the observation equation)
- G : See the equation above. A nobs x nfact double.
- observables : A 1 x nobs cellstr with the decleared observable variables.
- R : Variance/covariance matrix of the residuals/shocks of the observation equation.

As a nobs x nobs double. If not provided, it is assumed to be 0.

DSGE:

- ss : A nendo x 1 double with the steady-state of the model.
- jacobian : A neq x (nforward + nendo + nbackward + nres) sparse double storing the jacobian of the model.
- jacobianType: A 1 x (nforward + nendo + nbackward + nres) indicating the type of each column of the jacobian. 1 indicate leaded variables, 0 current period variables, -1 indicate lagged variables, and 2 indicate residuals (innovations).

DSGE (with break-points):

In this case the fields A, B, C and ss are all cell arrays with size 1 x nbbreaks. Each element has the size in the standard case.

Inherited from superclass NB_MODEL_GENERIC

- **transformations** ↑

A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

All methods of the nb_math_ts class that perserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Can also be empty.

See also: nb_ts.createVariable and nb_ts.createShift.

Inherited from superclass NB_MODELDATA

- **userData** ↑

Adds the possibility to add user data. Can be of any type

► ABidentification ↑

```
S = nb_var.ABidentification(ident,A,sigma,maxDraws,draws,ask)
```

Description:

Identification of VAR model using combination of zero and sign restrictions. See Binning (2013), "Underidentified SVAR models: A framework for combining short and long-run restrictions with sign-restrictions". Many thanks to him for supplying help!

As a extension to Binning (2013) this code also allow for magnitude restrictions.

Input:

- ident : The identification assumption, as a struct. See set_identification method of the nb_var class for more
- A : Transition matrix
- sigma : Covariance matrix of the VAR residuals.
- maxDraws : The number of maximal rotations when looking for a identification satifying the sign restrictions. Can be set to inf. Default is 10000.
- draws : The number of wanted draws of the matrix of the map from structural shocks to dependent variables (C). Default is one.

Output:

- S : A nb_struct with field W, with the stored map from structural shocks to dependent variables.

Written by Kenneth Sæterhagen Paulsen,
Subfunctions of this code are written by Andrew Binning.

► **appendData** ↑

```
obj = appendData(obj,DB)
```

Description:

Append more data to existing data stored in the nb_model_generic object.

Caution : If append == 1 (true) then the DB input has precedence over the existing dat of the object.

Input:

- obj : An object of class nb_model_generic
- DB : An object of class nb_ts or nb_cs

Optional input:

- interpolateDate : See nb_ts.merge for more help on this input.
- method : See nb_ts.merge for more help on this input.
- rename : See nb_ts.merge for more help on this input.
- append : See nb_ts.merge for more help on this input.
- type : See nb_ts.merge for more help on this input.

Output:

- obj : An object of class nb_model_generic

See also:

[nb_ts](#), [nb_cs](#), [nb_ts.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **applyLongRunPriors** ↑

```
obj = applyLongRunPriors(obj,H,phi)
```

Description:

Apply priors for the long run as in Giannone et. al (2014).

If the prior field of the options property is not yet assign a prior, a jeffrey prior is used as default.

Caution: Please do not call this method before nb_var.setPrior!

Input:

- obj : A N x M matrix of nb_var objects, with nDep dependent variables.

- phi : Either a nDep x 1 double vector with the prior shrinkage parameter for each equation, or a m x 2 cell. m <= nDep. The format of the cell input must be as follows;

```
{'var1',1;'var2',0.5}
```

If some dependent variables are not assigned any parameter the default is 1.

- H : A q x nDep matrix, where q <= nDep. Each row is the cointegration vector to apply on the prior. If q < nDep the null space will be applied to the rest of the rows.

Or it can be a q x 1 cellstr with the cointegration relations. Again q <= nDep, and if q < nDep the null space will be applied to the rest of the rows. Please note that only dependent variables may be applied in the cointegration relations! Example:

```
{'var1 - var2','var3 + var1'}
```

Output:

- obj : A N x M matrix of nb_var objects.

See also:

[nb_var.set](#), [nb_var.setPrior](#)

Written by Kenneth Å!terhagen Paulsen

► assignParameters ↑

```
obj = assignParameters(obj,varargin)
```

Description:

Assign calibrated parameters of underlying model.

Input:

Either:

> One input:

- A struct with the fieldnames as the parameter names and the fields as the parameter values.

> Two input pairs:

```

- 'param' : The names of the assign parameters. As a cellstr vector.

- 'value' : The values of the assign parameters. As a double vector.

> Optional number of input pairs:

- 'beta'   : Assign all the estimated parameters of the main equation.
              Must be of same size as obj.results.beta.

- 'sigma'  : Assign all the estimated parameters of the covariance
              matrix of the main equation. Must be of same size as
              obj.results.sigma.

- 'lambda' : Assign all the estimated parameters of the observation
              equation. Must be of same size as obj.results.lambda. Only
              for factor models.

- 'R'      : Assign all the estimated parameters of the covariance
              matrix of the observation equation. Must be of same size
              as obj.results.R. Only for factor models.

```

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignPosteriorDraws** ↑

obj = assignPosteriorDraws(obj, varargin)

Description:

Assign posterior draws made outside the NB Toolbox.

Input:

Either

> Two input pairs:

- 'param' : The names of the assign parameters. As a cellstr vector.
- 'value' : The values of the assign parameters. As a double nParam x nReg x nDraws vector.

> Optional number of input pairs:

- 'beta' : Assign all the posterior draws of the parameters of the main equation. Must be of same size as obj.results.beta. The draws must come in the third dimension.

- 'sigma' : Assign all the posterior draws of the parameters of the covariance matrix of the main equation. Must be of same size as obj.results.sigma. The draws must come in the third dimension.
- 'lambda' : Assign all the posterior draws of the parameters of the observation equation. Must be of same size as obj.results.lambda. Only for factor models. The draws must come in the third dimension.
- 'R' : Assign all the posterior draws of the parameters of the covariance matrix of the observation equation. Must be of same size as obj.results.R. Only for factor models. The draws must come in the third dimension.
- 'period' : When the model is recursively estimated, you can choose which period your current posterior draws are to be assigned to. Default is the last period.

Output:

- obj : An object of class nb_model_generic, where the parameters of the underlying model has been changed. See solve to get the solution of the model with the updated parameters.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **assignTexNames ↑**

obj = assignTexNames(obj, names, texNames)

Description:

Assign tex names to variables and parameters. Tex names should not include subscripts for any variable, as _{t} is automatically appended to each variable! Use superscripts instead.

Input:

- obj : An object of class nb_model_generic.
- names : A Nx1 cellstr with the names of the variables and/or parameters of the model.
- texNames : A Nx1 cellstr with the corresponding tex names of the variables and/or parameters of the model.

Output:

- obj : A nb_model_generic object where the dependent, endogenous, exogenous, residuals or parameters properties has been set some of its tex_name fields. (Also observables and observablesFast for factor model.)

See also:

[nb_dsge.writeTex](#), [nb_dsge.writePDF](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateMultipliers** ↑

```
mult = calculateMultipliers(obj,varargin)
```

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Caution: This function assumes that the variables given to the variables input is delta_Y and delta_G not Y and G of the formula (3)!

Input:

- obj : An object of class nb_dsge.

Optional input:

- 'variables' : A cellstr with the variables to produce the multipliers of. Must be provided!
- 'instrument' : A one line char with the name of the instrument. Must be provided!
- 'rate' : A one line char with the name of the interest rate to use calculate the net present value. Must be provided!
- 'shocks' : A cellstr with the shocks to produce the multipliers of. Must be provided!
- 'gross' : Give false if the rate input is the net interest rate. Default is true, i.e. that the rate input is the gross interest rate.
- 'perc' : Error band percentiles. As a 1 x nPerc double. E.g. [0.3,0.5,0.7,0.9]. If empty all the simulation will be returned.
- rest : Use the 'replic' option to produce error bands.

Output:

- mult : A nShocks x nVars x nSim (nPerc) nb_cs object. Use the double method on this output to convert it to a double matrix.

See also:

[nb_var.irf](#), [nb_calcMultiplier](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **calculateStandardError** ↑

obj = calculateStandardError(obj,method,draws)

Description:

Calculate standard errors by bootstrap (classical) or posterior draws (bayesian).

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Input:

- obj : A scalar nb_model_generic object
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.

Output:

- obj : A scalar nb_model_generic object, where the results property is updated with the bootstrapped standard errors.
Extra outputs (all based on bootstrapped draws):
 - stdBeta : Standard deviation of coefficient of the main equation.
 - tStatBeta : T-statistic for the coefficient of the main equation.
 - pValBeta : Calculated P-value based on a kernel density estimator of the parameter distribution. Two-sided test against the null hypothesis of the parameters being 0.
 - stdLambda : Standard deviation of coefficient of the observation equation.

```
- tStatLambda : T-statistic for the coefficient of the  
observation equation.  
  
- pValLambda : Calculated P-value based on a kernel  
density estimator of the parameter  
distribution. Two-sided test against the  
null hypothesis of the parameters being 0.  
  
- ci : Confidence interval/probability interval calculated based on  
a kernel density estimation instead of assuming asymptotic  
normal distribution. Only for the parameter in beta! As a  
(nCoeff * nEq) + 1 x 3 cell array.  
  
- dist : Estimated distribution of the coefficients of the main  
equation. As a (nCoeff * nEq) x 1 nb_distribution object.
```

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkModel** ↑

```
obj = checkModel(obj)
```

Description:

Secure that the object is up to date when it comes to the options,
estOptions and results struct properties.

Input:

```
- obj : An object of class nb_model_generic.
```

Output:

```
- obj : An object of class nb_model_generic.
```

Written by Kenneth Återhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **checkPosteriors** ↑

```
[DB,plotter,pAutocorr] = checkPosteriors(obj,varargin)
```

Description:

Plot posteriors draws in the order they were drawn. This to check for
problems with posterior draws that may be autocorrelated.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optional input:

- 'nLags' : Number of lags to include in the autocorrelation plot. Default is 10.
- 'iter' : The recursive iteration date. Either as a string or a nb_date object. If recursive estimation is done, this input must be provided.

Output:

- DB : A nb_data object with size nDraws x numCoeff.
- plotter : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.
- pAutocorr : A nb_graph_data object. Use the graphSubPlots or the nb_graphSubPlotGUI class to plot it on screen.

Caution: Only plots the autocorrelation for the first chain if the sampler has used more than one chain.

See also:

[nb_graph_data](#), [nb_graphSubPlotGUI](#), [nb_model_sampling.checkUpdatedPriors](#)

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► checkReporting ↑

obj = checkReporting(obj)

Description:

Check reporting, and store historical observation of reported variables.

Input:

- obj : A NxM nb_modelData object with the reporting property set.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODELDATA

► conditionalTheoreticalMoments ↑

```
c = conditionalTheoreticalMoments(obj,varargin)
```

Description:

Calculate conditional theoretical moments; I.e.
(auto)covariance/(auto)correlation matrix.

Caution : This method stack all autocorrelations in one matrix.
Equivalent to the output of the theoreticalMoments method
when the 'stacked' input is set to true.

Caution : For recursively estimated model only the full sample estimation
results is used.

Input:

- obj : An object of class nb_model_generic

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return
the moment of the dependent variables of the model without
lag, while full will include all lags as well. 'dependent'
is default.

Can also be a cellstr, with a subset of variables
from 'full'.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'type' : Either 'covariance' or 'correlation'. Default is
'correlation'.

- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the
estimate parameters.

- 'perc' : Error band percentiles. As a 1 x numErrorBand double.
E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
all draws.

Caution: 'draws' must be set to a number > 1.

- 'method' : The selected method to make the parameter draws.
Default is ''. See below for what that means.

> 'bootstrap' : Create artificial data to bootstrap
the estimated parameters. Default
for models estimated with classical
methods.

> 'wildBootstrap' : Create artificial data by wild
bootstrap, and then "draw" parameters
based on estimation on these data.
Only an option for models estimated
with classical methods.

> 'blockBootstrap' : Create artificial data by
non-overlapping block bootstrap,

and then "draw" paramters based on estimation on these data.
 Only an option for models estimated with classical methods.

> 'mBlockBootstrap' : Create artificial data by overlapping block bootstrap, and then "draw" paramters based on estimation on these data.
 Only an option for models estimated with classical methods.

> 'rBlockBootstrap' : Create artificial data by overlapping random block length bootstrap, and then "draw" paramters based on estimation on these data.
 Only an option for models estimated with classical methods.

> 'wildBlockBootstrap' : Create artificial data by wild overlapping random block length bootstrap., and then "draw" paramters based on estimation on these data.
 Only an option for models estimated with classical methods.

> 'posterior' : Posterior draws. Only for models estimated with bayesian methods.
 Default for models estimated with bayesian methods.

Caution : Posterior draws is already made at the estimation stage.

- 'nSteps' : Number of steps ahead. As an integer.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **constructCondDB** ↑

```
condDB          = nb_model_generic.constructCondDB(data,exo)
[condDB,shockProps] = nb_model_generic.constructCondDB(data,exo,endo,...  

                                         horizon,shocks,activeShocks,shockHorizon)
```

Description:

Restrict conditional information.

Static method.

Input:

- data : An nb_ts object.
- exo : The exogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- endo : The endogenous variables to condition on. As a cellstr. Must be included as a variable of the data input.
- horizon : The number of periods to condition on the endo variables. Either as a scalar or a vector of size 1 x nEndo. Default is to use the number of observations of the data input.
- shocks : The shocks to condition on. As a cellstr. Must be included as a variable of the data input.
- activeShocks : A cellstr with the shocks to match your endogenous restrictions. Size 1 x nActiveShock.
- shockHorizon : The number of periods to activate the given shock. Either as a scalar or a vector of size 1 x nActiveShock. Be aware that you must at least have as many periods of active shocks as you have endogenous restrictions. (It may also be important which shock(s) to meet your restrictions!).

Caution: This option will overrun the restrictions you make with the shocks input when you call the forecast method!

Output:

- condDB : The restricted conditional database, which can be given as input to the forecast method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► constructScore ↑

```
score = nb_model_generic.constructScore(forecastOutput,type)
score = nb_model_generic.constructScore(forecastOutput,type, ...
                                         allPeriods,startDate,endDate,nSteps,rollingWindow,lambda)
```

Description:

Construct forecast evaluation score given forecast output.

Input:

- forecastOutput : See the forecastOutput property of the nb_model_forecast class
- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error.
 - 'MSE' : One over mean squared error.
 - 'MAE' : One over mean absolute error.
 - 'ME' : Mean error.
 - 'STD' : One over Standard error of the forecast error.
 - 'ESLS' : Exponential of the sum of the log scores.
 - 'EELS' : Exponential of the mean of the log scores.
 - 'MLS' : Mean log score.
- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. False is default.
- startDate : The date to begin constructing the score. Can be empty.
- endDate : The date to end constructing the score. Can be empty.
- nSteps : Select the number of forecasting steps. Can be empty.
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- score : As a nHor x nVar x nPeriods

► **convert ↑**

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convert.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convert.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

► **convertEach** ↑

obj = convert(obj,freq,methods,varargin)

Description:

Convert the frequency of the data of the nb_modelData object. Both the data property will be transformed to the wanted frequency.

Caution: The shift property is not handle correctly, so de-trending cannot be used in this case!

Input:

- See the documentation of nb_ts.convertEach.
- 'options' : Provide this as one of the optional inputs, and the conversion of the frequency will be applied to options.data and not the dataOrig property.

Output:

- See the documentation of nb_ts.convertEach.

► **createVariables** ↑

```
obj = createVariables(obj,expressions,fcstHorizon)
[obj,plotter] = createVariables(obj,expressions,fcstHorizon)
```

Description:

Create model variables given input data.

Caution : Only for time-series models!

Input:

- obj : A NxM nb_modelData object
- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While the fourth column is for comments.

More on:

- > second column : Any expression that can be interpreted by the nb_ts.createVariable method.
 - > third column : Any expression that can be interpreted by the nb_ts.createShift method.
 - > fourth column : Comments
- fcstHorizon : The forecast horizon. As an integer. Default is 8. It is important that this option is higher than the number of forecasting/irf steps, or else the output will be nan!

Output:

- obj : The NxM object itself added the model variables. The expressions input is stored in the property transformations.
- plotter : A NxM nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```

expressions = {%
  Name, input, shift, description
  'VAR1_G', 'pcn(VAR1)', 'avg', 'VAR1 growth'
  'VAR2_G', 'pcn(VAR2)', 'avg', 'VAR2 growth'
  'VAR3_G', 'pcn(VAR3)', 'avg', 'VAR3 growth'};

model = model.createVariables(expressions)

```

► **dieboldMarianoTest** ↑

```
[test,pval,res] = dieboldMarianoTest(obj1,obj2,varargin)
```

Description:

Diebold-Mariano test. The null is that the models produce equally good forecast.

Only the forecast variables from both models are tested! I.e. the intersect.

Caution : The actual data is taken from obj1.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj1 : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- obj2 : An object of class nb_model_generic. You need to call one of the forecasting functions first!

Optional inputs:

- 'startDate' : The start date of the test, as a string or a nb_date object. If it is not provided the default is to use the first date which there exist forecast from the two models.
- 'endDate' : The end date of the test, as a string or a nb_date object. If it is not provided the default is to use the last date which there exist forecast from the two models.
- 'precision' : The precision of the printed result. As a string. Default is '%8.6f'.

- 'bandWidth' : The selected band width of the frequency zero spectrum estimation. Default is to use a automatic selection criterion. See the 'bandWithCrit' input. Must be set to an integer greater then 0.
- 'bandWithCrit' : Band width selection criterion. Either:
 - > 'nw' : Newey-West selection method. Default.
 - > 'a' : Andrews selection method. AR(1) specification.
- 'multivariate' : Set to true to do the multivariate test, i.e. test for equal panel forecast. Default is to test each variable separately.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

► **doForecastPerc2ParamDist ↑**

`[obj,dist] = doForecastPerc2ParamDist(obj,distribution,draws,varargin)`

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the `nb_distribution.perc2ParamDist` function.

Input:

- `obj` : A `nb_model_forecast` object.
- `distribution` : The distribution you want to estimate based on the percentiles. You must have at least as many percentiles as there are parameters!
- `draws` : Number of draws to make from the estimated distributions.

Optional input:

- `'optimizer'` : See doc of the optimizer input to the `nb_callOptimizer` function. Default is `'fmincon'`.
- `'optimset'` : See doc of the `opt` input to the `nb_callOptimizer` function.

Output:

- `obj` : A `nb_model_forecast` object. See the property `forecastOutput`.

See also:

`nb_var.forecast, nb_distribution.perc2ParamDist`

Inherited from superclass `NB_MODEL_FORECAST`

► **doSimulateFromDensity ↑**

`obj = doSimulateFromDensity(obj,draws)`

Description:

Simulates from the estimated kernel density.

Input:

- obj : A nb_model_forecast object.
- draws : Number of draws to use for simulation.

Output:

- obj : A nb_model_forecast object. See the property forecastOutput.

See also:

[nb_model_generic.forecast](#), [nb_var.simulateFromDensity](#)

Written by Per Bjarne Bye and Atle Loneland

► **empiricalMoments** ↑

```
[m,c] = empiricalMoments(obj,varargin)
[m,c,ac1] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2] = empiricalMoments(obj,varargin)
[m,c,ac1,ac2,...] = empiricalMoments(obj,varargin)
```

Description:

Calculate empirical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation of the data of the nb_model_generic object. The options.data property must contain the selected variables!

Caution: This method only works on time-series models

Input:

- obj : An object of class nb_model_generic
- Optional inputs;
- 'vars' : Either 'dependent' or a cellstr with the wanted variables. 'dependent' will return the moment of the dependent variables. 'dependent' is default.
 - 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
 - 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
 - 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'startDate' : The start date of the calculations. Default is the start date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'endDate' : The end date of the calculations. Default is the end date of the options.data property. Only for time-series! Must be a string or a nb_date object.
- 'demean' : true (demean data during estimation of the autocovariance matrix), false (do not). Default is true.

Output:

- varargout{1} : The mean, as a 1 x nVar nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : X > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use
getVariable(varargin{i}, 'y', 'x'),
while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

See also:

[nb_var.graphCorrelation](#)

Inherited from superclass NB_MODEL_GENERIC

► [eq](#) ↑

ret = eq(obj,other)

Description:

Test if nb_model_generic objects are equal. In the sens they have the same properties.

Input:

- obj : A nb_model_generic object either with same size as others, or equal to 1.
- others : A nb_model_generic model with dim == 3 or less

Output:

- ret : A logical matching the others input

Examples:

```
v(1,5) = nb_var;  
ind     = v(1) == v
```

See also:

[isequal](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► estimate ↑

```
obj      = estimate(obj,varargin)  
[obj,valid] = estimate(obj,varargin)
```

Description:

Estimate the model(s) represented by nb_model_estimate object(s).

Input:

- obj : A vector of nb_model_generic objects.
- 'parallel' : Use this string as one of the optional inputs to run the estimation in parallel.
- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is given.
- 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
- 'waitbar' : Use this string to give a waitbar during estimation. I.e. when looping over models. If 'parallel' is used this option is not supported!
- 'write' : Use this option to write errors to a file instead of throwing the error.

Optional input:

- varargin : See the the set method.

Output:

- obj : A vector of nb_model_generic objects, where the estimation results are stored in the property results.
- valid : A logical with size nObj x 1. true at location ii if estimation of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Inherited from superclass NB_MODEL_ESTIMATE

► **evalFcstAtDates ↑**

```
[evaluation,errorDates] = evalFcstAtDates(obj, dates, type, density,...  
quart)
```

Description:

Evaluates a models forecasting capabilities compared to actual data. If a date is given before day number 15 it uses data from up until two months before. If a date is given on day number 15 or later, it uses data from up until one month before the date. For quarterly data it uses the same, but restricted to also beeing in the first month in the quarter, i.e. if it is the second or third month it will always use data up until one quarter before the released.

Input:

- obj : A nb_model_generic or nb_model_group object containing forecasts.
- dates : A cellstring containing the dates that the forecast should be evaluated at. Can also be a nb_date object.
- type : The evaluation criteria. A cellstr with one or more of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores

```
- 'EELS'   : Exponential of the mean of the log scores
- 'MLS'    : Mean log score

- density : Set true if you have a density forecast.

- quart   : Set true if you want to compare the quarterly forecasts. This
option automatically detects and uses the quarterly estimates
when evaluating.
```

Output:

- evaluation : A nb_data object with the evaluation scores for each observation and variable.
- errorDates : Since it is not always the case that all of the dates are being used, errorDates returns those dates as a cellstr.

Examples:

```
m = evalFcstAtDates(b,d',{'MSE'},0,1)
m = evalFcstAtDates(b,d',{'MSE','RMSE'},0,1)
```

► **evaluateForecast** ↑

```
obj = evaluateForecast(obj,varargin)
```

Description:

Evaluate forecast using (a) selected loss function(s)

Input:

- obj : An object of class nb_model_generic.

Optional Input:

- 'draws' : Number of draws used when simulating from the distribution. Default is 1000.
- 'fcstEval' : See the documentation of the same input in the forecast method.
- 'compareToRev' : See the documentation of the same input in the forecast method.
- 'compareTo' : See the documentation of the same input in the forecast method.

Output:

- obj : An object of class nb_model_generic.

Inherited from superclass NB_MODEL_FORECAST

► evaluatePrior ↑

```
logPriorD = nb_model_generic.evaluatePrior(prior,par)
```

Description:

Evaluate the prior at a point in the parameter space.

Input:

- prior : See options.prior.
- par : A nEst x 1 double with the value of the point of evaluation.

Output:

- logPriorD: The log prior density at the evaluated point.

See also:

[nb_dsge.objective](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► forecast ↑

```
obj      = forecast(obj,nSteps,varargin)
[obj,valid] = forecast(obj,nSteps,varargin)
```

Description:

Produced conditional point and density forecast of nb_model_generic objects.

The conditional forecasting routines in this code is based on work by Junior Maih. As in his code it also handle anticipated shocks (only

for foward looking models!). See Junior Maih (2010), Conditional forecast in DSGE models.

If the 'condDB' input is set to a nb_distribution object the code uses the algorithm given in the paper Kenneth S. Paulsen (2010), Conditional forecasting with DSGE models - A conditional copula approach.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional input:

- 'waitbar' : Give 'waitbar' anywhere as an optional input to create a waitbar that iterates the models being forecasted.
 - 'write' : Give 'write' anywhere as an optional input to write errors to a file instead of throwing them. This input is not stored to the forecastOutput property of the objects.
 - 'remove' : Give 'remove' to remove the models that return errors from the obj output. This input is not stored to the forecastOutput property of the objects.
 - 'fcstEval' :
 - '' : No forecast evaluation. Default
 - 'se' : Square error forecast evaluations.
 - 'abs' : Absolute forecast error
 - 'diff' : Forecast error
- Only for density forecast:
- 'logScore' : Log score
- Can also be a cellstr with the above listed evaluation types.
- Caution: If you have done recursive estimation, this option, if not empty, will do out of sample forecasting. Else it will do in sample forecasting, i.e. use the estimated parameters for the whole sample.
- 'estDensity' : The method to estimate the density. As a string. Either:
 - 'normal' : Normal density approximation.
 - 'kernel' : Kernel density estimation. Default.
 - 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!

```

- 'parallel'      : Give true if you want to do the forecast in
                    parallel. I.e. spread models to different threads.
                    Default is false.

- 'cores'         : The number of cores to open, as an integer. Default
                    is to open max number of cores available. Only an
                    option if 'parallel' is set to true.

- 'parameterDraws' : Number of draws of the parameters. When set to 1
                     it will discard parameter uncertainty. Default is 1.

- 'draws'          : Number of residual/innovation draws per parameter
                     draw. Default is 1, i.e. only produce point
                     forecast.

- 'regimeDraws'   : Number of drawn regime paths when doing density
                     forecast. This will have no effect if the states
                     input is providing the full path of regimes. Default
                     is 1.

- 'newDraws'       : When out of parameter draws, this factor decides how
                     many new draws are going to be made. Default is 0.1.
                     I.e. 1/10 of the parameterDraws input.

- 'perc'           : Error band percentiles. As a 1 x numErrorBand
                     double. The input must be given as the coverage, and
                     not the percentiles itself. E.g. [0.3,0.5,0.7,0.9].
                     0.3 means to return the two percentiles 35 and 65,
                     which will cover 30% of the distribution around the
                     median. So [0.3,0.5,0.7,0.9] will get the
                     percentiles [5,15,25,35,65,75,85,95], i.e. this
                     will restrict the percentiles to be symmetric.
                     Default is 0.9.

If set to empty, all simulations will be returned.

Caution: 'draws' must be set to produce density
forecast.

- 'method'         : The selected method to create density forecast.
                     Default is ''. See help on the method input of the
                     nb_model_generic.parameterDraws method for more
                     this input.

- 'bins'            : The length of the bins og the domain of the density.
                     Either;

                     > []      : The domain will be found. See
                     nb_getDensityPoints (default is that 1000
                     observations of the density is stored).

                     > integer : The min and max is found but the length
                     of the bins is given by the provided
                     integer.

                     > cell     : Must be on the format:

                     {'Var1',lowerLimit1,upperLimit1,binsL1;
                      'Var2',lowerLimit2,upperLimit2,binsL2;

```

```

    ...
}

- lowerLimit1 : An integer, can be nan,
  i.e. will be found.

- upperLimit1 : An integer, can be nan,
  i.e. will be found.

- binsL1      : An integer with the
  length of the bins. Can
  be nan. I.e. bins length
  will be adjusted to
  create a domain of 1000
  elements.

Caution : The variables not included will be given
the default domain. No warning will be
given if a variable is provided in the
cell but not forecast by the model. (This
because different models can forecast
different variables)

Caution : The combineForecast method of the
nb_model_group class is much faster if the
lower limit, upper limit! Or else
it must simulate new draws and do kernel
density estimation for each model again
with the shared domain of all models
densities.

- 'startDate'   :
  : The start date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

Caution: If 'fcstEval' is not empty this will set
the start date of the recursive forecast.
Default is to start from the first possible
date.

- 'endDate'    :
  : The end date of forecast. Must be a string or an
  object of class nb_date. If empty the estim_end_date
  + 1 will be used.

Caution: If 'fcstEval' is empty this input will
have nothing to say.

- 'saveToFile'  :
  : Logical. Save densities and domains to files. One
  file for each model. Default is false (do not).

- 'observables' :
  : A cellstr with the observables you want the
  forecast of. Only for factor models. Will be
  discarded for all other types of models.

- 'condDB'       :
  : One of the following:

    > A nb_ts object with size nSteps x nCondVar
    with the information to condition on.

  If you condition on endogenous variables (possibly

```

residuals/shocks also) this function will find the linear combination of the shock that minimize its variance.

- > A nb_data object with size nSteps x nCondVar x nPeriods with the information to condition on. The dataNames property must be set to the start dates of the recursive conditional information. nPeriods will be the number of recursive periods.
- > A nb_ts object with size nSteps x nCondVar x 3 with the information to condition on. Page 2 must include the upper bound and page 3 the lower bound of the truncated normal distribution for the given conditional information. Both bound can be given as nan (-inf or inf). Be aware that it is also possible to use truncated distribution with the next input type, but that the algorithm used by this options is much faster. (Of course here all conditional information must be either normal or truncated normal.)
- > A nb_distribution object with size nSteps x nCondVar x 1 with the distributions to condition on. The defualt is to assume that the shock are iid with mean = 0 and std = sqrt(diag(model.vcv))

If you condition on endogenous variables (possibly residuals/shocks also) this function will find the linear combination of the shock that minimize its variance for each draw from the multivariate distribution created by using a copula with the provided marginals and the correlation matrix (See inputs.sigma).

All the variables in the x_t matrix must be provided. I.e. model.exo variables. (Except seasonals, constant and time-trend). The data must be ordered accordingly to condDBVars (second dimension), and the first observation is taken to be startInd, as long as the input is not nb_ts or nb_data.

To be able to match your restrictions on endogenous variables to a specified group of shock use the shockProps input.

Caution : If empty unconditional forecast will be produced.

- 'condDBType' : 'hard' or 'soft'. When 'hard' is choosen it is assumed that all conditional information should be interpreted with no uncertainty, i.e. actual data. When 'soft' the conditional data is interpret with uncertainty and the distribution is either taken from the 'condDB' input or simulated from the model. Default is 'soft'.
- 'condDBVars' : A cellstr with the variables to condition on. Can

include both endogenous, exogenous and shock variables. Only needed when condition on a nb_distribution object.

- 'condDBStart' : Do the conditional information contain intial values or not. Set to 0 to indicate that the conditional information also contain intial values. In this case all variables that have missing observation for the initial values are replaced with the data supplied by the condDB input. Otherwise the estimated initial observations for missing data is used (default).
- 'shockProps' : A 1 x nRes struct with fields:
 - > Name : The name of the shock/residual to use to match the conditional information. If an shock/residual is not included here, it means that it is not activated.
 - > StandardDeviation : Standard deviation of the shock. This option can be used to adjust the standard deviation away from the estimated one. If given as nan the estimated one is used.
 - Caution: If a shock is included in the condDB input, and it is a nb_distribution object. The std is taken from that distribution instead.
 - If not provided. Model stds are used.
- > Horizon : Anticipated horizon of the shocks/residual. 1 is default.
- > Periods : The active periods of the shocks/residual. If nan, the shocks/residual is active for all periods. Must be given!
- 'kalmanFilter' : Set to true to use a Kalman filter to do conditional forecasting (on endogenous variables). Only supported for the nb_var and nb_pitvar classes.
- 'sigma' : A nCondVar*nSteps x nCondVar*nSteps double with the correlation matrix of the endogneous variables to condition on. Used when drawing from the copula.

This must be the stacked autocorrelation matrix of the multivariate distribution to draw the endogenous variables from. As the endogneous variables are autocorrelated all variables for all periods must be draw at the same time, using this

autocorrelation matrix.

- 'sigmaType' : Type of correlation calculated. For more on this input see nb_copula.type.
- 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.
 - > 'fullendo' : All the endogenous variables are returned included the lag variables.
 - > 'full' : All the variables are returned included the lag variables. Also including exogenous and shocks.
 - > 'all' : All variables are returned (but not the lags). Including exogenous and shocks.
- 'startingValues' : Either a double or a char:
 This option is mainly used for making simulations from a model.
 - > double : A nPeriods x nVar or a 1 x nVar double. nPeriods refer to the number of recursive periods to forecast.
 - > 'mean' : Start from the mean of the data observations. Default.
 - > 'steadystate' : Start from the steady state. For now only an option for nb_dsgc models. If you are dealing with a MS-model or break-point model you can indicate the regime by 'steadystate(regime)'. E.g. to start in regime 1 give; 'steadystate(1)'. If the regime is not given, you will start in the ergodic steady-state for MS-model, and in the last regime for break-point models.
 - > 'zero' : Start from zero on all variables (Except for the deterministic exogenous variables)
- 'startingProb' : Either a double or a char:
 > [] : If the model is filtered the starting value is calculated on filtered transition probabilities. Otherwise the

ergodic mean is used.

> double	: A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
> 'ergodic'	: Start from the ergodic transition probabilities.
- 'stabilityTest'	: Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'states'	: Either an integer with the regime to forecast/simulate in, or an object of class nb_ts with the regimes to condition on. The name of the variable must be 'states'.
Caution: For break-point models this is decided by the dates of the breaks, and cannot be set by this option!	
- 'compareToRev'	: Which revision to compare to. Default is final revision, i.e. []. Give 5 to get fifth revision. must be an integer. Keep in mind that this number should be larger than the nSteps input.
- 'compareTo'	: Sometime you want to evaluate the forecast of one variable against another variable which is not part of the model. E.g. if you use the first release of a variable and want to compare it against the final release. To do this you can give a cellstr with size n x 2, where n is the number of variables to change the the actual observations to test against. {'VAR_1','VAR_FINAL',...}.
- 'estimateDensities'	: true or false. true if you want to do a kernel density estimation of the density forecast.
- 'exoProj'	: Tolerate missing exogenous variables by projecting them by a fitted model. Only when the 'condDB' input is empty!
Options are:	
- ''	: No projection are done. Error will be given if some exogenous variables are not given any conditional information. Default.
- 'ar'	: The exogenous variables will be fitted by a univaiate AR model with the lag length chosen with a 'aicc' criterion.
Caution : If density forecast are produced the AR estimates will be bootstrapped, and the exogenous	

variables will be re-sampled based on the bootstrapped values.

Caution : If forecast are being produced recursively with recursively estimated parameters, the forecast/bootstrapping of the exogenous variables will be done based on recursively estimated AR coefficients as well.

- 'exoProjHist' : If this option is set to true, it will first try to get the data on the exogenous variables for the full forecast horizon from the data assigned to the model object. If the data is not found it will extrapolate the exogenous variables by the method given to the 'exoProj' option.

- 'exoProjDiff' : Set to a cell array on the format {'Var1',1, 'Var2',1} to apply 1st difference to the series 'Var1' and 'Var2'. If a variable is not given a value it is not 1st differences (or the value is set to 0).

Caution: Only applies to the nb_exprModel class.

- 'exoProjAR' : Set the number of lags of the AR(X) models when exogenous variables are projected, i.e. set X. Default is nan, i.e. a information criterion is used to select the number of lags (Set this option to nan).

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjDummies' : A cellstr with the dummy variables to include in the AR model when projecting exogenous variables. These dummies are assumed to be predicted by 0.

Caution: Only applies when exoProj is set to 'AR'.

- 'exoProjCalib' : Calibrate the AR process to extrapolate the exogenous variables with. As a 1 x 2*N cell array. N is equal to the number of exogenous variables you extrapolate. An example {'exoVar1',[0,0.8],'exoVar2',[0.2,0.7]}. Here the 'exoVar1' variable is extrapolated with an AR model with a constant term equal to 0 and AR coefficient 0.8, while 'exoVar2' with a constant term equal to 0.2 and AR coefficient 0.8. The exogenous variables not listed will be estimated.

Caution: Only applies when exoProj is set to 'AR'.

- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:

- 'shock' : Name of the shock to match the restriction on the bounds of the given

variable.

- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'inputs' : This is a special input the overwrites all other inputs. This must be given by a struct with fields that include all the other optional options.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution:** You still need to set 'parameterDraws' to the number of draws you want to do.
- 'condAssumption' : Set to 'after' to make the conditional information be interpreted in the states simulated or conditioned on. Otherwise the conditional information is interpreted in the state of end of history.
 - 'seed' : Set simulation seed. Default is 2.0719e+05.

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.
- valid : A logical with size nObj x 1. true at location ii if forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **forecastPerc2Dist** ↑

```
forecastOutput = nb_model_forecast.forecastPerc2Dist(forecastOutput)
```

Description:

Calculates a density from percentiles using kernel estimation.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_var.forecast](#)

Written by Per Bjarne Bye, Kenneth Sæterhagen Paulsen and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► **forecastPerc2ParamDist** ↑

```
[forecastOutput,dist] = nb_model_forecast.forecastPerc2ParamDist(...  
    forecastOutput,distribution,draws,varargin)
```

Description:

Calculates a parameterized density from percentiles using a matching percentiles estimator, and then simulate draws from this distribution. See the nb_distribution.perc2ParamDist function.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.data stores the forecast of the percentiles.
- distribution : The distribution you want to estimate based on the

percentiles. You must have at least as many percentiles as there are parameters!

- draws : Number of draws to make from the estimated distributions.

Optional input:

- 'optimizer' : See doc of the optimizer input to the nb_callOptimizer function. Default is 'fmincon'.
- 'optimset' : See doc of the opt input to the nb_callOptimizer function.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_var.forecast](#), [nb_distribution.perc2ParamDist](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getActual** ↑

```
actual = nb_model_generic.getActual(options,solution,vars,startFcst,...  
nSteps,inputs,nowcast)
```

Description:

Get actual data to compare against the forecast.

Input:

- options : See the (hidden) property estOptions of the nb_model_generic. For real-time models, the last element of this struct array should be used.
- solution : See the property solution of the nb_model_generic object.
- vars : A cellstr with the names of the variables to get the actual data of.
- startFcst : The recursive forecasting periods. Either as a double with the indecies or a cellstr with the dates.
- nSteps : Number of forecasting steps. If empty the sample will not be split.

- inputs : A struct with some options passed to the nb_forecast.getActual function. Optional.
- nowcast : Indicate how many periods there has been produced nowcast of.

Output:

- actual : A nSteps x nVars x nPeriods double with the actual data for each recursive forecast if nSteps is given, otherwise a nobs x nVars double.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getCondDB** ↑

```
[condDB,obj] = getCondDB(obj,endDate,nSteps,exoOnly,recursive,recStart)
```

Description:

Get conditional information on the variables of the model given a end date of estimation. May also provide recursive conditional information.

Caution : If the dataset is of type real-time, this function interprets the endDate input as the estimation end date for the last recursion. It also assumes that each vintage gives rise to one new historical observation on each series of the model! It will also remove the conditional information from the obj.options.data option to make the estimation with real-time data work as supposed to.

Caution : If you do some transformation of your data using the nb_modelData.createVariables you should run this before calling this method!

Input:

- obj : An object of class nb_model_generic.
- endDate : An object of class nb_date or a string representing a date. This option will be interpreted as the end date of estimation or as the end date of the last recursion if recursive estimation is done. See description for a note on real-time estimation.
- nSteps : Number of forecasting steps. As a scalar integer.
- exoOnly : Set to true if you only want the conditional information on the exogenous variables of the model. Default is false.
- recursive : Indicate if you want recursive conditional information or not. If you want to do recursive conditional forecast you should set this input to true, otherwise false. Default

is false.

- `recStart` : An object of class `nb_date` or a string representing a date. This option will be interpreted as the start date of recursive forecast, i.e. the first forecast period of the recursive forecast. Only needed if `recursive` is set to true.

Output:

- `condDB` : As a `nb_ts` or `nb_data` object. Can be given as input to the `condDB` option of the `nb_model_generic.forecast` method.
- `obj` : An object of class `nb_model_generic`. When dealing with real-time data we want to strip the data of forecast before going to estimation, so the `options.data` option may change.

► **getDSGEVARPriorMoments** ↑

```
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR)
[GammaYY, GammaXX, GammaXY] = getDSGEVARPriorMoments(obj, dsgeVAR, varargin)
```

Description:

Get DSGE-VAR prior matrices. See the prior struct returned by `nb_var.priorTemplate('dsge')`.

Input:

- `obj` : An object of class `nb_model_generic`.
- `dsgeVar` : A `nb_var` object set up with options for estimation of a DSGE-VAR.

Optional input:

- `'maxIter'` : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.
- `'tol'` : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

Output:

Let N be number of dependent variables, L the number of lags of the VAR, and C is equal to 1 if a constant is included. otherwise 0.

- GammaYY : A N x N double with the nonstandardized sample moments of the left-hand variables of the VAR.
- GammaXX : A (C + N*L) x (C + N*L) double with the nonstandardized sample moments of the right-hand variables of the VAR.
- GammaXY : A (C + N*L) x N double with the nonstandardized sample moments between the right-hand variables and the left-hand variables of the VAR.

Inherited from superclass NB_MODEL_GENERIC

► **getDependent** ↑

```
dependent = getDependent(obj)
```

Description:

Get dependent variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- dependent : Either a nb_ts or a nb_cs object with dependent variable(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getDependentNames** ↑

```
dependentNames = getDependentNames(obj)
```

Description:

Get all the unique dependent variables names of a vector of nb_model_generic objects

Input:

- obj : A vector of nb_model_generic objects

Output:

- dependentNames : A cellstr with the unique dependent variables names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getEstimationOptions ↑

```
outOpt = getEstimationOptions(obj)
```

Written by Kenneth Sæterhagen Paulsen

► getEstimationStartDate ↑

```
start = getEstimationStartDate(obj)
```

Description:

Get the start date of the estimation of the model.

Input:

- obj : An object of class nb_model_generic

Output:

- start : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► getFiltered ↑

```
data = getFiltered(obj,type)
data = getFiltered(obj,type,normalize)
data = getFiltered(obj,type,normalize,econometricians,varargin)
```

Description:

Get filtered variables as a nb_ts object. This will include endogenous, exogenous, shocks, states and regime probabilities, if any.

Caution: Model must already be filtered!

Input:

- obj : An object of class nb_model_generic
- type : Either 'filtered', 'smoothed' or 'updated'. Default is 'smoothed'.
- normalize : Normalize the shock to be N(0,1). Default is false.
- econometricians : Get econometricians view of the filtered variables. I.e. the filtered variables of each regime multiplied by the regime probabilities.

Optional input:

- 'reporting' : Either 'stored' or a N x 3 cell array on the format of the reporting property. If 'stored' it will use the reporting property stored in the object. If that is empty, no reporting is done. Default is not to do any reporting.

Output:

- data : A nb_ts object with size nobs x nvars included the filtered variables.

See also:

[nb_dsgen.filter](#), [nb_var.estimate](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getForecast ↑**

```
fcstData = getForecast(obj)
[fcstData,fcstPercData] = getForecast(obj,outputType)
[fcstData,fcstPercData] = getForecast(obj,outputType,includeHist,varargin)
```

Description:

Get the forecast as a nb_ts object.

Caution: Nowcast will be added to the output. Even for those variables with known observations will be returned. For the 'default' and 'graph' output types the nowcast will be abbreviated with period 0,-1 etc. If outputType is set to a date the nowcast will be added as observation date - 1, date - 2, etc.

Input:

- obj : An object of class nb_model_forecast. Must have produced forecast.

- outputType :

> 'default' : The fcstData output is a nb_ts with size nHor x nVars x nPeriods. nPeriods is the number of iterative forecast. The start date of each forecast will be saved in the dataNames property of the nb_ts object.

The fcstPercData output is a struct where the fields are the percentiles/simulations of the density forecast if produced. (Else it is an empty struct). Each field has the same sizes as the fcstData output.

> 'graph' : This option can be used to make it easier to plot the recursive densities.

The fcstData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x 1. Only storing the mean forecast.

The fcstPercData output is a struct where the fields are the recursive forecast periods. Each field has size nHor x nVars x nPerc. Storing the percentiles/simulations of the forecast if they are calculated, or else it is an empty struct.

To graph the recursive forecast use this example:

```
fields = fieldnames(fcstData);
for ii = 1:length(fields)

    fcstMean = fcstData.(fields{ii});
    fcstPerc = fcstPercData.(fields{ii});
    plotter = nb_graph_ts(fcstMean);
    plotter.set('fanDatasets',fcstPerc);
    plotter.graph();

end

> 'date' : A string or a nb_date object with the date of the wanted forecast. E.g. '2012Q1'. The fcstData will be a nb_ts object with size nHor x nVar x nPerc + 1, while fcstPercData will be empty. nPerc will then be the number of percentiles/simulations. Mean will be at last page.
```

For real-time forecast the vintage at the time is returned as the historical data, when includeHist is true.

> 'horizon' : This option will return the forecast as a nPeriods + nHor x nVar x nHor nb_ts object. This option will only return the mean forecast.

If includeHist is true the actual data is added as an additional page of the nb_ts object.

