

NB Toolbox

Reference Manual

Kenneth Sæterhagen Paulsen

January 6, 2023

Abstract

The NB toolbox is an object oriented toolbox for managing data, creating graphics and doing econometrics.¹ ² This reference manual will provide a general description of the main classes and functions of this toolbox. Some examples will be given along the way. The last section will give an extensive description of all classes, methods and functions found in this toolbox.

¹Developers; Kenneth Sæterhagen Paulsen, Per Bjarne Bye, Eyo Alexander Ildahl Herstad, Henrik Halvorsen Hortemo, Tobias Ingebrigtsen, Atle Loneland and Andreas Haga Raavand.

²Special thanks to; Knut Are Aastveit, SeHyoun Ahn, André Kallåk Anundsen, Andrew Binning, Christian Bjørland, Tuva Marie Fastbø, Karsten R. Gerdrup, Erling Motzfeldt Kravik, Junior Maih, Sara Skjeggestad Meyer, Yasin Mimir, Ørjan Robstad and Pål Bergset Ulvedal for comments and suggestions.

1 Setup toolbox

You can add functions and classes of this toolbox with the `nb_startup` function. To be able to run this function you must add the main folder of the toolbox to the MATLAB paths. E.g:

```
addpath('XXX\NBTOOLBOX-main');
```

where XXX refers to the path you have placed the NBTOOLBOX-main folder. You can now execute the `nb_startup` function. It has two optional inputs. The first is the wanted functionalities:

- `'all'`: Same as `'gui'`.
- `'dg'`: Only add the data management and graphics functions and classes.
- `'full'`: Will add all the functionalities of the toolbox, except the GUI part. Default.
- `'g'`: Only add the basic plot functions and classes.
- `'gui'`: Add all the functionalities needed to get the GUI classes for graphics.

With the second input you could tell the `nb_startup` function not to print anything on the screen. I.e. give 'silent'.

1.1 System requirements

You need eps2pdf and ghostscript installed on your PC to be able to save down figures and tables to PDFs. You need MiKTeX\2.8 or similar to be able to produce LaTeX related outputs.

1.2 Resolution and screen setup

You can set the property `plotAspectRatio`, of the classes `nb_graph_ts`, `nb_graph_cs` or `nb_graph_ts` to make the graphs produced invariant to the screen resolution. I.e set it to `'[4,3]'` or `'[16,9]'`. `'[16,9]'` is default for the graph styles `'presentation'` and `'presentation_white'`. Do not dock the figures, it may result in a lot of white space around the graph in the printed files and a warning may be displayed. To prevent this, write the following on the command line:

```
set(0,'DefaultFigureWindowStyle','normal');
```

2 Theoretical foundation

See [Paulsen \(2021\)](#) for a theoretical discussion of the methods made available in this MATLAB code. I.e. check the corresponding section header.

3 Get help on classes and functions

Of course you can use this manual to look for help on some classes or functions, but sometimes it could be easier to use some MATLAB functionalities to get this help inside MATLAB. The main function is the MATLAB function `help`. Say you want to get the

some help on the class `nb_ts`, then you can type in the following on the command line; `help nb_ts`. A full description of this class will then be printed on the command line, including how to initialize an object of this class, its properties and its methods. This will show you that the `nb_ts` class has the method `abs`, but it does not say anything about what this method does or how to use it. If you want some help one this method, you can type in the following on the command line; `help nb_ts.abs`. In the same way you can get help on some specific property of the `nb_ts` class, for example the property `data`, by typing in the following on the command line; `help nb_ts.data`.

For all classes that can be initialized with no input, you can type in `methods(classname)` and `properties(classname)` to get the methods and properties of the class respectively.

To get help on some function, say the `nb_readExcel`, you can type the following on the command line; `help nb_readExcel`.

4 Dates

This toolbox supports both dates as strings and date objects. I.e. if some function or method calls for a date as an input, both date types are supported. Some exceptions exist though. For example the functions `nb_dateplus` and `nb_dateminus`. The supported frequencies are daily (also business when read from an excel spreadsheet), weekly, monthly, quarterly, semiannually and yearly.

4.1 Dates as strings

When you use/call functions or methods of this toolbox it is easiest to use date inputs as strings. The code will be easier to read. However, using date inputs as strings require a strict date format. In this toolbox the following date formats are supported:

- Daily: 'dd.mm.yyyy' or 'yyyyMm(m)D(d)'
- Weekly: 'dd.mm.yyyy' or 'yyyyWw(w)'
- Monthly: 'dd.mm.yyyy', 'ddmonyyyy' or 'yyyyMm(m)'
- Quarterly: 'dd.mm.yyyy' or 'yyyyQq'
- Semiannually: 'dd.mm.yyyy' or 'yyyySs'
- Yearly: 'dd.mm.yyyy' or 'yyyy'

4.2 Dates as objects

As already mentioned dates will generally be stored as objects instead of as strings in this toolbox. The main reason for this is to speed up the code and it makes it easier to write general code.

In this toolbox each frequency is represented by its own class:

- Daily: `nb_day`
- Weekly: `nb_week`
- Monthly: `nb_month`
- Quarterly: `nb_quarter`
- Semiannually: `nb_semiAnnual`
- Yearly: `nb_year`

All these classes are subclasses of the superclass `nb_date`. I will not go into the technicalities for why this is so, but again it is for practical reasons. All the date classes also share the same main methods, which makes them generic. Another important feature of these objects are the frequency property stored in each date object. This property is a scalar and its value will depend on the frequency of the date. The property will take the values:

- Daily: 365
- Weekly: 52
- Monthly: 12
- Quarterly: 4
- Semianually: 2
- Yearly: 1

So when a method or function asks for the frequency of the dates (or data) as a double one of the above given values must be provided. I.e. the number matching the wanted frequency of the dates (or data).

For some examples of the usage of the date classes I refer to the listing ??.

4.3 Examples

See the example script file found at \\NBTOOLBOX\\Examples\\Dates\\nb_datesExamples.m

5 Data management

To store data in a practical way is always important when using large amount of data. With this toolbox it is possible to store the data in objects. Mainly as a `nb_data`, `nb_ts` or `nb_cs` object. Where the `nb_data` stores dimensionless data, the `nb_ts` class stores time-series data, and the `nb_cs` stores cross-sectional data. The following parts explain the usage of all classes in turn.

5.1 Time series data

As already mentioned, the `nb_ts` class will be the main class for storing time-series data.³ This class supports reading data from excel. It also supports some MATLAB objects as inputs. When I say MATLAB objects I also mean basic objects as double and struct. Some user created objects such as tseries (IRIS toolbox) and `nb_math_ts` can also be "read" by the `nb_ts` class. I will now describe how to read data from the different sources into an object of class `nb_ts`. I.e. how to initialize an object.