```
Caution : Nowcast will be skipped!
Caution : If the horizon input is set you will set nHor
          to one, and the fcstPercData will be
          non-empty, if density forecast has been
          produced.

- includeHist : Give true (1) to include history in the output. Only an
               options for the 'date' and 'horizon' outputType.
               Default is false (0).
```

Optional inputs:

```
> 'horizon' : The fcstData output will be a nb_ts object with
               size nRec x nVars. While the fcstPercData output
               will be a nb_ts object with size nRec x nVars x nSim.
               You can set the horizon to return by the optional
               input 'horizon'. See the 'timing' option also.
```

Output:

- fcstData : See the input outputType
- fcstPercData : See the input outputType

See also:

[nb_var.plotForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getForecastVariables ↑**

```
vars = getForecastVariables(obj)
```

Description:

Get the variables that the model forecast.

Input:

- obj : An object of class nb_model_forecast.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getHistory** ↑

```
histData = getHistory(obj,vars,date,notSmoothed,type)
```

Description:

Get historical data

Input:

- obj : A scalar nb_model_generic object
- vars : A cellstr with the variables to get. May include shocks/residuals. Only the variables found is returned, i.e. no error is provided if not all variables are found.
- date : For recursively estimated models, the residual and smoothed estimates vary with the date of recursion, so by this option you can get the residual and smoothed estimates of a given recursion.
The same apply for real-time data.
- notSmoothed : Prevent getting history from smoothed estimates.
- type : Either 'smoothed' or 'updated'. Default is 'smoothed'.

Output:

- histData : A nb_ts object with the historical data.

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getIdentification** ↑

```
matrix = getIdentification(obj)
```

Description:

Get restrictions on the structural shock matrix, i.e C in the equation below:

$$y(t) = A*y(t-1) + B*x(t) + C*e(t), \text{ where } e(t) \sim N(0, I).$$

Input:

- obj : A identified scalar nb_var object.

Output:

- matrix : nEndo x nEndo cell array.

See also:

[nb_var.set_identification](#)

Written by Kenneth Sæterhagen Paulsen

► **getIdentifiedResidual** ↑

```
residual = getIdentifiedResidual(obj)
```

Description:

Get identified residual from a estimated nb_var object

If we have a VAR it can be written as (dropping exogenous variables):

$y_t = A*y_{t-1} + e_t$

A identified VAR can be written as:

$y_t = A*y_{t-1} + C*d_t$

Therefore the identified residuals/shocks can be found as:

$d_t = \text{inv}(C)*e_t$

Caution: Will only return the residual that uses the full sample. I.e. when recursive estimation is done, only the residuals from the last estimation will be returned.

Input:

- obj : An object of class nb_var

Output:

- residual : A nb_ts object with the identified residual(s) stored.
As a nobs x nEq x nIdent. Where nIdent is the number of identified C matrices, i.e. when the user have asked to identify more than one matrix (underidentification).

Written by Kenneth Sæterhagen Paulsen

► **getLHSVars** ↑

```
vars = getLHSVars(obj)
vars = getLHSVars(obj, varsIn)
```

Description:

Get all left hand side variables of the model.

For factor models the observable (+ observableFast) are added as well.

The list will be sorted.

Caution : For nb_dsgc object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getModelNames** ↑

names = getModelNames(obj)

Description:

Get model names, if some model names are empty, they will be given the default name 'Model<ii>'.

Input:

- obj : A N x M nb_model_forecast object.

Output:

- names : A N x M cellstr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_NAME

► **getModelVars** ↑

```
vars = getModelVars(obj)
vars = getModelVars(obj, varsIn)
```

Description:

Get all variables to the model. That include dependent, endogenous and exogenous variables.

For factor models the observable (+ observableFast) are added as well.

Caution : For nb_dsg object only the observables are returned!

Input:

- obj : A scalar nb_model_generic object.
- varsIn : The variables that can be found in the data of the model.
If empty, they are found at obj.options.data.variables.

Caution: Only used in special cases.

Output:

- vars : A cellstr array with the variables of the model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getOriginalVariables** ↑

```
vars = getOriginalVariables(obj)
```

Description:

Get the variables of the original data source assign to the model.

Input:

- obj : An object of class nb_model_generic.

Output:

- vars : A cellstr with the variables of the original data source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **getPIT** ↑

```

pit                  = getPIT(obj)
[pit,plotter]        = getPIT(obj)
[pit,plotter,pitTest] = getPIT(obj,startDate,endDate,onlyFinal)

```

Description:

Calculate PIT of a density forecast given actual data.

Caution : If recursive density forecast has been produced it will get the PIT from the start date of the recursive forecast and use the density forecast at each periods to produce the pits.

If only one density forecast has been produce it will construct the PITs based on the period from the estimation start date until the end date of forecast horizon.

Caution : Nowcasts will be skipped!

Input:

- obj : A nb_model_forecast object.
- startDate : The start date of the PIT calculations, as a string or a nb_date object. Default is as written above.

Caution : If you do recursive density forecast, this date cannot be before the start date of the recursive forecast (if not onlyFinal is set to true). Otherwise the start date cannot be before the start date of the data stored in the model object.
- endDate : The start date of the PIT calculations, as a string or a nb_date object. Default is to use the last forecast recursion or the date the density is constructed. This input cannot be after that, except when onlyFinal option is set to 1 or only one density is estimated. The end date can then be set to a date as long you have observations on the actual data. (Stored in options.data)
- onlyFinal : Logical. If true the final density forecast is used to calculate the PITs even if recursive density forecast exists. Default is false. If startDate is empty the start date of estimation will be used as default.

Output:

- pit : A nb_data object with size nPeriods x nHor x nVars
- plotter : A nb_graph_data object. please use the graph method, if you want to plot it.
- pitTest : Test for a uniformly distributed PITs using a Pearson chi-squared test. As a 2 x nHor x nVar nb_cs object.

See also:

nb_calculatePIT

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getParameterDrawsMethods** ↑

```
methods = parameterDraws(obj)
```

Description:

Get supported methods for drawing parameters for the given model.

Input:

- obj : A scalar object of a subclass of the nb_model_generic class.
- gui : true or false. Default is false.
- forecast : For forecast. true or false. Default is false.

Output:

- methods : The supported methods for drawing parameters for the given model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getParameters** ↑

```
p = getParameters(obj,varargin)
```

Description:

Same as obj.parameters only that the name and values are concatenated into a nParam x 2 cell matrix instead of a struct.

Input:

- obj : An object of class nb_model_generic.

Optional input

- varargin : If 'struct' is provided among the optional inputs the returned will be a struct where the parameters are the fieldnames and the parameter values as fields. Otherwise a nParam x 2 cell matrix. First column is the parameter names, while the second column is the

```
parameter values ('struct' is not supported if
numel(obj) > 1).

: Give 'headers' to add model names as headers for each
column of the return cell. Only if numel(obj) > 1.

: Give 'double' to return the value as a numerical array.

: Give 'skipBreaks' to not remove any break-point parameters.
```

Output:

- p : See the type input.

See also:

[parameters](#)

Written by Kenneth Sæterhagen Paulsen

► **getPosteriorDistributions ↑**

```
distr          = getPosteriorDistributions(obj)
[distr,paramNames] = getPosteriorDistributions(obj,'draws',1000)
```

Description:

Get posterior distributions of model.

Input:

- obj : An object of class nb_model_generic.

Optitonal input:

- 'draws' : The number of draws to sample from the posterior to base
the kernel estimation on, if empty all draws are used for
estimation.

Output:

- distr : A 1 x numCoeff nb_distribution object.

- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPredicted ↑**

```
residual = getPredicted(obj)
```

Description:

Get predicted variables from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with predicted variable(s) stored.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getPriorDistributions** ↑

```
[distr,paramNames] = getPriorDistributions(obj)
```

Description:

Get prior distributions of B-VAR model.

Input:

- obj : An object of class nb_var.

Output:

- distr : A 1 x numCoeff nb_distribution object.
- paramNames : A 1 x numCoeff cellstr with the names of the parameters.

Written by Kenneth Å!terhagen Paulsen

► **getRecursiveEstimationGraph** ↑

```
plotter = getRecursiveEstimationGraph(obj)
```

Description:

Get recursive estimation graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphSubPlots method on to get the figure(s).

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph_ts. Use the graphSubPlots method or the nb_graphSubplotGUI class to produce the graphs.

Examples:

```
plotter = getRecursiveEstimationGraph(obj);  
plotter.graphSubPlots();
```

► [getRecursiveScore ↑](#)

```
score          = getRecursiveScore(obj,type)  
[score,plotter] = getRecursiveScore(obj,type,startDate,endDate,invert)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_forecast objects.
- type : A string with one of the following:
 - 'RMSE' : Root mean squared error
 - 'MSE' : Mean squared error
 - 'MAE' : Mean absolute error
 - 'MEAN' : Mean error
 - 'STD' : Standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score
- dim : Either 'variables' to get the recursive scores of all the variables forecast by a model (the obj input must be a scalar object), or else the name of the variable to get the score of (must be part of all models!).
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.

- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : true | false. Default true. If true it will invert the score for 'RMSE', 'MSE', 'MAE' and 'STD'.

Output:

- score : A nb_ts object with size nPeriods x nVars x nHorizon if dim equal 'variables', else a nb_ts object with size nPeriods x nObj x nHorizon.
- plotter : A nb_graph_ts object to plot the recursive scores. Use the graph method. One figure per horizon!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getResidual** ↑

```
residual = getResidual(obj)
```

Description:

Get residual from a estimated nb_model_generic object

Input:

- obj : An object of class nb_model_generic

Output:

- residual : Either a nb_ts or a nb_cs object with residual(s) stored.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualGraph** ↑

```
plotter = getResidualGraph(obj)
```

Description:

Get residual graph from the given estimator. The returned will be an object of class nb_graph, which you can call the graphInfoStruct method on to get the figure(s).

Caution : Will only plot the residual of the last period of recursive estimation.

Caution : For quantile regression this will only report the graph for the median regression.

Input:

- obj : An object of class nb_model_generic (or a subclass of this class).

Output:

- plotter : An object of class nb_graph. Use the graphInfoStruct method or the nb_graphInfoStructGUI class.

Examples:

```
plotter = getResidualGraph(obj);  
plotter.graphInfoStruct();
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getResidualNames ↑**

```
residualNames = getResidualNames(obj)
```

Description:

Get all the unique residual names of a vector of nb_model_generic object

Input:

- obj : A vector of nb_model_generic objects

Output:

- residualNames : A cellstr with the unique residual names of all the models

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getRoots** ↑

```
roots = getRoots(obj)
```

Description:

Get the eigenvalues of the companion for. If all these eigenvalues are inside the unit circle the model is stable.

If some eigenvalues are on the unit circle the model is non-stationary and you need to use cointegration relations.

If the eigenvalues are outside the unit circle the model is explosive.

Caution : The models must be solved! See the method solve.

Caution : For recursively estimated model each period solution is calculated. See page ModelX (ii), where ii will be the index for the recursive estimation.

Input:

- obj : A vector of nb_model_generic objects

Output:

- roots : A nb_data object. Each page (dataset) gives the roots of each model. This output has three variables 'Real', 'Imaginary' and 'Modulus' storing the given parts of the roots.

- plotter : A nb_graph_data object. Use the graph method.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getScore** ↑

```
scores = getScore(obj,type,allPeriods)
scores = getScore(obj,type,allPeriods,startDate,endDate,invert,... 
                  rollingWindow,lambda)
```

Description:

Get forecasting scores using recursive evaluation.

Input:

- obj : A vector of nb_model_group or nb_model_generic objects.

- type : A string with one of the following:
 - 'RMSE' : One over root mean squared error
 - 'MSE' : One over mean squared error
 - 'MAE' : One over mean absolute error
 - 'MEAN' : One over mean error
 - 'STD' : One over standard error of the forecast error
 - 'ESLS' : Exponential of the sum of the log scores
 - 'EELS' : Exponential of the mean of the log scores
 - 'MLS' : Mean log score

If the object input is a vector, the type input can also be a cellstr array with matching length.

Caution: See comment to the invert input!

- allPeriods : true if you want the scores to be calculated for all periods recursively, or else give false, i.e. only calculate the score for the last period. false is default.
- startDate : The date to begin constructing the score. Can be empty. Either as a string or an object of class nb_date.
- endDate : The date to end constructiong the score. Can be empty. Either as a string or an object of class nb_date.
- invert : false or true. Default is false. Default is to report the score so that high value means good model. E.g. setting type to 'RMSE' and invert to true will give NOT inverted root mean squared error!
- rollingWindow : Set it to a number if the combination weights are to be calculated using a rolling window. Default is empty, i.e. to calculate the weights recursively using the full history at each recursive step.
- lambda : Give the value of the parameter of the exponential decaying weights on past forecast errors when constructing the score. If empty the weights on all past forecast errors are equal.

Output:

- scores : A struct. Each field gives the forecasting evaluation for each model, and for each model the output is given as a nb_data object with size nHor x nVars x nPeriods. nPeriod is 1 if allPeriod is given as false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **getSolution** ↑

```
value = getSolution(obj,type)
```

Description:

Get different objects of the solution.

Input:

- obj : An object of class nb_model_generic
- type : Type of matrix to return. One of:
 - > 'A' : Transition matrix.
 - > 'B' : Impact of exogenous matrix.
 - > 'C' : Impact of shocks matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **getVariablesList** ↑

```
[vars,observables] = getVariablesList(obj,type)
```

Description:

Get list of variables given nb_model_generic object that may analyzed

Input:

- obj : A scalar nb_model_generic object
- type : 'forecast' or 'others'. Default is 'forecast'.

Output:

- vars : A cellstr with the variables the model may forecast.
These are the variables that may be given to the
'varOfInterest' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'.
- observables : A cellstr with the observables the model may forecast.
These are the observables that may be given to the
'observables' input to the forecast method of the
nb_model_generic forecast, when the 'output' input is
set to 'all'. Only some specific class of models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► grangerCausalityTest ↑

```
[test,pval,results] = grangerCausalityTest(obj,precision)
```

Description:

Test for granger causality between variables using a joint F-test that all the parameters of the lags of a variable y is zero in the equation where x is the dependent variable. If the hypothesis can be rejected we say that y granger cause x.

Caution: If recursive estimation is done it will anyway only do the test using the parameters estimated over the full sample.

Input:

- obj : A 1 x 1 nb_var object
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : The test statistics. As a nDep x nDep double. The diagonal will return nan.
- pval : The p-value of the test statistics. As a nDep x nDep double. The diagonal will return nan.
- results : A string with the printed results of the test.

Written by Kenneth Sæterhagen Paulsen

► graphCorrelation ↑

```
plotter = nb_model_generic.graphCorrelation(variable,movingVar,...  
c,cEmp,ac1,ac1Emp,ac2,ac2Emp,...)
```

Description:

Graph model correlations against empirical.

Input:

- variable : The main variable, as a string.
- movingVar : A cellstr or char with the variables to plot the covariance/correlations with the main variable.

Optional input:

- 'fan' : true or false. Give true to make shaded areas between the
- The first input must be the c output from nb_model_generic.simulatedMoments (SIM) or nb_model_generic.theoreticalMoments (THEO), the second input must be the c output from nb_model_generic.empiricalMoments (EMP), the third input can be the acl output from SIM or THEO, the fourth input can be the acl output from EMP, and so on.

Caution : The inputs must be given as nb_cs objects.

Caution : Inputs must come in pairs.

Output:

- plotter : An object of class nb_graph_cs. Use the graph method or the nb_graphPagesGUI class.

See also:

[nb_var.simulatedMoments](#), [nb_var.theoreticalMoments](#)
[nb_var.empiricalMoments](#), [nb_graphPagesGUI](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **handleCondInfo** ↑

ret = handleCondInfo(obj)

Description:

Check if a nb_model_estimate object handle conditional info.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle conditional info.

Written by Kenneth Sæterhagen Paulsen

► **handleMissing** ↑

```
ret = handleMissing(obj)
```

Description:

Check if a nb_model_estimate object handle missing observations.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model handle missing data.

Written by Kenneth Sæterhagen Paulsen

► **help ↑**

```
helpText = nb_var.help
helpText = nb_var.help(option)
helpText = nb_var.help(option,maxChars)
```

Description:

Get the help on the different model options.

Input:

- option : Either 'all' or the name of the option you want to get the help on.
- maxChars : The max number of chars in the printout of (approx). This applies to the second column of the printout. Default is 40.

Output:

- helpText : A char with the help.

Written by Kenneth Sæterhagen Paulsen

► **identDraws2Solutions ↑**

```
sol = identDraws2Solutions(obj)
```

Description:

This function assumes that you have used the set_identification function with the input 'type' set to 'combination'.

Input:

- obj : An object of class nb_var.

Output:

- sol : A struct storing the solution of the model. Same format as the solution property of the nb_var class.

Written by Kenneth Sæterhagen Paulsen

► **initialize** ↑

```
obj = initialize(template)
```

Description:

Initialize multiple model objects, see output from the template method of each subclass of the nb_model_generic class.

Input:

- objClass : The name of any of the subclasses of the nb_model_generic class. As a string.
- template : The output from the template method of each subclass of the nb_model_generic class. Multiple model objects will be initialized if the num input that method is greater than one.

Output:

- obj : An object which is of nb_model_generic

Examples:

```
template = nb_var.template(4);
obj      = nb_model_generic.initialize('nb_var',template);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **interpretForecast** ↑

```
[obj,lik,normDiff] = interpretForecast(obj,varargin)
```

Description:

Input:

- obj : A vector of nb_model_generic objects.

Optional input:

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if 'parallel' is set to true.
- 'fcstDB' : A nSteps x nVars nb_ts object. These are the forecast to be interpreted by the model represented by obj.
- 'model' : A nb_model_generic object that produces some forecast to be interpreted by the model represented by obj. The forecast method is used to produce these forecast.
- 'nSteps' : Number of forecasting steps. As a 1x1 double. Default is 8 if the 'model' options is given, otherwise this option does not apply.
- 'optimizer' : The optimizer used to solve the problem. Default is 'fmincon'. Use the nb_getOptimizers method to get optimizer to select from.
- 'optimset' : Set options for forecast matching. See the nb_getDefaultOptimset function. Which fields that are important depend on the 'optimizer' input.
- 'parallel' : Give true if you want to do the forecast in parallel. I.e. spread models to different threads. Default is false. Default is 1.
- 'parameters' : To use parameters to interpret the forecast, you need to list it using this input. As a 1 x nParam cellstr. Caution: You must assign some prior distributions using the setPrior method to be able to utilize this input. It is also only supported if obj is of class nb_dsgc.
- 'periods' : The number of periods that you let innovations from the model represented by obj be active.
- 'startDate' : The start date of forecast. Must be a string or an object of class nb_date. Is empty the estim_end_date + 1 will be used. This option only applies if the 'model' option is provided.
- 'varOfInterest' : A char with the variable to produce the forecast of. Default is '', i.e. all variables. Can also be given a cellstr with the variables to forecast. Variables provided which is not part of the model will be discarded and no error will be given!
- 'varsToMatch' : If the 'model' input is given these are the

variables that are matched, otherwise these are taken from the 'fcstDB' option.

- 'scale' : Sets the relative weight between the concern to match the forecast from the alternative model, and the likelihood of the innovation that are used to match those restrictions. $\text{norm}(\text{fcst} - \text{fcstA}) + \text{scale} * \text{logFunc}$, where logFunc is either the minus log likelihood or the minus the log posterior. A number greater than or equal to 0. Default is 0.
- 'weights' : A nb_ts object with same timespan and variables as 'fcstDB' or the forecast output from the 'model' input. Each row should sum to 1, and will be used to weight the concern of matching the different forecast. Default is equal weights.

[nb_var.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **irf ↑**

[irfs, irfsBands, plotter] = irf(obj, varargin)

Description:

Create impulse responses of the given vector of nb_model_generic objects

Caution : If recursive estimation is done, only the last estimated model will be used.

Input:

- obj : A vector of nb_model_generic objects

Optional input:

- 'addSS' : Set to false to not add the steady-state to IRF of nb_dsgen objects.
- 'compare' : Give true if you have a scalar nb_dsgen model and you want to graph the irfs from the different regimes from a NBToolbox solved model against eachother. Default is false.
- 'compareShocks' : Give true if you want to plot all the IRFs of different shocks in the same graphs (one separate graph for each variable). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'compareVars' : Give true if you want to plot all the IRFs of different variables in the same graphs (one separate graph for each shock). In this case you need a scalar nb_model_generic object as the obj input!

Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs in this case.

- 'continue' : true or false. If true it will continue from a paused call to this method, or else it will start from the beginning.

Caution : All the inputs will be taken from the paused run!

- 'cores' : The number of cores to open, as an integer. Default is to open max number of cores available. Only an option if either 'parallel' or 'parallelL' is set to true.

- 'draws' : Number of draws for calculating girf. Default is 1000. For Markov switching models this will set the number of simulated paths of states. For more see the 'type' input.

- 'factor' : A cell array with the factors to multiply the irf of the individual model variables.
I.e. {'var1',100,...} or {{'var1','var2'},100,...}

If the string starts with a asterisk you will multiply all the variables that contain that string with the given factor.
E.g. {'*_GAP',100}

- 'fanPerc' : This options sets the error band percentiles of the graph, when the 'perc' input is empty. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.

- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

- 'irfCompare' : A struct on the same format as the irfs output from this function with the IRFs to compare to.

- 'levelMethod' : One of the following:

```

> 'cumulative product' : cumprod(1 + X,1)
> 'cumulative sum' : cumsum(X,1)
> 'cumulative product (log)' : log(cumprod(1 + X,1))
> 'cumulative sum (exponential)' : exp(cumsum(X,1))
> 'cumulative product (%)' : cumprod(1 + X/100,1)
> 'cumulative sum (%)' : cumsum(X/100,1)
> 'cumulative product (log) (%)' : log(cumprod(1 + X/100,1))
> 'cumulative sum (exponential) (%)' : exp(cumsum(X/100,1))
> '4 period growth (log approx)' : nb_msum(X,3)

- 'method' : The selected method to create error bands.
  Default is ''. See help on the method input of the
  nb_model_generic.parameterDraws method for more
  this input. An extra option is:

    > 'identDraws' : Uses the draws of the matrix with
      the map from structural shocks to dependent
      variables. See nb_var.set_identification. Of
      course this option only makes sense for VARs
      identified with sign restrictions.

- 'normalize' : A 1 x 3 cell. First element must be the variable
  name as a string. The second element must be the
  value to normalize to, as an integer. While the
  third element is the period to be normalized, if
  set to inf, it will normalize the max impact
  period.

  E.g. {'Var',1,2}, {'Var',1,inf}

  Caution: 2 means observation 2 of the IRF, and as
  the IRF start at period 0, this means that
  observation 2 is period 1.

- 'normalizeTo' : 'draws' or 'mean'. 'draws' normalize each draw of
  irfs, while 'mean' normalize the mean and scale
  percentiles/other draws accordingly. Default is
  'draws'.

  Caution: Setting this to 'mean' will not work for
  reported variables that is not measured
  as % deviation from steady-state/mean.

- 'newReplic' : When out of parameter draws, this factor decides how
  many new draws are going to be made. Default is 0.1.
  I.e. 1/10 of the replic input.

- 'parallel' : Give true if you want to do the irfs in parallel.
  This option will parallelize over models. Default
  is false.

```

- 'parallelL' : Give true if you want to do the irfs in parallel. This option will parallelize over parameter simulations. Only an option if numel(obj) == 1. Default is false.
- 'pause' : true or false, Enable or disable pause option when calculating the irfs. Default is true.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. The input must be given as the coverage, and not the percentiles itself. E.g. [0.3,0.5,0.7,0.9]. 0.3 means to return the two percentiles 35 and 65, which will cover 30% of the distribution around the median. So [0.3,0.5,0.7,0.9] will get the percentiles [5,15,25,35,65,75,85,95], i.e. this will restrict the percentiles to be symmetric. If empty (default) all the simulation will be returned. (The graph will give percentiles specified by the 'fanPerc' input (0.68).)
- 'periods' : Number of periods of the impulse responses.
- 'plotSS' : Set to true to plot the steady-state in the IRF graphs. Default is false. Only for nb_dsg objects.
- 'plotDevInitSS' : Set to true to plot the IRFs as deviation from the initial steady state. Only an option if 'plotSS' is set to true. Only for nb_dsg objects.
- 'replic' : The number of parameter draws.

Caution: 'perc' must be used to produce error bands!

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'settings' : Extra graphs settings given to nb_plots function. Must be a cell.
- 'shocks' : Which shocks to create impulse responses of. Default is the residuals defined by the first model.

For Markov switching or break point models it may be wanted to only run a IRF when switching the state. To do so set this option to {'states'}. You should also set 'startingValues' to 'steadystate(r)', where r is the regime you start in. For a Markov switching model also set 'startingProb' to the same r. This is only an option if 'type' is set to 'irf'.
- 'sign' : Sign of the impulse. Either 1 or -1. Can also be a vector of the same size as 'shocks' input.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default

```

is false.

- 'startingProb' : Either a double or a char (Only for Markov-switching
models):

    > scalar      : Select the the regime to take the
                     initial transition probabilities
                     from.

    > double      : A draws x nRegime or a 1 x
                     nRegime double. draws refer to
                     the number set by the 'draws'
                     input.

    > 'ergodic'   : Start from the ergodic transition
                     probabilities. Default for 'irf'.

    > 'random'    : Randomize the starting values
                     using the simulated starting
                     points. Default for 'girf'.

- 'startingValues' : Either a double or a char:

    > double      : A nVar x 1 double.

    > 'steadystate' : Start from the steady state. If you are dealing
                      with a MS-model or a break-point model you can
                      indicate the regime by 'steadystate(regime)'. E.g.
                      to start in regime 1 give; 'steadystate(1)'. For
                      MS - models the default is the ergodic mean
                      (default as long as 'girf' is not selected as
                      'type'), while for break-point models it is to
                      start from the first regime.

    > 'zero'       : Start from zero on all variables.

    > 'random'    : Randomize the starting values using the simulated
                     starting points. Default when 'type' set to
                     'girf'.

- 'states'       : Either an integer with the states to produce irf in,
                     or a double with the states to condition on. Must
                     have size periods x 1 in the last case. Applies to
                     both MS - models and break-point models.

- 'type'         : 'girf' or 'irf'. (If empty 'irf' will be used)

    > 'girf' : Generlized impulse response function
               calculated as the mean difference between
               shocking the model with a one period shock
               (1 std) and no shock at all. Use the 'draws'
               input to set the number of simulations to use
               to base the calculation on. This type of
               irfs must be used for non-linear models.

    > 'irf'  : Standard irf for linear models. Calculated by
               shocking the model with a one period shock
               (1 std).

```

- 'variables' : The variables to create impulse responses of.
Default is the dependent variables defined by the first model.

Caution: The variables reported by the reporting property may also be asked for here!

- 'variablesLevel' : As a cellstr. The variables to transform to level using the method specified by 'levelMethod'.

Output:

- irfs : The (central) impulse response function stored in a structure of nb_ts object. Each field stores the the impulse responses of each shock. Where the variables of the nb_ts object is the impulse responses of the wanted endogenous variables.

I.e. the impuls responses to the shock 'E_X_NW' is stored in irfs.'('E_X_NW'). Which will then be a nb_ts object of all the wanted variables.

Caution: If more nb_model_generic objects are given, the responses from each model are saved as different datasets (pages) of the nb_ts object.

Caution: Each nb_model_generic object can have different variables and shocks.

- irfsBands : A struct with the shocks as fieldnames. Each field store a nb_ts object with the error bands of all variables. The pages of the nb_ts object is the percentiles (from lower to upper)/simulations.

Caution: Only the first model will get error bands!

- plotter : An object of class nb_graph_ts.
 - > 'compareShocks' set to false (default)
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
 - > 'compareShocks' set to true
Use the graphSubPlots method or the nb_graphSubPlotGUI class to produce the graphs.
- obj : If the process has been paused, some temporary output will be stored in the object, and if you want to continue at a later stage you can take up from this point using this returned output. If not paused this output is empty.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isDensityForecast** ↑

```
ret = isDensityForecast(obj)
```

Description:

Has the nb_model_forecast object produced density forecast or not?

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **isFiltered** ↑

```
ret = isFiltered(obj)
```

Description:

Test if a nb_dsgc object is filtered or not.

Input:

- obj : An object of class nb_dsgc.

- tested : Either 'smoothed', 'filtered' or 'updated'. Default is 'smoothed'.

Output:

- ret : 1 if filtered, otherwise 0.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isIdentified** ↑

```
ret = isIdentified(obj)
```

Description:

Is the nb_var object identified or not.

Input:

- obj : A nb_var object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► **isMS** ↑

ret = isMS(obj)

Description:

Is the nb_model_genric object a Markov switching model or not.

Caution : Model must be solved, otherwise ret is always false!

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isMixedFrequency** ↑

ret = isMixedFrequency(obj)

Description:

Does the model support mixed frequency?

Input:

- obj : An object of class nb_model_generic.

Output:

- ret : True or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► isNB ↑

```
ret = isNB(obj)
```

Description:

This will return true for all objects except nb_dsge objects!

For nb_dsge objects it will return true if the DSGE model is parsed/solved using the NB Toolbox solver for DSGE models, otherwise it will return false.

Input:

- obj : A M x N x Q nb_model_generic object.

Output:

- ret : A M x N x Q logical. An element is set to true if the model uses a NB toolbox solver.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► isStateSpaceModel ↑

```
ret = isStateSpaceModel(obj)
```

Description:

Check if a nb_model_generic object is a state-space model or not.

Input:

- obj : A scalar nb_model_generic object.

Output:

- ret : true or false. true if the estimation settings is so that the solution to the model is a state-space model.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isStatic** ↑

```
ret = isStatic(obj)
```

Description:

Check if a nb_model_estimate object is a static model or not.

Input:

- obj : A scalar nb_model_etimate object.

Output:

- ret : true or false. true if the estimation settings is so that the model is static.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **isbayesian** ↑

```
ret = isbayesian(obj)
```

Description:

Can the nb_model_genric object be estimated using bayesian methods (using the NB Toolbox) or not.

Input:

- obj : A nb_model_genric object (matrix).

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isestimated** ↑

```
ret = isestimated(obj)
```

Description:

Is the nb_model_genric object empty (not estimated) or not.

Caution: For DSGE model it will return true also if the model is only filtered.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **isforecasted ↑**

ret = isforecasted(obj)

Description:

Is the nb_model_forecast object forecasted or not.

Input:

- obj : A nb_model_forecast object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **issolved ↑**

ret = issolved(obj)

Description:

Is the nb_model_genric object solved or not.

Input:

- obj : A nb_model_genric object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► jointPredictionBands ↑

```
[bands,plotter] = jointPredictionBands(obj,varargin)
```

Description:

Calculate joint predication bands.

Input:

obj : An scalar nb_model_generic object

Optional inputs:

- 'vars' : A cellstr with the variables to return the calculated joint prediction bands of.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9] (default) or 0.9. Cannot be empty!
- 'date' : If recursive forecast has been produced, you can use this option to choose which of the recursive forecast to construct the joint prediction bands of. Default is empty, i.e. use the last forecast.
- 'method' : Choose between:
 - > 'kolsrud' : See Akram et al (2016), Joint prediction bands for macroeconomic risk management
 - > 'copula' : Using a copula likelihood approach.
 - > 'mostlik' : Group the paths based on how likely they are.
- 'nSteps' : Number of forecasting steps to use when constructing the error bands. If empty (default) all forecasting steps stored in the object is used.

Output:

- JPB : An nb_ts object storing the joint prediction bands. The percentiles are stored as datasets. See the

dataNames property for which page represent which percentile.

The data of the nb_ts object has size nSteps x nVars x nPerc.

- plotter : A nb_graph_ts object. Use the graphSubPlots method to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **loadPosterior** ↑

```
posterior = loadPosterior(obj)
```

Description:

Load posterior of the estimated model. Bayesian models only!

Input:

- obj : An object of class nb_model_generic.

Output:

- posterior : A struct with the posterior output (The format will depend on the sampling method used).

See also:

[nb_model_estimate.estimate](#), [nb_var.assignPosteriorDraws](#)
[nb_model_sampling.sample](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **mcfRestriction** ↑

```
f = mcfRestriction(obj,type,restriction)
```

Description:

Create restriction function for use in the monteCarloFiltering method

Caution: To combine more restriction you can use `@(x)f1(x)&&f2(x)`, where f1 and f2 are the output from this function.

Input:

- obj : An object of class nb_model_generic.
- type : The type of restriction. Either 'irf', 'corr' or 'cov'.
- restriction : Depends on the type input:
 - > 'irf' : A N x 4 cell, where the elements of each row are:
 1. Name of the shock. 'E_X'
 2. Name of the variable. 'X'
 3. Horizon. E.g. 1 or 1:3.
 4. Restriction. E.g. @(x)gt(x,0), @(x)gt(x,0)||lt(x,1), i.e. a function_handle that takes a scalar double as input and a scalar logical as output.
 - > 'rirf' : A N x 7 cell, where the elements of each row are:
 1. Name of the shock 1. 'E_X'
 2. Name of the variable 1. 'X'
 3. Horizon of variable 1. E.g. 1.
 4. Name of the shock 2. 'E_Y'
 5. Name of the variable 2. 'Y'
 6. Horizon of variable 2. E.g. 2.
 7. Restriction. E.g. @(x,y)gt(x,y), @(x,y)gt(x-y,0)||lt(x-y,1), i.e. a function_handle that takes a two scalar double as inputs and a scalar logical as output.
 - > 'corr' : A N x 4 cell, where the elements of each row are:
 1. Name of the first variable.
 2. Name of the second variable.
 3. Number of periods to lag the 2. variable.
 4. Same as 4 for 'irf'.

E.g. {'Var1','Var1',1,@(x)gt(x,0.1)}, to test a restriction on the autocorrelation at lag for variable 'Var1'.

E.g. {'Var1','Var2',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous correlation between 'Var1' and 'Var2'.
 - > 'cov' : Same as for 'corr'.

E.g. {'Var1','Var1',0,@(x)lt(x,0.1)}, to test a restriction on the contemporaneous variance.
 - > 'ss' : A N x 2 cell, where the elements of each row are:
 1. The expression using any of the endogenous variables of the model.
 2. Same as 4 for 'irf'.

Output:

- f : A function_handle that can be used as an input to the monteCarloFiltering method.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [mincerZarnowitzTest](#) ↑

[test,pval,res] = mincerZarnowitzTest(obj,precision)

Description:

Do the Mincer-Zarnowitz test for bias in the recursive forecast.

For real-time forecast the final revision of the actual data is used to test against.

Caution: Testing of nowcasts is not supported, and are skipped!

Input:

- obj : An object of class nb_model_generic. You need to call one of the forecasting functions first!
- precision : The precision of the printed result. As a string. Default is '%8.6f'.

Output:

- test : A nb_ts object with the test statistic. As a nHor x nModel x nVar nb_ts object.
- pval : A nb_ts object with the p-values of the test. As a nHor x nModel x nVar nb_ts object.
- res : A char with the printout of the test.

See also:

[nb_var.uncondForecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► monteCarloFiltering ↑

```
paramD = monteCarloFiltering(obj,varargin)
[paramD,values,solvingFailed,objAcc] = monteCarloFiltering(obj,varargin)
```

Description:

Draws parameter values from a compact space, which is spesified with some lower and upper bounds. For each draws the model is tried to be solved, if success the behavior of the model is tested and if that is a success that model is returned.

The draws are made using the function nb_monteCarloSim.

Input:

- obj : A scalar nb_model_generic object.

Optional input:

- 'draws' : The number of draws from the compact set to be tested. Default is 10000.
- 'func' : A function_handle or a string with the name of a function. The function should take one input, and that input is assumed to be an object of class nb_model_generic. The (only) output must be either true or false, if 'output' is set to 'logical' (default), or it must be a scalar double, if 'output' is set to 'double'. Return true if the model fit a certain criteria.
- 'method' : The method used to draw the monte carlo simulated parameters. See the method input to the nb_monteCarloSim function for the supported values. Default is 'latin'.
- 'parallel' : Give true to run the MCF in parallel. Default is false.
- 'parameters' : A 1 x N cellstr with the parameter names to be drawn from. Must be part of model, and must be provided!
- 'lowerBound' : A 1 x N double with the lower bound on the parameters of interest.
- 'upperBound' : A 1 x N double with the upper bound on the parameters of interest.
- 'waitbar' : true or false. Default is true.
- 'output' : Either 'double' or 'logical'. Default is 'logical'.
- 'seed' : Set the seed to use to draw the monte carlo simulated parameter sets. Default is 1. Seed is set back to old state after this method is called!

Output:

- paramD : The draws made from the parameter space. As a draws x N double. Use paramD(success,:) to get the accepted draws.
- values : A N x 1 logical/double. An element is true/not nan if the model where solved and the test function returned a value.
- solvingFailed : A N x 1 logical. An element is true if the model could not be solved.
- objAcc : A 1 x nAcc vector of nb_model_generic objects representing the accepted models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **parameterDraws** ↑

```
out = parameterDraws(obj)
out = parameterDraws(obj,draws,method,output,stable)
```

Description:

Make either posterior draws or bootstrapped draws from the distribution of the estimated parameters.

Caution : Not yet supported for recursively estimated models.

Input:

- obj : An object of a subclass of the nb_model_generic class.
- draws : Number of draws, as an integer. Default is 1000.
- method : The selected method to make draws.
 - > 'asymptotic' : Draw from the confidence set using the assumption of asymptotic normality. See the nb_mlEstimator.drawParameters for more on this option. Applies to models estimated with maximum likelihood.
 - > 'bootstrap' : Create artificial data to bootstrap the estimated parameters. Default for models estimated with classical methods.

```

> 'wildBootstrap'      : Create artificial data by wild
                           bootstrap, and then "draw" paramters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'blockBootstrap'    : Create artificial data by
                           non-overlapping block bootstrap,
                           and then "draw" paramters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'mblockBootstrap'   : Create artificial data by
                           overlapping block bootstrap,
                           and then "draw" paramters based
                           on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'rblockBootstrap'   : Create artificial data by
                           overlapping random block length
                           bootstrap, and then "draw" paramters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'wildBlockBootstrap' : Create artificial data by wild
                           overlapping random block length
                           bootstrap., and then "draw" paramters
                           based on estimation on these data.
                           Only an option for models estimated
                           with classical methods.

> 'copulaBootstrap'    : Uses a copula approach to draw residual
                           that are autocorrelated, Does not handle
                           heteroscedasticity. Only an option for
                           models estimated with classical methods.

> 'posterior'          : Posterior draws. Only for models
                           estimated with bayesian methods.
                           Default for models estimated with
                           bayesian methods.

- output : 'param' | 'solution' | 'object'. See output section for more
  on this option.

- stable : Give true if you want to discard the parameter draws
  that give rise to an unstable model. Default is false.

```

Optional input:

- 'parallel' : Run in parallel. true or false.
- 'cores' : Number of cores to use. Default is to use all cores
 available.
- 'newDraws' : When out of parameter draws, this factor decides how

many new draws are going to be made. Default is 0.1.
I.e. 1/10 of the draws input.

Caution: When setting 'parallel' to true on MATLAB version later than R2017B this number will be the number of new draws, and not the factor!!! E.g. set it to 100. If it is given as a number less than 1, it will by default be set to 100.

- 'initialDraws' : When drawing parameters this factor decides how many many draws that are produced before solving the model. Default is 1. I.e. it is equal to draws input. For VAR models with underidentification it may be a good idea to set this to a value > 1 as you may drop a lot of parameters when identification fails. Default is 1.

Output:

- out : The output depend on the input output:
> 'param' : Default. A struct with the following fields:
 beta : A nPar x nEq x draws double with the estimated parameters.
 sigma : A nEq x nEq x draws double with the estimated covariance matrix.

For factor models these fields are also returned:
 lambda : Estimated coefficients of the observation equation. As a nFac x nObservables x draws double.
 R : Estimated covariance matrix of the observation equation. As a nFac x nFac x draws double.
 factors : Draws of the factors as a T x nFac x draws double.

> 'solution' : Get the solution of the model for each draw from the distribution of parameters. The output will be a struct with size 1 x draws. The struct will have the same format as the solution property of the underlying object. I.e. only one output!

> 'object' : Get the draws as a 1 x draws nb_model_generic object. Each element will be a model representing a given draw from the distribution of the parameters. I.e. only one output!

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► parameterIntervals ↑

```
ci = parameterIntervals(obj,alpha)
```

Description:

Get confidence intervals (classic) or probability intervals (bayesian).

Confidence intervals are constructed as:

```
beta + (+/-nb_distribution.t_icdf(alpha/2))*stdBeta.
```

Probability intervals are constructed as the per

Input:

- obj : A scalar object of class nb_model_generic.
- alpha : Confidence level/probability band.

Output:

- ci : A nPar x 3 cell matrix.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► plotForecast ↑

```
plotter = plotForecast(obj)
[plotter,plotFunction2Use] = plotForecast(obj,type,startDate, ...
increment,varargin)
```

Description:

Plot forecast.

Caution density forecast will only be displayed for the first model in the vector of nb_model_forecast objects

Input:

- obj : A vector of nb_model_forecast objects
- type : Type of plot, as a string;
 - > 'default' : Plot the forecast for the last period of estimation and ahead. Possibly with density for the first model in the model vector. Can have different variables. If startDate is given this date will be the start of the graph instead.

```

> 'hairyplot' : Plot the recursive point forecast in the same
graph as the actual data.

- startDate : A string with the start date of the forecast to plot. As a
string or an object of class nb_date. Only an option when
type is 'default'. Default is to plot the latest forecast
produced.

- increment : Number of periods between the hairs when doing a
hairy-plot. Default is 1.

```

Optional input:

```

- 'type'      : If the history is of some variables are filtered, you can
use this input to choose to plot the smoothed or updated
estimates of the filtered variables. Either 'smoothed' or
'updated'. Default is 'smoothed'.

```

Output:

```

- plotter       : An object of class nb_graph. Use the graphSubPlots
method or the nb_graphSubPlotGUI class.

- plotFunction2Use : A string with the name of the method to call on the
plotter object to produce the graphs.

```

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotForecastDensity** ↑

```
plotter = plotForecastDensity(obj,date,variable)
```

Description:

Plot the density forecast at a given date for a given variable. It will
be compared to the normal distribution with the same mean and std.

Caution : If the model produce nowcast this nowcast will start before the
provided date. See the dataNames property of the DB
property of the returned plotter object. If the model has
produced nowcast the names will 'horizon0' (a variable lag one
period), 'horizon-1' (a variable lag two periods), etc.

Input:

- obj : A 1x1 nb_model_forecast object.
- date : A string or nb_date object with the date of the wanted forecast.
- variable : A string with the variable of interest.

Output:

plotter = A nb_graph_data object. Use the graph method to produce the figure, or the nb_graphPagesGUI class.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_FORECAST

► **plotMCF ↑**

plotter = nb_model_generic.plotMCF(paramD,params,lowerBound,...
upperBound,method)

Description:

Plot parameter draws from Monte Carlo filtering.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- lowerBound : A 1 x N double with the lower bound on the parameters of interest.
- upperBound : A 1 x N double with the upper bound on the parameters of interest.
- method : Either 'biplot' or 'allInOne'. 'biPlot' will plot all pairwise combination against each other in a scatter plot. 'allInOne' will plot the parameters on the x-axis and the accepted parameter values of each of the parameters on the y-axis. Default is 'allInOne'.

Output:

- plotter : > 'allInOne' : A nb_graph_cs object. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- > 'biplot' : A vector of nb_graph_data objects with size equal to the number of pairwise combination of the parameters that can be made. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFDistTest** ↑

```
plotter = nb_model_generic.plotMCFDistTest(paramD,params,values,test)
```

Description:

Split parameter sets from monte carlo filtering into two pools of sets, one for the parameter sets that lead to success, and the other for those that did not. Then for each pool the CDF of each parameter is compared in graph. In the title the p-value of the selected test is provided.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- test : Name of the test to apply. Either 'smirnov' or 'cucconi' (default). Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotMCFValues** ↑

```
plotter = nb_model_generic.plotMCFValues(paramD,params,nameValue)
```

Description:

Plot parameter draws from Monte Carlo filtering and matching results.