5.1.1 Read data from excel

To import an excel spreadsheet into an `nb_ts` object in MATLAB you can write the following:

```
obj = nb_ts('example_ts_quarterly.xlsx');
```

³`nb_ts` is a value class. Therefore you must assign all method calls when using this class. I.e. `obj = obj.growth()` not `obj.growth()`

Here the data saved in the excel spreadsheet is stored in the object obj, which will be an object of class `nb_ts`. See table 1 for an example of the needed format of the excel spreadsheet. If you now write obj on the command line you will get the following:

```
obj =
```

'Time'	'Var1'	'Var2'	'Var3'
'2000Q1'	[0.6280]	[0.9831]	[0.8555]
'2000Q2'	[0.2920]	[0.3015]	[0.6448]
'2000Q3'	[0.4317]	[0.7011]	[0.3763]
'2000Q4'	[0.0155]	[0.6663]	[0.1909]
'2001Q1'	[0.9841]	[0.5391]	[0.4283]
'2001Q2'	[0.1672]	[0.6981]	[0.4820]
'2001Q3'	[0.1062]	[0.6665]	[0.1206]
'2001Q4'	[0.3724]	[0.1781]	[0.5895]
'2002Q1'	[0.1981]	[0.1280]	[0.2262]
'2002Q2'	[0.4897]	[0.9991]	[0.3846]
'2002Q3'	[0.3395]	[0.1711]	[0.5830]
'2002Q4'	[0.9516]	[0.0326]	[0.2518]
'2003Q1'	[0.9203]	[0.5612]	[0.2904]
'2003Q2'	[0.0527]	[0.8819]	[0.6171]
'2003Q3'	[0.7379]	[0.6692]	[0.2653]
'2003Q4'	[0.2691]	[0.1904]	[0.8244]
'2004Q1'	[0.4228]	[0.3689]	[0.9827]
'2004Q2'	[0.5479]	[0.4607]	[0.7302]
'2004Q3'	[0.9427]	[0.9816]	[0.3439]
'2004Q4'	[0.4177]	[0.1564]	[0.5841]

Which looks a lot like the excel spreadsheet. It is important to note that the `nb_ts` class only read the first worksheet of the excel file as default. The read worksheet must only contain the data to read (No comments or figures). The required date format is the same as described in the section 4. With the second input you can specify a specific worksheet to read. It must then be given as a string.⁴. Please see the example below.

```
obj = nb_ts('example_ts_quarterly', 'sheet1')
```

If you only want a subset of the data stored in the excel spreadsheet read the data as ascribed above, and then use the `window` method of the `nb_ts` class to shrink the data to the wanted dates and/or variables.

5.1.2 Read data from a .mat file

It is also possible to load data from a .mat file with the code:

```
obj = nb_ts('example_ts_quarterly_mat')
```

To use .mat files are generally much faster than using excel spreadsheets. Type help `nb_ts` on the command line to get more info on the needed format of the .mat file or see the example file stored in the folder:

`\NBTOOLBOX\Examples\DataManagement`.

⁴If it does not find the provided sheet name it will read the default sheet, and it will only add the provided string as the name of the data set.

	Time	Var1	Var2	Var3
2000Q1	0.6280	0.9831	0.8555	
2000Q2	0.2920	0.3015	0.6448	
2000Q3	0.4317	0.7011	0.3763	
2000Q4	0.0155	0.6663	0.1909	
2001Q1	0.9841	0.5391	0.4283	
2001Q2	0.1672	0.6981	0.4820	
2001Q3	0.1062	0.6665	0.1206	
2001Q4	0.3724	0.1781	0.5895	
2002Q1	0.1981	0.1280	0.2262

2002Q3	0.3395	0.1711	0.5830	
2002Q4	0.9516	0.0326	0.2518	
2003Q1	0.9203	0.5612	0.2904	
2003Q2	0.0527	0.8819	0.6171	
2003Q3	0.7379	0.6692	0.2653	
2003Q4	0.2691	0.1904	0.8244	
2004Q1	0.4228	0.3689	0.9827	
2004Q2	0.5479	0.4607	0.7302	
2004Q3	0.9427	0.9816	0.3439	
2004Q4	0.4177	0.1564	0.5841	

Table 1: Format of the excel spreadsheet

5.1.3 Initialize an data object with MATLAB types

There is also possible to initialize an object of class `nb_ts` with different MATLAB data types as inputs. I will not go into detail on all these possibilities, but some examples will now be provided. First an example of initializing an object with a double⁵:

```
obj = nb_ts([2,2;2,2;2,2], 'double', '2012M1', {'Var1', 'Var2'})
```

The result will be (when the object is displayed on the command line):

```
obj =
    'Time'      'Var1'      'Var2'
    '2012M1'    [ 2]      [ 2]
    '2012M2'    [ 2]      [ 2]
    '2012M3'    [ 2]      [ 2]
```

It is also possible to initialize an object of class `nb_ts` with user defined objects, such as tseries objects provided by the IRIS package and `nb_math_ts` objects provided by the NB toolbox. See the section 5.1.14 for more on the `nb_math_ts` class. As both these types of objects do not have a reference to the variables stored in the objects, it will be important to provide them when calling the constructor of the `nb_ts` class. An example:

```
nb_math_tsObj = nb_math_ts([2,2;2,2;2,2], '2012M1');
obj           = nb_ts(nb_math_tsObj, '', '', {'Var1', 'Var2'})
```

The object `obj` will represent the same data as the example above. See the documentation on the `nb_ts` class found in the library for a more comprehensive description of all the different ways of providing data to an object of class `nb_ts`.

⁵The 'double' string provided here is not necessary to be able to initialize an object of class `nb_ts` with a double. It only provides the data set a name.

5.1.4 Transformation of the data

The time-series data stored in an object of class `nb_ts` can be transformed by different methods of the class. An example is the `egrowth` method which calculates the growth rate of the time-series stored in the object. It is important to note that all the variables stored in the object is transformed by this method. Calling the method of the object can be done by writing:

```
obj = nb_ts('example_ts_quarterly')
obj = obj.egrowth();
```

Now the object `obj` stores all the growth series of the same variables instead. There are many supported methods that does different transformations of the time-series stored in an `nb_ts` object. All these methods are documented in the [library](#).

5.1.5 Creating new variables

The `nb_ts` class has a special method for creating (adding) a new variable to the object. This can be done by writing:

```
obj = nb_ts('example_ts_quarterly');
obj = obj.deleteVariables('Var3');
obj = obj.createVariable('New variable', 'Var1-Var2')
```

Which will result in (when display on the command line):

```
obj =

    'Time'      'New variable'      'Var1'      'Var2'
    '2000Q1'    [-0.3551]        [0.6280]    [0.9831]
    '2000Q2'    [-0.0095]        [0.2920]    [0.3015]
    '2000Q3'    [-0.2694]        [0.4317]    [0.7011]
    '2000Q4'    [-0.6509]        [0.0155]    [0.6663]
    '2001Q1'    [0.4449]         [0.9841]    [0.5391]
    '2001Q2'    [-0.5309]        [0.1672]    [0.6981]
    '2001Q3'    [-0.5603]        [0.1062]    [0.6665]
    '2001Q4'    [0.1943]         [0.3724]    [0.1781]
    '2002Q1'    [0.0701]         [0.1981]    [0.1280]
    '2002Q2'    [-0.5094]        [0.4897]    [0.9991]
    '2002Q3'    [0.1684]         [0.3395]    [0.1711]
    '2002Q4'    [0.9190]         [0.9516]    [0.0326]
    '2003Q1'    [0.3591]         [0.9203]    [0.5612]
    '2003Q2'    [-0.8292]        [0.0527]    [0.8819]
    '2003Q3'    [0.0687]         [0.7379]    [0.6692]
    '2003Q4'    [0.0787]         [0.2691]    [0.1904]
    '2004Q1'    [0.0539]         [0.4228]    [0.3689]
    '2004Q2'    [0.0871]         [0.5479]    [0.4607]
    '2004Q3'    [-0.0389]        [0.9427]    [0.9816]
    '2004Q4'    [0.2613]         [0.4177]    [0.1564]
```

We now see that a new variable have been added. The inputs to the `createVariable` method must be the input data stored in the `nb_ts` object, a string with the name of the new variable and a string with the expression to be evaluated. In the expression to be evaluated all the names of the variables stored in the `nb_ts` object can be used. All the special mathematical operator (+, -, .*, .^, ./) and methods of the `nb_math_ts` class are

supported.⁶ See section 5.1.14 or the [library](#) for more on the `nb_math_ts` class. It is also possible to create more new variables at the same time with one method call. Then the inputs to the method must be cell arrays of strings (`cellstr`) with the same length. For example:

```
obj = nb_ts('example_ts_quarterly');
obj = obj.createVariable({'Var4','Var5'},...
{'Var1-Var2','Var1./Var2'})
```

5.1.6 Converting data to a new frequency

At times a method for converting data to a different frequency is wanted. This could be done by the `convert` method of the `nb_ts` class. We will first start with an example:

```
obj = nb_ts('example_ts_quarterly');
obj = obj.convert(1)
```

Which will result in (when display on the command line):

```
obj =
    'Time'      'Var1'      'Var2'      'Var3'
    '2000'      [0.0155]   [0.6663]   [0.1909]
    '2001'      [0.3724]   [0.1781]   [0.5895]
    '2002'      [0.9516]   [0.0326]   [0.2518]
    '2003'      [0.2691]   [0.1904]   [0.8244]
    '2004'      [0.4177]   [0.1564]   [0.5841]
```

Here in this example we converted the frequency of the data from quarterly (4) to yearly (1). When calling the `convert` input with only one input (besides the `nb_ts` object itself) it must be [the frequency to be converted to as a double](#). If no further input are given it is default to take the last observation in each subperiod when converting the data to a lower frequency and to set the first period of the subperiods to the values of the lower frequency when converting to a higher frequency, where all the data points in between are set to nan. The following example converts the data from quarterly to monthly:

```
obj = nb_ts('example_ts_quarterly');
obj = obj.window('2000Q1','2000Q4');
obj = obj.convert(12)
```

Which will result in (when display on the command line):

```
obj =
    'Time'      'Var1'      'Var2'      'Var3'
    '2000M1'    [0.6280]   [0.9831]   [0.8555]
    '2000M2'    [  NaN]     [  NaN]     [  NaN]
    '2000M3'    [  NaN]     [  NaN]     [  NaN]
    '2000M4'    [0.2920]   [0.3015]   [0.6448]
    '2000M5'    [  NaN]     [  NaN]     [  NaN]
    '2000M6'    [  NaN]     [  NaN]     [  NaN]
    '2000M7'    [0.4317]   [0.7011]   [0.3763]
    '2000M8'    [  NaN]     [  NaN]     [  NaN]
```

⁶ Actually when calling the `createVariable` method all variables are dumped to `nb_math_ts` objects, which makes all methods defined for this class work (including all the special mathematical operators defined in MATLAB).

```
'2000M9'      [   NaN]      [   NaN]      [   NaN]
'2000M10'     [0.0155]    [0.6663]    [0.1909]
```

If you want to convert the data in another way there exists some more possibilities. When converting to a lower frequency the following methods for converting are supported:

- 'average': Takes averages over the subperiods
- 'discrete': Takes last observation in each subperiod (Default)
- 'first': Takes first observation in each subperiod
- 'max': Takes max observation in each subperiod
- 'min': Takes min observation in each subperiod
- 'sum': Takes sums over the subperiods

When converting to a higher frequency the following options are supported⁷:

- 'cubic': Shape-preserving piecewise cubic interpolation
- 'daverage': Uses the Denton 1971 method using that the average of the intra low frequency periods should preserve the average.
- 'dsum': Uses the Denton 1971 method using that the sum of the intra low frequency periods should preserve the sum.
- 'fill': No interpolation. All periods of the higher frequency get the same value as that of the lower frequency.
- 'linear': Linear interpolation
- 'none': No interpolation. All data in between is given by nans (missing values)(Default)
- 'spline': Piecewise cubic spline interpolation

So for example if we want to convert the quarterly data given in the last example by the linear interpolation we can write the following:

```
obj = nb_ts('example_ts_quarterly');
obj = obj.window('2000Q1','2000Q4');
obj = obj.convert(12,'linear')
```

Which will result in (when display on the command line):

```
obj =

```

'Time'	'Var1'	'Var2'	'Var3'
--------	--------	--------	--------

⁷All these option will by default use the first period of the subperiods as base for the conversion. Provide the optional input 'interpolateDate' if you want to set the base to the end periods instead ('end').

```

'2000M1'      [0.6280]    [0.9831]    [0.8555]
'2000M2'      [0.5160]    [0.7559]    [0.7853]
'2000M3'      [0.4040]    [0.5287]    [0.7150]
'2000M4'      [0.2920]    [0.3015]    [0.6448]
'2000M5'      [0.3385]    [0.4347]    [0.5553]
'2000M6'      [0.3851]    [0.5679]    [0.4658]
'2000M7'      [0.4317]    [0.7011]    [0.3763]
'2000M8'      [0.2929]    [0.6895]    [0.3145]
'2000M9'      [0.1542]    [0.6779]    [0.2527]
'2000M10'     [0.0155]    [0.6663]    [0.1909]

```

If it is wanted to change the base for the interpolation when converting, it could be done as follows. (Be aware that you must provide the second option when providing any of the optional options. I.e. the string with the conversion method.):

```

obj = nb_ts('example_ts_quarterly');
obj = obj.window('2000Q1','2000Q4');
obj = obj.convert(12,'linear','interpolateDate','end')

```

Which will result in (when display on the command line):

```

obj =

'Time'      'Var1'      'Var2'      'Var3'
'2000M3'    [0.6280]    [0.9831]    [0.8555]
'2000M4'    [0.5160]    [0.7559]    [0.7853]
'2000M5'    [0.4040]    [0.5287]    [0.7150]
'2000M6'    [0.2920]    [0.3015]    [0.6448]
'2000M7'    [0.3385]    [0.4347]    [0.5553]
'2000M8'    [0.3851]    [0.5679]    [0.4658]
'2000M9'    [0.4317]    [0.7011]    [0.3763]
'2000M10'   [0.2929]    [0.6895]    [0.3145]
'2000M11'   [0.1542]    [0.6779]    [0.2527]
'2000M12'   [0.0155]    [0.6663]    [0.1909]

```

5.1.7 Merging data

Another important method of the `nb_ts` class is the `merge` method. This method makes it possible to merge two `nb_ts` objects into one `nb_ts` object storing all the variables from the two input objects. An example will follow:

```

obj1 = nb_ts(ones(4,2),'', '2012', {'Var1','Var2'});
obj2 = nb_ts(ones(4,1),'', '2012', 'Var3');
obj3 = nb_ts(ones(4,2),'', '2012', {'Var1','Var3'});

% Merging two objects
obj4 = obj1.merge(obj2)
obj5 = obj1.merge(obj3)

```

Both will result in an object representing the same data, as is seen when display on the command line:

```

obj4 =

'Time'      'Var1'      'Var2'      'Var3'
'2012'      [ 1]       [ 1]       [ 1]
'2013'      [ 1]       [ 1]       [ 1]
'2014'      [ 1]       [ 1]       [ 1]

```

```

'2015'      [ 1]      [ 1]      [ 1]

obj5 =
    'Time'      'Var1'      'Var2'      'Var3'
    '2012'      [ 1]      [ 1]      [ 1]
    '2013'      [ 1]      [ 1]      [ 1]
    '2014'      [ 1]      [ 1]      [ 1]
    '2015'      [ 1]      [ 1]      [ 1]

```

This example shows that it is still possible to merge two objects storing the the same variable. This will be the case only as long as the variable represent the same time-series. It is also possible to merge databases with different frequencies. E.g:

```

obj1 = nb_ts(ones(2,2),'', '2012', {'Var1','Var2'});
obj2 = nb_ts(ones(8,1),'', '2012Q1', 'Var3');
obj3 = obj1.merge(obj2)

```

Will result in (when display on the command line):

```

obj3 =
    'Time'      'QUA_Var1'      'QUA_Var2'      'QUA_Var3'
    '2012Q1'      [ 1]      [ 1]      [ 1]
    '2012Q2'      [ NaN]      [ NaN]      [ 1]
    '2012Q3'      [ NaN]      [ NaN]      [ 1]
    '2012Q4'      [ NaN]      [ NaN]      [ 1]
    '2013Q1'      [ 1]      [ 1]      [ 1]
    '2013Q2'      [ NaN]      [ NaN]      [ 1]
    '2013Q3'      [ NaN]      [ NaN]      [ 1]
    '2013Q4'      [ NaN]      [ NaN]      [ 1]

```

As you see the data with the lowest frequency will be converted with the use of the `convert` method of the `nb_ts` class (with default inputs). If you want to change the way the data with the lowest frequency is converted you can provide more inputs to the `merge` method. See the examples that follows for more on these inputs:

```

% The default setting for merging data with different frequencies
obj3 = obj1.merge(obj2, 'start', 'none', 'on')

% (Only) change the base for the merging (Same converting method
% and with renaming)
obj3 = obj1.merge(obj2, 'end')

% Do linear interpolation with renaming
obj3 = obj1.merge(obj2, 'start', 'linear')

% Do linear interpolation without renaming
obj3 = obj1.merge(obj2, 'start', 'linear', 'off')

```

See the `library` for more on the `merge` method.