Input:

- paramD : A draws x N double with the parameter draws. E.g. use paramD(success,:) from the output of the monteCarloFiltering method. N is the number of parameters.
- params : A 1 x N cellstr with the names of the parameters.
- values : A draws x 1 double with the values of the monte carlo filtering.
- nameValue : Name of the values used in the graphs produced. Default is 'Value'. Must be a one line char.

Output:

- plotter : A vector of nb_graph_data objects with size 1 x N. Use the graph method or the nb_graphMultiGUI class to produce the graphs.

See also:

[nb_var.monteCarloFiltering](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [plotPosterioriors](#) ↑

```
plotter = plotPosterioriors(obj)
plotter = plotPosterioriors(obj,varargin)
```

Description:

Plot posteriors (and priors) drawn during estimation. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model that is estimated.

Optitonal input:

- 'prior' : Give this string as an input to compare posterior draws with the prior distributions (if available).
- 'updated' : Give this string as an input to compare posterior draws with the updated prior distributions (if available).

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.
- 'draws' : The number of draws to sample from the posterior to base the kernel estimation on, if empty all draws are used for estimation. If 'updated' is given as input, this will also set the the same options for the updated prior!

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the posteriors on screen.
Caution: If 'subplot' is given it will return a scalar nb_graph_data object. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the posteriors on screen.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **plotPriors ↑**

plotter = plotPriors(obj,varargin)

Description:

Plot priors. Only for bayesian models.

Input:

- obj : A scalar object of class nb_model_generic. It must represent a bayesian model with a set prior.

Optitonal input:

- 'subplot' : Give this string as an input to plot the priors and posteriors in subplots instead of one plot per parameter.

Output:

- plotter : A 1 x numCoeff vector of objects of class nb_graph_data. Use either the graph method or the nb_graphMultiGUI class to plot the priors on screen.

Caution: If 'subplot' is provided a scalar nb_graph_data object is returned. Use the graphSubPlots method or the nb_graphSubPlotGUI class to plot the priors on screen.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print** ↑

```
printed = print(obj)
```

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print_estimation_results](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **printCov** ↑

```
printed = printCov(obj)
```

Description:

Get the estimated covariance matrix results printed to a char array.

Caution: Some estimators may not support this option.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_model_estimate.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **print_estimation_results** ↑

printed = print_estimation_results(obj)

Description:

Get the estimation result printed to a char array.

Input:

- obj : A vector of nb_model_estimate objects.

Output:

- printed : A char array with the estimation results.

See also:

[nb_var.print](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **priorTemplate** ↑

prior = nb_var.priorTemplate()
prior = nb_var.priorTemplate(type)
prior = nb_var.priorTemplate(type, num)

Description:

Construct a struct which can be given to the method setPrior.

The structure provided the user the possibility to set different prior options.

Caution: Hyperpriors will only be used if both the empirical and hyperprior options are set to true!

Input:

- type : A string;

- 'glp' : This is the prior used in the paper by Giannone, Lenza and Primiceri (2014). Cannot apply block exogenous variables with this prior.

> 'ARcoeff' : Hyperparameter on first lag coefficient of each equation. Default is 1.

> 'coeff' : See same options for the 'minnesota' prior.

> 'lambda' : Hyperparameter that controls the overall tightness of this prior. Default is 0.2.

> 'Vc' : Hyperparamter on exogenous variables. Default is 1e7.

> 'S_scale' : Prior scale of prior on sigma. Default is 1, i.e. OLS.

- 'glpMF' : Same as 'glp', but as we now need a gibbs sampler the below options are added. This prior option supports missing observations. Cannot apply block exogenous variables with this prior. The 'ARcoeff' defaults to 0.9 in this case, as the model must be stationary at the prior to run the kalman filter.

> 'burn' : How many draws that should be used as burn in. Default is 500.

> 'thin' : Every k draws are kept when doing gibbs. This options sets k. Default is 2. Increase this option to prevent autocorrelated draws. See nb_model_generic.checkPosteriors to test for autocorrelated draws.

- 'jeffrey' : Diffuse jeffrey prior. No options.

- 'minnesota' : Minnesota prior options. See page 6 of Koop and Korobilis (2009). Output fields:

> 'a_bar_1' : Hyperparamter on own lags. Default is 0.5.

> 'a_bar_2' : Hyperparamter on other lags. Default is 0.5.

> 'a_bar_3' : Hyperparamter on exogenous variables. Default is 100.

> 'ARcoeff' : Hyperparameter on first lag coefficient of each equation. Default is 0.9.

> 'coeff' : A N x 2 cell array with specific priors on some coefficients. In the first column you must provide the name of the coefficient, name of dependent + _ + name of rhs variable

```

+ lag specifier. E.g. 'Var1_Var1_lag1' or
'Var1_Var2'. In the last example Var2 is an
exogenous variable. In the second column
you give the prior value, as a scalar double.

> 'method'   : Sets the method to use to draw from the
posterior. Either 'default' (default) or any
other string. 'default' uses (a fixed)
covariance matrix of the shocks (i.e. the
prior). Otherwise it also samples from the
posterior distribution of the covariance
matrix, as in the same way as in the case
of the independent normal wishart (inwishart)
prior. The 'burn', 'thin' and 'S_scale' options
only applies to this last case.

> 'burn'     : How many draws that should be used as burn
in. Default is 500.

> 'thin'      : Every k draws are kept when doing gibbs.
This options sets k. Default is 2. Increase
this option to prevent autocorrelated
draws. See nb_model_generic.checkPosteriorors
to test for autocorrelated draws.

> 'S_scale'   : Prior scale of prior on sigma. Default is 1,
i.e. OLS.

- 'minnesotaMF' : Same as 'minnesota'. This prior option
supports missing observations. Cannot apply
block exogenous variables with this prior.

- 'nwishart'    : Normal-Wishart prior options.

    > 'V_scale'   : Scale of the prior of the variance of the
coefficients. Default is 10.

    > 'S_scale'   : Prior scale of sigma. Default is 1.

- 'nwishartMF'  : Same as 'nwishart', but as we now need a
gibbs sampler the below options are added.
This prior option supports missing
observations. Cannot apply block exogenous
variables with this prior.

    > 'burn'      : How many draws that should be used as burn
in. Default is 500.

    > 'thin'       : Every k draws are kept when doing gibbs.
This options sets k. Default is 2. Increase
this option to prevent autocorrelated
draws. See nb_model_generic.checkPosteriorors
to test for autocorrelated draws.

- 'inwishart'   : Independent Normal-Wishart prior options.

    > 'V_scale'   : Scale of the prior of the variance of the
coefficients. Default is 10.

```

```

> 'S_scale' : Prior scale of sigma. Default is 1.

> 'burn'      : How many draws that should be used as burn
in. Default is 500.

> 'thin'      : Every k draws are kept when doing gibbs.
This options sets k. Default is 2. Increase
this option to prevent autocorrelated
draws. See nb_model_generic.checkPosterior
to test for autocorrelated draws.

- 'inwishartMF' : Same as 'inwishart'. This prior option
supports missing observations.

- For the 'glp', 'glpMF', 'jeffrey', 'minnesota', 'minnesotaMF',
'nwishart' and 'nwishartMF' priors you also have the
oppurtunity to apply the prior for the long run as in
Giannone et. al (2014).

> 'LR'        : Apply priors for the long run. See also
nb_var.applyLongRunPriors. true or false.

> 'phi'       : Shrinkage parameter for the long run prior.
For more see nb_var.applyLongRunPriors.

> 'H'         : Matrix that specifies the cointegration
relations. For more see
nb_var.applyLongRunPriors.

- For the 'glp', 'glpMF', 'jeffrey', 'minnesota', 'minnesotaMF',
'nwishart' and 'nwishartMF' priors you also have the
oppurtunity to apply the sum-of-coefficients prior by Doan,
Litterman, and Sims (1984).

> 'SC'        : Apply sum-of-coefficients prior. true or false.

> 'mu'        : Shrinkage parameter of the sum-of-coefficients
prior. As mu goes to 0 implies the presence
of a unit root in each equation and rules out
cointegration.

- For the 'glp', 'glpMF', 'jeffrey', 'minnesota', 'minnesotaMF',
'nwishart' and 'nwishartMF' priors you also have the
oppurtunity to apply the dummy-initial-observation prior by
Sims (1993).

> 'DIO'       : Apply dummy-initial-observation prior. true or
false.

> 'delta'     : Shrinkage parameter of the dummy-initial-
observation prior. As delta goes to 0 all the
variables of the VAR are forced to be at
their unconditional mean, or the system is
characterized by the presence of an
unspecified number of unit roots without
drift. As such, the dummy-initial observation
prior is consistent with cointegration

- For the 'glp', 'glpMF', 'jeffrey', 'minnesota', 'minnesotaMF',

```

'nwishart' and 'nwishartMF' priors you also have the opportunity to apply the stochastic-volatility-dummy prior "How to estimate a vector autoregression after March 2020" by Lenza and Primiceri (2020).

```

> 'SVD'           : Apply stochastic-volatility-dummy prior.
                     true or false.

> 'periodsMax'  : Number of periods we allow for estimation
                     of s_t. Default is 3.

> 'rho'          : Decay parameter, used for s_t after reaching
                     periodsMax. Default is 0.5.

> 'dateSVD'      : A one line char for where to start the
                     stochastic-volatility-dummy prior. E.g.
                     '2020Q1'. This must be set, if SVD == true!

- 'kkse'          : This is the prior used in the paper by
                     Koop and Korobilis (2014) extended by Schroder
                     and Eraslan (2021) to handle mixed frequency,
                     but adapted to the VAR setting.

> 'f0VarScale'   : Scale factor on the variance of the
                     prior on the initial value of factors.
                     Default is 10. N(0,f0VarScale*I)

> 'lambda0VarScale' : Scale factor on the variance of the
                     prior on the initial value of the factor
                     loadings. Default is 1.
                     N(0,lambdaVarScale*I). !!Remove!!

> 'V0VarScale'    : Scale factor on the mean of the
                     prior on the initial value of the
                     measurement equation covariance matrix.
                     Default is 0.1. Dogmatic prior set to
                     V0VarScale*I. !!Remove!!

> 'Q0VarScale'    : Scale factor on the mean of the
                     prior on the initial value of the
                     state equation covariance matrix.
                     Default is 0.1. Dogmatic prior set to
                     Q0VarScale*I.

> 'gamma'         : Hyperparameter on prior variance of the
                     coefficients of the state equations.
                     On the form V(i,j) = gamma./
                     (ceil(j/options.nFactors).^2). Where
                     V is a matrix with size option.nFactors
                     x option.nLags*option.nFactors. Default
                     value is 0.1.

> 'l_1m'          : Starting value of:
                     Decay factor for the measurement error
                     variance of the monthly variables. A
                     smaller value puts smaller weight on
                     past observations and thus allows for
                     faster parameter change. A value of 1
                     implies constant parameters. Default

```

```

is 1. Do not adjust!

> 'l_1q'      : Starting value of:  

Decay factor for the measurement error  

variance of the quarterly variables. A  

smaller value puts smaller weight on  

past observations and thus allows for  

faster parameter change. A value of 1  

implies constant parameters. Default  

is 1. Do not adjust!

> 'l_2'        : Starting value of:  

Decay factor for the factor error  

variance. A smaller value puts smaller  

weight on past observations and thus  

allows for faster parameter change. A  

value of 1 implies constant parameters.  

Default is 1.

> 'l_3'        : Starting value of:  

Decay factor for the loadings' error  

variance. A smaller value puts smaller  

weight on past observations and thus  

allows for faster parameter change. A  

value of 1 implies constant parameters.  

Default is 1. Do not adjust!

> 'l_4'        : Starting value of:  

Decay factor for the factor VAR  

parameters' error variance.  

A smaller value puts smaller  

weight on past observations and thus  

allows for faster parameter change. A  

value of 1 implies constant parameters.  

Default is 1.

> 'l_1_endo_update' : Controls the endogenous forgetting  

factors  

1: l_1m and l_1q are time-varying/  

endogenous  

0: l_1m and l_1q are constant/static  

Default is 0. Do not adjust!

> 'l_2_endo_update' : Controls the endogenous forgetting  

factors  

1: l_2 is time-varying/endogenous  

0: l_2 is constant/static  

Default is 0.

> 'l_3_endo_update' : Controls the endogenous forgetting  

factors  

1: l_3 is time-varying/endogenous  

0: l_3 is constant/static  

Default is 0. Do not adjust!

> 'l_4_endo_update' : Controls the endogenous forgetting  

factors  

1: l_4 is time-varying/endogenous  

0: l_4 is constant/static

```

```

Default is 0.

- 'dsge' : DSGE-VAR prior. See Del Negro and Schorfheide
(2004), "Priors from General Equilibrium Models for
VARs". Let N be number of dependent variables, L the
number of lags of the VAR, and C is equal to 1 if a
constant is included. otherwise 0.

> 'lambda' : DSGE-VAR weight.

> 'GammaYY' : A N x N double with the nonstandardized sample
moments of the left-hand variables of the VAR.

> 'GammaXX' : A (C + N*L) x (C + N*L) double with the
nonstandardized sample moments of the right-hand
variables of the VAR.

> 'GammaXY' : A (C + N*L) x N double with the nonstandardized
sample moments between the right-hand
variables and the left-hand variables of the
VAR.

```

The last 3 fields can be found from a nb_model_generic model using the method nb_model_generic.getDSGEVARPriorMoments.

Settings for econometric bayesian and hyper-learning:

```

> 'logTransformation' : Set to true to use the log
transformation -log((MAX-VALUE)
./ (VALUE-MIN)) to the parameters to
optimize over. May be important if the
optimizer chosen do not support lower
and upper bounds!

> 'optParam' : A cellstr with the parameters to
optimize over or empty. If empty
it tries to optimize over all hyper
parameters of the selected prior.

```

Settings for missing observations priors:

```

> 'nonStationary' : Set to true to use some tricks to be able
to handle problems related to models in
levels.

- num : Number of prior templates to make.

```

Output:

- options : A struct.

See also:

[nb_model_generic.getDSGEVARPriorMoments](#)

Written by Kenneth Sæterhagen Paulsen

► **removeObservations** ↑

```
obj = removeObservations(obj,numPer)
```

Description:

Remove the number of wanted observation from each series stored in the data of the object. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_modelData object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.

Output:

- obj : A nb_modelData object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODELDATA

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties or fields of the options property of the nb_model_estimate objects (or objects which is of a subclass of this class).

Caution : It may also set the fields of the options property of the object. See the <class>.template and <class>.help for more on the different fields of the options property. E.g. nb_var.template and nb_var.help.

Caution : If the model is reformulated the estimation results and solution will be deleted.

Input:

- obj : A vector of nb_model_estimate objects.

Optional input:

If number of inputs equals 1:

- varargin{1} : A structure of fields to be set. See the template method of each model class for more.

Else:

- varargin : ..., 'inputName', inputValue, ... arguments.

Where you can set all fields of some properties of the object. (options, endogenous, exogenous)

Output:

- obj : A vector of nb_model_estimate objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **setMeasurementEqRestriction** ↑

obj = setMeasurementEqRestriction(obj, restrictions)

Description:

Add restrictions in the measurement equation of the model on the form;

restricted = parameters*variables'

e.g.

X = [0.5, 0.5]*[Y; Z]

where X is a observed variable, while Y and Z are state variables.
So for a mixed frequency var, X and Y must be included in the state equation. An error is provided if this is not the case!

For the xxxMF priors this information is taken into account, otherwise it will only be used during conditional forecasting, i.e. the measurement restrictions will be appended to the solution after estimation is done.

See nb_var.priorTemplate for more on the supported priors.

Input:

- obj : An object of class nb_var

- restrictions : A struct array with fields
> 'restricted' : A one line char with the variable to

restrict. It must be a dependent variable or block exogenous variable.

- > 'parameters' : A cellstr with the names of the variables storing the parameters of the restriction, or a double array. Must have same length as 'variables'.
- > 'variables' : A cellstr with the names of the variables included in the restriction.
- > 'frequency' : Set to the frequency of the observables. This is only important for the mixed frequency VAR model. Give [], if the restriction is on the same frequency as the data. Either 1 (yearly), 4 (quarterly) or 12 (monthly).
- > 'mapping' : Sets the mapping to use for this restricted variable. See the method nb_mfvar.setMapping for more on the mappings to choose from.
- > 'R_scale' : Inverse prior scale of the variance of the measurement error of this restrictions.

The variance of the measurement error is constructed by dividing the variance of each 'restricted' variable by this scaling parameter.

Output:

- obj : An object of class nb_var where the measurement equation restrictions are added.

See also:

[nb_var.template](#), [nb_bVarEstimator.applyMeasurementEqRestriction](#)
[nb_var.priorTemplate](#), [nb_mfvar.setMapping](#)

Written by Kenneth Åkerhagen Paulsen

► **setPrior** ↑

obj = setPrior(obj,prior)

Description:

Set priors of a vector of nb_var objects. The prior input must either be a struct or nb_struct with same size as obj or have size 1.

The provided struct will be added to the property options as the field prior.

See [nb_var.priorTemplate](#) for the format of the struct.

```
Caution : The estim_method field of the option property will  
automatically be set to 'bvar'.
```

```
Caution : Not yet supported for the subclass nb_favar!
```

Input:

- obj : A vector of nb_var objects
- prior : A struct or nb_struct with either matching numel of obj or size
1. If size is 1 all models gets the same prior settings.

Output:

- obj : A vector of nb_var objects with the priors set.

See also:

[nb_var.priorTemplate](#)

Written by Kenneth Sæterhagen Paulsen

► **set_identification ↑**

```
obj = set_identification(obj,type,varargin)
```

Description:

Identify a VAR model. Either using cholesky restrictions or combinations of sign and zero restrictions (short, mid and long term).

The method solve must be called after adding the identifying restrictions

See Andrew Binning (2013), "Underidentified SVAR models: A framework for combining short and long-run restrictions with sign-restrictions". This code is an adaption of his code to the NBToolbox, except that also magnitude restriction is possible using this code.

Input:

- obj : A vector of nb_var objects, or subclasses of this class.
- type : Either 'cholesky' or 'combination'
- varargin (Optional inputs) :
 - > 'cholesky' :
 - 'ordering' : A cellstr with the ordering of the identification.
Default is to use the ordering of the dependent variables of the model. The ordering is so that the

first variable is the variable that is only influenced by one shock in period 1, the second variable is the variable that is influenced by two shock in period 1, and so on.

Caution : All variables of the VAR must be included in this option.

> 'combination' :

- 'maxDraws' : The number of maximal rotations when looking for a identification satifying the sign restrictions. Can be set to inf. Default is 10000.

- 'draws' : The number of wanted draws of the matrix of the map from structural shocks to dependent variables (C). Default is one.

Caution : When it comes to producing IRFs with sign restrictions you have two options. The first is to set 'draws' to a large number, say 1000, and then produce irf for each of those draws. The second approach is to draw parameters using bootstrap, MC methods or from the posterior, and then to make one draw of the C for each draw of the paramters.

- 'restrictions' : A nRestriction x 4 cell;

{Dep, Shock, period, type, value; ...}

> Dep : The dependent variable to add the restriction to. As a string.

> Shock : The name of the identified structural shock. As a string.

> period : The period of the restriction, as a double. For on impact set 0 and for cumulative restriction set it to inf.

Use s:e to add a restriction on the cumulative contribution of a shock to a variable starting at s and ending at e. E.g. 0:10.

> type : Either 0 for zero restriction, '+/' '-' for sign restrictions or '>'/'<' for magnitude restrictions.

Or 'none' : If you want to add a structural shock with no restriction, as you already have exactly identified N-1 shocks.

> value : A 1x1 double with the value of the

magnitude restriction.

Output:

- obj : Identified nb_var objects. See the property field identification of the property solution.

Examples:

See ...\\Econometrics\\test\\test_nb_var

Written by Kenneth Sæterhagen Paulsen
Subfunctions are written by Andrew Binning 2013

► **shock_decomposition ↑**

```
[decomp,decompBand,plotter] = shock_decomposition(obj,varargin)
```

Description:

Shock decomposition of a vector of nb_model_generic objects.

Caution : For recursively estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'packages' : Cell matrix with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

Caution: Two special identifiers can be used; 'Initial Conditions' and 'Steady-state'. The first represent the impact of all shocks that hit the system before the decomposition/estimation started. The second summarizes the impact of steady-state changes on the system, i.e. the impact of break points.

If empty no packing will be done.

- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.
- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'endDate' : End date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create error bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sence for VARs identified with sign restrictions.
- 'replic' : The number of simulation for posterior, bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'parallel' : Give true if you want to do the shock decomp in parallel. Default is false.
- 'fcstDB' : An object of class nb_ts with the forecast to decompose. must contain all model variables and shocks/residuals, and must start the period after the estimation/filtering end date or at the estimation/filtering start date. See the nb_model_generic.getForecast method.
- 'type' : Choose 'updated' or 'smoothed'. 'smoothed' is default.
- 'anticipationStartDate' : Start date of anticipating shocks. As a string. If different models has different frequency this date will be converted.
- 'model2' : A struct with the solution of the second model to use for decomposition.
- 'secondModelStartDate' : Start date of second model. As a string.

If different models has different frequency
this date will be converted.

Output:

- decomp : A structure of nb_ts objects with the shock decomposition for each model.
- decompBand : A nested structure of nb_ts objects with the uncertainty bounds of the shock decomposition for each model at each percentile.
- plotter : A 1 x nModel vector of nb_graph_ts objects. Use the graph method to produce the graphs or use the nb_graphPagesGUI on each element of the graph objects.

See also:

[nb_var.parameterDraws](#), [nb_shockDecomp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulate ↑**

```
out = simulate(obj,nSteps,varargin)
```

Description:

Make simulations from model.

Caution : Will only simulate using the full sample estimate of
recursively estimated model.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of simulation steps. As a 1x1 double. Default is 100.

Optional inputs:

- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'bounds' : A struct. Each fieldname must be the name of the variable to add bounds on. Each field must again be a struct with the following fields:
 - 'shock' : Name of the shock to match the restriction on the bounds of the given

variable.

- 'lower' : The lower bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.
- 'upper' : The upper bound of the selected variable. Either a 1x1 double value or a function handle to a probability distribution to draw from.

Caution : The function handles must take one input. I.e. the vector of current observations of the endogenous variables, as a nVar x nSteps double matrix. For the order of the variables see; obj.solution.endo. The value return by the function must be either a 1x1 double or a nSteps x 1 double.

This input can be used to use anticipated shocks to restrict variables to inside a range. E.g. effective lower bound on the interest rate.

- 'condDB' : A nb_ts object with the conditional information to base the simulation upon.
 - 'draws' : Number of residual/innovation draws per parameter draw. Default is 1000. Must be larger than 0.
 - 'foundReplic' : A struct with size 1 x parameterDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.
- Caution: You still need to set 'parameterDraws' to the number of draws you want to do.
- 'method' : The selected method to create density forecast. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input.
 - 'newDraws' : When out of parameter draws, this factor decides how many new draws are going to be made. Default is 0.1. I.e. 1/10 of the parameterDraws input.
 - 'observables' : A cellstr with the observables you want the simulation of. Only for factor models. Will be discarded for all other types of models.
 - 'output' : Either 'endo' (default), 'fullendo' or 'all'. This input indicates which variables to return the simulation of.
 - > 'endo' : All the endogenous variables are returned.

```

> 'fullendo' : All the endogenous variables are
   returned included the lag variables.

> 'full'      : All the variables are returned
   included the lag variables. Also
   including exogenous and shocks.

> 'all'       : All variables are returned (but not
   the lags). Also including exogenous
   and shocks.

- 'parallel'   : Give true if you want to do the simulations in
   parallel. I.e. spread models to different threads.
   Default is false.

- 'parameterDraws' : Number of draws of the parameters. When set to 1
   it will discard parameter uncertainty. Default is 1.

- 'regime'     : Select the regime you want to simulate. If empty
   the simulation will switch between regimes. Only
   an option for Markov switching models.

- 'regimeDraws' : Number of drawn regime paths when doing simulations.
   This will have no effect if the states input is
   providing the full path of regimes. Default is 1.

- 'seed'        : Set simulation seed. Default is 2.0719e+05.

- 'startDate'   : Give the start date of the simulation. If not
   provided the output will be a nb_data object
   without a spesific start date (default). If
   provided the output will be an object of class
   nb_ts.

Caution : If dealing with break-points or exogenous
   time-varying parameters this input must be
   provided.

- 'startingValues' : Either a double or a char:

    > double          : A 1 x nVar double.

    > 'mean'          : Start from the mean of the data
   observations. Default for all
   model except nb_dsge models.

    > 'steadystate'  : Start from the steady state. For
   now only an option for nb_dsge
   models. If you are dealing with a
   MS-model you can indicate the
   state by 'steadystate(state)'.
   E.g. to start in state 1 give;
   'steadystate(1)'. Default for
   nb_dsge models.

    > 'zero'          : Start from zero on all variables
   (Except for the deterministic
   exogenous variables)

```

- 'stabilityTest' : Give true if you want to discard the parameter draws that give rise to an unstable model. Default is false.
- 'startingProb' : Either a double or a char:
 - > double : A nPeriods x nRegime or a 1 x nRegime double. nPeriods refer to the number of recursive periods to forecast.
 - > 'ergodic' : Start from the ergodic transition probabilities. Default.

Output:

- out : A struct with the simulated variables from each model as separate fields. Each field consist of a nSteps x nVar x parameterDraws*draws*regimeDraws nb_data (or nb_ts if the 'startDate' input is used) object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **simulateFromDensity ↑**

```
obj = nb_model_forecast.simulateFromDensity(forecastOutput, draws)
```

Description:

Simulates from the estimated kernel density.

Input:

- forecastOutput : A forecast property of the nb_model_forecast class where the forecastOutput.evaluation stores the kernel density estimate.
- draws : Number of draws to use for simulation.

Output:

- forecastOutput : A struct on the same format as the nb_model_forecast.forecastOutput property

See also:

[nb_model_generic.forecast](#), [forecastPerc2Dist](#)

Written by Per Bjarne Bye and Atle Loneland

Inherited from superclass NB_MODEL_FORECAST

► simulatedMoments ↑

```
[m,c] = simulatedMoments(obj,varargin)
[m,c,ac1] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2] = simulatedMoments(obj,varargin)
[m,c,ac1,ac2,...] = simulatedMoments(obj,varargin)
```

Description:

Calculate simulated moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.
- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.
- 'nLags' : Number of lags to compute when 'stacked' is set to true.
- 'vars' : A cellstr, with a subset of dependent variables of the model. If empty (default), all dependent variables are returned.
- 'type' : Either 'covariance' or 'correlation'. Default is 'correlation'.
- 'draws' : Number of simulations per parameter draw. Default is 1000. Must at least be 1.
- 'pDraws' : Number of parameter draws. Default is 1. I.e. to use the estimate parameters.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return all draws.

Caution: 'pDraws' or 'draws' must be set to a number > 1.
- 'nSteps' : Number of simulation steps. As a 1x1 double. Default is 100.
- 'burn' : The number of periods to remove at start of the simulations. This is to randomize the starting values of the simulation. Default is 0.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more

this input.

- 'demean' : true (demean simulation during estimation of the autocovariance matrix), false (do not). Default is true.
- 'foundReplic' : A struct with size 1 x pDraws. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters. See the parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws' to the number of draws you want to do.

Output:

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.
- varargout{2} : The contemporaneous covariances/correlations, as a nVar x nVar nb_cs object or double. The variance is along the diagonal. (Will be symmetric)
- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar x nVar nb_cs object or double. Along the diagonal is the auto-covariance/correlation with the variable itself. In the upper triangular part the you can find cov(x,y(-i)), where x is the variable along the first dimension. In the lower triangular part the you can find cov(x(-i),y), where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find cov(x,y(-i)) you can use getVariable(varargin{i}, 'y', 'x'), while to get cov(x(-i),y) (== cov(x,y(+i))) you can use getVariable(varargin{i}, 'x', 'y'). (This example only works if the output is of class nb_cs)

► **solve ↑**

obj = solve(obj)

Description:

Solve estimated model(s) represented by nb_var object(s).

Input:

- obj : A vector of nb_var objects.

Output:

- obj : A vector of nb_var objects, where the solved model(s) is/are stored in the property solution.

See also:

[nb_model_generic.solveVector](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **solveNormal** ↑

```
tempSol = nb_var.solveRecursive(results,opt,ident)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **solveVector** ↑

```
obj = solveVector(obj)
```

Description:

Solve vector of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.

Output:

- obj : A vector of nb_model_generic objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **stateSpace** ↑

```
[x0,P0,d,H,R,T,c,A,B,Q,G,obs,failed] = nb_var.stateSpace(par,nDep,...  
nLags,nExo,restr,restrVal,stabilityTest)
```

Description:

Returns a state-space representation of an VARX(nLags) model.

Observation equation:

$$y = d + Hx + Tz + v$$

State equation:

$$x = c + Ax_{-1} + Gz + Bu$$

Input:

- par : The parameter vector of the VARX model.
 - Order:
 - constant
 - exogenous
 - lagged endogenous
 - residual std
- nDep : The number of dependent variables of the model.
- nLags : the number of lags of the VAR.
- constant : Include constant or not. true or false.
- nExo : Number of exogenous variables included in the model.
- restr : A nDep x nDep*nLags logical matrix. true for the non-restricted parameters.
- restrVal : Values of the restricted parameters.
- stabilityTest : Check stability of system. Sets failed to true if model is not stationary. Default is false.

Output:

- x0 : Initial state vector.
- P0 : Initial variance.
- See equation above
- obs : Index of observables in the state vector.
- failed : See stabilityTest input.

Examples:

See also:

[nb_kalmanlikelihood](#), [nb_kalmanlikelihood_missing](#)

Written by Kenneth Sæterhagen Paulsen

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct.

Input:

- obj : An object of class nb_model_estimate.

Output:

- s : A struct representing the nb_model_generic object.

See also:

[nb_var.unstruct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► **template** ↑

options = nb_var.template()
options = nb_var.template(num)

Description:

Construct a struct which can be provided to the nb_var class constructor.

This structure provided the user the possibility to set different estimation options.

Input:

- num : Number of models to create.

Output:

- options : A struct.

See also:

[nb_var](#), [nb_var.priorTemplate](#)

Written by Kenneth Sætherhagen Paulsen

► **testForecastRestrictions** ↑

probability = testForecastRestrictions(model, restrictions)

Description:

Calculate probability of passing all forecast restrictions

Caution: Nowcast can not yet be tested!

Input:

- obj : A nb_model_forecast object with density forecast
- restrictions : Restrictions as a n x 3 cell array,
{variable, date, test}.
 - > variable : The variable(s) to test,
as a string or cell array of strings.
 - > date : The date as a string. If a cell array is given, a
copy of the restriction will be made for every given
date.
 - > test : Restriction test as a function handle. The value(s)
of the variable(s) in 'variable' at time 'date' are
passed as arguments. Should return a logical.

Output:

- out : A double with the probability

Example:

```
restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...  
{'QSA_URR', 'QSA_DPK_CP'}, '2014Q1', @(x, y) x < y};  
probability = model.testForecastRestrictions(restrictions);
```

See also [nb_testForecastRestrictions](#)

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_FORECAST

► **testParameters** ↑

```
dist = testParameters(obj, expression, draws, method)
```

Description:

Test (non-)linear expression by using bootstrapping (classical) or posterior draws.

Caution (classical only): This method uses that stdBeta is known.
This is the same as using that the t-statistic is normally distributed when stdBeta is known.

Hint : The parameter name can be found by
obj.parameters.name!

Input:

- obj : A scalar solved nb_model_generic object.
- expression : A MATLAB expression as a string. Use parameter names as variables. See model.parameters.name.
- method : A string with the method to use. For bootstrap method see nb_bootstrap. For bayesian models 'posterior' is the only option. Default is 'bootstrap' for classical models, while 'posterior' is the default for bayesian models.
- draws : Number of draws from the parameter distribution. Default is 1000.
- alpha : Confidence level. Default is 0.05.
- type : Type of test:
 - > '=' : Two sided test. expression == 0 (default)
For two-sided tests it is assumed that the distribution is symmetric! Use confidenc/probabillty intervals instead.
 - > '>' : One sided test. expression > 0
 - > '<' : One sided test. expression < 0

Output:

- pval : > 'classical' : P-value of test.
> 'bayesian' : Probabilty of test.

A 1x1 double.
- ci : A 1 x 2 double with the lower and upper bound of the confidence/probabillty interval of the tested expression.
- dist : A nb_distribution object storing the distribution of the tested expression.

Example:

```
dist = obj.testParameters('Parameter1 - Parameter2');
```

Written by Henrik Halvorsen Hortemo

Inherited from superclass NB_MODEL_GENERIC

► theoreticalMoments ↑

```
[m,c]           = theoreticalMoments(obj,varargin)
[m,c,ac1]       = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2]   = theoreticalMoments(obj,varargin)
[m,c,ac1,ac2,...] = theoreticalMoments(obj,varargin)
```

Description:

Calculate theoretical moments; I.e. mean, covariance/correlation, autocovariance/autocorrelation.

Caution : For recursively estimated model only the full sample estimation results is used.

Caution : Only supported for models that can be solved in the following way: $y(t) = A*y(t-1) + B*x(t) + C*e(t)$.

Input:

- obj : An object of class nb_model_generic.

Optional inputs;

- 'vars' : Either 'dependent' or 'full'. 'dependent' will return the moment of the dependent variables of the model without lag, while full will include all lags as well. 'dependent' is default.

Can also be a cellstr, with a subset of variables from 'full'.

- 'maxIter' : Maximum number of iterations to solve the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'tol' : The tolerance level when solving the lyapunov equation. Needed to calculate the covariance matrix of the model.

- 'output' : Either 'nb_cs' or 'double'. Default is 'nb_cs'.

- 'stacked' : If the output should be stacked in one matrix or not. true or false. Default is false.

- 'nLags' : Number of lags to compute when 'stacked' is set to true.

- 'type' : Either 'covariance' or 'correlation'. Default is

```

'correlation'.

- 'pDraws'      : Number of parameter draws. Default is 1. I.e. to use
                   the estimate parameters.

- 'perc'        : Error band percentiles. As a 1 x numErrorBand double.
                   E.g. [0.3,0.5,0.7,0.9]. Default is []. I.e. return the
                   all draws.

Caution: 'pDraws' must be set to a number > 1.

- 'method'       : The selected method to create confidenc/probability
                   bands. Default is '''. See help on the method input of
                   the nb_model_generic.parameterDraws method for more
                   this input.

- 'foundReplic'  : A struct with size 1 x pDraws. Each element
                   must be on the same format as obj.solution. I.e.
                   each element must be the solution of the model
                   given a set of drawn parameters. See the
                   parameterDraws method of the nb_model_generic class.

Caution: You still need to set 'parameterDraws'
          to the number of draws you want to do.

```

Output:

```

- varargout{1} : The mean, as a 1 x nVar x draws nb_cs object or double.

- varargout{2} : The contemporaneous covariances/correlations, as a nVar
                  x nVar nb_cs object or double. The variance is along
                  the diagonal. (Will be symmetric)

- varargout{i} : i > 2. The auto-covariances/correlations, as a nVar
                  x nVar nb_cs object or double. Along the diagonal is the
                  auto-covariance/correlation with the variable itself. In
                  the upper triangular part the you can find cov(x,y(-i)),
                  where x is the variable along the first dimension. In
                  the lower triangular part the you can find cov(x(-i),y),
                  where x is the variable along the first dimension.

E.g: You have two variables x and y, then to find
      cov(x,y(-i)) you can use
      getVariable(varargout{i}, 'y', 'x'),
      while to get cov(x(-i),y) (== cov(x,y(+i))) you
      can use getVariable(varargout{i}, 'x', 'y'). (This
      example only works if the output is of class nb_cs)

```

[nb_var.graphCorrelation](#), [nb_var.parameterDraws](#)

Written by Kenneth Åkerhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncertaintyDecomposition ↑**

```
[data,plotter] = uncertaintyDecomposition(obj,varargin)
```

Description:

Decompose the density forecast into shocks uncertainty.

Caution : Parameter uncertainty is not yet supported!

Input:

- obj : A vector of nb_model_generic objects
- 'compare2' : An object of class nb_model_generic. If this option is given the decomposition will be done of the difference in the uncertainty between the models. Only an options for 'method' set to 'percentiles'.
- 'method' : One of:
 - > 'percentiles' : This method simulate forecast based on each shock alone, and then calculate the percentile of the variables of interest based on these simulations. Percentiles are not a linear concept, so when aggregating the percentiles of each shock will not add up to the percentile of the distribution of the variable of interest. Therefore the contributions of each residual/shock is scaled with a factor to sum to the the percentiles of this distribution (default).
 - > 'fev' : Calculate the forecast error variances contributed by each shock based on the simulated densities of the residuals/shocks of models forecast.
- 'perc' : At which percentile you want to decompose. Must be scalar double. Default is 0.9. Only an options for 'method' set to 'percentiles'.
- 'packages' : Cell structure with groups of shocks and the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Caution : Not yet supported!

- 'startDate' : Start date of the decomposition. As a string. If different models has different frequency this date will be converted.
- 'variables' : The variables to decompose. Default is the dependent variables defined by the first model.

Output:

- data : Depend on the 'method' input:
 - > 'percentiles' : A nHor x (nExo + nRes)*2 x nVars nb_ts object storing the uncertainty decomposition.
 - > {'fevd','fesd'} : A nHor x nRes x nVars nb_ts object storing the numerically calculated forecast error variances/skewnesses.
- plotter : A nb_graph_ts object which the method graph can be used to produce graphs.

Written by Kenneth Å!terhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **uncondForecast** ↑

obj = uncondForecast(obj,nSteps,varargin)

Description:

Produced unconditional point and density forecast of nb_model_generic objects.

Input:

- obj : A vector of nb_model_generic objects.
- nSteps : Number of forecasting steps. As a 1x1 double. Default is 8.

Optional inputs:

- See the nb_model_generic.forecast method

Output:

- obj : A vector of nb_model_generic objects. See the property forecastOutput.

See also:

[nb_var.forecast](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► [unstruct](#) ↑

```
obj = nb_model_estimate.unstruct(s)
```

Description:

Convert a struct to an object which is a subclass of the nb_model_estimate class. This is how the nb_model_estimate object is loaded.

Input:

- s : A struct. See nb_model_estimate.struct.

Output:

- obj : An object which is a subclass of the nb_model_estimate class.

See also:

[nb_var.struct](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_ESTIMATE

► [update](#) ↑

```
obj      = update(obj,type)
[obj,valid] = update(obj,type,warningOn,inGUI,groupIndex,varargin)
```

Description:

Update data of model, and optionally re-estimate, re-solve and forecast the models given the update data

Input:

- obj : A vector of object of class nb_model_generic
- type : > '' : Only update data. Default
 > 'estimate' : Update data and estimate.
 > 'solve' : Update data, estimate and solve
 > 'forecast' : Update data, estimate, solve and forecast.

- warningOn : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'. Set it to 'off', if the 'write' option is used.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'. When 'on' a waitbar will be created to tell the user about the status.
- groupIndex : A 1 x nLevel double with the group level. Default is [].

Optional input:

- 'write' : Give this string as one of the optional inputs to write an error file if updating of data, estimation or forecasting failes. All objects will be returned, but can be removed by indexing by the valid output.
- 'waitbar' : Give this string as one of the optional inputs to add waitbar for the loop over models in the estimation step.

Output:

- obj : A vector of object of class nb_model_generic
- valid : A logical with size 1 x nObj. true at location ii if estimation or forecasting of model ii succeeded, otherwise false. If 'write' is not used an error will be thrown instead, so in this case this output will be true for all models.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

► **variance_decomposition ↑**

```
[decomp, decompBands, plotter, plotterBands] = ...
    variance_decomposition(obj, varargin)
```

Description:

Variance decomposition of a vector of nb_model_generic objects.

Caution : For recursivly estimated model only the full sample estimation results is used.

Input:

- obj : A vector of nb_model_generic objects
- 'horizon' : The horizons. As a 1 x nHor double. Default is [1:8, inf].

- 'replic' : The number of simulation for bootstrap and MC methods. Default is 1. Only used when 'perc' is provided.

Caution: Will not have anything to say for the method 'identDraws'. See the option 'draws' of the method nb_var.set_identification for more.
- 'shocks' : Which shocks to calculate variance decomposition of. Default is the residuals defined by the first model.
- 'variables' : The variables to create variance decomp of. Default is the dependent variables defined by the first model.
- 'perc' : Error band percentiles. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is not to provide error bands.
- 'method' : The selected method to create confidenc/probability bands. Default is ''. See help on the method input of the nb_model_generic.parameterDraws method for more this input. An extra option is:
 - > 'identDraws' : Uses the draws of the matrix with the map from structural shocks to dependent variables. See nb_var.set_identification. Of course this option only makes sence for VARs identified with sign restrictions.
- 'output' : Either 'closest2median' (default) or 'median'.
 - > 'closest2median' : The median is represented by the model(s) that are closest to the actual median.
 - > 'median' : The median represented by the numerical statistic.

Caution : Only an option when 'replic' > 1 and 'perc' is nonempty.
- 'parallel' : Give true if you want to do the forecast in parallel. Default is false.
- 'regime' : Select the regime to do the FEVD of. Only for Markov-switching model. If empty the ergodic mean will be used.
- 'foundReplic' : A struct with size 1 x replic. Each element must be on the same format as obj.solution. I.e. each element must be the solution of the model given a set of drawn parameters.
- 'stabilityTest' : Give true if you want to discard the draws that give rise to an unstable model. Default is false.
- 'packages' : Cell matrix with groups of shocks and

the names of the groups. If you have not listed a shock it will be grouped in a group called 'Rest'

Must be given in the following format:

```
{'shock_group_name_1',...,'shock_group_name_N';
 'shock_name_1'      ,...,'shock_name_N'}
```

Where 'shock_name_x' must be a string with a shock name or a cellstr array with the shock names. E.g 'E_X_NW' or {'E_X_NW','E_Y_NW'}.

If empty no packing will be done.

Output:

- decomp : A structure of nb_ts objects with the variance decomosition for each model. (If simulated it will store the median or closest to median dependent on the 'output' option)
- decompBands : A structure of structs with the percentiles of the variance decomosition for each model. For each percentiles the output is as decomp.
- plotter : A 1 x nModel vector of nb_graph_cs objects. Use the graph method or the nb_graphPagesGUI class to produce the graphs.
- plotterBands: A 1 x nModel struct. Each field is a 1 x nVars vector of nb_graph_cs objects. Use the graphSubPlots method to produce the graphs of each of the fields. This graphs will plot the contribution of each shock to each variable with error bands.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_MODEL_GENERIC

◆ **nb_calcMultiplier**

```
m = nb_calcMultiplier(dx,dy,r,gross)
```

Description:

Calculate multiplier using the formula (3) page 11 of "Clearing Up the Fiscal Multiplier Morass" (2015) by Leeper, Traum and Walker.

Input:

```
- dx      : A nObs x nVar x nSim double with the affected variables.  
- dy      : A nObs x 1 x nSim double with the policy variable of interest.  
- r       : A nObs x 1 x nSim double with the gross or net interest rates.  
- gross   : Give true if r is the gross interest rate (default) or false  
            if it is the net interest rate.
```

Output:

```
- m      : A 1 x nVar x nSim double with the calculated multipliers.
```

See also:

[nb_dsge.calculateMultipliers](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_compareCoeffs**

```
out = nb_compareCoeffs(model1,model2,sort)
```

Description:

Use this function to compare parameters between two models. Inputs can be coefficient files (structs) or nb_dsge-model objects. Only parameters that are found in both models will be displayed.

Input:

```
- model1 : Model 1 (coefficient file (struct) or nb_dsge-model object)  
- model2 : Model 2 (coefficient file (struct) or nb_dsge-model object)  
- sort   : Sorts output by relative difference. Logical. (optional). Default  
            is false (no sorting).
```

Output:

```
out      : Cell matrix that shows parameter names, values and absolute  
            and relative differences.
```

Examples: `out = nb_compareCoeffs(m_old, m_new, TRUE)`

See also:

Written by Erling M. Kravik

◆ **nb_COMPARESteadystate**