5.1.8 Writing data to Excel

If you want to write the data to a excel spreadsheet you can write:

```

obj = nb_ts(ones(8,2), 'filename', '2012Q1', {'QUA_Var1', 'QUA_Var2'});
obj.saveDataBase()

```

In this example you will write the data to a file, where the name of that file will be given by the name of the data set. In this example 'filename'. (This name is stored in the property `dataNames` of the `nb_ts` object).

If you want to save the file to another name you can use the 'saveName' option. I.e:

```
obj = nb_ts(ones(8,2), 'filename', '2012Q1', {'QUA_Var1', 'QUA_Var2'});
obj.saveDataBase('saveName', 'test')
```

It is also possible to change the date format of the written excel spreadsheet:

```
obj = nb_ts(ones(8,2), 'filename', '2012Q1', {'QUA_Var1', 'QUA_Var2'});
obj.saveDataBase('saveName', 'test', 'dateFormat', 'xls')
```

The date formats supported are:

- 'default'
- 'fame'
- 'xls'
- 'NBNorsk' ('NBNorwegian')
- 'NBEnglish' ('NBEngelsk')

See the method `toDates` of the date classes for more on these different date formats. (I.e. `nb_day`, `nb_week`, `nb_month`, `nb_quarter`, `nb_semiAnnual` and `nb_year`.)

If your object consists of more then one data set (have more pages) the default will be to save each data set as a separate excel spreadsheet. (The default will again be to use the names of the data sets stored in the `dataNames` property of the object as the names of the saved files.) If you instead want to write all the data sets of the object to one excel file you can write (Each data sets will be stored as separate worksheets):

```
obj = nb_ts(ones(8,2,2), {'data1', 'data2'}, '2012Q1',...
            {'QUA_Var1', 'QUA_Var2'});
obj.saveDataBase('saveName', 'test', 'append', 1)
```

If the data are saved in this way it is not possible to read all the worksheets of the excel spreadsheet to an `nb_ts` object again. But you can use the `nb_readExcelMoreSheets` function to read it to an `nb_DataCollection` object. For more information on the `saveDataBase` look it up in the [library](#).

5.1.9 Writing data to other file formats

The method `saveDataBase` makes it also possible to write an `nb_ts` object to a .mat file or .txt file. This can be done with the 'ext' option:

```
% Save the data to a .mat file
obj = nb_ts(ones(8,2), 'filename', '2012Q1', {'QUA_Var1', 'QUA_Var2'});
obj.saveDataBase('saveName', 'filename', 'ext', 'mat')

% Save the data to a .txt file
obj = nb_ts(ones(8,2), 'filename', '2012Q1', {'QUA_Var1', 'QUA_Var2'});
obj.saveDataBase('ext', 'txt', 'saveName', 'filename')
```

From the example you can see that it is possible to save data of the object to a .txt ('txt') and .mat ('mat'), these are the only file formats supported besides excel ('xlsx').

5.1.10 Converting to other data types (objects)

In case you want to transform the `nb_ts` object to any other MATLAB object/type. The `nb_ts` class has some methods for doing this. See the examples below for how to do this.

```
data = nb_ts([2,2,2;2,2,2], '', '1994Q1', {'Var1', 'Var2', 'Var3'});  
  
% Convert to a structure  
s = data.toStructure()  
  
% Convert to a cell  
c = data.asCell()  
  
% Convert to a double  
d = data.double()  
  
% Convert to a nb_math_ts object  
mts = nb_math_ts(data)  
  
% Convert to a nb_cs object  
cs = data.tonb_cs();  
  
% Convert to a nb_data object  
data = data.tonb_data();
```

5.1.11 Mathematical operators

Mathematical operators act on `nb_ts` objects in a special way. The operators `.*`, `.^`, `+`, `-` and `./` will try to match the variables found in both objects and do the calculation on these variables only. The rest of the variables will be given nan values for all data points. So for example if an `nb_ts` object which includes the variables `var1` and `var2` and another object includes only `var1`, then the operator will only act on the data of the variable `var1` of the returned `nb_ts` object while the `var2` will have all nan values. When the dates of the two objects does not match all the data points outside the window of both object will also be returned as nan values.

The operators `*`, `^`, `+`, `-` and `/` act on all the data of the object, but they are only defined when combined with scalars. See the examples below.

```
data1 = nb_ts(ones(2,3)*3, '', '1994Q1', {'Var1', 'Var2', 'Var3'});  
data2 = nb_ts(ones(2,3)*2, '', '1994Q1', {'Var1', 'Var2', 'Var3'});  
  
% Element-wise operators  
data = data1-data2      % Element-wise minus  
data = data1+data2      % Element-wise plus  
data = data1.*data2     % Element-wise multiplication  
data = data1.^data2     % Element-wise power  
data = data1./data2     % Element-wise division  
  
% Operators that act on all the data of the object  
data = data1-2          % Minus (Only for scalars)  
data = data1+2          % Plus (Only for scalars)  
data = data1*2          % Multiplication (Only defined when  
                      % multiplied with a scalar)  
data = data1^2          % Power (Only defined when taken power with  
                      % a scalar)  
data = data1/2          % Only defined when divided by a scalar
```

5.1.12 Logical operators

The `nb_ts` also supports the logical operators `|`, `>`, `>=`, `==`, `<=`, `<` & `~`. All these operators will try to match the variables found in the objects and do the test element-wise

on the data of the matching variables. Contrary to the mathematical operators these operators will not work as long as the two objects do not include the same variables and dates. Examples are found below.

```

data1 = nb_ts(logical([ones(2,2), ...
    zeros(2,1)]),'', '1994Q1', {'Var1', 'Var2', 'Var3'});
data2 = nb_ts(logical([ones(2,1), ...
    zeros(2,2)]),'', '1994Q1', {'Var1', 'Var2', 'Var3'});

data = data1 & data2
data = data1 | data2

data1 = nb_ts(ones(2,3)*3, '', '1994Q1', {'Var1', 'Var2', 'Var3'});
data2 = nb_ts(ones(2,3)*2, '', '1994Q1', {'Var1', 'Var2', 'Var3'});

data = data1 > data2
data = data1 >= data2
data = data1 == data2
data = data1 <= data2
data = data1 < data2
data = data1 ~= data2

```

5.1.13 Other useful methods

There are also many other methods of the class which could make programming with time-series data more easy. I will not describe these methods here, but instead provide a list with links to the library at the end of this reference manual.

- [addVariable](#) Add a new variable to the object
- [dates](#) Return the dates of the object as a cellstr
- [deleteVariables](#) Delete some variables of the object
- [getRealEndDate](#) Get the last observation which is not nan or infinite
- [getRealStartDate](#) Get the first observation which is not nan or infinite
- [isempty](#) Checks if an object is empty
- [keepVariables](#) Keep some variables of the object
- [rename](#) Rename some variables or types of the object
- [setValue](#) Set the value of some data of the object
- [structure2Dataset](#) Add a data set from a structure
- [window](#) Shrink the window of the object

Type

```
methods(nb_ts)
```

in the command line to get the full list of method for the `nb_ts` class.

5.1.14 The `nb_math_ts` class

As mentioned earlier, the `nb_ts` class stores the data with reference to the variable names. This can be useful in many settings. For example when doing data manipulation as you can do with doubles, but at the same time have the data matched with some dates. If

so the `nb_math_ts` class could be utilized. This class has many of the same methods as the `nb_ts` class, but of course the input will differ given that the data has no link to the variable names.

The big difference is the mathematical operators `.*`, `.^`, `+`, `-` and `./`. They will now only be defined for object with the same number of observations (and same dates), and pages. In addition the number of variables (columns) of the object must either match, or one of the objects must have only one column. The examples below will show how these operators could be utilized to transform data.

```
%% Initializing an nb_math_ts object

var1 = nb_math_ts([1;2;3;4;5], '1994Q1')
var2 = nb_math_ts([0;1;2;3;4], '1994Q1')

%% Mathematical operators

var3 = var1-var2
var4 = var3./var1
var5 = (var4.*var2)./var3
```

When using the `createVariable` method of the `nb_ts` class, the functionality of the `nb_math_ts` class is being utilized. As these functionalities are very similar to the functionalities of double you can just pretend that the data are doubles. But contrary to the double class created by MATLAB, some special functions which relates to dates are defined for the `nb_math_ts` class:

- `reIndex` Makes it possible to re-indexing a time-series to a new date
- `sumOAF` Take the sum over a lower frequency

5.1.15 Examples

See the example script file found at \\NBTOOLBOX\Examples\DataManagement\nb_tsExamples.m

5.2 Cross sectional data

The `nb_cs` class is the main class for storing case data (cross-sectional data).⁸ You can read data from a excel spreadsheet and .mat (With a specific format). It is also possible to initialize an object of class `nb_cs` with MATLAB types as double and struct. For more see the following subsections. This class stores the data in a specific way. Where we from now on will call the first dimension the types dimension and the second dimension the variables dimension. The types of the data will be stored in the property `types` and the variables will be stored in the property `variables` of the `nb_cs` object. Both as cells with strings (cellstr).

5.2.1 Read data from excel

To read data from excel is simple. Just provide the name of the excel spreadsheet as the first input (with or without the extension). E.g:

```
obj = nb_cs('example_cs.xlsx')
```

⁸ `nb_cs` is a value class. Therefore you must assign all method calls when using this class. I.e. `obj = obj.growth()` not `obj.growth()`

Here the the data saved in the excel spreadsheet is stored in the object obj, which will be an object of class `nb_cs`. See table 2 for an example of the needed format of the excel spreadsheet. So if you now write obj on the command line you will get the following:

```
obj =
'Types'      'Var1'      'Var2'      'Var3'
'type1'      [ 2]      [ 2]      [ 2]
'type2'      [ 2]      [ 2]      [ 2]
'type3'      [ 2]      [ 2]      [ 2]
```

Which looks very much the same as the excel spreadsheet. It is important to note that the `nb_cs` class only reads the first worksheet of the excel file by default. The read worksheet must only contain the data to read (No comments or figures). By the second input you can specify a specific worksheet to read. It must then be given as a string.⁹

Types	Var1	Var2	Var3
type1	2	2	2
type2	2	2	2
type3	2	2	2

Table 2: Format of the excel spreadsheet

It is also possible to read a specific worksheet of the excel spreadsheet. Here is an example reading the worksheet sheet1.

```
obj = nb_cs('example_cs.xlsx','sheet1')
```

If you only want a subset of the data stored in the excel spreadsheet read the data as ascribed above, and then use the `window` method of the `nb_cs` class to shrink the data to the wanted types and/or variables.

5.2.2 Read data from a .mat file

It is also possible to load data from a .mat file with the code:

```
obj = nb_cs('example_cs_mat.mat')
```

To use .mat files are generally much faster then using excel spreadsheets. Type help `nb_cs` on the command line to get more info on the needed format of the .mat file or see the example file stored in the folder:

`\NBTOOLBOX\Examples\DataManagement.`

5.2.3 Initialize an data object with MATLAB types

It is also possible to initialize an object of class `nb_cs` with MATLAB data types as inputs. I will not go into detail on all these possibilities, but I will provide an example on how to initialize an object of class `nb_cs` with a double¹⁰:

```
obj = nb_cs([2,2,2;2,2,2;2,2,2], 'double',...
{'type1','type2','type3'}, {'Var1','Var2','Var3'})
```

⁹If it does not find the provided sheet name it will read the default sheet, and it will only add the provided string as the name of the data set.

¹⁰The 'double' string provided here is not necessary to be able to initialize an object of class `nb_ts` with a double. It only provides the data set a name.

Here we have that the first input is the double matrix, the second input will be the name of the data provided, the third input will be the types of the data and the last input will be the names of the variables. (This will result in the same data as reading the excel example file given above.)

5.2.4 Transformation of the data

The case data stored in an object of class `nb_cs` can be transform with the use of different methods of the class. An example is the `log` method which take log of the data stored in the object. It is important to note that it does this with all the variables stored in the object. Calling the method of the object can be done as follows:

```
obj = nb_cs('example_cs_mat');
obj = obj.log();
% Or
obj = log(obj);
```

Now the object `obj` stores all the variables data in logs instead. There are some supported methods which can do different transformations of the case data stored in an `nb_cs` object. All these methods are documented in the [library](#).

5.2.5 Creating new variables and types

The `nb_cs` class has a special method for creating (adding) a new variable to the object. This could be done as follows:

```
obj = nb_cs('example_cs');
obj = obj.createVariable('Var4', 'Var1./Var2')
```

Which will result in (when display on the command line):

```
obj =
    'Types'      'Var1'      'Var2'      'Var3'      'Var4'
    'type1'      [ 2]       [ 2]       [ 2]       [ 1]
    'type2'      [ 2]       [ 2]       [ 2]       [ 1]
    'type3'      [ 2]       [ 2]       [ 2]       [ 1]
```

We now see that a new variable have been added. The inputs to the `createVariable` method must be the input data stored in the `nb_cs` object, a string with the name of the new variable and a string with the expression to be evaluated. In the expression to be evaluated all the names of the variables stored in the `nb_cs` object can be used. All the special mathematical operator (+, -, .*, .^, ./) are supported.¹¹ It is also possible to create more variables at the same time with one method call. Then the inputs to the method must be cell arrays of strings (cellstr) with the same length. For example:

```
obj = nb_cs('example_cs');
obj = obj.createVariable({'Var4', 'Var0'}, {'Var1./Var2', '2*Var1'})
```

It is equally possible to create new types and add them to the object. Use the `createType` method of the `nb_cs` class.

¹¹ Actually when calling the `createVariable` method all variables are dumped to double vectors, which makes all methods defined for doubles work (including all the special mathematical operators defined in MATLAB).