```
out = nb_compareCoeffs(model1,model2,sort)
```

Description:

Use this function to compare steady state values between two models. Inputs are nb_dsge-models. Only variables that are found in both models will be displayed.

Input:

- model1 : Model 1 (nb_dsge-model object)
- model2 : Model 2 (nb_dsge-model object)
- sort : Sorts output by relative difference. Logical. (optional). Default is false (no sorting). Only available from MatLab 2017.

Output:

out : Cell matrix that shows variable names, values and absolute and relative differences.

Examples: `out = nb_compareSteadystate(m_old, m_new, TRUE)`

See also:

◆ **nb_estimateDensityForforecast**

```
[vars,dist,dates] = nb_estimateDensityForforecast(model,start,hor)
```

Description:

Estimate distribution of the density forecast at a given period (date).

Input:

- model : A scalar nb_model_generic or nb_model_group object.
- start : The start date of the forecast of interest. As a string or a nb_date object. Default is the last forecast data.
- hor : Max horizon of interest. Default is as many as the model has forecasted.
- vars : A cellstr with variables of interest. Default is all the variables that have been forecast by the model.

Output:

- dist : A hor x nVars nb_distribution object.
- dates : A hor x 1 cellstr with the dates of the forecast.
- vars : A 1 x nVars cellstr with the variables of the forecast.

Written by Kenneth Sætherhagen Paulsen

◆ nb_forecast2Excel

`nb_forecast2Excel(fcst,filename)`

Description:

Save down forecast return by the `nb_model_vintages.getForecast` method to excel.

Input:

- fcst : An object of class `nb_ts`.
- filename : Name of excel file. E.g. '`test`'.

See also:

[nb_model_vintages.getForecast](#)

Written by Kenneth Sætherhagen Paulsen

◆ nb_getModelNames

`names = nb_getModelNames(varargin)`

Description:

Get model names, if some model names are empty, they will be given the default name '`Model<ii>`'.

Input:

- varargin : Each input must be an object of class `nb_model_generic` or `nb_model_group`

Output:

- names : A 1 x N cellstr.

Written by Kenneth Sætherhagen Paulsen

◆ nb_isModelMarkovSwitching

```
ret = nb_isModelMarkovSwitching(model)
```

Description:

Test if a model is a Markov switching. See nb_model_generic.solution for more on the model input.

Output:

- ret : true if Markov switching model.

Written by Kenneth Sæterhagen Paulsen

◆ nb_plotPPAMultipliers

```
plotter = nb_plotPPAMultipliers(mult,shock,variable,perc)
```

Description:

Plot output from the priorPredictiveAnalysis method when the method input is set to calculateMultipliers.

Input:

- mult : The output from priorPredictiveAnalysis.
- shock : The shock you want to graph. As a one line char.
- variable : The variable you want to graph. As a one line char.
- perc : This options sets the error band percentiles of the graph. As a 1 x numErrorBand double. E.g. [0.3,0.5,0.7,0.9]. Default is 0.68.

Output:

- plotter : An object of class nb_graph_cs, use the graph method or the nb_graphPagesGUI class. If nargout == 0, the graph will be made using the nb_graphPagesGUI class.

► nb_fitness.standard ↑

```
fit = nb_fitness.standard(fVal,fMin,Q)
```

Description:

Calculates the fitness function

```
fit = 1/(1 + fVal) if fVal >= 0  
fit = 1 + abs(fVal) if fVal < 0
```

Input:

- fVal : Value of function. As a N x M double.
- fMin : Minimum value of function obtained until now. As a scalar double. Not in use.
- Q : Scaling parameter. Not in use.

Output:

- fit : Fitness score. As a N x M double.

Written by Kenneth Sæterhagen Paulsen

► nb_fitness.standardDev ↑

```
fit = nb_fitness.standardDev(fVal,fMin,Q)
```

Description:

Calculates the fitness function

```
fit = 1/(Q + fVal - fMin)
```

Input:

- fVal : Value of function. As a N x M double.
- fMin : Minimum value of function obtained until now. As a scalar double.
- Q : Scaling parameter.

Output:

- fit : Fitness score. As a N x M double.

Written by Kenneth Sæterhagen Paulsen

► **nb_fitness.standardDevSq** ↑

```
fit = nb_fitness.standardDevSq(fVal, fMin, Q)
```

Description:

Calculates the fitness function

```
fit = 1/(Q + (fVal - fMin)^2 )
```

Input:

- fVal : Value of function. As a N x M double.
- fMin : Minimum value of function obtained until now. As a scalar double.
- Q : Scaling parameter.

Output:

- fit : Fitness score. As a N x M double.

Written by Kenneth Sæterhagen Paulsen

► **nb_fitness.standardDevSqrt** ↑

```
fit = nb_fitness.standardDevSqrt(fVal, fMin, Q)
```

Description:

Calculates the fitness function

```
fit = 1/(Q + sqrt(fVal - fMin) )
```

Input:

- fVal : Value of function. As a N x M double.
- fMin : Minimum value of function obtained until now. As a scalar double.
- Q : Scaling parameter.

Output:

- fit : Fitness score. As a N x M double.

Written by Kenneth Sæterhagen Paulsen

► pso.binary ↑

```
psobinary(fitnessfcn,nvars)
psobinary(fitnessfcn,nvars,options)
```

Description:

Particle swarm optimization for binary genomes.

This function will optimize fitness functions where the variables are row vectors of size 1xnvars consisting of only 0s and 1s.

PSO.BINARY is provided as a wrapper for PSO.DO, to avoid any confusion. This is because the binary optimization scheme is not designed to take any constraints. PSO.BINARY does not allow the passing of constraints. It takes a given optimization problem with binary variables, and automatically sets the options structure so that 'PopulationType' is 'bitstring'.

This has exactly the same effect as setting the appropriate options manually, except that it is not possible to unintentionally define constraints, which would be ignored by the binary variable optimizer anyway.

Problems with hybrid variables (double-precision and bit-string combined) cannot be solved yet.

The output variables for PSO.BINARY is the same as for PSO.DO.

► pso.do ↑

```
x = pso.do(fitnessfcn,nvars)
x = pso.do(fitnessfcn,nvars,Aineq,bineq)
x = pso.do(fitnessfcn,nvars,Aineq,bineq,Aeq,beq)
x = pso.do(fitnessfcn,nvars,Aineq,bineq,Aeq,beq,LB,UB)
x = pso.do(fitnessfcn,nvars,Aineq,bineq,Aeq,beq,LB,UB,nonlcon)
x = pso.do(fitnessfcn,nvars,Aineq,bineq,Aeq,beq,LB,UB,nonlcon,options)
x = pso.do(problem)
[x, fval,exitflag] = pso.do(...)
[x, fval,exitflag,output] = pso.do(...)
[x, fval,exitflag,output,population] = pso.do(...)
[x, fval,exitflag,output,population,scores] = pso.do(...)
```

Description:

Find the minimum of a function using Particle Swarm Optimization.

This is an implementation of Particle Swarm Optimization algorithm using the same syntax as the Genetic Algorithm Toolbox, with some additional options specific to PSO. Allows code-reusability when trying different population-based optimization algorithms. Certain GA-specific parameters such as cross-over and mutation functions will not be applicable to the PSO algorithm. Demo function included, with a small library of test functions. Requires Optimization Toolbox.

New features will be added regularly until this is made redundant by an official MATLAB PSO toolbox.

```
x = pso.do(fitnessfcn,nvars)
Runs the particle swarm algorithm with no constraints and default
options. fitnessfcn is a function handle, nvars is the number of
parameters to be optimized, i.e. the dimensionality of the problem. x is
a 1xnvars vector representing the coordinates of the global optimum
found by the pso algorithm.
```

```
x = pso.do(fitnessfcn,nvars,Aineq,bineq)
Linear constraints, such that Aineq*x <= bineq. Aineq is a matrix of size
nconstraints x nvars, while b is a column vector of length nvars.
```

```
x = pso.do(fitnessfcn,nvars,Aineq,bineq,Aeq,beq)
Linear equality constraints, such that Aeq*x = beq. 'Soft' or 'penalize'
boundaries only. If no inequality constraints exist, set Aineq and bineq
to [].
```

```
x = pso.do(fitnessfcn,nvars,Aineq,bineq,Aeq,beq,lb,ub)
Lower and upper bounds defined as LB and UB respectively. Both LB and UB,
if defined, should be 1 x nvars vectors. Use empty arrays [] for Aineq,
```

bineq, Aeq, or beq if no linear constraints exist.

```
x = pso.do(fitnessfcn,nvars,Aineq,bineq,Aeq,beq,LB,UB,nonlcon)
Non-linear constraints. Nonlinear inequality constraints in the form c(x)
<= 0 have now been implemented using 'soft' boundaries, or
experimentally, using 'penalize' constraint handling method. See the
Optimization Toolbox documentation for the proper syntax for defining
nonlinear constraints. Use empty arrays [] for Aineq, bineq, Aeq, beq,
LB, or UB if they are not needed.
```

```
x = pso.do(fitnessfcn,nvars,Aineq,bineq,Aeq,beq,LB,UB,nonlcon,options)
Default algorithm parameters replaced with those defined in the options
structure:
Use >> options = psooptimset('Param1','value1','Param2','value2',...
to generate the options structure. Type >> psooptimset with no input or
output arguments to display a list of available options and their
default values.
```

NOTE: the swarm will perform better if the PopInitRange option is defined so that it closely bounds the expected domain of the feasible region. This is automatically done if the problem has both lower and upper bound constraints, but not for linear and nonlinear constraints.

NOTE 2: If options.HybridFcn is to be defined, and if it is necessary to pass a non-default options structure to the hybrid function, then the options structure may be included in a cell array along with the pointer to the hybrid function. Example:

```
>> % Let's say that we want to use fmincon to refine the result from PSO:
>> hybridoptions = optimset(@fmincon) ;
>> options.HybridFcn = {@fmincon, hybridoptions} ;
```

NOTE 3:

Perez and Behdinan (2007) demonstrated that the particle swarm is only stable if the following conditions are satisfied:

Given that C0 = particle inertia

```
C1 = options.SocialAttraction
C2 = options.CognitiveAttraction
1) 0 < (C1 + C2) < 4
2) (C1 + C2)/2 - 1 < C0 < 1
```

If conditions 1 and 2 are satisfied, the system will be guaranteed to converge to a stable equilibrium point. However, whether or not this point is actually the global minimum cannot be guaranteed, and its acceptability as a solution should be verified by the user.

```
x = pso.do(problem)
Parameters imported from problem structure.
```

```
[x,fval] = pso.do(...)
Returns the fitness value of the best solution.
```

```
[x,fval,exitflag] = pso.do(...)
Returns information on outcome of pso run. This should match exitflag
values for GA where applicable, for code reuseability between the two
toolboxes.
```

```
[x,fval,exitflag,output] = pso.do(...)
The structure output contains more detailed information about the PSO
run. It should match output fields of GA, where applicable.
```

```
[x,fval,exitflag,output,population] = pso.do(...)  
A matrix population of size MaxNodes x nvars, with the locations of  
particles across the rows. This may be used to save the final positions  
of all the particles in a swarm.
```

```
[x,fval,exitflag,output,population,scores] = pso.do(...)  
Final scores of the particles in population.
```

Edited by Kenneth S. Paulsen

- Made it into a function of the pso package. 10/2018
- Removed the default problem to solve. 11/2018

► **pso.optimset** ↑

```
pso.optimset  
options = pso.optimset  
options = pso.optimset(@pso)  
options = pso.optimset(@psomultiobj)  
options = pso.optimset('param1',value1,'param2',value2,...)  
options = pso.optimset(olddopts,'param1',value1,...)  
options = pso.optimset(olddopts,newopts)
```

Description:

`psooptimset` with no input or output arguments displays a complete list of parameters with their valid values.

`options = psooptimset` (with no input arguments) creates a structure called `options` that contains the options, or parameters, for the `pso` algorithm and sets parameters to `[]`, indicating default values will be used.

`options = psooptimset(@pso)` creates a structure called `options` that contains the default options for the genetic algorithm.

`options = psooptimset(@psomultiobj)` creates a structure called `options` that contains the default options for `psomultiobj`. Not yet implemented

`options = psooptimset('param1',value1,'param2',value2,...)` creates a structure options and sets the value of 'param1' to value1, 'param2' to value2, and so on. Any unspecified parameters are set to their default values. Case is ignored for parameter names.

`options = psooptimset(olddopts,'param1',value1,...)` creates a copy of oldopts, modifying the specified parameters with the specified values.

`options = psooptimset(olddopts,newopts)` combines an existing options structure, oldopts, with a new options structure, newopts. Any parameters in newopts with nonempty values overwrite the corresponding old parameters in oldopts.

Again, type `psooptimset` with no input arguments to display a list of options which may be set.

NOTE regarding the `ConstrBoundary` option:

The 'penalize' constraint management option as described in Perez 2007 is the default since it seems to provide the best combination of performance and versatility. It combines the best of the 'soft' and 'absorb' methods and adds a penalty calculated for every infeasible point in the search space.

Although the 'penalize' method is preferred, the 'soft' or 'absorb' style boundaries may still be used. They are described below. They are not very effective if your problem contains any nonlinear equality constraints of the form $c(x) = 0$ or linear equality constraints of the form $A_{eq}x = b_{eq}$. If your problem does not require any equality constraints, then calculations may be faster with 'soft' boundaries since infeasible solutions are not evaluated at all and simply assigned a fitness score of infinity.

A 'soft' boundary allows particles to leave problem bounds, but sets their fitness scores to Inf if they do. This can save time, since infeasible points are not evaluated. This will also save you some trouble if your fitness function has the possibility of throwing errors if it tries to evaluate an infeasible point in the search space.

The 'reflect' and 'absorb' options prevent the particles from travelling outside the problem bounds at all. Note that 'reflect' has only been implemented for bounded constraints, and is not really suitable for any other problem type at this time. The 'absorb' method may suffer from poor performance if linear or nonlinear equality constraints are used. Both are likely to be deprecated in the near future.

NOTE regarding cognitive and social attraction parameters:

Perez and Behdinan (2007) demonstrated that the particle swarm is only stable if the following conditions are satisfied:

Given that C_0 = particle inertia

C_1 = `options.SocialAttraction`

C_2 = `options.CognitiveAttraction`

- 1) $0 < (C_1 + C_2) < 4$
- 2) $(C_1 + C_2)/2 - 1 < C_0 < 1$

If conditions 1 and 2 are satisfied, the system will be guaranteed to converge to a stable equilibrium point. However, whether or not this point is actually the global minimum cannot be guaranteed, and its acceptability as a solution should be verified by the user.

An implementation of the artificial bee colony algorithm by Karaboga.

References:

"A comprehensive survey: Artificial bee colony (ABC) algorithm and applications", Karaboga et. al (2012).

"Modified artificial bee colony algorithm for constrained problems optimization", Stanarevic et. al (2015)

This class tries to solve the following problem

min Q(x)
x in S

Or the constrained problem

min Q(x)
x in S

s.t. x in F

Where Q is the objective to minimize and x is the inputs to the objective. S is the search space, i.e. the space to look for candidate values that minimizes the objective Q. F is the feasible space, and can be provided by using the constraints property. You can apply both inequality constraints $g(x) \leq 0$ or equality constraints $h(x) == 0$. In the latter case you will apply the inequality constraints $\text{abs}(h(x)) - \text{tolerance} \leq 0$, where tolerance is a small number. It can be set using the field tolerance of the options struct.

Caution: The steps of this implementation is slightly different from that of Karaboga et. al (2012).

Initialize employed bees by scouting.

Repeat:

1. Employed bees that has reached the cutLimit are sent out scouting. See nb_bee.scout.
2. Send onlookers to join the employed bees by random. Higher probabilities are assign to the employed bees that communicates good values of the objective. Finally onlookers are sent to explore the neighbourhood of the selected employed bee by changing the value of one parameter, which is selected at random. See nb_bee.joinDance. The probabilities are calculated accordingly to Stanarevic et. al (2015) in the case of constrained minimization.
3. Employed bees are then sent to explore their neighbourhood by changing the value of one parameter, which is selected at random. See nb_bee.dance.
4. All the new points of the bees are evaluated. (This is the step that can be ran in parallel.)
5. The best point in the parameter space is saved.

This is repeated until some of the limits (maxTime, maxFunEvals, maxIter or maxTimeSinceUpdate are reached).

Superclasses:

handle

Constructor:

```
obj = nb_abc(fh,init,lb,ub)
obj = nb_abc(fh,init,lb,ub,options,varargin)
```

Input:

- fh : See the documentation of the objective property of the nb_abc class.
- init : See the documentation of the initialXValue property of the nb_abc class.
- lb : See the documentation of the lowerBound property of the nb_abc class.
- ub : See the documentation of the upperBound property of the nb_abc class.
- options : See the nb_abc.optimset method for more on this input.

Optional inputs:

- varargin : Optional number of inputs given to the objective when it is called during the minimization algorithm.

Output:

- obj : An object of class nb_abc.

- saveName
- saveTime
- tolerance
- upperBound
- useParallel

- bees ↑

A vector of nb_bee objects.

- constraints ↑

A function handle that applies the linear or non-linear constraint on the parameters. If not given, or given as [], unconstrained minimization will be done.

It must return two outputs. The first output must be a vector with the values of the inequality constraints $g(x) \leq 0$. Positive numbers means violation. The second input must return a vector with the values of the equality constraints $h(x) == 0$. If $\text{abs}(h(x)) > \text{options.tolerance}$ means a violation.

Example:

```
function [c,ceq] = conFunc(x,a)
    c = a*x(1) - x(2); % inequality constraint a*x(1) - x(2) <= 0
    ceq = x(3) - x(2); % equality constraint x(3) - x(2) == 0
end
```

- cutLimit ↑

Positive integer. The maximum trial that is allowed for employed bee before it starts to scout for another area. Default is 20. Must be greater than 4.

- display ↑

'iter' Level of display. 'iter' displays output at each iteration. Only supported option.

- **display** ↑

An object of class nb_optimizerDisplayer. This object set the way the optimizer displayes result during the optimization.

- **doHessian** ↑

Set to false to not calculate the Hessian at the found minimum. If true the Hessian will be calculated using the nb_hessian function. Default is true

- **employedShare** ↑

This set the share of employed bees. Default is 0.33, i.e. 33%. Must be in the set (0.1,0.9).

- **exitFlag** ↑

The reason for exiting. One of:

```
> 0 : Maximum function evaluation limit exceeded (maxFunEvals).  
> -1 : Maximum iteration limit exceeded (maxIter).  
> -2 : Maximum time limit exceeded (maxTime).  
> -3 : Maximum time limit since last update exceeded  
        (maxTimeSinceUpdate).  
> -4 : User stop the optimization manually.
```

- **fitnessFunc** ↑

A function handle that return the fitness of each bee at each iteration of the optimization. See for example nb_fitness.standard, which is the default fitness function. Other proper fitness functions may be found in the nb_fitness package.

- **fitnessScale** ↑

This set the value of the fitness scaling parameter. Default is 1. This is the third input to the function given by the fitnessFunc property.

- **funEvals** ↑

Number of function evaluations.

- **hasConstraints** ↑

true if minimization is constrained, otherwise false. See constraints property.

- **hessian** ↑

A nVar x nVar double with the estimated Hessian at the found minimum.

- **initialXValue** ↑

The initial values of the optimization. Default is zero. As a N x 1 double.

- **iterations** ↑

Number of iteration of the abc algorithm.

- **lowerBound** ↑

The lower bound on the x values. As a N x 1 double. Must be finite!

- **maxFunEvals** ↑

Positive integer. Maximum number of function evaluation allowed. Default is inf.

- **maxIter** ↑

Positive integer. Maximum number of iterations allowed. Default is inf.

- **maxNodes** ↑

Positive integer. The number of bees to use during optimization.

- **maxTime** ↑

Positive integer. The maximum time spent on optimization in seconds.

- **maxTimeSinceUpdate** ↑

Positive integer. The maximum time spent on optimization since last time the minimum point where updated (in seconds).

- **maxTrials** ↑

Positive integer. The maximum trial that is allowed for finding initial candidates. Default is 100.

- **minFunctionValue** ↑

The minimized value found during the optimization. As a scalar double.

- **minXValue** ↑

The x values at the located minimum. As a nVar x 1 double.

- **numWorkers** ↑

Positive integer. Number of worker to use when running optimization in parallel.

- **objective** ↑

The objective to minimize. As a function handle. Must take a N x 1 double as the first input.

- **objectiveLimit** ↑

Double. If the objective return a value greater than this, a new candidate of x is drawn. Default is 1e9.

- **options** ↑

A struct with the options of the optimiziation. See the nb_abc.optimset method for more on this option.

- **saveName** ↑

Name of the file to save the object, with path, but without extension.

- **saveTime** ↑

The time between saving of the object.

- **tolerance** ↑

Tolerance value used for equality constraint optimization problems.

- **upperBound** ↑

The upper bound on the x values. As a n x 1 double. Must be finite!

- **useParallel** ↑

true or false. Give true if the nodes should be spread on different parallel workers.

Methods:

- call • minimize • optimset • restart • set
- test • testConstrained • testParallel • testSave

► **call** ↑

```
[x,fval,exitflag,hessian] = nb_abc.call(fh,init,lb,ub,options,constraints,varargin)
```

Description:

Call the artificial bee colony algorithm. See the documentation of the nb_abc class for more on this algorithm.

Input:

- fh : See the documentation of the objective property of the nb_abc class.
- init : See the documentation of the initialXValue property of the nb_abc class.
- lb : See the documentation of the lowerBound property of the nb_abc class.
- ub : See the documentation of the upperBound property of the nb_abc class.
- options : See the nb_abc.optimset method for more on this input.
- constraints : See the documentation of the constraints property of the nb_abc class.

Optional inputs:

- varargin : Optional number of inputs given to the objective when it is called during the minimization algorithm.

Output:

- x : See the documentation of the minXValue property of the nb_abc class.
- fval : See the documentation of the minFunctionValue property of the nb_abc class.
- exitflag : See the documentation of the exitFlag property of the nb_abc class.
- hessian : See the documentation of the hessian property of the nb_abc class.

Examples:

```
g = @(x)-sin(x);  
x3 = nb_abc.call(g,-3,-4,4)
```

See also:

[nb_abc.optimset](#), [fmincon](#), [fminunc](#), [fminsearch](#), [bee_gate](#)

Written by Kenneth Sæterhagen Paulsen

► **minimize** ↑

```
minimize(obj)
minimize(obj,varargin)
```

Description:

Run minimization on the given objective.

Input:

- obj : An object of class nb_abc.

Optional input:

- varargin : Given to the nb_abc.set method.

Output:

The provided object of class nb_abc has been updated the following properties;
> minXValue
> minFunctionValue
> exitFlag
> hessian

See also:

[nb_abc.call](#)

Written by Kenneth Sæterhagen Paulsen

► **optimset** ↑

```
options = nb_abc.optimset(varargin)
```

Description:

Get optimization settings or help.

Optional input:

- Run without inputs to get defaults.
- Run with 'list' as the first input to get a cellstr with the supported options.
- Run with 'help' to get a struct with help on each option.

- Run with 'optionName' to get help on a particular option, i.e. only one input.
- Use 'optionName', optionValue pairs to set options of the returned struct.

Output:

- Depends on the input.

See also:

[nb_abc.options](#)

Written by Kenneth Sæterhagen Paulsen

► **restart** ↑

```
[x,fval,exitflag,hessian] = restart(obj)
```

Description:

Call the artificial bee colony algorithm. See the documentation of the nb_abc class for more on this algorithm.

Input:

- obj : A nb_abc object that has been stopped or saved.

Output:

- x : See the documentation of the minXValue property of the nb_abc class.
- fval : See the documentation of the minFunctionValue property of the nb_abc class.
- exitflag : See the documentation of the exitFlag property of the nb_abc class.
- hessian : See the documentation of the hessian property of the nb_abc class.

See also:

[nb_abc.call](#)

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Set properties of the object using 'propertyName', PropertyValue pairs.

Input:

- obj : An object of class nb_abc.

Optional inputs:

- varargin: 'propertyName', PropertyValue pairs

Output:

- obj : An object of class nb_fmin where the wanted properties has been set.

Examples:

```
set(obj,'initialXValue',2,'lowerBound',0)
```

See also:

[nb_abc.optimset](#)

Written by Kenneth Sæterhagen Paulsen

► **test ↑**

```
nb_abc.test()
```

Description:

Test the ABC algorithm on the Rosenbrock Valley function;

```
f = 100*(x(2) - x(1)^2)^2 + (x(1) - 1)^2
```

The optimizer stops when it is 60 second since last time the minimum where updated.

Output:

- [x,fval,exitflag,hessian] : See the nb_abc.call method for more on these outputs.

See also:

[nb_abc.call](#)

Written by Kenneth Sæterhagen Paulsen

► **testConstrained** ↑

`nb_abc.testConstrained()`

Description:

Test the ABC algorithm on the Rosenbrock Valley function;

$$f = 100 * (x(2) - x(1)^2)^2 + (x(1) - 1)^2$$

$$\text{s.t. } x(2) - x(1) \leq 0$$

The optimizer stops when it is 60 second since last time the minimum where updated.

Output:

- `[x,fval,exitflag,hessian]` : See the `nb_abc.call` method for more on these outputs.

See also:

[nb_abc.call](#)

Written by Kenneth Sæterhagen Paulsen

► **testParallel** ↑

`nb_abc.testParallel()`

Description:

Test the ABC algorithm in parallel on the Rosenbrock Valley function;

$$f = 100 * (x(2) - x(1)^2)^2 + (x(1) - 1)^2$$

Output:

- `[x,fval,exitflag,hessian]` : See the `nb_abc.call` method for more on these outputs.

See also:

[nb_abc.call](#)

► **testSave** ↑

`nb_abc.test()`

Description:

Test the ABC algorithm on the Rosenbrock Valley function;

`f = 100*(x(2) - x(1)^2)^2 + (x(1) - 1)^2`

The optimizer stops when it is 60 second since last time the minimum where updated.

Output:

- `[x,fval,exitflag,hessian]` : See the `nb_abc.call` method for more on these outputs.

See also:

[nb_abc.call](#)

■ **nb_bee**

Go to: [Properties](#) | [Methods](#)

A class representing a bee in the artificial bee colony (ABC) algorithm by Karaboga et. al (2012) or the constrained version by Stanarevic et. al (2015).

Constructor:

`obj = nb_bee(n);`

Input:

- `n` : Number of objects to initialize, as a scalar integer.

Output:

- `obj` : An object of class `nb_bee`.

See also:

[nb_abc](#), [nb_abc.call](#)

Properties:

- **current**
- **currentFeasible**
- **currentValue**
- **currentViolation**
- **fitness**
- **index**
- **tested**
- **testedFeasible**
- **testedValue**
- **testedViolation**
- **trials**
- **type**

- **current** ↑

Current location of the bee. Used by employed bees only.

- **currentFeasible** ↑

Indicate if the current point is feasible or not given the constraints. Default is true.

- **currentValue** ↑

Current objective value of the bee. Used by employed bees only.

- **currentViolation** ↑

Current constraint violation of the bee. Used by employed bees only.

- **fitness** ↑

The fitness at the current point. Used by employed bees only.

- **index** ↑

The index of the employed bee that the onlooker bee is dancing with. Used by onlooker bees only.

- **tested** ↑

Tested location of the bee.

- **testedFeasible** ↑

Indicate if the tested point is feasible or not given the constraints. Default is false.

- **testedValue** ↑

Objective value of the bee at the tested location.

- **testedViolation** ↑

Constraint violation of the bee at the tested location.

- **trials** ↑

The number of trials at the current area. Used by employed bees only.

- **type** ↑

The type of bee. Either 'employed' or 'onlooker'.

Methods:

- calcFitness
- drawCandidates
- initialize
- scout
- updateLocation
- calculateProbabilities
- evaluate
- joinDance
- separate
- dance
- evaluateParallel
- relocate
- tournamentSelection

► **calcFitness** ↑

```
obj = calcFitness(obj, fitnessFunc, fitnessScale, fMin)
```

Description:

Calculate fitness score at the current best value of each employed bee.

Input:

- obj : A vector of nb_bee objects.
- fitnessFunc : See the property with the same name in the nb_abc class.
- fitnessScale : See the property with the same name in the nb_abc class.
- fMin : The smallest function evaluation found up until now.

Output:

- obj : A vector of nb_bee objects.

See also:

[nb_abc.doMinimization](#)

Written by Kenneth Sæterhagen Paulsen

► **calculateProbabilities** ↑

```
prob = calculateProbabilities(employed,hasConstraints)
```

Description:

Without constraints:

Calculate the probability values for the solutions using fitness of the solutions by

```
p(i) = f(i)/sum_i(f(i))
```

See "A comprehensive survey: Artificial bee colony (ABC) algorithm and applications", Karaboga et. al (2012).

With constraints:

Calculate the probability values for the solutions using fitness of the solutions and the constraint violations (CV) by

```
p(i) = 0.5 + f(i)/sum_i(f(i))*0.5, if solution is feasible.  
p(i) = (1 - CV(i)/sum_i(CV(i)))*0.5, if solution is infeasible.
```

See "Modified artificial bee colony algorithm for constrained problems optimization", Stanarevic et. al (2015)

Input:

- employed : A vector of employed nb_bee objects.
- hasConstraints : True if we are doing constrained maximization, or false otherwise.

Output:

- prob : The probabilities of onlooker bees to join the dance of employed bees.

See also:

[nb_bee.joinDance](#)

Written by Kenneth Sæterhagen Paulsen

► **dance ↑**

```
obj = dance(obj,lowerBound,upperBound)
```

Description:

Make the employed bees move at random in their dancing area.

See https://en.wikipedia.org/wiki/Artificial_bee_colony_algorithm for how the employed bees are dancing.

Input:

- obj : A vector of nb_bee objects.
- lowerBound : See the property with the same name in the nb_abc class.
- upperBound : See the property with the same name in the nb_abc class.

Output:

- obj : A vector of nb_bee objects.

See also:

[nb_bee.relocate](#)

Written by Kenneth Sæterhagen Paulsen

► **drawCandidates** ↑

```
draws = nb_bee.drawCandidates(lb,ub,nPar,nBees)
```

Description:

Draw candidates from a N dimensional box.

Input:

- lb : A double vector with size nPar x 1.
- ub : A double vector with size nPar x 1.
- nPar : The number of parameters.
- nBees : The number of bees.

Output:

- draws : A double with size nPar x nBees with the randomly selected parameters inside the box.

See also:

[nb_bee.initialize](#), [nb_bee.scout](#)

Written by Kenneth Sæterhagen Paulsen

► **evaluate** ↑

```
obj = evaluate(obj,objective,constrFunc)
```

Description:

Evaluate the bees at their tested locations.

Input:

- obj : A vector of nb_bee objects.
- objective : See the property with the same name in the nb_abc class.
- constrFunc : See the output from nb_abc.getConstraints.

Output:

- obj : A vector of nb_bee objects.

See also:

[nb_abc.doMinimization](#)

Written by Kenneth Sæterhagen Paulsen

► **evaluateParallel ↑**

```
obj = evaluateParallel(obj,objective,constrFunc)
```

Description:

Evaluate the bees at their tested locations.

Input:

- obj : A vector of nb_bee objects.
- objective : See the property with the same name in the nb_abc class.
- constrFunc : See the output from nb_abc.getConstraints.

Output:

- obj : A vector of nb_bee objects.

See also:

[nb_abc.doMinimization](#)

► **initialize** ↑

```
[obj,funEvals] = initialize(obj,objective,lowerBound,upperBound,...  
    objectiveLimit,maxTrials,constrFunc)
```

Description:

Initialize the bees that are going to be employed.

Input:

- obj : A vector of nb_bee objects.
- objective : See the property with the same name in the nb_abc class.
- objectiveInputs : See the property with the same name in the nb_abc class.
- lowerBound : See the property with the same name in the nb_abc class.
- upperBound : See the property with the same name in the nb_abc class.
- objectiveLimit : See the property with the same name in the nb_abc class.
- maxTrials : See the property with the same name in the nb_abc class.
- constrFunc : See the output from nb_abc.getConstraints.

Output:

- obj : A vector of nb_bee objects. The type property has been set to 'employed'.
- funEvals : Number of function evaluations during initialization.

► **joinDance** ↑

```
obj = joinDance(obj,employed,lowerBound,upperBound,hasConstraints)
```

Description:

Make the onlooker bees find a employed bee to dance with.

See https://en.wikipedia.org/wiki/Artificial_bee_colony_algorithm for how the onlooker bees are dancing.

Input:

- obj : A vector of nb_bee objects.
- lowerBound : See the property with the same name in the nb_abc class.
- upperBound : See the property with the same name in the nb_abc class.
- hasConstraints : See the property with the same name in the nb_abc class.

Output:

- obj : A vector of nb_bee objects.

See also:

[nb_bee.relocate](#)

Written by Kenneth Sæterhagen Paulsen

► **relocate ↑**

obj = relocate(obj,lowerBound,upperBound,cutLimit,hasConstraints)

Description:

Relocate the bees.

Input:

- obj : A vector of nb_bee objects.
- lowerBound : See the property with the same name in the nb_abc class.
- upperBound : See the property with the same name in the nb_abc class.
- cutLimit : See the property with the same name in the nb_abc class.
- hasConstraints : See the property with the same name in the nb_abc class.

Output:

- obj : A vector of nb_bee objects.

See also:

[nb_abc.doMinimization](#)

Written by Kenneth Sæterhagen Paulsen

► **scout** ↑

obj = scout(obj,lowerBound,upperBound,hasConstraints)

Description:

Employ scouts to new dancing areas.

See https://en.wikipedia.org/wiki/Artificial_bee_colony_algorithm for how the bees are scouting.

Input:

- obj : A vector of nb_bee objects.
- lowerBound : See the property with the same name in the nb_abc class.
- upperBound : See the property with the same name in the nb_abc class.
- hasConstraints : See the property with the same name in the nb_abc class.

Output:

- obj : A vector of nb_bee objects.

See also:

[nb_bee.relocate](#)

Written by Kenneth Sæterhagen Paulsen

► **separate** ↑

```
[employed,onlookers]      = separate(obj,cutLimit)
[employed,onlookers,scouts] = separate(obj,cutLimit)
```

Description:

Separate the bees into employed, scouts and onlookers.

Input:

- obj : A vector of nb_bee objects.
- cutLimit : See the property with the same name in the nb_abc class. Only needed if nargout > 2.

Output:

- employed : These are the employed bees that are keep dancing in their current area if nargout == 3, else it is all the employed bees.
- onlookers : These are the bees that are joing the dance of the most succesful employed bees.
- scouts : These are the employed bees that are going to scout for a new dancing area.

Written by Kenneth SÃ¶therhagen Paulsen

► tournamentSelection ↑

```
ret = tournamentSelection(obj,currentLeader)
```

Description:

Play out pairwise tournament between two bees.

We use Deb's rules to select the best candidate:

1. Any feasible solution is preferred to any infeasible solution.
2. Among two feasible solutions, the one having better objective function value is preferred.
3. Among two infeasible solutions, the one having smaller constraint violation is preferred.

Here a feasible solution does satisfies the constrains applied to the parameters, while a infeasible solution does not.

Input:

- obj : The tested bee.
- currentLeader : The bee that is currently the best.

Output:

- ret : If true is returned tested be should be made the new leader.

See also:

[nb_bee.updateLocation](#)

Written by Kenneth Sæterhagen Paulsen

► **updateLocation** ↑

obj = updateLocation(obj)

Description:

Update the location based on their last evaluation.

Input:

- obj : A vector of nb_bee objects.

Output:

- obj : A vector of nb_bee objects.

See also:

[nb_abc.doMinimization](#)

Written by Kenneth Sæterhagen Paulsen

■ **nb_optimizerDisplayer**

Go to: [Properties](#) | [Methods](#)

A class you can use to display the progress during optimization, i.e. you can pass the method handle

@(x,optVal,state) obj.update(x,optVal,state)

to the OutputFcn option to the optimizer you use. Here obj must be an object of class nb_optimizerDisplayer.

Superclasses:

handle

Constructor:

obj = nb_optimizerDisplayer(varargin)

Input:

- See the set method.

Output:

- obj : An object of class nb_optimizerDisplayer.

See also:

[fmincon](#), [fminunc](#), [fminsearch](#), [nb_fmin](#)

Written by Kenneth Sølnerhagen Paulsen

Properties:

- `axesHandle`
- `figureHandle`
- `formatDone`
- `formatIter`
- `fval`
- `includeStop`
- `includeTime`
- `iteration`
- `names`
- `notifyStep`
- `plotHandle`
- `problemSize`
- `stepLength`
- `stopped`
- `storeMax`
- `textBoxHandle`
- `type`
- `usedNorm`
- `x`

- **axesHandle** [↑](#)

The handle to the axes object where the iterations values are plotted.

- **figureHandle** [↑](#)

The handle to the figure where the optimization iterations are displayed.

- **formatDone** [↑](#)

Format of printed output when the optimizer has converged. The first input is the function value and the second input is step length measured as the norm of the change in the x-values. Then the x-values will be given as the next inputs, i.e. each element of x will be pasted as a separate input in the order they are in the vector x. At last each element of the names property will be pasted as a separate input.

E.g:

```
'Optimal value found: f(x): %1$20.6f    x: %3$20.6f\n' (Scalar)
'Optimal value found: %5$s: %3$20.6f %6$s: %4$20.6f\n' (Two)
'Optimal value found: f(x): %1$20.6f\n' (Multivariate)
```

If empty default print out is used.

Caution: Give a multi-lined char to print it one more lines.

- **formatIter** [↑](#)

Format of printed output for each stored iteration of the optimization. The first input is the iteration count, the second input is the function value and the third input is step length measured as the norm of the change in the x-values. Then the x-values will be given as the next inputs, i.e. each element of x will be pasted as a separate input in the order they are in the vector x. At last each element of the names property will be pasted as a separate input.

E.g:

```
'Iter: %1$13d  f(x): %2$20.6f    x: %4$20.6f\n' (Scalar)
```

```
'Iter: %1$13d f(x): %6$s: %4$20.6f %7$s: %5$20.6f\n' (Two)
```

```
'Iter: %1$13d f(x): %2$20.6f\n' (Multivariate)
```

If empty default print out is used.

Caution: Give a multi-lined char to print it one more lines.

- **fval** ↑

Storing the function values at each iteration. See the iteration property for which iteration that has been stored.

- **includeStop** ↑

Set to true to include a stop button in the figure when the type property is set to 'text'.

- **includeTime** ↑

Set to true to include a time left in the figure when the type property is set to 'text'.

- **iteration** ↑

Storing the iteration count of the stored values of x and fval properties.

- **names** ↑

Give the names of each element in x. Must be set to a cellstr. If generic names will be assign, i.e. {'x1','x2',...}.

See also formatDone or formatIter on how to use the names in print out.

Caution: Must either be empty or has the same length as the number of values in x.

- **notifyStep** ↑

This property sets the number of steps between the notification of the optimizer current value.

- **plotHandle** ↑

The handle to the line object with the plotted iterations.

- **problemSize** ↑

The size of the problem to solve.

- **stepLength** ↑

Stores the step length between each stored iteration. See the usedNorm property for more on how it is measured.

- **stopped** ↑

Will be set to true if the stop button of the display is pushed.

- **storeMax** ↑

Maximum number of iterations to store. Default is to store all. Minimum is 2.

- **textBoxHandle** ↑

The handle to the uicontrol object where the optimization iterations are displayed.

- **type** ↑

Set the type of reporting;
> 'text' : The reporting displayed as text in a window.
> 'command' : The reporting displayed as text in the command window
> 'graph' : The reporting displayed as a graph in a window.
> 'textgraph' : The reporting displayed as text and a graph in a window.

- **usedNorm** ↑

The used norm for calculating the step length. Default is the 2-norm.

- **x** ↑

Storing the x-values at each iteration. See the iteration property for which iteration that has been stored.

Methods:

- [getOutputFunction](#)
- [notifyError](#)
- [set](#)
- [update](#)

► **getOutputFunction** ↑

`fh = getOutputFunction(obj)`

Description:

Get function handle that can be assign to the field OutputFcn of the options struct given to the given optimizer (fminsearch, fmincon, fminunc) or solver (fsolve).

Input:

- obj : An object of class nb_optimizerDisplayer.

Output:

- fh : A function_handle object.

See also:

optimset, fminsearch, fmincon, fminunc, fsolve, nb_solver

Written by Kenneth Sæterhagen Paulsen

► **notifyError** ↑

notifyError(obj,err)

Description:

Call to notify about errors occurring optimization or solving.

Input:

- obj : An object of class nb_optimizerDisplayer
- err : The error message to display.

Written by Kenneth Sæterhagen Paulsen

► **set** ↑

set(obj,varargin)

Description:

Set properties of the object using 'propertyName', PropertyValue pairs.

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

stop = update(obj,x,optVal,state,varargin)

Description:

The method you need to pass to the OutputFcn as a function handle on the form `@(x,optVal,state) obj.update(x,optVal,state)`.

Input:

- `obj` : An object of class nb_optimizerDisplayer
- `x` : The point computed by the algorithm at the current iteration
- `optVal` : Structure containing data from the current iteration.
- `state` : The current state of the algorithm ('init', 'interrupt', 'iter', or 'done')

Output:

- `stop` : Always return false.

Written by Kenneth Sæterhagen Paulsen

◆ nb_callOptimizer

```
[estPar,fval,Hessian] = ...
    nb_callOptimizer(optimizer,fh,init,lb,ub,opt,message,varargin)
[estPar,fval,Hessian,err] = ...
    nb_callOptimizer(optimizer,fh,init,lb,ub,opt,message,varargin)
```

Description:

Generic function to call different optimizers on a specific job.

Input:

- `optimizer` : A one line char with the optimizer to use. Go to see also section for a list of the supported optimizers.
- `fh` : A function handle with the function to minimize.
- `init` : Initial values on the parameters. As a nPar x 1 double.
- `lb` : Lower bound on the parameters. These may need to finite for some optimizers! As a nPar x 1 double.
- `ub` : Upper bound on the parameters. These may need to finite for some optimizers! As a nPar x 1 double.
- `opt` : A struct with the optimization options. See `nb_getDefaultOptimset`.
- `message` : Extra message given when some error happened during estimation. May be set to ''.

Optional input:

- 'Aeq' : Apply linear equality constraints. For more see the documentation of the Aeq input to the fmincon function. Only supported when optimizer is set to 'fmincon'.
- 'Beq' : Apply linear equality constraints. For more see the documentation of the Beq input to the fmincon function. Only supported when optimizer is set to 'fmincon'.
- 'NONLCON' : Apply non-linear constraints. For more see the documentation of the constraints property of the nb_abc class or the NONLCON input to the fmincon function. Only supported when optimizer is set to 'nb_abc' or 'fmincon'.
- varargin : Optional inputs given to the function handle fh when being evaluated.

Output:

- estPar : The values of the parameters that minimizes the function. As a nPar x 1 double.
- fval : Value of the function at the minimum. As a scalar double.
- Hessian : Estimate of the Hessian at the found minimum.
- err : Provide this output to return error instead of throwing it inside this function.

See also:

Written by Kenneth Sætherhagen Paulsen

◆ **nb_getDefaultOptimset**

```
opt = nb_getDefaultOptimset(funcName)
opt = nb_getDefaultOptimset(opt,funcName)
```

Description:

If the opt input is empty or a struct without any fields, then this method will return the default setting for the optimizer/solver used.

I.e. for the MATLAB functions 'fmincon', 'fminunc', 'fminsearch' and 'fsolve' this amounts to calling optimset with the name of the function as the only input.

If this function doesn't recognize the function given by funcName, it will just return the opt input as it is (except that it will add the 'Display' and 'OutputFcn' fields if not already added).

Input:

- opt : A struct (with or without fields) or any other empty object.
- funcName : Name of the optimizer/solver to be used.

Output:

- opt : A struct with the options used by the optimizer/solver.

See also:

[optimset](#), [nb_abc.optimset](#), [nb_solve.optimset](#), [nb_abcSolve.optimset](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_getOptimizers**

`optimizers = nb_getOptimizers(type)`

Description:

Get the optimizers you have available for different estimation jobs.

This function also tries to detect optimizer of other toolboxes, such as csminwel (Chris Sims) and bee_gate (RISE toolbox). You need to add these optimizers separately, as they are not part of NB toolbox.

Input:

- type : Either 'arima', 'ml' or '' (all). When set to 'arima' or 'ml' optimizers that needs fixed bound, as nb_abc, are not returned.

Output:

- optimizers : A cellstr with the supported optimizers.

See also:

[nb_getDefaultOptimset](#), [nb_abc](#), [nb_pso](#), [fmincon](#), [fminunc](#), [fminsearch](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_interpretExitFlag**

```
nb_interpretExitFlag(e,type)
message = nb_interpretExitFlag(e,type,extra,homotopyErr)
```

Description:

Interpret error from given optimizers or zero root finders.

If nargout == 1, the error will not be thrown! Instead the error message will be returned.

Input:

- e : The exit flag of the given optimizer or solver.
- type : The optimizer or solver used as a string. E.g. 'fmincon', 'fminsearch', 'fsolve', etc.
- extra : A string with extra information on the error. Will be appended. Default is ''.
- homotopyErr : If nb_homotopy is used you can provide the err output of that function as this input.

Output:

- message : If asked for the error message is returned instead of thrown.

Written by Kenneth Sæterhagen Paulsen

◆ nb_optimizerMessageState

nb_optimizerMessageState(value)

Description:

If state is set to 'true'/true, the nb_interpretExitFlag and nb_callOptimizer functions only throws warnings instead of errors

Caution: Ignored if the error message is asked to be returned as a one line char!.

Input:

- e : The exit flag of the given optimizer or solver.
- type : The optimizer or solver used as a string. E.g. 'fmincon', 'fminsearch', 'fsolve', etc.
- extra : A string with extra information on the error. Will be appended. Default is ''.
- homotopyErr : If nb_homotopy is used you can provide the err output of that function as this input.

Written by Kenneth Sæterhagen Paulsen

◆ nb_pso

```
[x,fval,exitflag] = nb_pso(fh,init,lb,ub,options,varargin)
```

Description:

Find the minimum of a function using Particle Swarm Optimization.

This is a wrapper function of the pso.do function made by S. Samuel Chen.

This makes it possible to add optional input arguments to the optimizer function, which is not possible to do in pso.do.

Input:

- fh : The objective to minimize. As a function handle.
- init : The initial values of the optimization. Default is zero. As a n x 1 double.
- lb : The lower bound on the x values. Set it to -inf for the elements in x that is not constrained. Default is to set it to -inf for all elements. As a n x 1 double.
- ub : The upper bound on the x values. Set it to inf for the elements in x that is not constrained. Default is to set it to inf for all elements. As a n x 1 double.
- options : See the pso.optimset method for more on this input.

Optional inputs:

- varargin : Optional number of inputs given to the objective when it is called during the minimization algorithm.

Output:

- x : The point at the found minimum, as a n x 1 double.
- fval : The value of the objective at the found minimum, as a scalar double.
- exitflag : See the documentation of the exitFlag property of the pso.do class.

Examples:

```
g = @(x)-sin(x);
x1 = nb_pso(g,1)
x2 = nb_pso(g,-3)
x3 = nb_pso(g,-3,-4,4)

opt.Display = 'final';
x4 = nb_pso(g,-3,-4,4,opt)
```

25.20 Parallel coding

- WorkerObjWrapper
 - nb_closePool
 - nb_funcToWrite
 - nb_parCheck
 - nb_updateWaitbarParallel
 - nb_availablePoolSize
 - nb_fileToWrite
 - nb_openPool
 - nb_poolSize
-

◆ nb_availablePoolSize

```
s = nb_availablePoolSize()
```

Description:

Get number of available workers when running in parallel.

Output:

- s : An interger with the number of workers.

Caution: If the environment variable clusterProfile is set, then inf is returned, as in this case the number of cores used cannot be set anyway.

See also:

[nb_openPool](#), [nb_closePool](#), [nb_poolSize](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_closePool

```
nb_closePool(ret)
```

Description:

Close a parallel session. Invariante to MATLAB version.

Input:

- ret : 1 if the matlabpool should be close otherwise 0. Default is 1.

See also:

[nb_openPool](#), [nb_poolSize](#), [nb_availablePoolSize](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_fileToWrite

```
h = nb_fileToWrite(name)
```

Description:

Get handle to a file to communicate with when running in parallel

Input:

- name : Name of file to write to. As a string.
- gui : Give 'gui' to place the file in the nb_userpath('gui') folder.

Output:

- h : A file identifier object. See fopen.

Written by Kenneth Sæterhagen Paulsen

◆ nb_funcToWrite

```
w = nb_funcToWrite(name,gui)
```

Description:

Get handle to a function that can communicate with a file when running in parallel. See

Input:

- name : Name of file to write to. As a string.
- gui : Give 'gui' to place the file in the nb_userpath('gui') folder.

Output:

- w : A WorkerObjWrapper object.

Example:

```
w = nb_funcToWrite('test','gui');
parfor ii = 1:10
    fprintf(w.Value,'Some text');
end
clear w;
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_openPool

```
ret = nb_openPool()      : Uses all cores
ret = nb_openPool(cores) : Uses the number of selected cores
```

Description:

Open up a parallel session if not already open.

Caution: To open a cluster pool set the environment variable
clusterProfile; setenv('clusterProfile','yourProfileName')

Input:

- cores : Number of cores to open, as an integer. Default is available.

Output:

- ret : 1 if matlabpool was opened, else 0.

See also:

[nb_closePool](#), [nb_poolSize](#), [nb_availablePoolSize](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_parCheck**

```
[ret,D] = nb_parCheck()
```

Description:

Test if it is possible to make a waitbar in parfor using the
parallel.pool.DataQueue class or not.

Output:

- ret : true or false

- D : Handle to the parallel.pool.DataQueue object if ret is true,
otherwise D is empty.

See also:

[nb_waitbar](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_poolSize**

```
s = nb_poolSize()
```

Description:

Get number of active workers when running in parallel.

Output:

- s : An interger with the number of workers.

See also:

[nb_openPool](#), [nb_closePool](#), [nb_availablePoolSize](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_updateWaitbarParallel**

`nb_updateWaitbarParallel(note,h)`

Description:

Function that can be given to the `afterEach` method of the `parallel.pool.DataQueue` to update the `nb_waitbar` class during parfor.

Input:

- note : The increment at update.
- h : The handle to the `nb_waitbar` object.

Examples:

```
D = parallel.pool.DataQueue;
afterEach(D,@(x)nb_updateWaitbarParallel(x,h));
```

► **[nb_perfectForesight.getStackedEnd](#)** ↑

```
[stackedEnd,endN,varsN] = nb_perfectForesight.getStackedEnd(eqs,...  
matches,pars,paramN,varsExo,varsExoN,varsCLag,endVal)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth Sæterhagen Paulsen

► **[nb_perfectForesight.getStackedFirst](#)** ↑

```
[stackedFirst,initN,varsN] = nb_perfectForesight.getStackedFirst(eqs,...  
matches,pars,paramN,varsExo,varsExoN,varsCLead,initVal)
```

Syntax:

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth Sæterhagen Paulsen

► **nb_perfectForesight.getStackedJacobian** ↑

```
JF = nb_perfectForesight.getStackedJacobian(Y,inputs,funcs,iter)
```

Description:

Evaluate the Jacobian at the current iteration.

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_perfectForesight.getStackedJacobianAutomatic** ↑

```
[YT,err] = nb_perfectForesight.blockIteration(obj,funcs,inputs,iter,...  
      outer,YT)
```

Description:

Evaluate the Jacobian at the current iteration using automatic derivatives that handles sparsity. For more see the myAD class written by SeHyoun Ahn and Martin Fink.

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_perfectForesight.getStackedJacobianSymbolic** ↑

```
JF = nb_perfectForesight.getStackedJacobianSymbolic(inputs,funcs,Y,iter)
```

Description:

Evaluate the Jacobian at the current iteration using symbolic derivatives that handles sparsity. For more see the nb_mySD and nb_Param classes written by Kenneth S. Paulsen.

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶therhagen Paulsen

► **nb_perfectForesight.getStackedSystemFunction** ↑

```
[funcs,inputs] = nb_perfectForesight.getStackedSystemFunction(obj,...  
      inputs,parser)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_perfectForesight.getStartingValues** ↑

```
Y = nb_perfectForesight.getStartingValues(obj,inputs)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_perfectForesight.normalIteration** ↑

```
[YT,err] = nb_perfectForesight.normalIteration(obj,funcs,inputs,iter,...  
outer,YT)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_perfectForesight.normalSolution** ↑

```
[YT,err] = nb_perfectForesight.normalSolution(obj,Y,inputs,funcs)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_perfectForesight.normalSolutionStochInitVal** ↑

```
[YT,err] = nb_perfectForesight.normalSolutionStochInitVal(obj,Y,...  
inputs,funcs)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth Sæterhagen Paulsen

► **nb_perfectForesight.optimset** ↑

```
opt = nb_getDefaultOptimset(solver)
```

Description:

Get default options for solving the perfect foresight problem.

Input:

- solver : Name of the solver to be used. Use nb_solve.optimset('help') or nb_abcSolve.optimset('help') for more on the different options.

Output:

- opt : A struct with the options used by the solver.

See also:

[nb_solve.optimset](#), [nb_abcSolve.optimset](#)

Written by Kenneth Sæterhagen Paulsen

► **nb_perfectForesight.proSolver** ↑

```
[Y,err] = nb_perfectForesight.proSolver(obj,inputs,Y,iter)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth Sæterhagen Paulsen

► **nb_perfectForesight.substituteSS** ↑

```
[YT,err] = nb_perfectForesight.blockIteration(obj,funcs,inputs,iter,...  
outer,YT)
```

Description:

Here we need to substitute in for the end values where the steady-state operator is used.

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth Sæterhagen Paulsen

► nb_perfectForesight.unexpectedSolver ↑

```
[YT,err] = nb_perfectForesight.unexpectedSolver(obj,funcs,inputs,Y,...  
funcHandle)
```

Description:

Solver used when we are dealing with unexpected shocks.

Part of the perfect forseight solver package nb_perfectForesight.

Input:

- funcHandle : Either @nb_perfectForesight.normalIteration or
@nb_perfectForesight.blockIteration

Written by Kenneth Sæterhagen Paulsen

► nb_perfectForesight.updateEpiFunctionOnePeriod ↑

```
funcs = nb_perfectForesight.updateEpiFunctionOnePeriod(funcs,...  
Yepi,YNotEpi,parExoVal,varsSS)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth Sæterhagen Paulsen

► nb_perfectForesight.updateStackedSystemFunction ↑

```
funcs = nb_perfectForesight.updateStackedSystemFunction(obj,funcs,...  
inputs,iter)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth Sæterhagen Paulsen

► **nb_perfectForesight.updateStackedSystemFunctionOnePeriod** ↑

```
funcs = nb_perfectForesight.updateStackedSystemFunctionOnePeriod(obj, ...
    funcs, inputs, init, iter)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶terhagen Paulsen

► **nb_perfectForesight.updateSystemFunctionOnePeriod** ↑

```
funcs = nb_perfectForesight.updateSystemFunctionOnePeriod(obj, ...
    funcs, inputs, init, exoVal, iter)
```

Description:

Part of the perfect forseight solver package nb_perfectForesight.

Written by Kenneth SÃ¶terhagen Paulsen

■ **nb_abcSolve**

Go to: [Properties](#) | [Methods](#)

An implementation of the artificial bee colony algorithm for solving a multivariate non-linear system of equations.

References:

"A comprehensive survey: Artificial bee colony (ABC) algorithm and applications", Karaboga et. al (2012).

"Modified artificial bee colony algorithm for constrained problems optimization", Stanarevic et. al (2015)

This class tries to solve the following problem

```
F(x) = 0
x in S
```

where $F(x)$ is a set of non-linear solutions. S is the search space, i.e. the space to look for candidate values to solve $F(x) = 0$.

Caution: The steps of this implementation is slightly different from that of Karaboga et. al (2012).

Initialize employed bees by scouting.

Repeat:

1. Employed bees that has reached the cutLimit are sent out scouting. See nb_beeSolver.scout (local == false) or nb_beeSolve.joinDance (local == true).
2. Send onlookers to join the employed bees by random. Higher probabilities are assign to the employed bees that communicates good values of the objective. Finally onlookers are sent to explore the neighbourhood of the selected employed bee See nb_beeSolver.joinDance.
3. Employed bees are then sent to explore their neighbourhood by changing the current value of x. This is done by changing a random number of elements in x, the move is selected using $x(n) = x(n-1) + \alpha * F(x)$, where alpha is random search direction matrix. Each element is drawn from the uniform distribution in [-1,1]. See nb_beeSolver.dance.
4. All the new points of the bees are evaluated. (This is the step that can be ran in parallel.)
5. The solution is then selected and stored.

This is repeated until some of the limits (maxTime, maxFunEvals, maxIter, maxSolutions or maxTimeSinceUpdate are reached).

Superclasses:

handle

Constructor:

```
obj = nb_abcSolve(fh,init,lb,ub)
obj = nb_abcSolve(fh,init,lb,ub,options,varargin)
obj = nb_abcSolve(fh,init,[],[],options,varargin)
```

Input:

- fh : See the documentation of the objective property of the nb_abcSolve class.
- init : See the documentation of the initialXValue property of the nb_abcSolve class.
- lb : See the documentation of the lowerBound property of the nb_abcSolve class.
- ub : See the documentation of the upperBound property of the nb_abcSolve class.
- options : See the nb_abcSolve.optimset method for more on this input.

Optional inputs:

- varargin : Optional number of inputs given to the objective when it is called during the minimization algorithm.

Output:

- obj : An object of class nb_abcSolve.

See also:

- **useParallel**
- **xValue**

- **F** ↑

The function to solve. As a function handle. Must take a N x 1 double as the first input, and return a N x 1 double.

- **bees** ↑

A vector of `nb_beeSolver` objects.

- **cutLimit** ↑

Positive integer. The maximum trial that is allowed for employed bee before it starts to scout for another area. Default is 20. Must be greater than 4.

- **display** ↑

'iter' Level of display. 'iter' displays output at each iteration. Only supported option.

- **display** ↑

An object of class `nb_optimizerDisplayer`. This object set the way the optimizer displays result during the optimization.

- **employedShare** ↑

This set the share of employed bees. Default is 0.33, i.e. 33%. Must be in the set (0.1,0.9).

- **exitFlag** ↑

The reason for exiting. One of:

```
> 6 : Maximum number of solutions exceeded.  
> 5 : User stop the optimization manually with finding of at  
      least the minimum number of solution asked for.  
> 4 : Maximum time limit since last update exceeded  
      (maxTimeSinceUpdate) with finding of at least the  
      minimum number of solution asked for.  
> 3 : Maximum time limit exceeded (maxTime) with finding of at  
      least the minimum number of solution asked for.  
> 2 : Maximum iteration limit exceeded (maxIter) with finding  
      of at least the minimum number of solution asked for.  
> 1 : Maximum function evaluation limit exceeded (maxFunEvals)  
      with finding of at least the minimum number of solution  
      asked for.  
> -1 : Maximum function evaluation limit exceeded (maxFunEvals)  
      without finding the minimum number of solution  
      asked for.  
> -2 : Maximum iteration limit exceeded (maxIter) without  
      finding the minimum number of solution asked for.  
> -3 : Maximum time limit exceeded (maxTime) without finding  
      the minimum number of solution asked for.  
> -4 : Maximum time limit since last update exceeded  
      (maxTimeSinceUpdate) without finding the minimum number  
      of solution asked for.  
> -5 : User stop the optimization manually without finding  
      the minimum number of solution asked for.
```

- **fitnessFunc** ↑

A function handle that return the fitness of each bee at each iteration of the optimization. See for example `nb_fitness.standard`, which is the default fitness function. Other proper fitness functions may be found in the `nb_fitness` package.

- **fitnessScale** ↑

This set the value of the fitness scaling parameter. Default is 1. This is the third input to the function given by the `fitnessFunc` property.

- **funEvals** ↑

Number of function evaluations.

- **initialXValue** ↑

The initial values of the optimization. Default is zero. As a N x 1 double.

- **iterations** ↑

Number of iteration of the abc algorithm.

- **jacobianFunction** ↑

A function handle that return the jacobian at the current evaluation point. Must return a N x N double or sparse matrix. Default is [], i.e. the newton type bees used a Steffensen update instead.

- **local** ↑

Use the algorithm for finding a local solutions, i.e. if set to true, this will not search globally in S, but instead search for a solution in the neighborhood of the current best candidate of the employed bees. During initialization the bees are not sent out to search the full space S at random, but instead doing random small steps away from the initial value.

- **lowerBound** ↑

The lower bound on the x values. As a N x 1 double. Must be finite!

- **maxFunEvals** ↑

Positive integer. Maximum number of function evaluation allowed. Default is inf.

- **maxIter** ↑

Positive integer. Maximum number of iterations allowed. Default is inf.

- **maxNodes** ↑

Positive integer. The number of bees to use during optimization.

- **maxSolutions** ↑

Positive integer. The maximum number of solutions to allow. To trigger a local solution algorithm set this to 1 and local to true. Default is 20.

- **maxTime** ↑

Positive integer. The maximum time spent on optimization in seconds. Default is 60 seconds.

- **maxTimeSinceUpdate** ↑

Positive integer. The maximum time spent on optimization since last time the minimum point where updated (in seconds).

- **maxTrials** ↑

Positive integer. The maximum trial that is allowed for finding initial candidates. Default is 100.

- **meritFunction** ↑

A function handle with the merit function to be applied to test for solution candidates. A G : R^N → R function. Default is @(x)norm(x,2).

- **meritFunctionValue** ↑

The merit function value of the solutions found.

- **minFFunctionValue** ↑

The value of F(minXValue). As a N x 1 double.

- **minFunctionValue** ↑

The minimized merit function value found during the solving. As a 1 x nSolutions double.

- **minSolutions** ↑

Positive integer. The minimum number of solutions to find. An negative exitFlag will be thrown if the number of solutions are not greater then or equal to this number. Default is 1.

- **minXValue** ↑

The x values at the located minimum of the merit function. As a N x 1 double.

- **newtonShare** ↑

Share of employed bees being of newton type, i.e. use a newton step of getting a new solution candidate instead of random search in the dancing area. If the derivative of the function F(x) is everywhere defined, you should set it to 1. Default is 0.1, i.e. 10%.

- **newtonStop** ↑

Set to true to make the employed bees that uses newton update to move to convert too random shearch if they breach the cutLimit without finding a solution to the problem.

- **numSolutions** ↑

Number of solutions found (N).

- **numWorkers** ↑

Positive integer. Number of worker to use when running optimization in parallel.

- **objectiveLimit** ↑

Double. If the objective return a value greater than this, a new candidate of x is drawn. Default is 1e9.

- **options** ↑

A struct with the options of the optimiziation. See the nb_abcSolve.optimset method for more on this option.

- **tolerance** ↑

Tolerance value for accepting a solution.

- **toleranceX** ↑

Tolerance value for differencing between different solutions.

- **upperBound** ↑

The upper bound on the x values. As a n x 1 double. Must be finite!

- **useParallel** ↑

true or false. Give true if the nodes should be spread on different parallel workers.

- **xValue** ↑

The suggested solution of x. As a N x nSolutions double.

Methods:

- call • optimset • set • solve • test
- test2 • test2local • test3 • testParallel

► **call** ↑

```
[x,fval,exitflag] = nb_abcSolve.call(F,init,lb,ub,options,varargin)
```

Description:

Call the artificial bee colony algorithm to solve a multivariate non-linear system of equations ($F(x) = 0$). See the documentation of the nb_abcSolve class for more on this algorithm.

Input:

- F : See the documentation of the objective property of the nb_abcSolve class.
- init : See the documentation of the initialXValue property of the nb_abcSolve class.
- lb : See the documentation of the lowerBound property of the nb_abcSolve class.
- ub : See the documentation of the upperBound property of the nb_abcSolve class.
- options : See the nb_abcSolve.optimset method for more on this input.

Optional inputs:

- varargin : Optional number of inputs given to the objective when it is called during the solving algorithm.

Output:

- x : See the documentation of the minXValue property of the nb_abcSolve class.
- fval : See the documentation of the minFunctionValue property of the nb_abcSolve class.
- exitflag : See the documentation of the exitFlag property of the nb_abcSolve class.

Examples:

```
g           = @(x)-sin(x);
opt         = nb_getDefaultOptimset('nb_abcSolve');
opt.maxSolutions = 3;
x           = nb_abcSolve.call(g,1,-4,4,opt)
opt.jacobianFunction = @(x)-cos(x);
x2          = nb_abcSolve.call(g,1,-4,4,opt)
```

See also:

[nb_abcSolve.optimset](#), [nb_solve.call](#), [fsolve](#)

Written by Kenneth Sæterhagen Paulsen

► [optimset ↑](#)

```
options = nb_abcSolve.optimset(varargin)
```

Description:

Get solving settings or help.

Optional input:

- Run without inputs to get defaults.
- Run with 'list' as the first input to get a cellstr with the supported options.
- Run with 'help' to get a struct with help on each option.
- Run with 'optionName' to get help on a particular option, i.e. only one input.
- Use 'optionName', optionValue pairs to set options of the returned struct.

Output:

- Depends on the input.

See also:

[nb_abcSolve.options](#)

Written by Kenneth Sæterhagen Paulsen

► **set ↑**

```
obj = set(obj,varargin)
```

Description:

Set properties of the object using 'propertyName', PropertyValue pairs.

Input:

- obj : An object of class nb_abcSolve.

Optional inputs:

- varargin: 'propertyName', PropertyValue pairs

Output:

- obj : An object of class nb_fmin where the wanted properties has been set.

Examples:

```
set(obj,'initialXValue',2,'lowerBound',0)
```

See also:

[nb_abcSolve.optimset](#)

Written by Kenneth Sæterhagen Paulsen

► **solve** ↑

```
solve(obj)
solve(obj,varargin)
```

Description:

Run solving of the given problem.

Input:

- obj : An object of class nb_abcSolve.

Optional input:

- varargin : Given to the nb_abcSolve.set method.

Output:

The provided object of class nb_abcSolve has been updated the following properties;
> xValue
> meritFunctionValue
> exitFlag

See also:

[nb_abcSolve.call](#)

Written by Kenneth Sæterhagen Paulsen

► **test** ↑

```
[x,fval,exitflag] = nb_abcSolve.test()
```

Description:

Test the ABC algorithm on the Rosenbrock Vally function;

```
f = 100*(x(2) - x(1)^2)^2 + (x(1) - 1)^2
```

The solver stops when it is 60 second since last time the minimum where updated.

Output:

- [x,fval,exitflag] : See the nb_abcSolve.call method for more on these outputs.

See also:

[nb_abcSolve.call](#)

Written by Kenneth Sæterhagen Paulsen

► **test2** ↑

```
[x,fval,exitflag] = nb_abcSolve.test2(varargin)
```

Description:

Test method for solving

```
min(x(1) + x(2),0.01) = 0  
x(1).^2 - x(2) = 0
```

Uses only newton updating bees!

Output:

- [x,fval,exitflag] : See the nb_abcSolve.call method for more on these outputs.

See also:

[nb_abcSolve.call](#)

Written by Kenneth Sæterhagen Paulsen

► **test2local** ↑

```
[x,fval,exitflag] = nb_abcSolve.test2local(varargin)
```

Description:

Test method for solving

```
min(x(1) + x(2),0.01) = 0  
x(1).^2 - x(2) = 0
```

without bounds, i.e. a local method must be used.

Output:

- [x,fval,exitflag] : See the nb_abcSolve.call method for more on these outputs.

See also:

[nb_abcSolve.call](#)

Written by Kenneth Sæterhagen Paulsen

► **test3** ↑

```
[x,fval,exitflag] = nb_abcSolve.test3(varargin)
```

Description:

Test method for solving

```
max(min(x(1) + x(2),0.01),-0.01) = 0  
x(1).^2 - x(2) = 0
```

Output:

- [x,fval,exitflag] : See the nb_abcSolve.call method for more on these outputs.

See also:

[nb_abcSolve.call](#)

Written by Kenneth Sæterhagen Paulsen

► **testParallel** ↑

```
nb_abcSolve.testParallel()
```

Description:

Test the ABC algorithm in parallel on the Rosenbrock Vally function;

```
f = 100*(x(2) - x(1)^2)^2 + (x(1) - 1)^2
```

Output:

- [x,fval,exitflag,hessian] : See the nb_abcSolve.call method for more on these outputs.

See also:

[nb_abcSolve.call](#)

Written by Kenneth Sæterhagen Paulsen

■ nb_beeSolver

Go to: [Properties](#) | [Methods](#)

A class representing a bee in the artificial bee colony (ABC) algorithm by Karaboga et. al (2012) applied to solving the problem

```
F(x) = 0  
s.t. x in S
```

where $F(x)$ is a set of non-linear solutions. S is the search space, i.e. the space to look for candidate values to solve $F(x) = 0$.

Constructor:

```
obj = nb_beeSolver(n);
```

Input:

- n : Number of objects to initialize, as a scalar integer.

Output:

- obj : An object of class nb_beeSolver.

See also:

[nb_abcSolve](#), [nb_abcSolve.call](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- | | | | |
|----------------|--------------------|----------------|-----------|
| • current | • currentFValue | • currentValue | • fitness |
| • index | • maxNumberChanged | • method | • tested |
| • testedFValue | • testedValue | • trials | • type |

- **current** ↑

Current location of the bee. Used by employed bees only. A double with size N x 1.

- **currentFValue** ↑

F(currentValue), as a double with size N x 1.

- **currentValue** ↑

Current merit function value of the bee. Used by employed bees only. As a scalar double.

- **fitness** ↑

The fitness at the current point. Used by employed bees only.

- **index** ↑

The index of the employed bee that the onlooker bee is dancing with. Used by onlooker bees only.

- **maxNumberChanged** ↑

Maximum number of changed parameters at a given dance. If empty It gets the value N.

- **method** ↑

Method to use for updating the current point.

> 1 : Random search.

> 2 : Newton (either with numerical jacobian or function handle).
The function handle may return a sparse matrix.

- **tested** ↑

Tested location of the bee. A double with size N x 1.

- **testedFValue** ↑

F(testedValue), as a double with size N x 1.

- **testedValue** ↑

Objective value of the bee at the tested location.

- **trials** ↑

The number of trials at the current area. Used by employed bees only.

- **type** ↑

The type of bee. Either 'employed' or 'onlooker'.

Methods:

- calcFitness
- dealZeros
- evaluate
- joinBestDancer
- scout
- updateLocation
- calculateProbabilities
- drawCandidates
- evaluateParallel
- joinDance
- separate
- dance
- drawCandidatesLocal
- initialize
- relocate
- tournamentSelection

► **calcFitness** ↑

```
obj = calcFitness(obj, fitnessFunc, fitnessScale, fMin)
```

Description:

Calculate fitness score at the current best value of each employed bee.

Input:

- obj : A vector of nb_beeSolver objects.
- fitnessFunc : See the property with the same name in the nb_abcSolve class.
- fitnessScale : See the property with the same name in the nb_abcSolve class.
- fMin : The smallest function evaluation found up until now.

Output:

- obj : A vector of nb_beeSolver objects.

See also:

[nb_abcSolve.doSolving](#)

Written by Kenneth Sæterhagen Paulsen

► **calculateProbabilities** ↑

```
prob = calculateProbabilities(employed)
```

Description:

Calculate the probability values for the solutions using fitness of the solutions by

```
p(i) = f(i)/sum_i(f(i))
```

where $f(i)$ is the value of the fitness of the value of the merit function by employed bee number i .

See "A comprehensive survey: Artificial bee colony (ABC) algorithm and applications", Karaboga et. al (2012).

Input:

- employed : A vector of employed bees. As a vector of nb_beeSolver objects.

Output:

- prob : The probabilities of onlooker bees to join the dance of employed bees.

See also:

[nb_beeSolver.joinDance](#)

Written by Kenneth Sæterhagen Paulsen

► **dance ↑**

```
[employed,newScouts] = dance(employed,lowerBound,upperBound,F,...  
jacobianFunction)
```

Description:

Make the employed bees move at random in their dancing area or some move by some other updating rule.

Input:

- employed : A vector of employed bees. As a vector of nb_beeSolver objects.
- lowerBound : See the property with the same name in the nb_abcSolve class.
- upperBound : See the property with the same name in the nb_abcSolve class.
- jacobianFunction : See the property with the same name in the nb_abcSolve class.

Output:

- employed : A vector of nb_beeSolver objects.
- newScouts : A vector of nb_beeSolver objects. These are the ones that breach the bounds during the newton update.

See also:

[nb_beeSolver.relocate](#)

Written by Kenneth Sæterhagen Paulsen

► dealZeros ↑

obj = dealZeros(obj, nPar)

Description:

Initialize the bees to the trivial solution.

Input:

- obj : A vector of nb_beeSolver objects.
- nPar : Number of values to find the solution of.

Output:

- obj : A vector of nb_beeSolver objects.

Written by Kenneth Sæterhagen Paulsen

► drawCandidates ↑

draws = nb_beeSolver.drawCandidates(lb, ub, nPar, nBees)

Description:

Draw candidates from a N dimensional box.

Input:

- lb : A double vector with size nPar x 1.
- ub : A double vector with size nPar x 1.
- nPar : The number of parameters.
- nBees : The number of bees.

Output:

- draws : A double with size nPar x nBees with the randomly selected parameters inside the box.

See also:

[nb_beeSolver.initialize](#), [nb_beeSolver.scout](#)

Written by Kenneth Sæterhagen Paulsen

► drawCandidatesLocal ↑

```
draws = nb_beeSolver.drawCandidates(fVal,cVal,x,nBees)
```

Description:

Draw candidates from a stochastic searching rule

$$x(n) = x(n-1) + \alpha * fVal / cVal, \quad \alpha \sim U(0,1)$$

Input:

- fVal : F(x), as N x 1 double.
- cVal : meritFunction(F(x)), as a scalar double.
- x : As a N x 1 double.
- nBees : The number of bees.

Output:

- draws : A double with size N x nBees with the randomly selected values of x around the current value.

See also:

[nb_beeSolver.initialize](#), [nb_beeSolver.scout](#)

Written by Kenneth Sæterhagen Paulsen

► evaluate ↑

```
obj = evaluate(obj,F,meritFunction)
```

Description:

Evaluate the bees at their tested locations.

Input:

- obj : A vector of nb_beeSolver objects.
- F : See the property with the same name in the nb_abcSolve class.
- meritFunction : See the property with the same name in the nb_abcSolve class.

Output:

- obj : A vector of nb_beeSolver objects.

See also:

[nb_abcSolve.doSolving](#)

Written by Kenneth Sæterhagen Paulsen

► **evaluateParallel ↑**

obj = evaluateParallel(obj,F,meritFunction)

Description:

Evaluate the bees at their tested locations.

Input:

- obj : A vector of nb_beeSolver objects.
- F : See the property with the same name in the nb_abcSolve class.
- meritFunction : See the property with the same name in the nb_abcSolve class.

Output:

- obj : A vector of nb_beeSolver objects.

See also:

[nb_abcSolve.doSolving](#)

Written by Kenneth Sæterhagen Paulsen

► **initialize** ↑

```
[obj,funEvals] = initialize(obj,F,meritFunction,initialXValue,...  
    lowerBound,upperBound,objectiveLimit,maxTrials,...  
    local,newtonShare)
```

Description:

Initialize the bees that are going to be employed.

Input:

- obj : A vector of nb_beeSolver objects.
- See the properties with the same name in the nb_abcSolve class for help on the rest of the inputs.

Output:

- obj : A vector of nb_beeSolver objects. The type property has been set to 'employed'.
- funEvals : Number of function evaluations during initialization.

Written by Kenneth Sæterhagen Paulsen

► **joinBestDancer** ↑

```
joiners = joinBestDancer(joiners,minXValue,minFunctionValue,...  
    minFFunctionValue)
```

Description:

When we use the local option, the employed bees that runs out of nectar (exceeds the cutLimit) goes to the best nectar location of all time.

Input:

- joiners : A vector of nb_beeSolver objects.
- Otherwise see the properties with the same names in the nb_abcSolve class.

Output:

- joiners : A vector of nb_beeSolver objects.

See also:

[nb_beeSolver.relocate](#)

Written by Kenneth Sæterhagen Paulsen

► **joinDance** ↑

```
obj = joinDance(obj,employed,lowerBound,upperBound,local)
```

Description:

Make the onlooker or scout bees find a employed bee to dance with.

Input:

- obj : A vector of onlookers bees, as a vector of nb_beeSolver objects.
 - See the properties with the same names in the nb_abcSolve class.

Output:

- obj : A vector of nb_beeSolver objects.

See also:

[nb_beeSolver.relocate](#)

Written by Kenneth Sæterhagen Paulsen

► **relocate** ↑

```
obj = relocate(obj,lowerBound,upperBound,cutLimit,local,...  
              F,jacobianFunction,tolerance,newtonStop,minXValue,...  
              minFunctionValue,minFFunctionValue)
```

Description:

Relocate the bees.

Input:

- obj : A vector of nb_beeSolver objects.
- Otherwise see the properties with the same names in the nb_abcSolve class.

Output:

- obj : A vector of nb_beeSolver objects.

See also:

[nb_abcSolve.doSolving](#)

Written by Kenneth Sæterhagen Paulsen

► **scout** ↑

obj = scout(obj,lowerBound,upperBound)

Description:

Employ scouts to new dancing areas.

Input:

- obj : A vector of nb_beeSolver objects.
- lowerBound : See the property with the same name in the nb_abcSolve class.
- upperBound : See the property with the same name in the nb_abcSolve class.

Output:

- obj : A vector of nb_beeSolver objects.

See also:

[nb_beeSolver.relocate](#)

Written by Kenneth Sæterhagen Paulsen

► **separate** ↑

[employed,onlookers] = separate(obj,cutLimit,tolerance,newtonStop)
[employed,onlookers,scouts] = separate(obj,cutLimit,tolerance,newtonStop)

Description:

Separate the bees into employed, scouts and onlookers.

Input:

- obj : A vector of nb_beeSolver objects.
- cutLimit : See the property with the same name in the nb_abcSolve class. Only needed if nargout > 2.

Output:

- employed : These are the employed bees that are keep dancing in their current area if nargout == 3, else it is all the employed bees. As a vector of nb_beeSolver objects.
- onlookers : These are the bees that are joing the dance of the most succesful employed bees. As a vector of nb_beeSolver objects.
- scouts : These are the employed bees that are going to scout for a new dancing area. As a vector of nb_beeSolver objects.

Written by Kenneth SÃ¶terhagen Paulsen

► **tournamentSelection** ↑

```
ret = tournamentSelection(obj,currentLeader)
```

Description:

Play out pairwise tournament between two bees.

Input:

- obj : The tested bee.
- currentLeader : The bee that is currently the best.

Output:

- ret : If true is returned tested be should be made the new leader.

See also:

[nb_beeSolver.updateLocation](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **updateLocation** ↑

```
obj = updateLocation(obj)
```

Description:

Update the location based on their last evaluation.

Input:

- obj : A vector of nb_beeSolver objects.

Output:

- obj : A vector of nb_beeSolver objects.

See also:

[nb_abcSolve.doSolving](#)

Written by Kenneth Sæterhagen Paulsen

■ nb_solve

Go to: [Properties](#) | [Methods](#)

A class for solving non-linear problems on the form

$F(x) = 0$

Constructor:

```
obj = nb_solve(fh,init)
obj = nb_solve(F,init,options,JF,varargin)
```

Input:

- F : See the documentation of the F property of the nb_solve class. Must be given.
- init : See the documentation of the init property of the nb_solve class. Must be given.
- options : See the nb_solve.optimset method for more on this input. Can be empty.
- JF : See the documentation of the JF property of the nb_solve class. Can be empty.

Optional inputs:

- varargin : Optional number of inputs given to the F (and JF) function(s) when it is called during the solution algorithm.

Output:

- obj : An object of nb_solve

Examples:

```
obj      = nb_solve(@(x)x^2,1);
[x,fVal] = nb_solve.call(@(x)x^2,1)
```

See also:

[fsolve](#), [nb_solve.call](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- | | | | |
|--------------------------------|-------------------------------|---------------------------------|--------------------------------------|
| • F | • JF | • alphaMethod | • criteria |
| • display | • display | • exitFlag | • fVal |
| • funEvals | • gamma | • initialXValue | • iter |
| • jacobian | • maxFunEvals | • maxIter | • maxIterSinceUpdate |
| • maxTime | • memory | • meritFVal | • meritFunction |
| • meritXChange | • method | • numWorkers | • options |
| • stepLength | • tolerance | • useParallel | • x |

- [F](#) [↑](#)

A function handle with the problem to solve. It is assumed to take a double with size M x 1 as input.

- [JF](#) [↑](#)

A function handle that return the jacobian of the problem to solve (F). It is assumed to take a double with size M x 1 as input. Only needed for the methods that uses derivative based methods.

- [alphaMethod](#) [↑](#)

Select the method to use to update the spectral step length when using the methods 'sane' or 'dfsane'. Choose amoung 1,2 or 3. Default is 2. See the methods [nb_solve.alphaMethod1](#), [nb_solve.alphaMethod2](#) and [nb_solve.alphaMethod3](#).

- [criteria](#) [↑](#)

Convergence criteria to use. Either 'function' (default) or 'stepSize'. 'function' means that the criteria being used is the first norm of F(x), while 'stepSize' means that the first norm of the step size (x(n) - x(n-1)) is used. See the property tolerance for the convergence measure.

- [display](#) [↑](#)

'off' | 'iter' | 'final' | 'notify' Level of display. 'off' displays no output; 'iter' displays output at each iteration 'final' displays just the final output; 'notify' displays output only if the function does not converge.

- [display](#) [↑](#)

An object of class nb_optimizerDisplayer. This object set the way the optimizer displays result during the optimization.

- **exitFlag** ↑

Reason for exiting the solving. A 1 means that the solver succeeded, while a value less than 1 means it failed. See the function nb_interpretExitFlag for how to interpret the exitFlag property.

- **fVal** ↑

Function value at last iteration, as M x 1 double. If the solver converged it will have norm less than given by the tolerance property.

- **funEvals** ↑

The number of function evaluations done during the solving of the problem.

- **gamma** ↑

Parameter used in the non-monotone line search step of the 'dfsane' and 'sane' methods.

- **initialXValue** ↑

Initial values. A M x 1 double.

- **iter** ↑

The number of iterations done during the solving of the problem.

- **jacobian** ↑

Jacobian matrix at last iteration, as M x M double.

- **maxFunEvals** ↑

Positive integer. Maximum number of function evaluation allowed. Default is inf.

- **maxIter** ↑

Positive integer. Maximum number of iterations allowed. Default is 10000.

- **maxIterSinceUpdate** ↑

Positive integer. Maximum number of iterations allowed between effective update. Default is 500. Used for global algorithm only.

- **maxTime** ↑

Positive integer. The maximum time spent on optimization in seconds.

- **memory** ↑

Positive integer. Set the number of periods that is remember in the 'dfsane' and 'sane' method. Normal to have a value between 5-20. Default is 10. High value will garanti a better approximation.

- **meritFVal** ↑

Merit value of $F(x)$. See meritFunction for the function applied. Default merit function is the first norm.

- **meritFunction** ↑

A function handle that specifies the merit function to use when convergence is checked. Default is $\ell_1(x)$. The merit function must map a $M \times 1$ double into a scalar double. A number close to 0 is taken as convergence.

- **meritXChange** ↑

Merit value of $x(n) - x(n-1)$. See meritFunction for the function applied. Default merit function is the first norm.

- **method** ↑

Select the method to use to solve the problem.

- > 'newton' : Uses a the Newton-Raphson method. The JF property must be given in this case.
- > 'steffensen' : Uses the Steffensen method. Where the derivative is numerically estimated.
- > 'steffensen2' : Uses a two steps steffensen method. Where the derivative is numerically estimated.
- > 'broyden' : Uses the Broyden method. Where the derivative is numerically updated at each iteration. Default method.
- > 'sane' : Uses the La Cruz and Raydan (2003) method.
- > 'dfsane' : Uses the La Cruz, Martínez, and Raydan (2006) method. Which is a derivativ free version of 'sane'.

- **numWorkers** ↑

Positive integer. Number of worker to use when running optimization in parallel.

- **options** ↑

Options of the solver selected. See the nb_solve.optimset method. If given as empty (struct) default options will be used.

- **stepLength** ↑

Step length applied when calculating numerical first difference objects. For example $(F(x + h) - F(x))/h$. h is here the selected step length

- **tolerance** ↑

Tolerance value for convergence. Default is 1e-7.

- **useParallel** ↑

true or false. Give true if the nodes should be spread on different parallel workers.

- **x** ↑

Solution at last iteration, as a M x 1 double. If the solver converged it will be the solution to the problem.

Methods:

- alphaMethod1
- alphaMethod2
- alphaMethod3
- broyden
- call
- dfsane
- get
- getMethods
- newton
- optimset
- sane
- set
- solve
- steffensen
- steffensen2
- test
- test2
- ypl

► **alphaMethod1** ↑

```
alpha = nb_solve.alphaMethod1(s,y)
```

Description:

Implements the spectral step length in equation 3 of Varadhan and Gilbert (2009).

```
alpha(k) = s(k-1)' * s(k-1) / ( s(k-1)' * y(k-1) )
```

See also:

[nb_solve.alphaMethod2](#), [nb_solve.alphaMethod3](#)

Written by Kenneth Sæterhagen Paulsen

► **alphaMethod2** ↑

```
alpha = nb_solve.alphaMethod2(s,y)
```

Description:

Implements the spectral step length in equation 4 of Varadhan and Gilbert (2009).

```
alpha(k) = s(k-1)' * s(k-1) / ( y(k-1)' * y(k-1) )
```

See also:

[nb_solve.alphaMethod1](#), [nb_solve.alphaMethod3](#)

Written by Kenneth Sæterhagen Paulsen

► **alphaMethod3** ↑

```
alpha = nb_solve.alphaMethod3(s,y)
```

Description:

Implements the spectral step length in equation 5 of Varadhan and Gilbert (2009).

```
alpha(k) = sgn(s(k-1)' * y(k-1)) * ||s(k-1)|| / ||y(k-1)||
```

where $\text{sgn}(x) = x/|x|$

See also:

[nb_solve.alphaMethod1](#), [nb_solve.alphaMethod2](#)

Written by Kenneth Sæterhagen Paulsen

► **broyden** ↑

```
results = nb_solve.broyden(opt,fVal)
```

Description:

Solve the problem using the Broyden algorithm.

See also:

[nb_solve.solve](#)

Written by Kenneth Sæterhagen Paulsen

► call ↑

```
[x,fval,exitflag,JAC] = nb_solve.call(F,init,options,JF,varargin)
```

Description:

Call the nb_solve class to solve the $F(x) =$ problem. See the documentation of the nb_abc class for more on this algorithm.

Input:

- F : See the documentation of the F property of the nb_solve class. Must be given.
- init : See the documentation of the init property of the nb_solve class. Must be given.
- options : See the nb_solve.optimset method for more on this input. Can be empty.
- JF : See the documentation of the JF property of the nb_solve class. Can be empty.

Optional inputs:

- varargin : Optional number of inputs given to the F (and JF) function(s) when it is called during the solution algorithm.

Output:

- x : See the documentation of the minXValue property of the nb_abc class.
- fval : See the documentation of the minFunctionValue property of the nb_abc class.
- exitflag : See the documentation of the exitFlag property of the nb_abc class.
- JAC : Jacobian at last iteration.

Examples:

```
g = @(x)x^2;
x1 = nb_solve.call(g,1)
x2 = nb_solve.call(g,-3)
```

See also:

[nb_solve.optimset](#), [fsolve](#)

Written by Kenneth Sætherhagen Paulsen

► **dfsane** ↑

```
results = nb_solve.dfsane(opt,fVal)
```

Description:

Solve the problem using the Spectral Residual Method of La Cruz W, Martínez JM, Raydan M (2006). The implementation follows Varadhan and Gilbert (2009) with some adjustments.

See also:

[nb_solve.solve](#)

Written by Kenneth Sæterhagen Paulsen

► **get** ↑

```
get(obj,propertyName)
```

Description:

Gets the property of an object of class `nb_getable`.

Input:

- `obj` : An object of class `nb_getable`.
- `propertyName` : Name of the property to get the value of, as a string.

Output:

- `value` : The value of the property asked for.