5.2.6 Merging data

To merge data of different `nb_cs` objects you can utilize the `merge` method of the `nb_cs` class. E.g:

```
obj1 = nb_cs([2,2,2;2,2,2;2,2,2], 'double', ...
             {'type1', 'type3', 'type2'}, {'Var1', 'Var2', 'Var3'});
obj2 = nb_cs([2,2,2;2,2,2;2,2,2], 'double', ...
             {'type1', 'type3', 'type2'}, {'Var4', 'Var5', 'Var6'});
m    = merge(obj1,obj2)
```

It is also possible to merge two `nb_cs` objects which share some variables, but only as long as they also share the same data. I.e. this code works:

```
obj1 = nb_cs([2,2,2;2,2,2;2,2,2], 'double', ...
             {'type1', 'type3', 'type2'}, {'Var1', 'Var2', 'Var3'});
obj2 = nb_cs([2,2,2;2,2,2;2,2,2], 'double', ...
             {'type1', 'type3', 'type2'}, {'Var3', 'Var4', 'Var5'});
m    = merge(obj1,obj2)
```

But not this code (because the data of the same variable differ):

```
obj1 = nb_cs([2,2,2;2,2,2;2,2,1], 'double', ...
             {'type1', 'type3', 'type2'}, {'Var1', 'Var2', 'Var3'});
obj2 = nb_cs([2,2,2;2,2,2;2,2,2], 'double', ...
             {'type1', 'type3', 'type2'}, {'Var3', 'Var4', 'Var5'});
m    = merge(obj1,obj2)
```

It is also possible to merge `nb_cs` objects which does not share the same types. And it is also possible to merge two objects which has the same type(s) as long as they represents the same data as the following example will illustrate:

```
obj1 = nb_cs([2,2,2;2,2,2;1,1,1], 'double', ...
             {'type1', 'type3', 'type2'}, {'Var1', 'Var2', 'Var3'});
obj2 = nb_cs([1,1,1;2,2,2], 'double', ...
             {'type2', 'type5'}, {'Var1', 'Var2', 'Var3'});
m    = merge(obj1,obj2)
% or
m = [obj1;obj2]
```

5.2.7 Writing data to Excel

When you want to write the data to a excel spreadsheet. You can write:

```
obj = nb_cs([2,2,2;2,2,2;1,1,1], 'double', ...
            {'type1', 'type3', 'type2'}, {'Var1', 'Var2', 'Var3'});
obj.saveDataBase()
```

In this example you will write the data to a file, where the name of that file will be given by the name of the data set. In this example 'double'. (This name is stored in the property `dataNames` of the `nb_cs` object).

If you want to save the file to another name you can use the 'saveName' option. I.e:

```

obj = nb_cs([2,2,2;2,2,2;1,1,1], 'double',...
            {'type1','type3','type2'}, {'Var1','Var2','Var3'});
obj.saveDataBase('saveName', 'test')

```

If your object consists of more then one data set (has more pages) the default will be to save each data set as a separate excel spreadsheet. (The default will again be to use the names of the data sets stored in the dataNames property of the object as the names of the saved files.) If you instead want to write all the data sets of the object to one excel file you can write (Each data set will be stored as a separate worksheet):

```

obj = nb_cs(ones(3,3,2)*2, 'double',...
            {'type1','type3','type2'}, {'Var1','Var2','Var3'});
obj.saveDataBase('saveName', 'test', 'append', 1)

```

If the data are saved in this way it will not be possible to read all the worksheets of the excel spreadsheet to an `nb_cs` object again. But you can use the `nb_readExcelMoreSheets` function to read it to a `nb_DataCollection` object. For more information on the `saveDataBase` look it up in the [library](#).

5.2.8 Writing data to other file formats

The method `saveDataBase` makes it also possible to write an `nb_ts` object to a .mat file or .txt file. This can be done with the 'ext' option:

```

% Save the data to a .mat file
obj = nb_cs([2,2,2;2,2,2;1,1,1], 'double',...
            {'type1','type3','type2'}, {'Var1','Var2','Var3'});
obj.saveDataBase('saveName', 'filename', 'ext', 'mat')

% Save the data to a .txt file
obj = nb_cs([2,2,2;2,2,2;1,1,1], 'double',...
            {'type1','type3','type2'}, {'Var1','Var2','Var3'});
obj.saveDataBase('ext', 'txt', 'saveName', 'filename')

```

From the example you can see that it is possible to save data of the object to a .txt ('txt') and .mat ('mat'), these are the only file formats supported besides excel ('xlsx').

5.2.9 Converting to other data types (objects)

In case you want to transform the `nb_cs` object to any other MATLAB object/type. The `nb_cs` class has some methods for doing this. See the examples below for how to do this.

```

data = nb_cs([2,2,2;2,2,2;1,1,1], 'double',...
            {'type1','type3','type2'}, {'Var1','Var2','Var3'});

% Convert to a structure
s = data.toStructure()

% Convert to a cell
c = data.asCell()

% Convert to a double
d = data.double()

```

5.2.10 Mathematical operators

The mathematical operators work in the same way as is the case for the `nb_ts` class, see section [5.1.11](#), except that now each row is linked to a type instead of a date.

5.2.11 Logical operators

The logical operators work in the same way as is the case for the `nb_ts` class, see section 5.1.12, except that now each row is linked to a type instead of a date.

5.2.12 Other useful methods

There are also many other methods of the class which could make programming with case data easier. I will not describe these methods here, but instead provide a list with links to the library at the end of this reference manual.

- `addType` Add a new type to the object
- `addVariable` Add a new variable to the object
- `deleteVariables` Delete some variables of the object
- `isempty` Checks if an object is empty
- `keepVariables` Keep some variables of the object
- `rename` Rename some variables or types of the object
- `setValue` Set the value of some data of the object
- `structure2Dataset` Add a data set from a structure
- `window` Shrink the window of the object

5.2.13 Examples

See the example script file found at \\NBTOOLBOX\\Examples\\DataManagement\\nb_csExamples.m

5.3 Dimensionless data

The `nb_data` class will be the main class for storing data without reference to dates or types, i.e. dimensionless.¹² This class supports reading data from excel. It also supports some MATLAB objects as inputs. When I say MATLAB objects I also mean basic objects as double and struct. I will now describe how to read data from the different sources into an object of class `nb_data`. I.e. how to initialize an object.

5.3.1 Read data from excel

To import an excel spreadsheet into an `nb_data` object in MATLAB you can write the following:

```
obj = nb_data('example_data.xlsx')
```

Here the data saved in the excel spreadsheet is stored in the object `obj`, which will be an object of class `nb_data`. See table 3 for an example of the needed format of the excel spreadsheet. If you now write `obj` on the command line you will get the following:

```
obj =
    'Observation'    'Var1'      'Var2'      'Var3'
```

¹²`nb_data` is a value class. Therefore you must assign all method calls when using this class. I.e. `obj = obj.growth()` not `obj.growth()`

'1'	[0.5870]	[0.4087]	[0.4588]
'2'	[0.2077]	[0.5949]	[0.9631]
'3'	[0.3012]	[0.2622]	[0.5468]
'4'	[0.4709]	[0.6028]	[0.5211]
'5'	[0.2305]	[0.7112]	[0.2316]
'6'	[0.8443]	[0.2217]	[0.4889]
'7'	[0.1948]	[0.1174]	[0.6241]
'8'	[0.2259]	[0.2967]	[0.6791]
'9'	[0.1707]	[0.3188]	[0.3955]
'10'	[0.2277]	[0.4242]	[0.3674]
'11'	[0.4357]	[0.5079]	[0.9880]
'12'	[0.3111]	[0.0855]	[0.0377]
'13'	[0.9234]	[0.2625]	[0.8852]
'14'	[0.4302]	[0.8010]	[0.9133]
'15'	[0.1848]	[0.0292]	[0.7962]
'16'	[0.9049]	[0.9289]	[0.0987]
'17'	[0.9797]	[0.7303]	[0.2619]
'18'	[0.4389]	[0.4886]	[0.3354]
'19'	[0.1111]	[0.5785]	[0.6797]
'20'	[0.2581]	[0.2373]	[0.1366]

Which looks a lot like the excel spreadsheet. It is important to note that the `nb_data` class only read the first worksheet of the excel file as default. The read worksheet must only contain the data to read (No comments or figures). With the second input you can specify a specific worksheet to read. It must then be given as a string.¹³ Please see the example below.