Examples:

```
fig = obj.get('parent');
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_GETABLE`

► **getMethods** ↑

```
methods = getMethods()
```

Description:

Get a list of the supported methods of the nb_solve class.

Output:

- methods : A cellstr with the supported methods of the nb_solve class.

See also:

[nb_solve.call](#), [nb_solve.optimset](#)

Written by Kenneth Sæterhagen Paulsen

► [newton](#) ↑

results = nb_solve.newton(opt,fVal)

Description:

Solve the problem using the Newton-Raphson algorithm.

See also:

[nb_solve.solve](#)

Written by Kenneth Sæterhagen Paulsen

► [optimset](#) ↑

options = nb_solve.optimset(varargin)

Description:

Get solution options or help.

Optional input:

- Run without inputs to get defaults.
- Run with 'list' as the first input to get a cellstr with the supported options.
- Run with 'help' to get a struct with help on each option.
- Run with 'optionName' to get help on a particular option, i.e. only one input.
- Use 'optionName', optionValue pairs to set options of the returned struct.

Output:

- Depends on the input.

See also:[nb_abc.options](#)

Written by Kenneth SÃ¶terhagen Paulsen

► sane ↑

```
results = nb_solve.sane(opt,fVal)
```

Description:

Solve the problem using the Spectral Residual Method of La Cruz and Raydan (2003). The implementation follows Varadhan and Gilbert (2009) with some adjustments.

See also:[nb_solve.solve](#)

Written by Kenneth SÃ¶terhagen Paulsen

► set ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_settable. Give the property name as a string. The input that follows should be the value you want to assign to that property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_settable.
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_settable with the given properties reset.

Examples:

```
obj = obj.set('parent',figure);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_SETTABLE

► **solve** ↑

```
solve(obj,varargin)
```

Description:

Solve the problem.

Input:

- obj : An object of class nb_solve.

See also:

[nb_solve.call](#)

Written by Kenneth Sæterhagen Paulsen

► **steffensen** ↑

```
results = nb_solve.steffensen(opt,fVal)
```

Description:

Solve the problem using the Steffensen algorithm.

See also:

[nb_solve.solve](#)

Written by Kenneth Sæterhagen Paulsen

► **steffensen2** ↑

```
results = nb_solve.steffensen2(opt,fVal)
```

Description:

Solve the problem using a two step version of the Steffensen algorithm.

See also:

[nb_solve.solve](#)

Written by Kenneth Sæterhagen Paulsen

► **test** ↑

```
solver = nb_solve.test(varargin)
```

Description:

Solve the following problem:

$x^2 = 0$

Which has the trivial solution 0.

Optional input:

- varargin : Optional inputs given to the set method.

Output:

- solver : An object of class nb_solve.

See also:

[nb_solve](#), [nb_solve.call](#)

Written by Kenneth Sæterhagen Paulsen

► **test2** ↑

```
solver = nb_solve.test2(varargin)
```

Description:

Solve the following problem:

$x(1)^2 - x(2) = 0$
 $x(1) * x(2) = 0$

Which has the trivial solution [0;0].

Optional input:

- varargin : Optional inputs given to the set method.

Output:

- solver : An object of class nb_solve.

See also:

[nb_solve](#), [nb_solve.call](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **yp1** ↑

```
results = nb_solve.dfsane(opt,fVal)
```

Description:

Solve the problem using the projection method suggested by Yan, Peng and Li (2008).

See also:

[nb_solve.solve](#)

Written by Kenneth SÃ¶terhagen Paulsen

◆ **nb_blockDecompose**

```
blocks = nb_blockDecompose(F,y,p,tol,fixed,varargin)
```

Description:

Block decompose system of non-linear equations $F(y, p, \text{varargin}{:}) = 0$.

For more see see Mihoubi (2011), "Solving and estimating stochastic models with block decomposition" section 2.

Input:

- F : A function_handle that takes 2 inputs.
- y : The initial values of the variables to solve for, as a nVar x 1 double.
- p : The parameters of the function F (this may include exogenous variables!). As a nPar x 1 double.
- tol : The tolerance level for setting elements of the jacobian to 0.
- fixed : A 1 x nVar logical with elements set to true if the variable value is already known.

Optional input:

- varargin : Optional inputs given to the function handle F when being evaluated.

Output:

- blocks : A struct with how to block the model.

See also:

[nb_solver](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_getSolvers

solvers = nb_getSolvers()

Description:

Get the solvers that solves systems of nonlinear equations of several variables.

This function also tries to detect solvers of other toolboxes, such as csolve (Chris Sims). You need to add these optimimzer separately, as they are not part of NB toolbox.

Output:

- solvers : A cellstr with the supported solvers.

See also:

[fsolve](#), [nb_getDefaultOptimset](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_homotopy

```
x           = nb_homotopy(algorithm,steps,start,finish,...  
                           names,solveFunc,fHandle,options)  
[x,fVal,exitflag,err] = nb_homotopy(algorithm,steps,start,finish,...  
                           names,solveFunc,fHandle,init,options,varargin)
```

Description:

Find the solution of the problem $F(x) = 0$ using homotopy.

At each step of the homotopy algorithm the solver function (solveFunc) will be called.

Caution: It is assumed that the problem can be solved with the parameters in start with the given initial conditions.

Input:

- algorithm : Either 1, 2 or 3.
 - > 1: The problem is solved iteratively. Starting with the vector of parameters in start until it reaches the parameter vector finish. All the parameters will change at the same time. This means that the problem is solved steps times.
 - > 2: Same as 1, but know the only one parameter is change at each recursion. One step of this algorithm is when all the parameters have changed. This means that the problem is solved nParam x steps times.
 - > 3: Now it tries to solve the problem at finish with the solution from the parameters in start as the initial condition. If this fails, it will try to solve it with the parameter that are the mid point between start and finish. If that fails, it splits this interval in two again, and it will continue in this way until it finds a point it can solve the problem. It will do this for each sub interval until it reaches the parameter vector finish.
- steps : Depends on the algorithm input.
 - > 1: The number of recursive steps from the start vector of parameters until the finish vector of parameter.
 - > 2: The number of recursive steps from the start vector of parameters until the finish vector of parameter.
 - > 3: The maximum number of allowed steps of this algorithm.
- start : The nParam x 1 parameter vector at the starting point, where we assume we already know that the problem can be solved.
- finish : The nParam x 1 parameter vector at the finishing point. This point is the point where we are really interested in solving the problem.
- names : A cellstr with the names of the parameters to do the homotopy over. If given as empty default names will be given. This is to throw a correct error message when homotopy algorithm 2 fails.
- solveFunc : See the same input to the nb_solver function.
- fHandle : See the same input to the nb_solver function.
- init : See the same input to the nb_solver function.
- options : See the same input to the nb_solver function. To prevent it from printing iteration on the command line set the silent field to true.

Optional input:

- varargin : See the same input to the nb_solver function.

Output:

```
- x      : The solution of the problem F(x) = 0, as a vector of double values.

- fVal   : The value of F(x) at the return x.

- exitflag : The exit flag return by the solver. If only to outputs are returned this exit flag will be interpreted by the nb_interpretExitFlag and an error will be thrown by inside this function.

- err     : A struct with the information on the error during the homotopy steps. Empty if no errors occur. This can be given to the nb_interpretExitFlag function to throw a generic error message. The fields are:

  > iter    : If exitflag return that the problem could not be solve, this output will give the iteration number it first failed. Otherwise it is empty. For algorithm 2 this will be a 1x2 double, where the 2 element is the parameter index it failed.

  > points  : If exitflag return that the problem could not be solve, this output will give the parameter vector it first failed.

  > algorithm : Same as the algorithm input.

  > names    : Same as the names input.
```

Written by Kenneth Sætherhagen Paulsen

◆ nb_lyapunovEquation

```
[X,failed] = nb_lyapunovEquation(A,B,tol,maxiter)
```

Description:

Solve the problem $X = A \cdot X \cdot A' + B$ using the fact that:

```
X = sum A^i * B * (A')^i over i = 1:inf
```

This method iterate the sum above until convergence.

Input:

```
- A      : A symmetric matrix with size N x N

- B      : A symmetric matrix with size N x N

- tol    : The tolerance of the iteration procedure. Default is eps^(1/3).

- maxiter : Maximum number of iterations. Default is 1000.
```

Output:

- X : Solution of the problem. As a N x N double.
- failed : True if the calculation failed.

Written by Kenneth Sæterhagen Paulsen

◆ nb_lyapunovEquation2

```
[X,failed] = nb_lyapunovEquation2(A,B,C,tol,maxiter)
```

Description:

Solve the problem $X = A \cdot X \cdot B + C$ using the fact that:

$X = \sum A^i \cdot C \cdot B^i$ over $i = 1:\inf$

This method iterate the sum above until convergence.

Input:

- A : A symmetric matrix with size N x N
- B : A symmetric matrix with size N x N
- C : A symmetric matrix with size N x N
- tol : The tolerance of the iteration procedure. Default is $\text{eps}^{(1/3)}$.
- maxiter : Maximum number of iterations. Default is 1000.

Output:

- X : Solution of the problem. As a N x N double.
- failed : True if the calculation failed.

Written by Kenneth Sæterhagen Paulsen

◆ nb_solveLinearRationalExpModel

```
[D,L,err] = nb_solveLinearRationalExpModel(A,B,nState)
```

Description:

Solves for the recursive representation of the stable solution to a system of linear difference equations.

Klein, Paul, 2000. "Using the generalized Schur form to solve a multivariate linear rational expectations model," Journal of Economic

Dynamics and Control, Elsevier, vol. 24(10), pages 1405–1423, September.

Solves $A[x(t+1)] = B x(t)$. $x(t)$ is ordered so that the state variables comes first.

Inputs:

- A, B : Two square matrices A and B in the equation above.
- nState : Number of state variables.

Outputs:

- D, L : The decision rule D and the law of motion L. Lets decompose $x(t)$ into $x(t) = [s(t); c(t)]$, where $s(t)$ are the state variables. Then the solution can be found to be:

$$\begin{aligned}c(t) &= D*s(t) \text{ and} \\s(t+1) &= L*s(t).\end{aligned}$$

- err : Non-empty if either the Blanchard-Kahn rank condition or order condition is not satisfied.

◆ **nb_solver**

```
x = nb_solver(solveFunc,fHandle,init,options)
[x,fVal,exitflag] = nb_solver(solveFunc,fHandle,init,options,varargin)
```

Description:

Call a solver function (solveFunc) that can be called like

```
[x,fVal,exitflag] = solveFunc(fHandle,init,options,varargin{:})
```

The function should solve the problem $F(x) = 0$ for x .

Input:

- solveFunc : A string with the name or a function_handle of the function to use to solve the problem
- fHandle : A function handle that represents F.
- init : The initial values of x to be used by the solver.
- options : A struct with the options to use by the solver. For some optimizers see the optimset function by MATLAB.

Options input:

- varargin : These inputs is passed on to the function fHandle during the solving of the problem.

Output:

- x : The solution of the problem $F(x) = 0$, as a vector of double values.
- fVal : The value of $F(x)$ at the return x.
- exitflag : The exit flag return by the solver. If only to outputs are returned this exit flag will be interpreted by the nb_interpretExitFlag and an error will be thrown by inside this function.

► **gaimc.bfs** ↑

```
[d, dt, pred] = gaimc.bfs(A,u,target)
```

Description:

Compute breadth first search distances, times, and tree for a graph

```
[d, dt, pred] = bgl.bfs(A,u) returns the distance (d) and the discover time (dt) for each vertex in the graph in a breadth first search starting from vertex u.  
d = dt(i) = inf if vertex i is not reachable from u  
pred is the predecessor array. pred(i) = 0 if vertex (i) is in a component not reachable from u and i != u.  
[...] = bgl.bfs(A,u,v) stops the bfs when it hits the vertex v
```

Examples:

```
W = ones(1,11);  
DG = sparse([6 1 2 2 3 4 4 5 5 6 1],[2 6 3 5 4 1 6 3 4 3 5],W);  
[dist,dt,pred] = gaimc.bfs(DG,1)
```

See also:

[gaimc.dijkstra](#), [nb_shortestpath](#)

Written by David F. Gleich

Edited by Kenneth S. Paulsen

- Return inf instead of -1 if vertex is not reachable from u.

► **gaimc.convert_sparse** ↑

```
As = gaimc.convert_sparse(A)
```

Description:

Convert a sparse matrix to the native gaimc representation

As = convert_sparse(A) returns a struct with the three arrays defining the compressed sparse row structure of A.

Examples:

```
load('graphs/all_shortest_paths_example')  
As = bgl.convert_sparse(A)
```

See also:

[gaimc.sparse_to_csr](#), [sparse](#)

Written by David F. Gleich

► **gaimc.csr_to_sparse** ↑

```
[nzi,nzj,nzv] = gaimc.csr_to_sparse(rp,ci,ai,ncols)
```

Description:

Convert from compressed row arrays to a sparse matrix.

A = gaimc.csr_to_sparse(rp,ci,ai) returns the sparse matrix represented by the compressed sparse row representation rp, ci, and ai. The number of columns of the output sparse matrix is max(max(ci),nrows). See the call below.

A = gaimc.csr_to_sparse(rp,ci,ai,ncol) While we can infer the number of rows in the matrix from this expression, you may want a different number of.

[nzi,nzj,nzv] = gaimc.csr_to_sparse(...) returns the arrays that feed the sparse call in matlab. You can use this to avoid the sparse call and customize the behavior.

This command "inverts" the behavior of gaimc.sparse_to_csr.
Repeated entries in the matrix are summed, just like sparse does.

Examples:

```
A          = sparse(6,6);
A(1,1)    = 5;
A(1,5)    = 2;
A(2,3)    = -1;
A(4,1)    = 1;
A(5,6)    = 1;
[rp, ci, ai] = gaimc.sparse_to_csr(A);
A2         = gaimc.csr_to_sparse(rp,ci,ai)
```

See also:

[gaimc.sparse_to_csr](#), [sparse](#)

Written by David F. Gleich

► **gaimc.dijkstra** ↑

```
[d,dt,pred,m] = gaimc.dijkstra(A,u)
```

Description:

Compute shortest paths using Dijkstra's algorithm

d = gaimc.dijkstra(A,u) computes the shortest path from vertex u to all nodes reachable from vertex u using Dijkstra's algorithm for the problem. The graph is given by the weighted sparse matrix A, where A(i,j) is the distance between vertex i and j. In the output vector d, the entry d(v) is the minimum distance between vertex u and vertex v.

A vertex w unreachable from u has d(w)=Inf.

[d,dt,pred,m] = gaimc.dijkstra(A,u) also returns the discover time (dt) for each vertex in the graph and the predecessor tree to generate the actual shortest paths. In the predecessor tree pred(v) is the vertex preceding v in the shortest path and pred(u)=0. Any unreachable vertex has pred(w)=0 as well. m is the number of nodes along the path.

If your network is unweighted, then use bfs instead.

See also BFS

Examples:

```
W = [.41 .99 .51 .32 .15 .45 .38 .32 .36 .29 .21];
DG = sparse([6 1 2 2 3 4 4 5 5 6 1],[2 6 3 5 4 1 6 3 4 3 5],W);
[dist,dt,pred] = gaimc.dijkstra(DG,1)
```

See also:

[gaimc.bfs](#), [nb_shortestpath](#)

Written by David F. Gleich

Edited by Kenneth S. Paulsen
- Added the m output.

► **[gaimc.sparse_to_csr](#)** ↑

```
[rp,ci,ai,ncol] = gaimc.sparse_to_csr(A,varargin)
```

Description:

Convert a sparse matrix into compressed row storage arrays

[rp, ci, ai] = gaimc.sparse_to_csr(A) returns the row pointer (rp), column index (ci) and value index (ai) arrays of a compressed sparse representation of the matrix A.

[rp ci ai] = gaimc.sparse_to_csr(i,j,v,n) returns a csr representation of the index sets i,j,v with n rows.

Example:

```
A = sparse(6,6); A(1,1)=5; A(1,5)=2; A(2,3)=-1; A(4,1)=1; A(5,6)=1;
[rp, ci, ai] = gaimc.sparse_to_csr(A)
```

```
x = le(x,y)
```

Description:

Less than or equal. Only tests the values not derivatives.

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **length** ↑

```
mylength = length(x)
```

Description:

length operator.

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **log** ↑

```
x = isnan(x)
```

Description:

Natural logarithm.

Edited by SeHyoun Ahn, May 2016

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **logncdf** ↑

```
x = logncdf(x,m,k)
```

Description:

Log normal cdf.

Written by Kenneth Sæterhagen Paulsen

► **lognpdf** ↑

```
x = lognpdf(x,m,k)
```

Description:

Log normal pdf.

Written by Kenneth SÅ!terhagen Paulsen

► **lt** ↑

x = ge(x,y)

Description:

Less than. Only tests the values not derivatives.

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **max** ↑

varargout = max(x,varargin)

Description:

Max operator.

Edited by SeHyoun Ahn, Jan 2016

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **min** ↑

varargout = min(x,varargin)

Description:

Min operator.

Edited by SeHyoun Ahn, Jan 2016

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **minus** ↑

```
x = minus(x,y)
```

Description:

Minus.

Edited by SeHyoun Ahn, Oct 2017

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **mldivide** ↑

```
y = mldivide(x,y)
```

Description:

Matrix left division (\).

Written by SeHyoun Ahn, Jan 2016

► **mpower** ↑

```
x = plus(x,y)
```

Description:

Redirect to power (.^) if x is a scalar.

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **mrdivide** ↑

```
y = mldivide(x,y)
```

Description:

Matrix right division (/).

Written by SeHyoun Ahn, Jan 2016

► **mtimes** ↑

```
y = mldivide(x,y)
```

Description:

Matrix multiplication.

Note that in the original package by Martin Fink, this redirected to element-wise multiplication

Written by SeHyoun Ahn, Jan 2016

► **ne** ↑

```
x = ne(x,y)
```

Description:

Not equal. Only tests the values not derivatives.

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **normcdf** ↑

```
x = normcdf(x,m,k)
```

Description:

Normal cdf.

Written by Kenneth Sæterhagen Paulsen

► **norminv** ↑

```
x = norminv(x,m,k)
```

Description:

Inverse normal cdf.

Written by SeHyoun Ahn, May 2022
Edited by Kenneth S. Paulsen
- Added the m and k inputs

► **normpdf** ↑

```
x = normcdf(x,m,k)
```

Description:

Normal cdf.

Written by Kenneth Sæterhagen Paulsen

► **numel** ↑

```
x = numel(x)
```

Description:

The numel operator.

Written by SeHyoun Ahn, July 2016

► **permute** ↑

```
x = permute(x,order)
```

Description:

Permute matrix operator.

Written by SeHyoun Ahn, July 2016

► **plus** ↑

```
x = plus(x,y)
```

Description:

Plus (+).

Edited by SeHyoun Ahn, Oct 2017

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **power** ↑

x = plus(x,y)

Description:

power (.^).

Edited by SeHyoun Ahn, Jan 2016

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **prod** ↑

x = prod(x,varargin)

Description:

Product.

Written by SeHyoun Ahn, July 2016

► **rdivide** ↑

x = rdivide(x,y)

Description:

Right division (./).

Edited by SeHyoun Ahn, Jan 2016

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **repmat** ↑

x = repmat(x,varargin)

Description:

Replicate object.

Written by SeHyoun Ahn, Jan 2016

► **reshape** ↑

```
x = reshape(x,varargin)
```

Description:

Reshape object.

Written by SeHyoun Ahn, Jan 2016

► **sin** ↑

```
x = sin(x)
```

Description:

Sine.

Edited by SeHyoun Ahn, May 2016

In Package myAD - Automatic Differentiation
by Martin Fink, June 2006
martinfink 'at' gmx.at

► **sinh** ↑

```
x = sin(x)
```

Description:

Hyperbolic sine.

Written by SeHyoun Ahn, Jan 2016

► **size** ↑

```
x = size(x,varargin)
```

Description:

Size of object.

Written by SeHyoun Ahn, July 2016

► **sort ↑**

```
varargout = sort(x,varargin)
```

Description:

Sort based on the values.

Edited by SeHyoun Ahn, July 2016
Edited by SeHyoun Ahn, Jan 2016

In Package myAD - Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **sparse ↑**

```
A = sparse(i,j,v,n,m)
```

Description:

Make object sparse.

Written by SeHyoun Ahn, Oct 2017

► **spdiags ↑**

```
x = spdiags(x,varargin)
```

Description:

Note that spdiags will keep the derivative matrix in column-major order %
Therefore, given matrix A(i,j), the first few rows of the derivative
matrices are

```
D_x A_{1,1} (These are row vectors of derivative of A_{1,1})  
D_x A_{2,1}  
...  
D_x A_{n,1}  
D_x A_{1,2}  
...
```

Written by SeHyoun Ahn, Jan 2016

► **sqrt** ↑

```
x = isnan(x)
```

Description:

Test for nan in values or derivatives.

Edited by SeHyoun Ahn, May 2016

In Package myAD - Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **steady_state** ↑

```
x = steady_state(x)
```

Description:

Derivative of the steady_state operator. Used by nb_DSGE. Will return a double.

Written by Kenneth Sæterhagen Paulsen

► **steady_state_first** ↑

```
x = steady_state_first(x)
```

Description:

Derivative of the steady_state_first operator. Used by nb_DSGE. Will return a double.

Written by Kenneth Sæterhagen Paulsen

► **subsasgn** ↑

```
y = subsasgn(y, S, x)
```

Description:

Subs asgment of object.

Edited by SeHyoun Ahn, July 2016
Edited by SeHyoun Ahn, Jan 2016

In Package myAD - Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **subsref** ↑

x = subsref(x, S)

Description:

Subs reference object.

Edited by SeHyoun Ahn, July 2016
Edited by SeHyoun Ahn, Jan 2016

In Package myAD - Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **sum** ↑

x = sum(x,varargin)

Description:

Sum.

Edited by SeHyoun Ahn, July 2016
Edited by SeHyoun Ahn, Jan 2016

In Package myAD - Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **tan** ↑

x = tan(x)

Description:

Tangent.

Edited by SeHyoun Ahn, May 2016

In Package myAD – Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **tanh** ↑

`x = tanh(x)`

Description:

Hyperbolic tangent.

Edited by SeHyoun Ahn, May 2016

In Package myAD – Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **times** ↑

`x = times(x, varargin)`

Description:

Multiplication ($\cdot\ast$).

Edited by SeHyoun Ahn, Jan 2016

► **transpose** ↑

`x = transpose(x)`

Description:

Transpose.

Written by SeHyoun Ahn, Jan 2016

► **uminus** ↑

```
x = uminus(x)
```

Description:

Unary minus.

In Package myAD - Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **uplus** ↑

```
x = uplus(x)
```

Description:

Unary plus.

In Package myAD - Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

► **vertcat** ↑

```
x = vertcat(varargin)
```

Description:

Vertical concatenation.

Written by SeHyoun Ahn, Jan 2016

► **zeros** ↑

```
x = zeros(x)
```

Description:

Zero out all values and derivatives.

In Package myAD - Automatic Differentiation
by Martin Fink, May 2007
martinfink 'at' gmx.at

■ nb_base

Go to: [Properties](#) | [Methods](#)

A class for representing a variable. Used by the nb_term class.

Superclasses:

nb_term

Constructor:

obj = nb_base(value,sign);

Input:

- value : A variable name. E.g. 'x'.

Output:

- obj : An object of class nb_base.

Examples:

```
base = nb_base('x');
```

See also:

[nb_term](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [numberOfTerms](#)
- [operator](#)
- [terms](#)
- [value](#)

- [numberOfTerms](#) ↑

The number of terms. As a scalar integer.

Inherited from superclass NB_TERM

- [operator](#) ↑

Type of operator splitting the terms.

Inherited from superclass NB_TERM

- [terms](#) ↑

A vector of nb_term objects.

Inherited from superclass NB_TERM

- [value](#) ↑

Base value, as a one line char.

Methods:

- [callExpOnSub](#)
- [callFuncOnSub](#)
- [cellstr](#)
- [clean](#)
- [correct](#)
- [eq](#)
- [exp](#)
- [gap](#)
- [generalFunc](#)
- [initialize](#)
- [intersect](#)
- [ismember](#)
- [log](#)
- [logncdf](#)
- [lognpdf](#)
- [minus](#)
- [mpower](#)
- [mrdivide](#)
- [mtimes](#)
- [normcdf](#)
- [norminv](#)
- [normpdf](#)
- [plus](#)
- [power](#)
- [rdivide](#)
- [removePar](#)
- [simplify](#)
- [split](#)
- [sqrt](#)
- [steady_state](#)
- [times](#)
- [toString](#)
- [uminus](#)
- [union](#)
- [uplus](#)

► **callExpOnSub** ↑

```
obj = callExpOnSub(obj)
```

See also:

[nb_term.exp](#)

Written by Kenneth Sæterhagen Paulsen

► **callFuncOnSub** ↑

```
obj = callFuncOnSub(obj, func, varargin)
```

See also:

[nb_term.generalFunc](#)

Written by Kenneth Sæterhagen Paulsen

► **cellstr** ↑

```
c = toString(obj)
```

Description:

Convert array of nb_term objects to cellstr.

Inputs:

- obj : An array of nb_term objects.

Output:

- c : A cellstr with same size as obj.

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **clean** ↑

obj = clean(obj)

Description:

Clean up nb_term object after operations.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **correct** ↑

expr = nb_term.correct(expr)

Description:

Correct term for .*, ./ and .^ operators.

Input:

- expr : A one line char with a mathematical expression.

Output:

- expr : Corrected version of the input.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **eq** ↑

test = eq(obj,another)

Description:

Test for equality of two objects. They are only equal if the value property is equal.

Inputs:

- obj : A nb_base object.
- another : A nb_base object.

Output:

- test : true or false.

Written by Kenneth Sæterhagen Paulsen

► **exp ↑**

obj = exp(obj)

Description:

exp operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **gap ↑**

obj = gap(obj)

Description:

Gap operator.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► generalFunc ↑

```
obj = generalFunc(obj,func,varargin)
```

Description:

Call general function on a nb_term objects.

Input:

- obj : A vector of nb_term objects.
- func : A one line char with the function to apply on the nb_term objects.

Optional input:

- nb_term objects representing the extra inputs to the function.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► initialize ↑

```
obj = nb_term.initialize(rows,cols)
```

Description:

Initialize vector of nb_term objects.

Input:

- rows : Number of rows. As a scalar integer.
- cols : Number of columns. As a scalar integer.

Output:

- obj : A rows x cols nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► intersect ↑

```
int = intersect(obj,another)
```

Description:

Get the intersect of two vectors of nb_term objects.

Input:

- obj : A vector of nb_term objects.
- another : A vector of nb_term objects.

Output:

- int : The intersect, as a vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► ismember ↑

```
[ind,loc] = ismember(obj,another)
```

Description:

Check if the terms in obj is member of the terms in another.

Input:

- obj : A vector of nb_term objects.
- another : A vector of nb_term objects.

Output:

- ind : A logical vector with same size as obj. Elements that are true are found to be in the another input.
- loc : A double vector with same size as obj. Locations of the

elements that are found in the another input. If not found 0 is returned.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **log** ↑

obj = log(obj)

Description:

log operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **logncdf** ↑

obj = logncdf(obj,m,k)

Description:

Log-normal cdf.

Input:

- obj : A vector of nb_term objects.

- m : The mean of the distribution, as an object of class nb_term.

- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **lognpdf** ↑

```
obj = lognpdf(obj,m,k)
```

Description:

Log-normal pdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **minus** ↑

```
obj = minus(obj,another)
```

Description:

Minus operator (-) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **mpower** ↑

```
obj = mpower(obj,another)
```

Description:

Power operator (*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **mrdivide** ↑

```
obj = mrdivide(obj,another)
```

Description:

Division operator (/) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► mtimes ↑

```
obj = mtimes(obj,another)
```

Description:

Times operator (*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► normcdf ↑

```
obj = normcdf(obj,m,k)
```

Description:

Normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► norminv ↑

```
obj = norminv(obj,m,k)
```

Description:

Inverse normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► normpdf ↑

```
obj = normpdf(obj,m,k)
```

Description:

Normal pdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► plus ↑

obj = plus(obj,another)

Description:

Plus operator (+) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► power ↑

obj = power(obj,another)

Description:

Power operator (.^) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **rdivide** ↑

obj = rdivide(obj,another)

Description:

Division operator (./) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **removePar** ↑

expr = removePar(expr)

Description:

Is the expression enclosed with parentheses?

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **simplify** ↑

```
expr = nb_term.simplify(expr)
expr = nb_term.simplify(expr,waitbar)
```

Description:

Simplify the mathematical expressions.

Input:

- expr : A one line char with a mathematical expression or a cellstr with the mathematical expressions.
- waitbar : A nb_waitbar5 object. It will use the next available waitbar of the given object. If empty no waitbar is added.

Output:

- obj : A cellstr with the simplified mathematical expressions.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **split** ↑

```
obj = nb_term.split(expr)
obj = nb_term.split(expr,waitbar)
```

Description:

Split the mathematical expression into separate terms.

Input:

- expr : A one line char with a mathematical expression.
- waitbar : A nb_waitbar5 object. If empty no waitbar is added.

Output:

- obj : A nb_term object representing the mathematical expression.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **sqrt** ↑

```
obj = sqrt(obj)
```

Description:

sqrt operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **steady_state** ↑

```
obj = steady_state(obj)
```

Description:

Steady-state operator.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **times** ↑

```
obj = times(obj,another)
```

Description:

Times operator (.*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► [toString](#) ↑

c = toString(obj)

Description:

Convert nb_base object to string or cellstr.

Inputs:

- obj : A nb_base object. May also be a matrix.

Output:

- c : If obj is scalar the output will be a one line char, otherwise it will be a cellstr with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► [uminus](#) ↑

obj = uminus(obj)

Description:

Unary minus operator (-) for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term object.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **union** ↑

uni = union(obj,another)

Description:

Get the union of two vectors of nb_term objects.

Input:

- obj : A vector of nb_term objects.

- another : A vector of nb_term objects.

Output:

- uni : The union, as a vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **unique** ↑

uniq = unique(obj,another)

Description:

Locate the unique nb_term objects in a vector of nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- uniq : The unique nb_term objects.

- ind : Vector such that uniq = obj(ind).

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **uplus** ↑

```
obj = uplus(obj)
```

Description:

Unary plus opertor (+) for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_TERM

■ **nb_bgrowth**

Go to: [Properties](#) | [Methods](#)

A class for deriving the balanced growth restrictions of a DSGE model.

Constructor:

```
obj = nb_bgrowth(varName,constant,precision);
```

Input:

- varName : Name of the variable(s) to take derivative respect to, either as a char or cellstr.

- constant : Set to true if this object represent a stationary variable or parameter.

- precision : See help on the property precision.

Output:

- obj : An object of class nb_bgrowth

See also:

[nb_st](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- constant
- equation
- final
- precision
- unaryMinus

- **constant** ↑

Set to true if this object represent a stationary variable or parameter.

- **equation** ↑

The property storing the expression as a char.

- **final** ↑

Set to true to make all operators stop working on an equation

- **precision** ↑

The precision on the converted numbers. See the nb_num2str function. Default is [], i.e. use num2str without any input.

- **uniaryMinus** ↑

Indicator for last method call being unary minus

Methods:

- | | | | | |
|----------------------|-----------|-----------|-----------|----------------|
| • bgp | • detrend | • disp | • exp | • log |
| • logncdf | • lognpdf | • minus | • mpower | • mrdivide |
| • mtimes | • normcdf | • norminv | • normpdf | • plus |
| • power | • rdivide | • sgp | • sqrt | • steady_state |
| • steady_state_first | • times | • uminus | • uplus | |

► **bgp** ↑

obj = bgp(obj)

Description:

Balanced growth path operator.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **detrend** ↑

```
obj = detrend(obj)
```

Description:

Detrend operator.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **disp** ↑

```
disp(obj)
```

Description:

Display object (In the command window)

Input:

- obj : An object of class nb_bgrowth

Output:

The object displayed on the command line.

Examples:

```
obj (Note without semicolon)
```

Written by Kenneth S. Paulsen

► **exp** ↑

```
obj = exp(obj)
```

Description:

Exponential function.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth SÃ¶terhagen Paulsen

► **log** ↑

obj = log(obj)

Description:

Log function (natural logarithm).

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth SÃ¶terhagen Paulsen

► **logncdf** ↑

obj = logncdf(obj,m,k)

Description:

CDF of the log normal distribution.

Input:

- obj : An object of class nb_bgrowth.

- m : The mean of the associated normal distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.

- k : The std of the associated normal distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► lognpdf ↑

```
obj = lognpdf(obj)
```

Description:

PDF of the log normal distribution.

Input:

- obj : An object of class nb_bgrowth.
- m : The mean of the associated normal distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.
- k : The std of the associated normal distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► minus ↑

```
obj = minus(obj,another)
```

Description:

Minus operator (-).

Input:

- another : A scalar number, nb_bgrowth object or string.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **mpower** ↑

```
obj = mpower(obj,another)
```

Description:

Power operator (^). This will call power (.^)!

Input:

- another : A scalar number, nb_bgrowth object or string.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **mrddivide** ↑

```
obj = mrddivide(obj,another)
```

Description:

Right division operator (/), same as (./).

Input:

- another : A scalar number, nb_bgrowth object or string.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **mtimes** ↑

```
obj = mtimes(obj,another)
```

Description:

Times operator (*). Here assumed equal to .* operator.

Input:

- another : A scalar number, nb_bgrowth object or string.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► normcdf ↑

```
obj = normcdf(obj)
```

Description:

CDF of the normal distribution.

Input:

- obj : An object of class nb_bgrowth.
- m : The mean of the distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.
- k : The std of the distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► norminv ↑

```
obj = norminv(obj)
```

Description:

Inverse normal cdf.

Input:

- obj : An object of class nb_bgrowth.
- m : The mean of the distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.
- k : The std of the distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► normpdf ↑

```
obj = normcdf(obj)
```

Description:

PDF of the normal distribution.

Input:

- obj : An object of class nb_bgrowth.
- m : The mean of the distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.
- k : The std of the distribution. Either as a scalar double, a one line char representing a number or a nb_bgrowth object.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► plus ↑

```
obj = plus(obj,another)
```

Description:

Plus operator (+).

Input:

- another : A scalar number, nb_bgrowth object or string.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **power** ↑

```
obj = power(obj,another)
```

Description:

Power operator (.^).

Input:

- another : A scalar number, nb_bgrowth object or string.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **rdivide** ↑

```
obj = rdivide(obj,another)
```

Description:

Right division operator (./).

Input:

- another : A scalar number, nb_bgrowth object or string.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **sgp** ↑

```
obj = sgp(obj)
```

Description:

Stochastic growth path operator.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth SÃ¶terhagen Paulsen

► **sqrt** ↑

obj = sqrt(obj)

Description:

Square root.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth SÃ¶terhagen Paulsen

► **steady_state** ↑

obj = steady_state(obj)

Description:

Steady-state operator.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth SÃ¶terhagen Paulsen

► **steady_state_first** ↑

```
obj = steady_state_first(obj)
```

Description:

Steady-state (first regime) operator.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **times** ↑

```
obj = times(obj,another)
```

Description:

Times operator (.*) .

Input:

- another : A scalar number, nb_bgrowth object or string.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth Sæterhagen Paulsen

► **uminus** ↑

```
obj = uminus(obj)
```

Description:

Unary minus.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth SÃ¶terhagen Paulsen

► uplus ↑

```
obj = uplus(obj)
```

Description:

Unary plus.

Input:

- obj : An object of class nb_bgrowth.

Output:

- obj : An object of class nb_bgrowth.

Written by Kenneth SÃ¶terhagen Paulsen

■ nb_eq2Latex

Go to: [Properties](#) | [Methods](#)

A class for converting equations to latex format.

Constructor:

```
obj = nb_eq2Latex(varName,precision);
```

Input:

- varName : Name of the variable(s) of the expression(s) that is converted to latex code, as a one line char or a cellstr.

- precision : See help on the property precision.

Output:

- obj : An object of class nb_eq2Latex.

Examples:

```
d = nb_eq2Latex('x');
d = d.^2
```

See also:

[nb_eq2Latex.parse](#), [nb_dsge.writeTex](#)

Written by Kenneth Søsterhagen Paulsen

Properties:

- [latex](#)
- [precision](#)
- [values](#)

- **latex** [↑](#)

The property storing the latex code of the equation, as a one line char.

- **precision** [↑](#)

The precision on the converted numbers. See the [nb_num2str](#) function. Default is 14, i.e. use [nb_num2str](#) with the second input set to 14.

- **values** [↑](#)

The property storing the original equation as a string.

Methods:

- | | | | |
|--------------------------------------|----------------------------|--------------------------|--------------------------------|
| • addLatexPar | • eq | • exp | • gap |
| • ge | • gt | • le | • log |
| • logncdf | • lognpdf | • lt | • minus |
| • mpower | • mrdivide | • mtimes | • ne |
| • normcdf | • normpdf | • parse | • plus |
| • power | • rdivide | • sqrt | • steady_state |
| • steady_state_first | • times | • uminus | • uplus |
| • writePDF | • writeTex | | |

► **addLatexPar** [↑](#)

`str = nb_eq2Latex.addLatexPar(str,type)`

Description:

Add latex matched parentheses if needed to a term during parsing.

Input:

- `str` : A one line char.
- `type` : Give true to always add parentheses, even if no `+, -,` or `\frac` is found.

Output:

- str : A one line char.

Written by Kenneth SÃ¶terhagen Paulsen

► eq ↑

```
obj = eq(obj,another,flip)
```

Description:

Equality operator (==), will be subst. by the = sign in the latex equations!

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth SÃ¶terhagen Paulsen

► exp ↑

```
obj = exp(obj)
```

Description:

Exponential.

Input:

- obj : An object of class nb_eq2Latex.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth SÃ¶terhagen Paulsen

► **gap** ↑

```
obj = gap(obj)
```

Description:

The gap operator.

Input:

- obj : An object of class nb_eq2Latex.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **ge** ↑

```
obj = ge(obj,another,flip)
```

Description:

Greater than or equal operator (\geq).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **gt** ↑

```
obj = gt(obj,another,flip)
```

Description:

Greater than operator (>).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- another : A scalar number, nb_eq2Latex object, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **le** ↑

obj = le(obj,another,flip)

Description:

Less than or equal operator (<=)

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **log** ↑

obj = log(obj)

Description:

Natural logarithm.

Input:

- obj : An object of class nb_eq2Latex.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth SÃ¶terhagen Paulsen

► **logncdf** ↑

```
obj = logncdf(obj,m,k)
```

Description:

Log normal cdf.

Input:

- obj : An object of class nb_eq2Latex.
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double, a one line char representing a number or an object of class nb_param.
- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double, a one line char representing a number or an object of class nb_param.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth SÃ¶terhagen Paulsen

► **lognpdf** ↑

```
obj = lognpdf(obj,m,k)
```

Description:

Log normal pdf.

Input:

- obj : An object of class nb_eq2Latex.
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double or a one line char representing a number.
- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double or a one line char representing a number.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **lt** ↑

obj = lt(obj,another,flip)

Description:

Less than operator (<).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **minus** ↑

obj = minus(obj,another,flip)

Description:

Minus operator (-).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **mpower** ↑

obj = mpower(obj,another)

Description:

Power operator (^). This will call power (.^)!

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **mrddivide** ↑

obj = mrddivide(obj,another)

Description:

Right division operator (/), same as (./).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sætherhagen Paulsen

► **mtimes** ↑

```
obj = mtimes(obj,another)
```

Description:

Times operator (*). Here assumed equal to .* operator.

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sætherhagen Paulsen

► **ne** ↑

```
obj = ne(obj,another,flip)
```

Description:

Not equal to operator (~=).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sætherhagen Paulsen

► **normcdf** ↑

```
obj = normcdf(obj,m,k)
```

Description:

Normal cdf.

Input:

- obj : An object of class nb_eq2Latex.
- m : The mean of the distribution. Either as a scalar double or a one line char representing a number.
- k : The std of the distribution. Either as a scalar double or a one line char representing a number.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **normpdf** ↑

```
obj = normcdf(obj,m,k)
```

Description:

Normal cdf.

Input:

- obj : An object of class nb_eq2Latex.
- m : The mean of the distribution. Either as a scalar double or a one line char representing a number.
- k : The std of the distribution. Either as a scalar double or a one line char representing a number.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **parse** ↑

```
obj = nb_eq2Latex.parse(expr,varargin)
```

Description:

Parse mathematical expressions and turn them into a vector of nb_eq2Latex objects.

Input:

- expr : A N x 1 cellstr with the mathematical expressions to parse.

Optional input:

- 'latexVars' : Use this input to translate the names of the variables/parameters of the mathematical expression to latex names. In this case 'vars' must also be given. Each element of the 'vars' input is translated into the corresponding element of this input. Must be a M x 1 cellstr.

- 'precision' : See help on the precision property. Default is 14.

- 'vars' : A M x 1 cellstr with the variables of the expression. If not provided or empty, the variables will be parsed at the cost of speed.

Output:

- obj : A N x 1 vector of nb_eq2Latex objects.

See also:

[nb_eq2Latex.writePDF](#)

Written by Kenneth Sætherhagen Paulsen

► **plus** ↑

```
obj = plus(obj,another,flip)
```

Description:

Plus operator (+).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **power** ↑

obj = power(obj,another,flip)

Description:

Power operator ($.^$).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **rdivide** ↑

obj = rdivide(obj,another,flip)

Description:

Right division operator ($./$).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **sqrt** ↑

obj = sqrt(obj)

Description:

Square root.

Input:

- obj : An object of class nb_eq2Latex.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **steady_state** ↑

obj = steady_state(obj)

Description:

The steady_state operator.

Input:

- obj : An object of class nb_eq2Latex.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth Sæterhagen Paulsen

► **steady_state_first** ↑

```
obj = steady_state_first(obj)
```

Description:

The steady_state (first regime) operator.

Input:

- obj : An object of class nb_eq2Latex.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth SÃ¶terhagen Paulsen

► **times** ↑

```
obj = times(obj,another,flip)
```

Description:

Times operator (.*).

Input:

- obj : An object of class nb_eq2Latex, scalar double or string.
- another : An object of class nb_eq2Latex, scalar double or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth SÃ¶terhagen Paulsen

► **uminus** ↑

```
obj = uminus(obj)
```

Description:

Unary minus.

Input:

- obj : An object of class nb_eq2Latex.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth SÃ¶terhagen Paulsen

► **uplus** ↑

obj = uplus(obj)

Description:

Uniary plus.

Input:

- obj : An object of class nb_eq2Latex.

Output:

- obj : An object of class nb_eq2Latex.

Written by Kenneth SÃ¶terhagen Paulsen

► **writePDF** ↑

writePDF(obj,filename)

Description:

Write the equations to PDF

Input:

- obj : An object of class nb_eq2Latex.

- filename : The filename of the saved pdf file. As a one line char.
Extension is ignored.

Examples:

obj.writePDF('test')

Written by Kenneth S. Paulsen

► **writeTex** ↑

```
code = writeTex(obj,filename)
```

Description:

Write tex file of the equations.

Input:

- obj : An object of class nb_eq2Latex.
- filename : Give the name of the written .tex file. If not given or empty no file will be written. Extension is ignored.

Output:

- code : A Q x 1 cellstr with the latex code.

Written by Kenneth Sæterhagen Paulsen

■ **nb_equation**

Go to: [Properties](#) | [Methods](#)

A class for representing an equation with a set of nb_term objects.

Superclasses:

nb_term

Constructor:

```
obj = nb_equation(expr);
```

Input:

- expr : Expression to simplify, as a one line char or a cellstr.

Output:

- obj : An object of class nb_equation.

Examples:

```
terms = nb_equation('x+x*y');
```

See also:

[nb_term](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- `numberOfTerms` • `operator` • `terms`
- **`numberOfTerms` ↑**

The number of terms. As a scalar integer.

Inherited from superclass NB_TERM

- **`operator` ↑**

Type of operator splitting the terms.

Inherited from superclass NB_TERM

- **`terms` ↑**

A vector of nb_term objects.

Inherited from superclass NB_TERM

Methods:

- `callExpOnSub` • `callFuncOnSub` • `cellstr` • `clean` • `correct`
- `eq` • `equalToThePower` • `exp` • `gap` • `generalFunc`
- `getTerms` • `initialize` • `intersect` • `isempty` • `ismember`
- `log` • `logncdf` • `lognpdf` • `minus` • `mpower`
- `mrdivide` • `mtimes` • `normcdf` • `norminv` • `normpdf`
- `plus` • `power` • `rdivide` • `removePar` • `simplify`
- `sort` • `split` • `sqrt` • `steady_state` • `times`
- `toString` • `uminus` • `union` • `unique` • `uplus`

► **`callExpOnSub` ↑**

`obj = callExpOnSub(obj)`

See also:

`nb_term.log`

Written by Kenneth Sæterhagen Paulsen

► **`callFuncOnSub` ↑**

`obj = callFuncOnSub(obj, func, varargin)`

See also:

[nb_term.generalFunc](#)

Written by Kenneth Sæterhagen Paulsen

► **cellstr** ↑

c = toString(obj)

Description:

Convert array of nb_term objects to cellstr.

Inputs:

- obj : An array of nb_term objects.

Output:

- c : A cellstr with same size as obj.

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **clean** ↑

obj = clean(obj)

Description:

Clean up nb_term object after operations.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **correct** ↑

expr = nb_term.correct(expr)

Description:

Correct term for $\cdot*$, $\cdot/$ and $\cdot^$ operators.

Input:

- expr : A one line char with a mathematical expression.

Output:

- expr : Corrected version of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **eq** ↑

```
test = eq(obj,another)
```

Description:

Test for equality of two objects. They are only equal if they represents the same equation.

Inputs:

- obj : A nb_equation object.
- another : A nb_equation object.

Output:

- test : true or false.

Written by Kenneth SÃ¶terhagen Paulsen

► **equalToThePower** ↑

```
[test,obj] = equalToThePower(obj,another)
```

Description:

Test for equality of two objects ignoring powers.

Inputs:

- obj : A nb_equation object.
- another : A nb_equation object.

Output:

- test : true or false.
- obj : A nb_equation object representing the simplified object. E.g:
$$\begin{aligned} \text{eq}^*(\text{eq})^{-1} &\rightarrow 1, \quad \text{eq}^2 * \text{eq}^1 \rightarrow \text{eq}^3 \\ \text{eq} / (\text{eq} + \text{eq} * x) &\rightarrow 1 / (1 + x) \end{aligned}$$
But not yet:
$$\text{eq}^2 / (\text{eq}^2 + \text{eq} * x) \rightarrow \text{eq} / (\text{eq} + x)$$

Written by Kenneth SÃ¶terhagen Paulsen

► exp ↑

obj = exp(obj)

Description:

exp operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► gap ↑

obj = gap(obj)

Description:

Gap operator.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **generalFunc** ↑

```
obj = generalFunc(obj, func, varargin)
```

Description:

Call general function on a nb_term objects.

Input:

- obj : A vector of nb_term objects.
- func : A one line char with the function to apply on the nb_term objects.

Optional input:

- nb_term objects representing the extra inputs to the function.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **getTerms** ↑

```
terms = getTerms(obj)
```

Description:

Get the expression(s) the object(s) represents.

Input:

- obj : A Nx1 vector of nb_term objects.

Output:

- expr : A Nx1 cellstr with the terms of the nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **initialize** ↑

```
obj = nb_equation.initialize(rows,cols)
```

Description:

Initialize vector of nb_equation objects.

Input:

- rows : Number of rows. As a scalar integer.
- cols : Number of columns. As a scalar integer.

Output:

- obj : A rows x cols nb_term object.

Written by Kenneth Sætherhagen Paulsen

► **intersect ↑**

```
int = intersect(obj,another)
```

Description:

Get the intersect of two vectors of nb_term objects.

Input:

- obj : A vector of nb_term objects.
- another : A vector of nb_term objects.

Output:

- int : The intersect, as a vector of nb_term objects.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_TERM

► **isempty ↑**

```
ret = isempty(obj)
```

Description:

Is the nb_term object empty or not. Also work for matrices of nb_term objects.

Input:

- obj : A nb_term object (matrix)

Output:

- ret : A logical with same size as obj.

Written by Kenneth SÃ¶terhagen Paulsen

► **ismember** ↑

```
[ind,loc] = ismember(obj,another)
```

Description:

Check if the terms in obj is member of the terms in another.

Input:

- obj : A vector of nb_term objects.
- another : A vector of nb_term objects.

Output:

- ind : A logical vector with same size as obj. Elements that are true are found to be in the another input.
- loc : A double vector with same size as obj. Locations of the elements that are found in the another input. If not found 0 is returned.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **log** ↑

```
obj = log(obj)
```

Description:

log operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► logncdf ↑

```
obj = logncdf(obj,m,k)
```

Description:

Log-normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► lognpdf ↑

```
obj = lognpdf(obj,m,k)
```

Description:

Log-normal pdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **minus** ↑

obj = minus(obj,another)

Description:

Minus operator (-) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **mpower** ↑

obj = mpower(obj,another)

Description:

Power operator (*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **mrdivide** ↑

obj = mrdivide(obj,another)

Description:

Division operator (/) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **mtimes** ↑

obj = mtimes(obj,another)

Description:

```
Times operator (*) for nb_term objects.
```

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **normcdf** ↑

```
obj = normcdf(obj,m,k)
```

Description:

Normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **norminv** ↑

```
obj = norminv(obj,m,k)
```

Description:

Inverse normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **normpdf** ↑

obj = normpdf(obj,m,k)

Description:

Normal pdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **plus** ↑

obj = plus(obj,another)

Description:

Plus operator (+) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **power** ↑

obj = power(obj,another)

Description:

Power operator (.^) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **rdivide** ↑

```
obj = rdivide(obj,another)
```

Description:

Division operator (./) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **removePar** ↑

```
expr = removePar(expr)
```

Description:

Is the expression enclosed with parentheses?

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **simplify** ↑

```
expr = nb_term.simplify(expr)
expr = nb_term.simplify(expr,waitbar)
```

Description:

Simplify the mathematical expressions.

Input:

- expr : A one line char with a mathematical expression or a cellstr with the mathematical expressions.
- waitbar : A nb_waitbar5 object. It will use the next available waitbar of the given object. If empty no waitbar is added.

Output:

- obj : A cellstr with the simplified mathematical expressions.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **sort ↑**

```
sorted = sort(obj)
```

Description:

Sort terms in an equation.

Written by Kenneth SÃ¶terhagen Paulsen

► **split ↑**

```
obj = nb_term.split(expr)
obj = nb_term.split(expr,waitbar)
```

Description:

Split the mathematical expression into separate terms.

Input:

- expr : A one line char with a mathematical expression.
- waitbar : A nb_waitbar5 object. If empty no waitbar is added.

Output:

- obj : A nb_term object representing the mathematical expression.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **sqrt** ↑

```
obj = sqrt(obj)
```

Description:

sqrt operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **steady_state** ↑

```
obj = steady_state(obj)
```

Description:

Steady-state operator.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **times** ↑

```
obj = times(obj,another)
```

Description:

Times operator (.*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► [toString ↑](#)

c = toString(obj)

Description:

Convert nb_num object to string or cellstr.

Inputs:

- obj : A nb_num object. May also be a matrix.

Output:

- c : If obj is scalar the output will be a one line char, otherwise it will be a cellstr with same size as obj.

Written by Kenneth Sæterhagen Paulsen

► [uminus ↑](#)

obj = uminus(obj)

Description:

Unary minus operator (-) for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term object.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **union** ↑

uni = union(obj,another)

Description:

Get the union of two vectors of nb_term objects.

Input:

- obj : A vector of nb_term objects.

- another : A vector of nb_term objects.

Output:

- uni : The union, as a vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **unique** ↑

uniq = unique(obj,another)

Description:

Locate the unique nb_term objects in a vector of nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- uniq : The unique nb_term objects.

- ind : Vector such that uniq = obj(ind).

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► uplus ↑

```
obj = uplus(obj)
```

Description:

Unary plus opertor (+) for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

■ nb_logLinearize

Go to: [Properties](#) | [Methods](#)

A class for doing symbolic log-linearization of a mathematical expression.

Constructor:

```
obj = nb_logLinearize(equations,variables,parameters,precision);
```

Input:

- equations : Name of the variable to take derivative respect to.

- variables : The variables to do the log-linearization wrt. I.e. the rest are treated as parameters.

- parameters : You can hard code in the parameters, if you already know them, otherwise these will be parsed out. If given it must be a 1 x nParam cellstr.

- precision : See the doc on the property precision.

Output:

- obj : An object of class nb_logLinearize.

Examples:

```
logLin = nb_logLinearize({'x+y','z=x*y^alpha'},{'x','y','z'});  
logLin = logLinearize(logLin);  
logLinEq = getLinearization(logLin);
```

See also:

[nb_mySD](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- deriv
- doSimplify
- eqFunc
- equations
- gapIdentifier
- logLinEq
- parameters
- precision
- ssEq
- ssIdentifier
- variables

- **deriv** ↑

A nb_mySD object storing the symbolic derivatives.

- **doSimplify** ↑

Set to false to prevent using nb_term.split to simplify the log-linearized equations. Default is false.

- **eqFunc** ↑

Function handle representing the equations.

- **equations** ↑

The equation we start with. As a N x 1 cellstr. Include a equality sign ('=') to indicate that is a equation and not only a term to log linearize.

- **gapIdentifier** ↑

The text that is used to enclose gap variables. Default is 'x_GAP'. Must be a 1x2 cellstr. The first element is added before the variable, and the second after.

- **logLinEq** ↑

The log-linearized equation. As a N x 1 cellstr.

- **parameters** ↑

A cellstr with the parameters. If not provided, they will be parsed out automatically at a cost of speed!

- **precision** ↑

The precision on the converted numbers. See the nb_num2str function. Default is 14, i.e. use nb_num2str with the second input set to 14.

- **ssEq** ↑

Equations in steady-state. As a N x 1 cellstr.

- **ssIdentifier** ↑

The text that is used to enclose steady-state variables. Default is 'steady_state(x)'. Must be a 1x2 cellstr. The first element is added before the variable, and the second after.

- **variables** ↑

A cellstr with the variables to log-linearize wrt.

Methods:

- [cellstr](#)
 - [logLinearize](#)
-

► **cellstr** ↑

eqs = cellstr(obj)

Description:

Get the equations as a cellstr.

Input:

- obj : An object of class nb_logLinearize
- type : Either 'logLinEq' (log-linearized equations, default), 'equations' (original equations) or 'ssEq' (equations in steady-state)

Output:

- eqs : A cellstr.

Written by Kenneth Sæterhagen Paulsen

► **logLinearize** ↑

obj = logLinearize(obj)

Description:

Do the log linearization.

Input:

- obj : An object of class nb_logLinearize

Output:

- obj : An object of class nb_logLinearize. See the property logLinEq for the log-linearized equations.

Written by Kenneth Sæterhagen Paulsen

■ nb_logger

Go to: [Properties](#) | [Methods](#)

A class for logging.

Superclasses:

handle

Constructor:

logger = nb_logger(folder,level)

Input:

- folder : Specify the folder to log to. Will set the environment variable 'LOGGERFILE'.

- level : Level of logging. Default is 0, i.e. to log everything. Will set the environment variable 'LOGGERLEVEL'.

Output:

- logger : A nb_logger object.

Written by Kenneth Sæterhagen Paulsen

Properties:

- ALL
- DEBUG
- DEFAULT
- ERROR
- INFO
- OFF
- WARN

- ALL ↑

nb_logger.ALL is a property.

- DEBUG ↑

nb_logger.DEBUG is a property.

- DEFAULT ↑

`nb_logger.DEFAULT` is a property.

- **ERROR** ↑

`nb_logger.ERROR` is a property.

- **INFO** ↑

`nb_logger.INFO` is a property.

- **OFF** ↑

`nb_logger.OFF` is a property.

- **WARN** ↑

`nb_logger.WARN` is a property.

Methods:

- `closeLoggerFile`
 - `getLoggerFolder`
 - `getParallelLoggerFile`
 - `logging`
 - `loggingDuringParallel`
 - `openLogFile`
-

► **closeLoggerFile** ↑

`nb_logger.closeLoggerFile(inputs)`

Description:

Close logger file.

Written by Kenneth Sæterhagen Paulsen

► **getLoggerFolder** ↑

`folder = nb_logger.getLoggerFolder()`

Description:

Get logger folder.

Written by Kenneth Sæterhagen Paulsen

► **getParallelLoggerFile** ↑

```
w = nb_logger.getParallelLoggerFile(type)
```

Description:

Write logger file.

Written by Kenneth Sæterhagen Paulsen

► **logging** ↑

```
nb_logger.logging(messageLevel,inputs,message,Err)
```

Description:

Write logger file.

Written by Kenneth Sæterhagen Paulsen

► **loggingDuringParallel** ↑

```
nb_logger.loggingDuringParallel(messageLevel,write,w,message,Err)
```

Description:

Write logger file.

Written by Kenneth Sæterhagen Paulsen

► **openLoggerFile** ↑

```
inputs = nb_logger.openLoggerFile(inputs,obj)
```

Description:

Open logger file.

Written by Kenneth Sæterhagen Paulsen

■ **nb_macro**

Go to: [Properties](#) | [Methods](#)

A class representing a macro variable that can be defined in a NB toolbox macro syntax.

Constructor:

```
obj = nb_macroVar(input)
```

Input:

- input : One of:
 - > Scalar double.
 - > Vector of numerical.
 - > Matrix of numerical, will be converted to a vector.
 - > One line char. Special cases;
 - * '"C"' will be converted to 'C'.
 - * '["C","B"]' will be converted to cellstr.
 - * '{"C","B"}' will be converted to cellstr.
 - * {'C','B'}' will be converted to cellstr.
 - * '2' will be converted to scalar numerical.
 - * 'true' or 'false' will be converted to scalar logical.
 - * '[1,0.2,3]' will be converted to a numerical vector.
 - * '[true,false]' will be converted to a logical vector.
 - * '[true,false,1]' will be converted to a numerical vector.
 - * Else it will be stored as a normal char.
 - > Multi-line char, converted to cellstr. No interpretation!
 - > Scalar logical.
 - > Vector of logicals.
 - > Matrix of logicals, will be converted to a vector.

Output:

- obj : A object of class nb_macroVar.

Written by Kenneth Sætherhagen Paulsen

Properties:

- name • value

- **name** ↑

Name of the the macro variable

- **value** ↑

Value that the macro variable represents

Methods:

• and	• colon	• define	• disp	• eq
• eval	• forEnd	• ge	• gt	• ifElseEnd
• in	• indexing	• interpret	• le	• lt
• minus	• mpower	• mrdivide	• mtimes	• ne
• not	• or	• parse	• plus	• power
• rdivide	• times	• type		

► **and** ↑

```
obj = and(obj1,obj2)
```

Description:

The && operator for nb_macro objects. This allows for;
> logical = numeric && numeric
> logical = logical && logical
> logical = logical && numeric

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',2) && 4 will result in a nb_macro object representing the logical true.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

or, not

Written by Kenneth Sæterhagen Paulsen

► colon ↑

```
obj = colon(obj1,obj2)
```

Description:

The : operator for nb_macro objects. This allows for;
> numeric = numeric : numeric

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',1) : 2 will result in a nb_macro object representing the double vector [1,2].

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

Written by Kenneth Sæterhagen Paulsen

► **define** ↑

`obj = define(obj, name, statement)`

Description:

Define a new macro variable.

Input:

- obj : A 1 x N vector of nb_macro objects.
- name : A one line char with the name of the defined variable.
- statement : A one line char to interpret.

Output:

- obj : A 1 x (N + 1) vector of nb_macro objects.

See also:

[nb_macro.parse](#)

Written by Kenneth Sæterhagen Paulsen

► **disp** ↑

`disp(obj)`

Description:

Displaying the macro variable in the command window.

Input:

- obj : A nb_macro object of any size.

Written by Kenneth Sæterhagen Paulsen

► **eq** ↑

obj = eq(obj1,obj2)

Description:

The == operator for nb_macro objects. This allows for;

```
> logical = numeric == numeric
> logical = logical == logical
> logical = logical == numeric
> logical = char == char = strcmp(char,char)
```

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',2) == 4 will result in a nb_macro object representing the logical false.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.

- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

[lt](#), [gt](#), [le](#), [ge](#), [ne](#)

Written by Kenneth Sæterhagen Paulsen

► **eval** ↑

value = eval(obj,expression)

Description:

Evaluate a expression using the macro processor language.

Input:

- obj : A vector of nb_macro objects.
- expression : A one line char.

Output:

- value : A scalar nb_macro object.

See also:

[nb_eval](#)

Written by Kenneth Sæterhagen Paulsen

► **forEnd** ↑

[obj,statement] = forEnd(obj,forVar,looped,forStatements)

Description:

Running an @#for @#endfor block in the macro processing language.

Input:

- obj : A vector of nb_macro objects storing the macro variables.
- forVar : A one line char with the name of the for loop variable.
- looped : Either a one line char or a scalar nb_macro object.
- forStatements : The statements in the body of the @#for loop, as a N x cellstr.

Output:

- statement : A Q x 1 cellstr with the parsed version of the model file statements.

See also:

[nb_macro.ifElseEnd](#), [nb_macro.parse](#)

Written by Kenneth Sæterhagen Paulsen

► **ge** ↑

```
obj = ge(obj1,obj2)
```

Description:

The `>=` operator for nb_macro objects. This allows for;

```
> logical = numeric >= numeric  
> logical = logical >= logical  
> logical = logical >= numeric
```

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. `nb_macro('a',2) >= 4` will result in a nb_macro object representing the logical false.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- `obj1` : An object of any class.
- `obj2` : An object of any class.

Output:

- `obj` : An object of class nb_macro.

See also:

[ne](#), [lt](#), [le](#), [gt](#), [eq](#)

Written by Kenneth Sæterhagen Paulsen

► **gt** ↑

```
obj = gt(obj1,obj2)
```

Description:

The `>` operator for nb_macro objects. This allows for;

```
> logical = numeric > numeric  
> logical = logical > logical  
> logical = logical > numeric
```

Caution : The above type is refer to as the type property of the

nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',2) > 4 will result in a nb_macro object representing the logical false.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

[ne](#), [lt](#), [le](#), [ge](#), [eq](#)

Written by Kenneth Sæterhagen Paulsen

► **ifElseEnd ↑**

[obj,statement] = ifElseEnd(obj,condition,statementTrue,statementFalse)

Description:

Running an @#if @#else @#endif block in the macro processing language.

Input:

- obj : A vector of nb_macro objects storing the macro variables.
- condition : The condition to be tested. If true the statementTrue lines will be used.
- statementTrue : A N x 1 (3) cellstr with a set of model file statements.
- statementFalse : A M x 1 (3) cellstr with a set of model file statements.

Output:

- statement : A Q x 1 cellstr with the parsed version of the model file statements.

See also:

[nb_macro.forEnd](#), [nb_macro.parse](#)

Written by Kenneth Sæterhagen Paulsen

► [in](#) ↑

`obj = in(obj,objIn)`

Description:

Check if the value represented by obj can be found in objIn.

Caution: If you try to check if a number is part of a cellstr array, or a char is part of a numerical (or logical) it will not give an error. Instead a nb_macro object representing false will be returned.

Input:

- `obj` : A nb_macro object.
- `objIn` : A nb_macro object.

Output:

- `obj` : A nb_macro object representing true or false.

Examples:

```
mString = nb_macro('var1','C');
mString2 = nb_macro('var2','ABC');
mLogical = mString.in(mString2)

mString = nb_macro('var1','C');
mArray = nb_macro('array1',{'C','D','E'});
mLogical = mString.in(mArray)

mNum = nb_macro('var1',2);
mArray = nb_macro('array1',[1,3,5]);
mLogical = mNum.in(mArray)

mNum = nb_macro('var1',2);
mNum2 = nb_macro('var2',1);
mLogical = mNum.in(mNum2)
```

Written by Kenneth Sæterhagen Paulsen

► [indexing](#) ↑

```
obj = indexing(obj, index)
```

Description:

Use this method to index the arrays that the nb_macro object represent.

Input:

- obj : An object of nb_macro.
- index : A numerical array of integers. E.g. 5, 1:4, [1,3], [1,3:5]

Output:

- obj : An object of nb_macro.

Examples:

```
m = nb_macro('I','DE');
m = indexing(m,2)

m = nb_macro('I2',{ 'A','B','C','D' });
m = indexing(m,1:3)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **interpret** ↑

```
obj = nb_macro.interpret(input)
```

Description:

Convert input to a vector of nb_macro objects.

Input:

- input : Either a 1 x N or N x 1 nb_macro object, struct with N fields or a N x 2 cell.

Output:

- obj : An object of class nb_macro with size 1 x N.

See also:

[nb_dsge](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **le** ↑

```
obj = le(obj1,obj2)
```

Description:

The <= operator for nb_macro objects. This allows for;

```
> logical = numeric <= numeric  
> logical = logical <= logical  
> logical = logical <= numeric
```

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',2) <= 4 will result in a nb_macro object representing the logical true.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

[ne](#), [gt](#), [lt](#), [ge](#), [eq](#)

Written by Kenneth Sæterhagen Paulsen

► **lt** ↑

```
obj = lt(obj1,obj2)
```

Description:

The < operator for nb_macro objects. This allows for;

```
> logical = numeric < numeric  
> logical = logical < logical  
> logical = logical < numeric
```

Caution : The above type is refer to as the type property of the

nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',2) <= 4 will result in a nb_macro object representing the logical true.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

ne, gt, le, ge, eq

Written by Kenneth Sæterhagen Paulsen

► **minus ↑**

obj = minus(obj1,obj2)

Description:

The - operator for nb_macro objects. This allows for;

```
> numeric = numeric - numeric
> numeric = logical - logical
> numeric = logical - numeric
> cellstr = cellstr - cellstr = setdiff(cellstr, cellstr)
> char = char - char = setdiff(char,char)
> cellstr = cellstr - char = setdiff(cellstr,{char})
> cellstr = char - cellstr = setdiff({char},cellstr)
```

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',{'C','D'}) - {'C'} will result in a nb_macro object representing the cellstr {'D'}.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

[plus](#), [times](#), [power](#), [rdivide](#)

Written by Kenneth Sæterhagen Paulsen

► **mpower** ↑

obj = mpower(obj1,obj2)

Description:

Redirect to power, i.e. .^ and ^ is the same operator.

See also:

[power](#)

Written by Kenneth Sæterhagen Paulsen

► **mrdivide** ↑

obj = mrdivide(obj1,obj2)

Description:

Redirect to times, i.e. ./ and / is the same operator.

See also:

[rdivide](#)

Written by Kenneth Sæterhagen Paulsen

► **mtimes** ↑

```
obj = mtimes(obj1,obj2)
```

Description:

Redirect to times, i.e. .* and * is the same operator.

See also:

[times](#)

Written by Kenneth Sæterhagen Paulsen

► **ne** ↑

```
obj = ne(obj1,obj2)
```

Description:

The ~= operator for nb_macro objects. This allows for;

```
> logical = numeric ~= numeric
> logical = logical ~= logical
> logical = logical ~= numeric
> logical = char ~= char = ~strcmp(char,char)
```

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',2) ~= 4 will result in a nb_macro object representing the logical true.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

[lt](#), [gt](#), [le](#), [ge](#), [eq](#)

Written by Kenneth Sæterhagen Paulsen

► **not** ↑

```
obj = not(obj)
```

Description:

The ~ operator for nb_macro objects. This allows for;
> logical = ~numeric
> logical = ~logical

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. ~nb_macro('a',2) will result in a nb_macro object representing the logical false.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

[ne](#), [lt](#), [le](#), [gt](#), [ge](#), [eq](#)

Written by Kenneth Sæterhagen Paulsen

► **or** ↑

```
obj = or(obj1,obj2)
```

Description:

The || operator for nb_macro objects. This allows for;
> logical = numeric || numeric
> logical = logical || logical
> logical = logical || numeric

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',2) || 4 will result in a nb_macro object representing the logical true.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

and, not

Written by Kenneth Sæterhagen Paulsen

► **parse ↑**

[obj,parsed] = parse(obj,statements)

Description:

Parse model file that utilizes the macro processing language.

Input:

- obj : A vector of nb_macro objects.
- statements : A N x 3 cell with the model file statements at the first column, the line number at the second and the filenames at the third column.

Caution: This input can also be a N x 1 cell, but then the error messages will be less informative.

Output:

- parsed : A Q x 3 (1) cellstr with the statements input cleeaned for the macro processing language.

See also:

► **plus ↑**

```
obj = plus(obj1,obj2)
```

Description:

The + operator for nb_macro objects. This allows for;

```
> numeric = numeric + numeric
> numeric = logical + logical
> numeric = logical + numeric
> cellstr = cellstr + cellstr = [cellstr, cellstr]
> char    = char + char = [char,char]
> cellstr = cellstr + char = [cellstr,char]
> cellstr = char + cellstr = [char,cellstr]
```

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',{'C','D'}) + {'F'} will result in a nb_macro object representing the cellstr {'C','D','F'}.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

minus, times, power, rdivide

► **power ↑**

```
obj = power(obj1,obj2)
```

Description:

The * operator for nb_macro objects. This allows for;
> numeric = numeric .^ numeric
> numeric = logical .^ logical
> numeric = logical .^ numeric

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the MATLAB basic type. E.g. nb_macro('a',2) .^ 4 will result in a nb_macro object representing the double 16.

Caution : This operator supports nb_macro object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- obj1 : An object of any class.
- obj2 : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

[plus](#), [minus](#), [times](#), [rdivide](#)

Written by Kenneth SÅterhagen Paulsen

► **rdivide** ↑

```
obj = rdivide(obj1,obj2)
```

Description:

The * operator for nb_macro objects. This allows for;
> numeric = numeric ./ numeric
> numeric = logical ./ logical
> numeric = logical ./ numeric

Caution : The above type is refer to as the type property of the nb_macro variable.

Caution : This operator is also supported for if one nb_macro object represent one of the above type but the other input is of the

MATLAB basic type. E.g. `nb_macro('a',2) ./ 4` will result in a `nb_macro` object representing the double 0.5.

Caution : This operator supports `nb_macro` object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- `obj1` : An object of any class.
- `obj2` : An object of any class.

Output:

- `obj` : An object of class `nb_macro`.

See also:

[plus](#), [minus](#), [times](#), [power](#)

Written by Kenneth Sæterhagen Paulsen

► **times** ↑

`obj = times(obj1,obj2)`

Description:

The `*` operator for `nb_macro` objects. This allows for;
> numeric = numeric `.*` numeric
> numeric = logical `.*` logical
> numeric = logical `.*` numeric

Caution : The above type is refer to as the type property of the `nb_macro` variable.

Caution : This operator is also supported for if one `nb_macro` object represent one of the above type but the other input is of the MATLAB basic type. E.g. `nb_macro('a',2) .* 4` will result in a `nb_macro` object representing the double 8.

Caution : This operator supports `nb_macro` object, numeric and logical matrices, as long as one is a scalar or their sizes matches.

Input:

- `obj1` : An object of any class.
- `obj2` : An object of any class.

Output:

- obj : An object of class nb_macro.

See also:

[plus](#), [minus](#), [power](#), [rdivide](#)

Written by Kenneth Sæterhagen Paulsen

► **type** ↑

t = type(obj)

Description:

Get the MATLAB basic class the nb_macro object represent.

Input:

- obj : An object of class nb_macro.

Output:

- t : If numel(obj) > 0: cellstr
else : one line char

Written by Kenneth Sæterhagen Paulsen

■ **nb_mySD**

Go to: [Properties](#) | [Methods](#)

A class for doing symbolic derivative of a function.

Superclasses:

[nb_varOrPar](#), [matlab.mixin.Heterogeneous](#)

Constructor:

obj = nb_mySD(varName,precision);

Input:

- varName : Name of the variable to take derivative respect to, as a one line char or a cellstr.

- precision : See help on the property precision.

Output:

- obj : An object of class nb_mySD

Examples:

```
d      = nb_mySD('x');
d      = d.^2;
strDer = d.derivatives;
```

See also:

[myAD](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- [bases](#)
- [derivatives](#)
- [precision](#)
- [values](#)

- **bases** [↑](#)

The base variable.

- **derivatives** [↑](#)

The property storing the derivatives as a cellstr.

- **precision** [↑](#)

The precision on the converted numbers. See the `nb_num2str` function. Default is 14, i.e. use `nb_num2str` with the second input set to 14.

- **values** [↑](#)

The property storing the original equation as a string.

Methods:

- | | | | | |
|--------------------------|---------------------------|---------------------------|--------------------------------|--------------------------------------|
| • addPar | • exp | • log | • logncdf | • lognpdf |
| • max | • min | • minus | • mpower | • mrdivide |
| • mtimes | • normcdf | • norminv | • normpdf | • plus |
| • power | • rdivide | • sqrt | • steady_state | • steady_state_first |
| • times | • uminus | • uplus | | |

► **addPar** [↑](#)

```
str = nb_mySD.addPar(str,type)
```

Description:

Add parentheses if needed to a term during parsing.

Input:

- str : A one line char.
- type : Give false to allways add parentheses, even if no +,-,
^ or * is found.

Output:

- str : A one line char.

Written by Kenneth SÃ¶terhagen Paulsen

► **exp ↑**

obj = exp(obj)

Description:

Exponential.

Input:

- obj : An object of class nb_mySD.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth SÃ¶terhagen Paulsen

► **log ↑**

obj = log(obj)

Description:

Natural logarithm.

Input:

- obj : An object of class nb_mySD.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth SÃ¶terhagen Paulsen

► **logncdf** ↑

```
obj = logncdf(obj,m,k)
```

Description:

Log normal cdf.

Input:

- obj : An object of class nb_mySD.
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double, a one line char representing a number or a nb_param object.
- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double, a one line char representing a number or a nb_param object.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **lognpdf** ↑

```
obj = lognpdf(obj,m,k)
```

Description:

Log normal pdf.

Input:

- obj : An object of class nb_mySD.
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double, a one line char representing a number or a nb_param object.
- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double, a one line char representing a number or a nb_param object.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **max** ↑

```
obj = max(obj,another,flip)
```

Description:

Max operator.

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **min** ↑

```
obj = min(obj,another,flip)
```

Description:

Min operator.

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **minus** ↑

```
obj = minus(obj,another,flip)
```

Description:

Minus operator (-).

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **mpower** ↑

```
obj = mpower(obj,another)
```

Description:

Power operator (^). This will call power (.^)!

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **mrddivide** ↑

```
obj = mrddivide(obj,another)
```

Description:

Right division operator (/), same as (./).

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **mtimes** ↑

obj = mtimes(obj,another)

Description:

Times operator (*). Here assumed equal to .* operator.

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **normcdf** ↑

obj = normcdf(obj,m,k)

Description:

Normal cdf.

Input:

- obj : An object of class nb_mySD.
- m : The mean of the distribution. Either as a scalar double, a one line char representing a number or a nb_param object.
- k : The std of the distribution. Either as a scalar double, a one line char representing a number or a nb_param object.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **norminv** ↑

obj = norminv(obj,m,k)

Description:

Inverse normal cdf.

Input:

- obj : An object of class nb_mySD.
- m : The mean of the distribution. Either as a scalar double, a one line char representing a number or a nb_param object.
- k : The std of the distribution. Either as a scalar double, a one line char representing a number or a nb_param object.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **normpdf** ↑

obj = normpdf(obj,m,k)

Description:

Normal pdf.

Input:

- obj : An object of class nb_mySD.
- m : The mean of the distribution. Either as a scalar double, a one line char representing a number or a nb_param object.
- k : The std of the distribution. Either as a scalar double, a one line char representing a number or a nb_param object.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **plus ↑**

obj = plus(obj,another,flip)

Description:

Plus operator (+).

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **power ↑**

obj = power(obj,another,flip)

Description:

Power operator (.^).

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sætherhagen Paulsen

► **rdivide** ↑

obj = rdivide(obj,another,flip)

Description:

Right division operator (./).

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sætherhagen Paulsen

► **sqrt** ↑

obj = sqrt(obj)

Description:

Square root.

Input:

- obj : An object of class nb_mySD.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **steady_state** ↑

obj = steady_state(obj)

Description:

Derivative of the steady_state operator. Used by nb_DSGE.

Input:

- obj : An object of class nb_mySD.

Output:

- obj : An object of class nb_param.

Written by Kenneth Sæterhagen Paulsen

► **steady_state_first** ↑

obj = steady_state_first(obj)

Description:

Derivative of the steady_state_first operator. Used by nb_DSGE.

Input:

- obj : An object of class nb_mySD.

Output:

- obj : An object of class nb_param.

Written by Kenneth Sæterhagen Paulsen

► **times** ↑

obj = times(obj,another,flip)

Description:

Times operator (.*).

Input:

- obj : A scalar number, nb_param object, nb_mySD object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.
- flip : Flip the obj and another order.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **uminus** ↑

obj = uminus(obj)

Description:

Unary minus.

Input:

- obj : An object of class nb_mySD.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **uplus** ↑

obj = uplus(obj)

Description:

Unary plus.

Input:

- obj : An object of class nb_mySD.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sætherhagen Paulsen

■ nb_num

Go to: [Properties](#) | [Methods](#)

A class for representing a number. Used by the nb_simplifyEq class.

Superclasses:

nb_term

Constructor:

obj = nb_num(value);

Input:

- value : A scalar double. E.g. 1.

Output:

- obj : An object of class nb_num.

Examples:

base = nb_num(1);

See also:

[nb_term](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

• [numberOfTerms](#) • [operator](#) • [terms](#) • [value](#)

- **numberOfTerms** ↑

The number of terms. As a scalar integer.

Inherited from superclass NB_TERM

- **operator** ↑

Type of operator splitting the terms.

Inherited from superclass NB_TERM

- **terms** ↑

A vector of nb_term objects.

Inherited from superclass NB_TERM

- **value** ↑

The number as a scalar double.

Methods:

- callExpOnSub
- callFuncOnSub
- cellstr
- clean
- correct
- eq
- exp
- gap
- ge
- generalFunc
- gt
- initialize
- intersect
- ismember
- le
- log
- logncdf
- lognpdf
- lt
- minus
- mpower
- mrdivide
- mtimes
- ne
- normcdf
- norminv
- normpdf
- plus
- power
- rdivide
- removePar
- simplify
- split
- sqrt
- steady_state
- times
- toString
- uminus
- union
- unique
- uplus

► **callExpOnSub** ↑

obj = callExpOnSub(obj)

See also:

[nb_term.exp](#)

Written by Kenneth Sæterhagen Paulsen

► **callFuncOnSub** ↑

obj = callFuncOnSub(obj, func, varargin)

See also:

[nb_term.generalFunc](#)

Written by Kenneth Sæterhagen Paulsen

► **cellstr** ↑

```
c = toString(obj)
```

Description:

Convert array of nb_term objects to cellstr.

Inputs:

- obj : An array of nb_term objects.

Output:

- c : A cellstr with same size as obj.

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► [clean](#) ↑

```
obj = clean(obj)
```

Description:

Clean up nb_term object after operations.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► [correct](#) ↑

```
expr = nb_term.correct(expr)
```

Description:

Correct term for .*, ./ and .^ operators.

Input:

- expr : A one line char with a mathematical expression.

Output:

- expr : Corrected version of the input.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **eq** ↑

test = eq(obj,another)

Description:

Test for equality of two objects. They are only equal if the value property is equal.

Inputs:

- obj : A nb_num object or a number.
- another : A nb_num object or a number.

Output:

- test : true or false.

Written by Kenneth Sæterhagen Paulsen

► **exp** ↑

obj = exp(obj)

Description:

exp operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **gap** ↑

```
obj = gap(obj)
```

Description:

Gap operator.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **ge** ↑

```
test = ge(obj,another)
```

Description:

Test if one object is greater than or equal to another.

Inputs:

- obj : A nb_num object or a number.
- another : A nb_num object or a number.

Output:

- test : true or false.

Written by Kenneth SÃ¶terhagen Paulsen

► **generalFunc** ↑

```
obj = generalFunc(obj,func,varargin)
```

Description:

Call general function on a nb_term objects.

Input:

- obj : A vector of nb_term objects.
- func : A one line char with the function to apply on the nb_term objects.

Optional input:

- nb_term objects representing the extra inputs to the function.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **gt** ↑

test = gt(obj,another)

Description:

Test if one object is greater than another.

Inputs:

- obj : A nb_num object or a number.
- another : A nb_num object or a number.

Output:

- test : true or false.

Written by Kenneth SÃ¶terhagen Paulsen

► **initialize** ↑

obj = nb_term.initialize(rows,cols)

Description:

Initialize vector of nb_term objects.

Input:

- rows : Number of rows. As a scalar integer.
- cols : Number of columns. As a scalar integer.

Output:

- obj : A rows x cols nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **intersect** ↑

```
int = intersect(obj,another)
```

Description:

Get the intersect of two vectors of nb_term objects.

Input:

- obj : A vector of nb_term objects.

- another : A vector of nb_term objects.

Output:

- int : The intersect, as a vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **ismember** ↑

```
[ind,loc] = ismember(obj,another)
```

Description:

Check if the terms in obj is member of the terms in another.

Input:

- obj : A vector of nb_term objects.

- another : A vector of nb_term objects.

Output:

- ind : A logical vector with same size as obj. Elements that are true are found to be in the another input.

- loc : A double vector with same size as obj. Locations of the

elements that are found in the another input. If not found 0 is returned.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **le** ↑

test = le(obj,another)

Description:

Test if one object is less than or equal to another.

Inputs:

- obj : A nb_num object or a number.
- another : A nb_num object or a number.

Output:

- test : true or false.

Written by Kenneth Sæterhagen Paulsen

► **log** ↑

obj = log(obj)

Description:

log operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **logncdf** ↑

```
obj = logncdf(obj,m,k)
```

Description:

Log-normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **lognpdf ↑**

```
obj = lognpdf(obj,m,k)
```

Description:

Log-normal pdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **lt ↑**

```
test = lt(obj,another)
```

Description:

Test if one object is less than another.

Inputs:

- obj : A nb_num object or a scalar number.
- another : A nb_num object or a scalar number.

Output:

- test : true or false.

Written by Kenneth Sæterhagen Paulsen

► **minus** ↑

obj = minus(obj,another)

Description:

Minus operator (-) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **mpower** ↑

obj = mpower(obj,another)

Description:

Power operator (*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **mrddivide** ↑

obj = mrddivide(obj,another)

Description:

Division operator (/) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_TERM

► **mtimes** ↑

```
obj = mtimes(obj,another)
```

Description:

Times operator (*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **ne** ↑

```
test = ne(obj,another)
```

Description:

Test for not equality (~=) of two objects. They are only not equal if the value property is not equal.

Inputs:

- obj : A nb_num object or a number.

- another : A nb_num object or a number.

Output:

- test : true or false.

Written by Kenneth Sæterhagen Paulsen

► **normcdf** ↑

```
obj = normcdf(obj,m,k)
```

Description:

Normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **norminv** ↑

```
obj = norminv(obj,m,k)
```

Description:

Inverse normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **normpdf** ↑

```
obj = normpdf(obj,m,k)
```

Description:

Normal pdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► plus ↑

```
obj = plus(obj,another)
```

Description:

Plus operator (+) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **power** ↑

```
obj = power(obj,another)
```

Description:

Power operator ($.^$) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **rdivide** ↑

```
obj = rdivide(obj,another)
```

Description:

Division operator ($./$) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► removePar ↑

```
expr = removePar(expr)
```

Description:

Is the expression enclosed with parentheses?

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► simplify ↑

```
expr = nb_term.simplify(expr)
expr = nb_term.simplify(expr,waitbar)
```

Description:

Simplify the mathematical expressions.

Input:

- expr : A one line char with a mathematical expression or a cellstr with the mathematical expressions.
- waitbar : A nb_waitbar5 object. It will use the next available waitbar of the given object. If empty no waitbar is added.

Output:

- obj : A cellstr with the simplified mathematical expressions.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► split ↑

```
obj = nb_term.split(expr)
obj = nb_term.split(expr,waitbar)
```

Description:

Split the mathematical expression into separate terms.

Input:

- expr : A one line char with a mathematical expression.
- waitbar : A nb_waitbar5 object. If empty no waitbar is added.

Output:

- obj : A nb_term object representing the mathematical expression.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **sqrt** ↑

obj = sqrt(obj)

Description:

sqrt operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **steady_state** ↑

obj = steady_state(obj)

Description:

Steady-state operator.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► times ↑

```
obj = times(obj,another)
```

Description:

Times operator (.*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► toString ↑

```
c = toString(obj)
```

Description:

Convert nb_num object to string or cellstr.

Inputs:

- obj : A nb_num object. May also be a matrix.

Output:

```
- c : If obj is scalar the output will be a one line char,  
      otherwise it will be a cellstr with same size as obj.
```

Written by Kenneth Sæterhagen Paulsen

► **uminus** ↑

```
obj = uminus(obj)
```

Description:

Unary minus operator (-) for nb_term objects.

Input:

```
- obj : A vector of nb_term objects.
```

Output:

```
- obj : A vector of nb_term object.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **union** ↑

```
uni = union(obj,another)
```

Description:

Get the union of two vectors of nb_term objects.

Input:

```
- obj      : A vector of nb_term objects.  
- another : A vector of nb_term objects.
```

Output:

```
- uni      : The union, as a vector of nb_term objects.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **unique** ↑

```
uniq = unique(obj,another)
```

Description:

Locate the unique nb_term objects in a vector of nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- uniq : The unique nb_term objects.
- ind : Vector such that uniq = obj(ind).

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

► **uplus** ↑

```
obj = uplus(obj)
```

Description:

Unary plus opertor (+) for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TERM

■ **nb_param**

Go to: [Properties](#) | [Methods](#)

A class for storing a parameter. Can be used to calculate symbolic derivatives of expressions with unassign parameters when combined with nb_mySD.

Superclasses:

`nb_varOrPar, matlab.mixin.Heterogeneous`

Constructor:

```
obj = nb_param(parameters);
```

Input:

- parameters : The parameter as a one line char or the parameters as a cellstr.
- precision : See help on the property precision.

Output:

- obj : An object of class nb_param

Examples:

```
p = nb_param({'x','y','z'});  
expr = p(1)*p(2)
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- derivatives • parameter • precision

- **derivatives** ↑

The property storing the derivatives as a cellstr. Always {'0'}.

- **parameter** ↑

A one line char with the parameter or a expression involving the parameter (and possibly others as well)

- **precision** ↑

The precision on the converted numbers. See the nb_num2str function. Default is 14, i.e. use nb_num2str with the second input set to 14.

Methods:

- exp • log • max • min • minus • mpower
- mrdivide • mtimes • plus • power • rdivide • sqrt
- times • uminus • uplus

► **exp** ↑

```
obj = exp(obj)
```

Description:

Exponential.

Input:

- obj : An object of class nb_param.

Output:

- obj : An object of class nb_param.

Written by Kenneth SÃ¶terhagen Paulsen

► **log ↑**

obj = log(obj)

Description:

Natural logarithm.

Input:

- obj : An object of class nb_param.

Output:

- obj : An object of class nb_param.

Written by Kenneth SÃ¶terhagen Paulsen

► **max ↑**

obj = max(obj,another)

Description:

Max operator.

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **min** ↑

```
obj = min(obj,another)
```

Description:

Min operator.

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **minus** ↑

```
obj = minus(obj,another)
```

Description:

Minus operator (-).

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_param or nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **mpower** ↑

```
obj = mpower(obj,another)
```

Description:

Power operator (^). This will call power (.^)!

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_param or nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **mrddivide** ↑

```
obj = mrddivide(obj,another)
```

Description:

Right division operator (/), same as (./).

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_param or nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **mtimes** ↑

```
obj = mtimes(obj,another)
```

Description:

Times operator (*). Here assumed equal to .* operator.

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_param or nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **plus** ↑

obj = plus(obj,another)

Description:

Plus operator (+).

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **power** ↑

obj = power(obj,another)

Description:

Power operator (.^).

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_param or nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **rdivide** ↑

```
obj = rdivide(obj,another)
```

Description:

Right division operator (./).

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_param or nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **sqrt** ↑

```
obj = sqrt(obj)
```

Description:

Square root.

Input:

- obj : An object of class nb_param.

Output:

- obj : An object of class nb_param.

Written by Kenneth Sæterhagen Paulsen

► **times** ↑

```
obj = times(obj,another)
```

Description:

Times operator (.*).

Input:

- obj : A scalar number, nb_param object or string.
- another : A scalar number, nb_param object, nb_mySD object or string.

Output:

- obj : An object of class nb_param or nb_mySD.

Written by Kenneth Sæterhagen Paulsen

► **uminus** ↑

```
obj = uminus(obj)
```

Description:

Unary minus.

Input:

- obj : An object of class nb_param.

Output:

- obj : An object of class nb_param.

Written by Kenneth Sæterhagen Paulsen

► **uplus** ↑

```
obj = uplus(obj)
```

Description:

Unary plus.

Input:

- obj : An object of class nb_param.

Output:

- obj : An object of class nb_param.