Obs	Var1	Var2	Var3
1	0.5870	0.4087	0.4588
2	0.2077	0.5949	0.9631
3	0.3012	0.2622	0.5468
4	0.4709	0.6028	0.5211
5	0.2305	0.7112	0.2316
6	0.8443	0.2217	0.4889
7	0.1948	0.1174	0.6241
8	0.2259	0.2967	0.6791
9	0.1707	0.3188	0.3955
10	0.2277	0.4242	0.3674
11	0.4357	0.5079	0.9880
12	0.3111	0.0855	0.0377
13	0.9234	0.2625	0.8852
14	0.4302	0.8010	0.9133
15	0.1848	0.0292	0.7962
16	0.9049	0.9289	0.0987
17	0.9797	0.7303	0.2619
18	0.4389	0.4886	0.3354
19	0.1111	0.5785	0.6797
20	0.2581	0.2373	0.1366

Table 3: Format of the excel spreadsheet

```
obj = nb_ts('example_ts_quarterly', 'sheet1')
```

¹³If it does not find the provided sheet name it will read the default sheet, and it will only add the provided string as the name of the data set.

If you only want a subset of the data stored in the excel spreadsheet read the data as ascribed above, and then use the `window` method of the `nb_data` class to shrink the data to the wanted dates and/or variables.

5.3.2 Read data from a .mat file

It is also possible to load data from a .mat file with the code:

```
obj = nb_data('example_data_mat.mat')
```

To use .mat files are generally much faster than using excel spreadsheets. Type `help nb_data` on the command line to get more info on the needed format of the .mat file or see the example file stored in the folder:

`\NBTOOLBOX\Examples\DataManagement`.

5.3.3 Initialize an data object with MATLAB types

There is also possible to initialize an object of class `nb_data` with different MATLAB data types as inputs. I will not go into detail on all these possibilities, but some examples will now be provided. First an example of initializing an object with a double¹⁴:

```
obj = nb_data([2,2;2,2;2,2], 'double', '1', {'Var1', 'Var2'})
```

The result will be (when the object is displayed on the command line):

```
obj =  
  
'Observation'    'Var1'      'Var2'  
'1'              [ 2]        [ 2]  
'2'              [ 2]        [ 2]  
'3'              [ 2]        [ 2]
```

See the documentation on the `nb_data` class found in the library for a more comprehensive description of all the different ways of providing data to an object of class `nb_data`.

5.3.4 Transformation of the data

The data stored in an object of class `nb_data` can be transformed by different methods of the class. An example is the `egrowth` method which calculates the growth rate of the series stored in the object. It is important to note that all the variables stored in the object is transformed by this method. Calling the method of the object can be done by writing:

```
obj = nb_data('example_data')  
obj = obj.egrowth();
```

Now the object `obj` stores all the growth series of the same variables instead. There are many supported methods that does different transformations of the series stored in an `nb_data` object. All these methods are documented in the [library](#).

¹⁴The 'double' string provided here is not necessary to be able to initialize an object of class `nb_data` with a double. It only provides the data set a name.

5.3.5 Creating new variables

The `nb_data` class has a special method for creating (adding) a new variable to the object. This can be done by writing:

```
obj = nb_data('example_data');
obj = obj.deleteVariables('Var3');
obj = obj.createVariable('New variable', 'Var1-Var2')
```

Which will result in (when display on the command line):

```
obj =

    'Observation'    'New variable'    'Var1'      'Var2'
    '1'              [ 0.1783]        [0.5870]    [0.4087]
    '2'              [-0.3872]        [0.2077]    [0.5949]
    '3'              [ 0.0390]        [0.3012]    [0.2622]
    '4'              [-0.1319]        [0.4709]    [0.6028]
    '5'              [-0.4807]        [0.2305]    [0.7112]
    '6'              [ 0.6226]        [0.8443]    [0.2217]
    '7'              [ 0.0773]        [0.1948]    [0.1174]
    '8'              [-0.0708]        [0.2259]    [0.2967]
    '9'              [-0.1481]        [0.1707]    [0.3188]
    '10'             [-0.1965]        [0.2277]    [0.4242]
    '11'             [-0.0722]        [0.4357]    [0.5079]
    '12'             [ 0.2256]        [0.3111]    [0.0855]
    '13'             [ 0.6609]        [0.9234]    [0.2625]
    '14'             [-0.3708]        [0.4302]    [0.8010]
    '15'             [ 0.1556]        [0.1848]    [0.0292]
    '16'             [-0.0240]        [0.9049]    [0.9289]
    '17'             [ 0.2494]        [0.9797]    [0.7303]
    '18'             [-0.0497]        [0.4389]    [0.4886]
    '19'             [-0.4674]        [0.1111]    [0.5785]
    '20'             [ 0.0208]        [0.2581]    [0.2373]
```

We now see that a new variable have been added. The inputs to the `createVariable` method must be the input data stored in the `nb_data` object, a string with the name of the new variable and a string with the expression to be evaluated. In the expression to be evaluated all the names of the variables stored in the `nb_data` object can be used. All the special mathematical operator (+, -, .*, .^, ./) and methods of the double class are supported.¹⁵ It is also possible to create more new variables at the same time with one method call. Then the inputs to the method must be cell arrays of strings (cellstr) with the same length. For example:

```
obj = nb_data('example_data');
obj = obj.createVariable({'Var4', 'Var5'}, ...
    {'Var1-Var2', 'Var1./Var2'})
```

5.3.6 Merging data

Another important method of the `nb_data` class is the `merge` method. This method makes it possible to merge two `nb_data` objects into one `nb_data` object storing all the variables from the two input objects. An example will follow:

¹⁵Actually when calling the `createVariable` method all variables are dumped to double objects, which makes all methods defined for this class work (including all the special mathematical operators defined in MATLAB).

```

obj1 = nb_data(ones(4,2),'',1,[ 'Var1','Var2']);
obj2 = nb_data(ones(4,1),'',1,[ 'Var3']);
obj3 = nb_data(ones(4,2),'',1,[ 'Var1','Var3']));

% Merging two object
obj4 = obj1.merge(obj2)
obj5 = obj1.merge(obj3)

```

Both will result in an object representing the same data, as is seen when display on the command line:

```

obj4 =

```

'Observation'	'Var1'	'Var2'	'Var3'
'1'	[1]	[1]	[1]
'2'	[1]	[1]	[1]
'3'	[1]	[1]	[1]
'4'	[1]	[1]	[1]

```

obj5 =

```

'Observation'	'Var1'	'Var2'	'Var3'
'1'	[1]	[1]	[1]
'2'	[1]	[1]	[1]
'3'	[1]	[1]	[1]
'4'	[1]	[1]	[1]

This example shows that it is still possible to merge two objects storing the the same variable. This will be the case only as long as the variable represent the same series. See the [library](#) for more on the `merge` method.

5.3.7 Writing data to Excel

If you want to write the data to a excel spreadsheet you can write:

```

obj = nb_data(ones(8,2),'filename','1',[ 'Var1','Var2']);
obj.saveDataBase()

```

In this example you will write the data to a file, where the name of that file will be given by the name of the data set. In this example 'filename'. (This name is stored in the property `dataNames` of the `nb_data` object).

If you want to save the file to another name you can use the 'saveName' option. I.e:

```

obj = nb_data(ones(8,2),'filename','1',[ 'Var1','Var2']);
obj.saveDataBase('saveName','test')

```

If your object consists of more then one data set (have more pages) the default will be to save each data set as a separate excel spreadsheet. (The default will again be to use the names of the data sets stored in the `dataNames` property of the object as the names of the saved files.) If you instead want to write all the data sets of the object to one excel file you can write (Each data sets will be stored as separate worksheets):

```

obj = nb_data(ones(8,2,2),{'data1','data2'},'1',...
              {'Var1','Var2'});
obj.saveDataBase('saveName','test','append',1)

```

If the data are saved in this way it is not possible to read all the worksheets of the excel spreadsheet to an `nb_data` object again. But you can use the `nb_readExcelMoreSheets` function to read it to an `nb_DataCollection` object. For more information on the `saveDataBase` look it up in the [library](#).