Written by Kenneth Sæterhagen Paulsen

■ nb_ss

Go to: [Properties](#) | [Methods](#)

Create a class representing a steady-state variable. Same as a double but indexing like (-d), (d) or (+1) on a scalar object just return the same value as the original data (otherwise indexing works as a normal double).

Superclasses:

double

Constructor:

obj = nb_ss(num)

Input:

- num : A double.

Output:

- obj : A nb_ss object array with same size as num.

Written by Kenneth Sæterhagen Paulsen

Properties:

Methods:

■ nb_st

Go to: [Properties](#) | [Methods](#)

An abstract superclass to make it possible to construct a vector of nb_stTerm, nb_stBase and nb_stParam.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- error
- string
- trend

- **error** ↑

Error message thrown during stationarization.

- **string** ↑

The string representing the new stationarized equation.

- **trend** ↑

The trend growth of this term/base/parameter.

Methods:

- | | | | | |
|----------------------|-----------|-----------|--------------|----------------|
| • bgp | • detrend | • exp | • isTrending | • log |
| • logncdf | • lognpdf | • minus | • mpower | • mrdivide |
| • mtimes | • normcdf | • norminv | • normpdf | • plus |
| • power | • rdivide | • sgp | • sqrt | • steady_state |
| • steady_state_first | • times | • uminus | • uplus | |

► **bgp** ↑

obj = bgp(obj)

Description:

Balanced growth path operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

► **detrend** ↑

obj = detrend(obj)

Description:

De-trend operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

► **exp ↑**

obj = exp(obj)

Description:

Exponential.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.log](#)

Written by Kenneth Sæterhagen Paulsen

► **isTrending ↑**

ret = isTrending(obj)

Description:

Test if nb_st object is trending.

Written by Kenneth Sæterhagen Paulsen

► **log** ↑

obj = log(obj)

Description:

Natural logarithm.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.exp](#)

Written by Kenneth Sæterhagen Paulsen

► **logncdf** ↑

obj = logncdf(obj,m,k)

Description:

Log normal cdf.

Input:

- obj : An object of class nb_st.

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

- k : A parameter such that the mean of the lognormal is $k \exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.lognpdf](#)

Written by Kenneth Sæterhagen Paulsen

► **lognpdf** ↑

obj = lognpdf(obj,m,k)

Description:

Log normal pdf.

Input:

- obj : An object of class nb_st.

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.logncdf](#)

Written by Kenneth Sæterhagen Paulsen

► **minus** ↑

obj = minus(obj,another)

Description:

Minus operator (-).

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.plus](#), [nb_st.uminus](#)

Written by Kenneth Sæterhagen Paulsen

► **mpower** ↑

obj = mpower(obj,another)

Description:

Power operator (^), which is the same as using .^.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.power](#)

Written by Kenneth Sæterhagen Paulsen

► **mrdivide** ↑

obj = mrdivide(obj,another)

Description:

Right division operator (/), which is the same as using ./.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.rdivide](#)

Written by Kenneth Sæterhagen Paulsen

► **mtimes** ↑

obj = mtimes(obj,another)

Description:

Times operator (*), which is the same as using .*.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.times](#)

Written by Kenneth Sæterhagen Paulsen

► **normcdf** ↑

obj = normcdf(obj,m,k)

Description:

Normal cdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth Sæterhagen Paulsen

► **norminv** ↑

```
obj = norminv(obj,m,k)
```

Description:

Inverse normal cdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth Sæterhagen Paulsen

► **normpdf** ↑

```
obj = normpdf(obj,m,k)
```

Description:

Normal pdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth Sæterhagen Paulsen

► **plus** ↑

obj = plus(obj,another)

Description:

Plus operator (+).

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.minus](#), [nb_st.uplus](#)

Written by Kenneth Sæterhagen Paulsen

► **power** ↑

obj = power(obj,another)

Description:

Power operator (.^), which is the same as using ^.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.mpower](#)

Written by Kenneth Sæterhagen Paulsen

► **rdivide** ↑

obj = rdivide(obj,another)

Description:

Right division operator (./), which is the same as using /.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.mrdivide](#)

Written by Kenneth Sæterhagen Paulsen

► **sgp** ↑

obj = sgp(obj)

Description:

Stochastic growth path operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

► **sqrt** ↑

obj = sqrt(obj)

Description:

Square root.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.power](#)

Written by Kenneth Sæterhagen Paulsen

► **steady_state** ↑

obj = steady_state(obj)

Description:

Steady-state operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

► **steady_state_first** ↑

obj = steady_state_first(obj)

Description:

Steady-state (first regime) operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

► **times** ↑

obj = times(obj,another)

Description:

Times operator (.*), which is the same as using *.

Input:

- obj : A scalar number or a nb_st object.

- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.mtimes](#)

Written by Kenneth Sæterhagen Paulsen

► **uminus** ↑

obj = uminus(obj)

Description:

Unary minus (-).

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.plus](#)

Written by Kenneth Sæterhagen Paulsen

► **uplus** ↑

obj = uplus(obj)

Description:

Unary plus (+).

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_st.plus](#)

Written by Kenneth Sæterhagen Paulsen

■ **nb_stParam**

Go to: [Properties](#) | [Methods](#)

A class representing a parameter in a equation during stationarization.

Superclasses:

[nb_st](#), [matlab.mixin.Heterogeneous](#)

See also:

[nb_stTerm](#), [nb_stBase](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [error](#)
- [string](#)
- [trend](#)
- [value](#)

- **error** ↑

Error message thrown during stationarization.

Inherited from superclass NB_ST

- **string** ↑

The string representing the new stationarized equation.

Inherited from superclass NB_ST

- **trend** ↑

The trend growth of this term/base/parameter.

Inherited from superclass NB_ST

- **value** ↑

The parameter value, as a scalar double.

Methods:

- | | | | | |
|--------------------------------------|---------------------------|---------------------------|------------------------------|--------------------------------|
| • bgp | • detrend | • exp | • isTrending | • log |
| • logncdf | • lognpdf | • minus | • mpower | • mrdivide |

► **bgp** ↑

```
obj = bgp(obj)
```

Description:

Balanced growth path operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► [detrend](#) ↑

```
obj = detrend(obj)
```

Description:

De-trend operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► [exp](#) ↑

```
obj = exp(obj)
```

Description:

Exponential.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.log](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► [isTrending](#) ↑

```
ret = isTrending(obj)
```

Description:

Test if nb_st object is trending.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► [log](#) ↑

```
obj = log(obj)
```

Description:

Natural logarithm.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.exp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **logncdf** ↑

obj = logncdf(obj,m,k)

Description:

Log normal cdf.

Input:

- obj : An object of class nb_st.
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.
- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.lognpdf](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **lognpdf** ↑

obj = lognpdf(obj,m,k)

Description:

Log normal pdf.

Input:

- obj : An object of class nb_st.
- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.
- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.logncdf](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► minus ↑

obj = minus(obj,another)

Description:

Minus operator (-).

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.plus](#), [nb_stparam.uminus](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► mpower ↑

```
obj = mpower(obj,another)
```

Description:

Power operator (^), which is the same as using \cdot^{\wedge} .

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.power](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **mrdivide** ↑

```
obj = mrdivide(obj,another)
```

Description:

Right division operator (/), which is the same as using $\cdot /$.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.rdivide](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **mtimes** ↑

```
obj = mtimes(obj,another)
```

Description:

Times operator (*), which is the same as using .*.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.times](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **normcdf** ↑

```
obj = normcdf(obj,m,k)
```

Description:

Normal cdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **norminv** ↑

```
obj = norminv(obj,m,k)
```

Description:

Inverse normal cdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **normpdf** ↑

```
obj = normpdf(obj,m,k)
```

Description:

Normal pdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **plus** ↑

```
obj = plus(obj,another)
```

Description:

Plus operator (+).

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.minus](#), [nb_stparam.uplus](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **power** ↑

```
obj = power(obj,another)
```

Description:

Power operator (.^), which is the same as using ^.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.mpower](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **rdivide** ↑

obj = rdivide(obj,another)

Description:

Right division operator (./), which is the same as using /.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.mrdivide](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **sgp** ↑

obj = sgp(obj)

Description:

Stochastic growth path operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **sqrt** ↑

obj = sqrt(obj)

Description:

Square root.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.power](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **steady_state** ↑

obj = steady_state(obj)

Description:

Steady-state operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **steady_state_first** ↑

obj = steady_state_first(obj)

Description:

Steady-state (first regime) operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **times** ↑

obj = times(obj,another)

Description:

Times operator (.*), which is the same as using *.

Input:

- obj : A scalar number or a nb_st object.

- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.mtimes](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_ST

► **uminus** ↑

obj = uminus(obj)

Description:

Unary minus (-).

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.plus](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_ST

► **uplus** ↑

obj = uplus(obj)

Description:

Unary plus (+).

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stparam.plus](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

■ nb_stTerm

Go to: [Properties](#) | [Methods](#)

A class representing a trending or non-trending variable/term during stationarization.

Superclasses:

nb_st, matlab.mixin.Heterogeneous

Constructor:

```
obj = nb_stTerm(varName,trend,leadOrLag)
```

Input:

- varName : A one line char with the name of the base variable, or a cellstr with a set of base variables.
- trend : A double matching the number of base variables given. It must store the trend growth of each base variable. Set to 0 to indicate a non-trending variable.
- leadOrLag : A double matching the number of base variables given. It must store the number of periods the base value is leaded or lagged.
- unitRoot : A logical matching the number of base variables given. Give true for the elements that are unit root variables. Default is false. If a scalar logical is given it will be applied to all base variables.

Output:

- obj : A vector of nb_stTerm objects.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- error • string • trend

- **error** ↑

Error message thrown during stationarization.

Inherited from superclass NB_ST

- **string** ↑

The string representing the new stationarized equation.

Inherited from superclass NB_ST

- **trend** ↑

The trend growth of this term/base/parameter.

Inherited from superclass NB_ST

Methods:

- bgp
- logncdf
- mtimes
- power
- steady_state_first
- detrend
- lognpdf
- normcdf
- rdivide
- times
- exp
- minus
- norminv
- sgp
- uminus
- isTrending
- mpower
- normpdf
- sqrt
- uminus
- log
- mrdivide
- plus
- steady_state
- uplus

► **bgp** ↑

obj = bgp(obj)

Description:

Balanced growth path operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **detrend** ↑

obj = detrend(obj)

Description:

De-trend operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **exp ↑**

obj = exp(obj)

Description:

Exponential.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.log](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **isTrending ↑**

ret = isTrending(obj)

Description:

Test if nb_st object is trending.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **log** ↑

obj = log(obj)

Description:

Natural logarithm.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.exp](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **logncdf** ↑

obj = logncdf(obj, m, k)

Description:

Log normal cdf.

Input:

- obj : An object of class nb_st.

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.lognpdf](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **lognpdf** ↑

obj = lognpdf(obj,m,k)

Description:

Log normal pdf.

Input:

- obj : An object of class nb_st.

- m : A parameter such that the mean of the lognormal is $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

- k : A parameter such that the mean of the lognormal is k $\exp((m+k^2)/2)$. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.logncdf](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **minus** ↑

obj = minus(obj,another)

Description:

Minus operator (-).

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.plus](#), [nb_stterm.uminus](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_ST

► **mpower** ↑

obj = mpower(obj,another)

Description:

Power operator (^), which is the same as using .^.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.power](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_ST

► **mrddivide** ↑

obj = mrddivide(obj,another)

Description:

Right division operator (/), which is the same as using ./.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.rdivide](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **mtimes** ↑

obj = mtimes(obj,another)

Description:

Times operator (*), which is the same as using .*.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.times](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **normcdf** ↑

```
obj = normcdf(obj,m,k)
```

Description:

Normal cdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_ST

► **norminv** ↑

```
obj = norminv(obj,m,k)
```

Description:

Inverse normal cdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_ST

► **normpdf** ↑

```
obj = normpdf(obj,m,k)
```

Description:

Normal pdf.

Input:

- obj : An object of class nb_st.
- m : The mean of the distribution. Either as a scalar double or a nb_stParam object.
- k : The std of the distribution. Either as a scalar double or a nb_stParam object.

Output:

- obj : An object of class nb_stTerm or nb_stParam.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **plus ↑**

```
obj = plus(obj,another)
```

Description:

Plus operator (+).

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.minus](#), [nb_stterm.uplus](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **power ↑**

```
obj = power(obj,another)
```

Description:

Power operator ($.^$), which is the same as using $^$.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.mpower](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **rdivide** ↑

```
obj = rdivide(obj,another)
```

Description:

Right division operator ($./$), which is the same as using $/$.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.mrdivide](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **sgp** ↑

obj = sgp(obj)

Description:

Stochastic growth path operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **sqrt** ↑

obj = sqrt(obj)

Description:

Square root.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.power](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **steady_state** ↑

```
obj = steady_state(obj)
```

Description:

Steady-state operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **steady_state_first** ↑

```
obj = steady_state_first(obj)
```

Description:

Steady-state (first regime) operator.

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **times** ↑

```
obj = times(obj,another)
```

Description:

Times operator (.*), which is the same as using *.

Input:

- obj : A scalar number or a nb_st object.
- another : A scalar number or a nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.mtimes](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **uminus** ↑

```
obj = uminus(obj)
```

Description:

Unary minus (-).

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.plus](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

► **uplus** ↑

```
obj = uplus(obj)
```

Description:

Unary plus (+).

Input:

- obj : A nb_st object.

Output:

- obj : An object of class nb_stParam or nb_stTerm.

See also:

[nb_stTerm](#), [nb_stParam](#), [nb_stterm.plus](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_ST

■ **nb_symMatrix**

Go to: [Properties](#) | [Methods](#)

An object that represent a matrix of symbolic parameters of a matrix.

The values of the symbols may be provided. Some methods may need these values to be used.

Constructor:

```
obj = nb_symMatrix(input1, input2)
```

Input:

> Alternativ 1:

- input1 : The number of rows of the symbolic matrix.
- input2 : The number of cols of the symbolic matrix.

> Alternativ 2:

- input1 : A rows x cols cellstr with the symbols, or a rows x 1 char (which will be converted to a rows x 1 cellstr).

> Alternative 3:

- input1 : A rows x cols numeric matrix.

Output:

> Alternativ 1:

- obj : A rows x cols nb_symMatrix object with all elements set to zero.

> Alternativ 2 and 3:

- obj : A rows x cols nb_symMatrix object.

Written by Kenneth Sæterhagen Paulsen

Properties:

• symbols

- **symbols** ↑

A rows x cols nb_term object with the symbolic representation of the matrix.

Methods:

• cellstr	• disp	• eq	• exp	• horzcat	• log
• minus	• mpower	• mrdivide	• mtimes	• plus	• power
• rdivide	• rref	• sqrt	• subsasgn	• subsref	• times
• uminus	• uplus	• vertcat			

► **cellstr** ↑

c = cellstr(obj)

Description:

Display object (In the command window)

Input:

- obj : An object of class nb_symMatrix.

Output:

The object displayed on the command line.

Written by Kenneth S. Paulsen

► **disp** ↑

```
disp(obj)
```

Description:

Display object (In the command window)

Input:

- obj : An object of class nb_symMatrix.

Output:

The object displayed on the command line.

Written by Kenneth S. Paulsen

► **eq ↑**

```
ret = eq(obj,another)
```

Description:

Equality operator (==) for nb_symMatrix objects.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

Written by Kenneth Sætherhagen Paulsen

► **exp ↑**

```
obj = exp(obj)
```

Description:

Exponential.

Input:

- obj : A nb_symMatrix object.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.log](#)

Written by Kenneth Sæterhagen Paulsen

► **horzcat** ↑

obj = horzcat(a,b,varargin)

Description:

Horizontal concatenation of nb_symMatrix objects ([a,b]).

Input:

- a : An object of class nb_symMatrix.
- varargin : Optional number of nb_symMatrix objects.

Output:

- obj : An nb_symMatrix object.

Examples:

```
obj = [a,b];
obj = [a,b,c];
```

See also:

[nb_symMatrix.vertcat](#)

Written by Kenneth S. Paulsen

► **log** ↑

obj = log(obj)

Description:

Natural logarithm.

Input:

- obj : A nb_symMatrix object.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.exp](#)

Written by Kenneth Sæterhagen Paulsen

► **minus** ↑

obj = minus(obj,another)

Description:

Minus operator (-) for nb_symMatrix objects.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.plus](#), [nb_symMatrix.uminus](#)

Written by Kenneth Sæterhagen Paulsen

► **mpower** ↑

obj = mpower(obj,another)

Description:

Power operator (^), which is the same as using .^.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.power](#)

Written by Kenneth Sæterhagen Paulsen

► **mrddivide** ↑

obj = mrddivide(obj,another)

Description:

Right division operator (/), which is the same as using ./.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.rdivide](#)

Written by Kenneth Sæterhagen Paulsen

► **mtimes** ↑

obj = mtimes(obj,another)

Description:

Times operator (*), which is the same as using .*.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.times](#)

Written by Kenneth Sæterhagen Paulsen

► **plus** ↑

obj = plus(obj,another)

Description:

Plus operator (+) for nb_symMatrix objects.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.minus](#), [nb_symMatrix.uplus](#)

Written by Kenneth Sæterhagen Paulsen

► **power** ↑

obj = power(obj,another)

Description:

Division operator ($.^$) for nb_symMatrix objects.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.power](#)

Written by Kenneth Sæterhagen Paulsen

► **rdivide** ↑

obj = rdivide(obj,another)

Description:

Division operator ($./$) for nb_symMatrix objects.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.times](#)

Written by Kenneth Sæterhagen Paulsen

► **rref** ↑

obj = rref(obj)

Description:

This method produces the row echelon form of A.

Input:

- obj : A NxM nb_symMatrix object.

Output:

- obj : A NxM nb_symMatrix object.

Examples:

See also:

[nb_rref](#)

Written by Kenneth Sæterhagen Paulsen

► **sqrt** ↑

obj = sqrt(obj)

Description:

Square root.

Input:

- obj : A nb_symMatrix object.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.power](#)

Written by Kenneth Sæterhagen Paulsen

► **subsasgn** ↑

varargout = subsasgn(obj,s,b)

Description:

Makes it possible to do subscripted assignment an object of class nb_symMatrix.

Input:

- obj : An object of class nb_symMatrix.
- s : The same input as when you do subscripted assignment one a double matrix
- b : The assign data at the given index s. Either numeric or an object of class nb_symMatrix.

Output:

- obj : An object of class nb_symMatrix.

Examples:

```
obj      = nb_symMatrix(2,2);
obj(1,1) = nb_symMatrix('X',1);
```

Written by Kenneth S. Paulsen

► **subsref ↑**

```
varargout = subsref(obj,s)
```

Description:

Makes it possible to do subscripted reference to an object of class nb_symMatrix.

Input:

- obj : An object of class nb_symMatrix.
- s : A structure on how to index the object.

Output:

- obj : An object of class nb_symMatrix.

Written by Kenneth S. Paulsen

► **times ↑**

```
obj = times(obj,another)
```

Description:

Times operator (.*) for nb_symMatrix objects.

Input:

- obj : A nb_symMatrix object or double.
- another : A nb_symMatrix object or double.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.rdivide](#)

Written by Kenneth Sæterhagen Paulsen

► **uminus** ↑

obj = uminus(obj)

Description:

Unary minus operator (-) for nb_symMatrix objects.

Input:

- obj : A nb_symMatrix object.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.minus](#)

Written by Kenneth Sæterhagen Paulsen

► **uplus** ↑

obj = uplus(obj)

Description:

Unary plus operator (+) for nb_symMatrix objects.

Input:

- obj : A nb_symMatrix object.

Output:

- obj : A nb_symMatrix object.

See also:

[nb_symMatrix.plus](#)

Written by Kenneth Sæterhagen Paulsen

► **vertcat ↑**

obj = vertcat(a,b,varargin)

Description:

Vertical concatenation of nb_symMatrix objects ([a;b]).

Input:

- a : An object of class nb_symMatrix.
- varargin : Optional number of nb_symMatrix objects.

Output:

- obj : An nb_symMatrix object.

Examples:

```
obj = [a;b];
obj = [a;b;c];
```

See also:

[nb_symMatrix.horzcat](#)

Written by Kenneth S. Paulsen

■ **nb_term**

Go to: [Properties](#) | [Methods](#)

The superclass of all mathematical terms included in an equation.

Be aware that you still cannot call any method on a vector of any of them!

Superclasses:

matlab.mixin.Heterogeneous

Subclasses:

nb_base, nb_num, nb_equation

See also:

[nb_base](#), [nb_num](#), [nb_equation](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [numberOfTerms](#)
- [operator](#)
- [terms](#)

- [numberOfTerms](#) ↑

The number of terms. As a scalar integer.

- [operator](#) ↑

Type of operator splitting the terms.

- [terms](#) ↑

A vector of nb_term objects.

Methods:

- | | | | | |
|-------------------------------|--------------------------------|-----------------------------|----------------------------|----------------------------|
| • cellstr | • clean | • correct | • exp | • gap |
| • generalFunc | • initialize | • intersect | • ismember | • log |
| • logncdf | • lognpdf | • minus | • mpower | • mrdivide |
| • mtimes | • normcdf | • norminv | • normpdf | • plus |
| • power | • rdivide | • removePar | • simplify | • split |
| • sqrt | • steady_state | • times | • toString | • uminus |
| • union | • unique | • uplus | | |

► [cellstr](#) ↑

c = [toString](#)(obj)

Description:

Convert array of nb_term objects to cellstr.

Inputs:

- obj : An array of nb_term objects.

Output:

- c : A cellstr with same size as obj.

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

► **clean** ↑

obj = clean(obj)

Description:

Clean up nb_term object after operations.

Written by Kenneth Sæterhagen Paulsen

► **correct** ↑

expr = nb_term.correct(expr)

Description:

Correct term for .*, ./ and .^ operators.

Input:

- expr : A one line char with a mathematical expression.

Output:

- expr : Corrected version of the input.

Written by Kenneth Sæterhagen Paulsen

► **exp** ↑

```
obj = exp(obj)
```

Description:

exp operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **gap** ↑

```
obj = gap(obj)
```

Description:

Gap operator.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **generalFunc** ↑

```
obj = generalFunc(obj, func, varargin)
```

Description:

Call general function on a nb_term objects.

Input:

- obj : A vector of nb_term objects.
- func : A one line char with the function to apply on the nb_term objects.

Optional input:

- nb_term objects representing the extra inputs to the function.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

► initialize ↑

```
obj = nb_term.initialize(rows,cols)
```

Description:

Initialize vector of nb_term objects.

Input:

- rows : Number of rows. As a scalar integer.
- cols : Number of columns. As a scalar integer.

Output:

- obj : A rows x cols nb_term object.

Written by Kenneth SÃ¶terhagen Paulsen

► intersect ↑

```
int = intersect(obj,another)
```

Description:

Get the intersect of two vectors of nb_term objects.

Input:

- obj : A vector of nb_term objects.
- another : A vector of nb_term objects.

Output:

- int : The intersect, as a vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

► **ismember** ↑

```
[ind,loc] = ismember(obj,another)
```

Description:

Check if the terms in obj is member of the terms in another.

Input:

- obj : A vector of nb_term objects.
- another : A vector of nb_term objects.

Output:

- ind : A logical vector with same size as obj. Elements that are true are found to be in the another input.
- loc : A double vector with same size as obj. Locations of the elements that are found in the another input. If not found 0 is returned.

Written by Kenneth SÃ¶terhagen Paulsen

► **log** ↑

```
obj = log(obj)
```

Description:

log operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **logncdf** ↑

obj = logncdf(obj,m,k)

Description:

Log-normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **lognpdf** ↑

obj = lognpdf(obj,m,k)

Description:

Log-normal pdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **minus** ↑

```
obj = minus(obj,another)
```

Description:

Minus operator (-) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

► **mpower** ↑

```
obj = mpower(obj,another)
```

Description:

Power operator (*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sætherhagen Paulsen

► mrdivide ↑

```
obj = mrdivide(obj,another)
```

Description:

Division operator (/) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sætherhagen Paulsen

► mtimes ↑

```
obj = mtimes(obj,another)
```

Description:

Times operator (*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

► **normcdf** ↑

obj = normcdf(obj,m,k)

Description:

Normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **norminv** ↑

obj = norminv(obj,m,k)

Description:

Inverse normal cdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

► normpdf ↑

```
obj = normpdf(obj,m,k)
```

Description:

Normal pdf.

Input:

- obj : A vector of nb_term objects.
- m : The mean of the distribution, as an object of class nb_term.
- k : The std of the distribution, as an object of class nb_term.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

► plus ↑

```
obj = plus(obj,another)
```

Description:

Plus operator (+) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sætherhagen Paulsen

► power ↑

```
obj = power(obj,another)
```

Description:

Power operator ($.^$) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sætherhagen Paulsen

► rdivide ↑

```
obj = rdivide(obj,another)
```

Description:

Division operator ($./$) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.
- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

► **removePar** ↑

```
expr = removePar(expr)
```

Description:

Is the expression enclosed with parentheses?

Written by Kenneth Sæterhagen Paulsen

► **simplify** ↑

```
expr = nb_term.simplify(expr)
expr = nb_term.simplify(expr,waitbar)
```

Description:

Simplify the mathematical expressions.

Input:

- expr : A one line char with a mathematical expression or a cellstr with the mathematical expressions.
- waitbar : A nb_waitbar5 object. It will use the next available waitbar of the given object. If empty no waitbar is added.

Output:

- obj : A cellstr with the simplified mathematical expressions.

Written by Kenneth Sæterhagen Paulsen

► **split** ↑

```
obj = nb_term.split(expr)
obj = nb_term.split(expr,waitbar)
```

Description:

Split the mathematical expression into separate terms.

Input:

- expr : A one line char with a mathematical expression.
- waitbar : A nb_waitbar5 object. If empty no waitbar is added.

Output:

- obj : A nb_term object representing the mathematical expression.

Written by Kenneth SÃ¶terhagen Paulsen

► **sqrt** ↑

```
obj = sqrt(obj)
```

Description:

sqrt operator for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth SÃ¶terhagen Paulsen

► **steady_state** ↑

```
obj = steady_state(obj)
```

Description:

Steady-state operator.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **times** ↑

obj = times(obj,another)

Description:

Times operator (.*) for nb_term objects.

Input:

Two cases:

One input:

- obj : A vector of nb_term objects.

Two inputs:

- obj : A scalar nb_term object.

- another : A vector of nb_term objects.

Output:

- obj : A scalar nb_term object.

Written by Kenneth Sæterhagen Paulsen

► **toString** ↑

string = toString(anyObject)

Description:

Converts object into a string.

Input:

- anyObject : A double, logical, nb_ts, nb_cs, nb_data or cell.

Output:

- string : A string

See also:

[num2str](#), [int2str](#), [nb_cellstr2String](#), [nb_any2String](#)

Written by Kenneth Sæterhagen Paulsen

► uminus ↑

obj = uminus(obj)

Description:

Unary minus operator (-) for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term object.

Written by Kenneth Sæterhagen Paulsen

► union ↑

uni = union(obj,another)

Description:

Get the union of two vectors of nb_term objects.

Input:

- obj : A vector of nb_term objects.
- another : A vector of nb_term objects.

Output:

- uni : The union, as a vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

► **unique** ↑

```
uniq = unique(obj,another)
```

Description:

Locate the unique nb_term objects in a vector of nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- uniq : The unique nb_term objects.

- ind : Vector such that uniq = obj(ind).

Written by Kenneth Sæterhagen Paulsen

► **uplus** ↑

```
obj = uplus(obj)
```

Description:

Unary plus opertor (+) for nb_term objects.

Input:

- obj : A vector of nb_term objects.

Output:

- obj : A vector of nb_term objects.

Written by Kenneth Sæterhagen Paulsen

■ **nb_writeHelp**

Go to: [Properties](#) | [Methods](#)

A class for writing the help for the estimator packages and model classes of the NB Toolbox.

Constructor:

```
obj = nb_writeHelp(name,option,typeName,dataType)

Input:

- name      : The name of the class or package to document.

- option    : Either the name of the option or 'all'.

- typeName : Indicate if it is a class ('class') or package
              ('package').

- dataType : Either 'timeSeries', 'crossSectional' or 'both'.
```

Output:

```
- obj      : An object of class nb_writeHelp.
```

Examples:

Written by Kenneth Sætherhagen Paulsen

Properties:

- [dataType](#)
- [helpStruct](#)
- [max](#)
- [nameOfPOrC](#)
- [option](#)

- [options](#)
- [typeName](#)

- [dataType](#) ↑

Either 'timeSeries', 'crossSectional' or 'both'.

- [helpStruct](#) ↑

A struct that stores the help text of all the options.

- [max](#) ↑

Max number of chars in the printed doc.

- [nameOfPOrC](#) ↑

Name of the package or class.

- [option](#) ↑

The option to get the help on, or 'all'.

- [options](#) ↑

A cellstr with the names of the options that the

- [typeName](#) ↑

Indicate if it is a class or package

Methods:

- help
 - set
-

► **help** ↑

```
helpText = help(obj)
```

Description:

Get the help given the property values of the object.

Input:

- obj : An object of class nb_writeHelp.

Output:

- helpText : A char with the help on the package or class.

Written by Kenneth SÅ!terhagen Paulsen

► **set** ↑

```
obj = set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_writeHelp. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties can be set with one method call.

Input:

- obj : An object of class nb_writeHelp.
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_writeHelp with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_bartlettKernel

```
y = nb_bartlettKernel(x)
```

Description:

Barlett kernel

Input:

- x : A double

Output:

- y : A double

Written by Kenneth Sæterhagen Paulsen

◆ nb_calculateMoments

```
[m,c] = nb_calculateMoments(A,B,C,vcv,mX,varX,nLags,type,tol,maxIter)
```

Description:

Calculate moments given the companion form of the model:

$y_t = Ay_{t-1} + Bx_t + Ce_t$, where $e_t \sim N(0, vcv)$ and
 $x_t \sim PHI(mX, varX)$

Input:

- A,B,C,vcv,,mX,varX : See description of function.
- nLags : The number of autocorrelation/autovariances to calculate.
- type : Either 'covariance' or 'correlation'.
- tol : The tolerance of the iteration procedure of the lyapunov equation. Default is $\text{eps}^{(1/3)}$.
- maxiter : Maximum number of iterations of the iteration procedure of the lyapunov equation.. Default is 1000.

Output:

- m : Unconditional mean of the model. As a nVar x 1 double.
- c : Unconditional (auto)covarianse/correlation matrix. As a nVar x nVar x nLags + 1 double.

See also:

[nb_model_generic.theoreticalMoments](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_cell2func

func = nb_cell2func(eqs,inputs)

Description:

Convert equations to function handle.

Input:

- eqs : A cellstr with the equations.
- inputs : A one line char with the inputs to the created function handle. E.g. '(x,y)'.

Output:

- func : A function handle.

Written by Kenneth Sæterhagen Paulsen

◆ nb_coeff2excel

◆ nb_constructInputPar

inputs = nb_constructInputPar(vars,pars)

Description:

Construct inputs enclosed in parenthesis. E.g. '(var1,var2,par1,par2)'.

Input:

- vars : A cellstr with the variables.
- pars : A cellstr with the parameters.

Output:

- inputs : A one line char. See description.

See also:

[nb_cell2func](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_constructStackedCorrelationMatrix**

`sigmaF = nb_constructStackedCorrelationMatrix(c)`

Description:

Construct the stacked correlation matrix.

Input:

- c : A nVar x nVar x nLags + 1 x nPage double storing the (auto)correlation matrices. The first page stores the contemporaneous correlation matrix, second the autocorrelation matrix with lag 1 and so on.

Output:

- sigmaF : The stacked correlation matrix. As a nVar*(nLags+1) x nVar*(nLags+1) x nPage double.

See also:

[nb_calculateMoments](#), [nb_model_generic.theoreticalMoments](#)

Written by Kenneth Sølnerhagen Paulsen

◆ **nb_cov2corr**

`c = nb_cov2corr(c)`

Description:

Go from covariance to correlation matrix.

Input:

- c : Page one is the contemporaneous correlation matrix. Page 2:end is the autocorrelation of degree ≥ 1 .

Output:

- c : Correlation matrix.

Written by Kenneth Sæterhagen Paulsen

◆ nb_createGenericNames

```
[out,outS,inS,reorder] = nb_createGenericNames(in,generic)
```

Description:

Create generic names index by integers, e.g. {'x(1)';'x(2)'}

Input:

- in : A cellstr with the original names.
- generic : The generic name, e.g. 'x'.

Output:

- out : A cellstr. See description.
- outS : in is sorted and out is index by the reordering.
- inS : The sorted version of in.
- reorder : Reordering index.

Written by Kenneth Sæterhagen Paulsen

◆ nb_doSymbolic

```
[derivFunc,I,J,V,jac] = nb_doSymbolic(fh,vars,varValues,pars,pValues)
```

Description:

Construct function handle with the derivatives of a given function, or evaluate the full jacobian.

Input:

- fh : A function handle. @(x,y)x*y or @(x,y,p)x*y^p. Please order parameters at the end!
- vars : List the variables input to the function. E.g. {'x','y'}.
- pars : List the parameters input to the function. E.g. {} or {'p'}.
- varValues : The values of the variables for where you want to evaluate the derivative. Only needed if the output V and/or jac are

asked for. Must have same length as vars input.

- pValues : The values of the parameters. Only needed if the output V and/or jac are asked for. Must have same length as pars input.

Output:

- derivFunc : Function handle with the symbolic derivatives.
- I,J,V : Vectors such that jac = sparse(I,J,V,nEqs,nVar), where nEqs is the number of equations and nVar is the number of variables.
- jac : The evaluated jacobian at the provided values. varValues and pValues must be given (also applies to V)!

Examples:

```
func          = @(x,y)x*y;
[fH,I,J,V,jac] = nb_doSymbolic(func,{'x','y'},[],[2,1]);
func          = @(x,y,p)x*y^p; % Parameters at the end!
[fH2,I2,J2,V2,jac2] = nb_doSymbolic(func,{'x','y'},{'p'},[2,1],0.5);
```

See also:

[nb_mySD](#)

Written by Kenneth Sæterhagen Paulsen

◆ **[nb_excel2coeff](#)**

◆ **[nb_funcWrapper](#)**

```
value = nb_funcWrapper(x,fHandle,inputs)
```

Description:

Create a wrapper function to assign optional inputs to a function handle.

Useful for speeding up function evaluation during parfor with use of feval.

Caution: For speed, the input are not tested!

Input:

- x : Main input to function.
- fHandle : A function handle.
- inputs : A cell array with the inputs passed to the function handle.

Output:

- value : The output of the function.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_functionHandle2Struct**

```
s = nb_functionHandle2Struct(f)
```

Description:

Convert function handle to struct.

Input:

- f : function_handle to convert to struct.

Output:

- s : A struct representing the function_handle

Examples:

```
s = 2;
s2 = 3;
f = @(x)x + s + s2
s = nb_functionHandle2Struct(f)
```

See also:

[nb_struct2functionHandle](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_getModelListFromLibrary**

```
modelList = nb_getModelListFromLibrary(folder)
```

Description:

Get model list from library folder.

Input:

- folder : A full absolute path to the model library.

Output:

- modelList : A list of all models stores as .mat files.

Written by Erlend Salvesen Njålstad

◆ nb_getSymbolicDerivIndex

```
[I,J] = nb_getSymbolicDerivIndex(symDeriv,all,derivEqs)
```

Description:

Find sparse indexes when utilizing the nb_mySD class and want to construct the full jacobian.

Input:

- symDeriv : A vector of nb_mySD objects.
- all : Either a cellstr with all bases of all equations or a one line char with the generic name used when using nb_mySD.
- derivEqs : The derivatives as a cellstr. If empty [symDeriv.derivatives] will be used.

Output:

- I,J : Sparse indexes that can be used to initialize the sparse jacobian.

Written by Kenneth Sæterhagen Paulsen

◆ nb_gradient

```
G = nb_gradient(func,x,h)
```

Description:

Calculate the gradient of the multivariate function func at the point x using a step length h.

See Abramowitz and Stegun (1965) formulas 25.3.21.

Input:

- func : A MATLAB function handle
- x : The point of evaluation. As a n x 1 double.
- h : Step length. Either a 1x1 double or a n x 1 double. Default is abs(x)*eps^(1/6).

Output:

G : A n x 1 double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_hessian

H = nb_hessian(func,x,h)

Description:

Calculate the hessian of the multivariate function func at the point x using a step length h.

See Abramowitz and Stegun (1965) formulas 25.3.23 and 25.3.27.

Input:

- func : A MATLAB function handle
- x : The point of evaluation. As a n x 1 double.
- h : Step length. Either a 1x1 double or a n x 1 double. Default is abs(x)*eps^(1/6).

Output:

H : A n x n double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_interpretPerc

newPerc = nb_interpretPerc(perc,inverse)

Description:

Input:

- perc : Depend on the inverse input.
 - inverse :
- > inverse == true : Input must be a 1 x N double with percentiles in the format [5,15,25,35,65,75,85,95], while the output is percentiles in the format [0.3,0.5,0.7,0.9].
- > inverse == false : Switch input and output from the inverse == true case.

Output:

- newPerc : Depend on the inverse input.

Written by Kenneth Sætherhagen Paulsen

◆ nb_isStructOfFunctionHandle

```
ret = nb_isStructOfFunctionHandle(structThatRepresentsTheFunctionHandle)
```

Description:

Is the struct representing a function_handle object?

Input:

- structThatRepresentsTheFunctionHandle : A struct which is an output from the nb_functionHandle2Struct function.

Output:

- ret : true or false.

See also:

[nb_functionHandle2Struct](#), [nb_struct2functionHandle](#)

Written by Kenneth Sætherhagen Paulsen

◆ nb_jacobian

```
JAC = nb_jacobian(func,x,y)
```

Description:

Calculate the jacobian of the multivariate function func at the point x using a step length x - w. The following formula is used:

```
JAC(:,j) = (func(x(1),...,x(j),y(j+1),...,y(m)) -  
func(x(1),...,x(j-1),y(j),...,y(m)))/(x(j) - y(j))
```

Input:

- func : A MATLAB function handle
- x : The point of evaluation. As a m x 1 double.
- y : x + step length. As a m x 1 double.

Output:

G : A m x m double.

Written by Kenneth Sæterhagen Paulsen

◆ nb_latinHypercubeSim

V = nb_latinHypercubeSim(nPoints, nVars)

Description:

Simulating optimized draws from the Latin hypercube from the uniform distribution to be used in monte-carlo integration or other such applications.

Algorithm is taken from:

Larson et. al. (2005) "Supplying Local Microphysics Parameterizations with Information about Subgrid Variability: Latin Hypercube Sampling"

See section 3b.

Input:

- nPoints : Number of points of the desired Latin hypercube (LH).
- nVars : Number of variables in the LH.

Output:

- V : A nPoints x nVars double.

See also:

[nb_monteCarloSim](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_loadModelsFromLibrary

models = nb_loadModelsFromLibrary(folder)

Description:

Load models from library folder.

Input:

- folder : A full absolute path to the model library.

Output:

- models : A vector of nb_model_update_vintages.

Written by Kenneth Sæterhagen Paulsen

◆ nb_maxDeriv

```
value = nb_maxDeriv(expr1,expr2,deriv1,deriv2)
```

Description:

Calculate the derivative of the max(expr1,expr2) function. The derivative is equal to the deriv1 if expr1 > expr2, equal to the deriv2 if expr1 < expr2, 1 when expr1 lim(+) -> expr2 and 0 when expr1 lim(-) -> expr2.

Input:

- expr1 : Value of expression 1. A vector with length N or scalar.
- expr2 : Value of expression 2. A vector with length N or scalar.
- deriv1 : Value of the derivative of expression 1. A vector with length N or scalar.
- deriv2 : Value of the derivative of expression 1. A vector with length N or scalar.

Output:

- value : Value of the derivative after the max function is applied.

Written by Kenneth Sæterhagen Paulsen

◆ nb_minDeriv

```
value = nb_minDeriv(expr1,expr2,deriv1,deriv2)
```

Description:

Calculate the derivative of the min(expr1,expr2) function. The derivative is equal to the deriv1 if expr1 < expr2, equal to the deriv2 if expr1 > expr2, 1 when expr2 lim(+) -> expr1 and 0 when expr2 lim(-) -> expr1.

Input:

- expr1 : Value of expression 1. A vector with length N or scalar.
- expr2 : Value of expression 2. A vector with length N or scalar.
- deriv1 : Value of the derivative of expression 1. A vector with length N or scalar.
- deriv2 : Value of the derivative of expression 1. A vector with length N or scalar.

Output:

- value : Value of the derivative after the min function is applied.

Written by Kenneth Sæterhagen Paulsen

◆ **nb_monteCarloSim**

X = nb_monteCarloSim(draws, numVar, method)

Description:

Make draws for monte carlo integration or other usch application.

Input:

- draws : The number of draws from the N-th uniform cube.

- lb : A 1 x N double with the lower bounds.

- ub : A 1 x N double with the upper bounds.

- method : > 'latin' : Uses nb_latinHypercubeSim.
 > 'sobol' : Uses sobolset (part of the MATLAB statistics
 package).
 > 'halton' : Uses haltonset (part of the MATLAB statistics
 package).

Output:

- X : As a draws x N double.

◆ **nb_parzenKernel**

y = nb_parzenKernel(x)

Description:

Barlett kernel

Input:

- x : A double

Output:

- y : A double

Written by Kenneth Sæterhagen Paulsen

◆ nb_quadraticSpectralKernel

```
y = nb_quadraticSpectralKernel(x)
```

Description:

Quadratic spectral kernel

Input:

- x : A double

Output:

- y : A double

Written by Kenneth Sæterhagen Paulsen

◆ nb_shortestpath

```
[dist,path,pred] = nb_shortestpath(A,u,e)
```

Description:

Calculate shortest distance and path between two vertices (nodes) in the graph A.

Input:

- A : A double or sparse double of size N x N.
- u : The vertix (node) to start from. As an scalar integer.
- e : The vertix (node) to end at. As an scalar integer.

Output:

- dist : A scalar double with the shortest distance between the vertices (nodes). If vertex e is not reachable from u inf will be returned.
- path : The shortes path between the two vertices. As a 1 x nSteps double. If vertex e is not reachable from u [] is returned.
- pred : The predecessors along the shortest path.

Examples:

```
W = [.41 .99 .51 .32 .15 .45 .38 .32 .36 .29 .21];
DG = sparse([6 1 2 2 3 4 4 5 5 6 1],[2 6 3 5 4 1 6 3 4 3 5],W);

[dist,path,pred] = nb_shortestpath(DG,1,6)
```

◆ **nb_struct2functionHandle**

```
f = nb_struct2functionHandle(structThatRepresentsTheFunctionHandle)
```

Description:

Convert struct to function_handle.

Input:

- structThatRepresentsTheFunctionHandle : A struct which is an output from the nb_functionHandle2Struct function.

Output:

- f : A function_handle.

See also:

[nb_functionHandle2Struct](#), [nb_isStructOfFunctionHandle](#)

◆ **nb_testForecastRestrictions**

```
probability = nb_testForecastRestrictions(data,startDate,variables,...  
                                         restrictions)
```

Description:

Calculate probability of passing all forecast restrictions

Input:

```

- data          : Simulation data as a 3D double
                  (nHorizons x nVariables x nDraws)

- startDate    : First date of the data as a string or nb_date object

- variables    : The variables of the data as a cell array of strings

- restrictions : Restrictions as a n x 3 cell array,
                  {variable, date, test}.

    - variable : The variable(s) to test,
                  as a string or cell array of strings.

    - date     : The date as a string. If a cell array is given, a copy
                  of the restriction will be made for every given date.

    - test      : Restriction test as a function handle. The value(s) of
                  the variable(s) in 'variable' at time 'date' are passed
                  as arguments. Should return a logical.

```

Output:

```
- out : The estimated probability as a double
```

Example:

```

restrictions = {'QSA_URR', {'2014Q1', '2014Q2'}, @(x) x < 0; ...
                {'QSA_URR', 'QSA_DPQ_CP'}, '2014Q1', @(x, y) x < y};
probability = nb_testForecastRestrictions(...,
    data, '2010Q1', {'QSA_URR', 'QSA_DPQ_CP'}, restrictions);

```

◆ **nb_writePostMacroFile**

```
nb_writePostMacroFile(parsedFile, filename)
```

Description:

Write post macro processor model file to a file with extension nbm file.

Input:

```

- parsedFile : The parsed model as a N x 3 cell.

- filename   : File to write the model file to. Extension will be
                  automatically set to .nbm.

```