5.3.8 Writing data to other file formats

The method `saveDataBase` makes it also possible to write an `nb_data` object to a `.mat` file or `.txt` file. This can be done with the 'ext' option:

```
% Save the data to a .mat file
obj = nb_data(ones(8,2),'filename','1',{'Var1','Var2'});
obj.saveDataBase('saveName','filename','ext','mat')

% Save the data to a .txt file
obj = nb_data(ones(8,2),'filename','1',{'Var1','Var2'});
obj.saveDataBase('ext','txt','saveName','filename')
```

From the example you can see that it is possible to save data of the object to a `.txt` ('`txt`') and `.mat` ('`mat`'), these are the only file formats supported besides excel ('`xlsx`').

5.3.9 Converting to other data types (objects)

In case you want to transform the `nb_data` object to any other MATLAB object/type. The `nb_data` class has some methods for doing this. See the examples below for how to do this.

```
data = nb_data([2,2,2;2,2,2],'', '1', {'Var1','Var2','Var3'});

% Convert to a structure
s = data.toStructure()

% Convert to a cell
c = data.asCell()

% Convert to a double
d = data.double()

% Convert to a nb_ts object
d = data.tonb_ts()

% Convert to a nb_cs object
cs = data.tonb_cs();
```

5.3.10 Mathematical operators

Mathematical operators act on `nb_data` objects in a special way. The operators `.*`, `.^`, `+`, `-` and `./` will try to match the variables found in both objects and do the calculation on these variables only. The rest of the variables will be given `nan` values for all data points. So for examples if an `nb_data` object which includes the variables `var1` and `var2` and another object includes only `var1`, then the operator will only act on the data of the variable `var1` of the returned `nb_data` object while the `var2` will have all `nan` values. When the observations of the two objects does not match all the data points outside the window of both object will also be returned as `nan` values.

The operators `*`, `^`, `+`, `-` and `/` act on all the data of the object, but they are only defined when combined with scalars. See the examples below.

```
data1 = nb_data(ones(2,3)*3,'','1',{'Var1','Var2','Var3'});
data2 = nb_data(ones(2,3)*2,'','1',{'Var1','Var2','Var3'});

% Element-wise operators
data = data1-data2      % Element-wise minus
data = data1+data2      % Element-wise plus
data = data1.*data2     % Element-wise multiplication
data = data1.^data2     % Element-wise power
data = data1./data2     % Element-wise division
```

```
% Operators that act on all the data of the object
data = data1-2           % Minus (Only for scalars)
data = data1+2           % Plus (Only for scalars)
data = data1*2           % Multiplication (Only defined when
                        % multiplied with a scalar)
data = data1^2           % Power (Only defined when taken power with
                        % a scalar)
data = data1/2           % Only defined when divided by a scalar
```

5.3.11 Logical operators

The `nb_data` also supports the logical operators `|`, `>`, `>=`, `==`, `<=`, `<` & `~=`. All these operators will try to match the variables found in the objects and do the test element-wise on the data of the matching variables. Contrary to the mathematical operators these operators will not work as long as the two objects do not include the same variables and dates. Examples are found below.

```
data1 = nb_data(logical([ones(2,2), zeros(2,1)]), '', '1', {'Var1', 'Var2', 'Var3'});
data2 = nb_data(logical([ones(2,1), zeros(2,2)]), '', '1', {'Var1', 'Var2', 'Var3'});

data = data1 & data2
data = data1 | data2

data1 = nb_data(ones(2,3)*3, '', '1', {'Var1', 'Var2', 'Var3'});
data2 = nb_data(ones(2,3)*2, '', '1', {'Var1', 'Var2', 'Var3'});

data = data1 > data2
data = data1 >= data2
data = data1 == data2
data = data1 <= data2
data = data1 < data2
data = data1 ~= data2
```

5.3.12 Other useful methods

There are also many other methods of the class which could make programming with dimensionless data more easy. I will not describe these methods here, but instead provide a list with links to the library at the end of this reference manual.

- [addVariable](#) Add a new variable to the object
- [deleteVariables](#) Delete some variables of the object
- [isempty](#) Checks if an object is empty
- [keepVariables](#) Keep some variables of the object
- [rename](#) Rename some variables or types of the object
- [setValue](#) Set the value of some data of the object
- [structure2Dataset](#) Add a data set from a structure
- [window](#) Shrink the window of the object

5.3.13 Examples

See the example script file found at \\NBTOOLBOX\\Examples\\DataManagement\\nb_dataExamples.m

5.4 Import multi-paged data

Some models can e.g. be estimated on real-time data. In the toolbox such data are stored as multi-paged datasets. The toolbox provide you two functions for making this process easier for you.

5.4.1 Excel spreadsheet

To import multi-paged dataset from an excel spreadsheet you can use the `nb_readExcelMorePages` function. Each worksheet must have the same format, for more on the needed format see section 1, 2 or 3. An example follows:

```
data1 = nb_readExcelMorePages('test.xlsx');
data2 = nb_readExcelMorePages('test.xlsx',sorted,'1',{'Sheet1','Sheet2'});
```

This function will create a link to the excel spreadsheet if the full path is provided.

5.4.2 A note on real-time data

To secure that your real-time data is structured correctly to be used by the different model objects provided to you by this toolbox, you should use the `cleanRealTime` method.

5.5 Create a link to the data source

The `nb_data`, `nb_ts` and `nb_cs` classes have an update method which will make it possible to create a link to the data source. The data source can be an excel spreadsheet, or a .mat file. To make the object updateable with the update method you need to provide the full path when you initialize the `nb_data`, `nb_ts` or `nb_cs`.

Be aware that even if you do transformations on the objects, by for example the egrowth method, the object is still updateable. I.e. it will read the source and do the method calls again on the updated data.

If the data source(s) of a `nb_graph_data`, `nb_graph_ts`, `nb_graph_cs`, `nb_graph_adv` or `nb_graph_package` object is (are) updatable, i.e. given by (an) updatable `nb_data`, `nb_ts` and `nb_cs` object(s), then that object is updatable too.

6 Graphics

With this toolbox you can create varieties of graphs. Be it line, bar, area or a combination of them. This could be done with the classes `nb_graph_data`, `nb_graph_ts` and `nb_graph_cs`, for dimensionless data, time-series data and cross sectional (case) data respectively. Given that these three classes do not share all the same functionalities they will be described separately.

6.1 Time-series data

In this section we will discover many of the possibilities of the `nb_graph_ts` class. First we need to provide the data of the graph. The data must be stored in an `nb_ts` object. A example of how this is done is provided below. In this example the data are loaded from an excel spreadsheet to an `nb_ts` object. To initialize an `nb_graph_ts` object you only need to provide the loaded `nb_ts` object as the input to the command `nb_graph_ts`.

```
%% Reading data from a excel spreadsheet
data = nb_ts('example_ts_quarterly');

% Initialize a nb_graph_ts object with the above data
plotter = nb_graph_ts(data);
```

Be aware that the `nb_graph_ts` object is a handle object. Which means that you do not need to assign changes to the object.

When this is done you can in practice graph the data, but the output graph may be unsatisfactory, because the default settings are used when plotting the data. To set the appearance of the graph you can use the `set` method of the `nb_graph_ts` class. The class has many different properties which will change the way the data are plotted. To set properties of the object use the `set` method. You must provide one or more property name, property value pair(s) of arguments. See the example below.

```
% Set one property of the object
plotter.set('title','test');

% Set more properties of the object at one function call
plotter.set('title','test','titleFontSize',14);
```

To get a list of all the properties of the `nb_graph_ts` class you can type `properties(nb_graph_ts)` in the command line. If you want some help on one property you can type `help nb_graph_ts.<propertyName>`. E.g. `help nb_graph_ts.title`. You can also look up the property in the `archive`. To get a list of the methods of the `nb_graph_ts` class type `methods(nb_graph_ts)` in the command line. If you want some help on some method you can type `help nb_graph_ts.<methodName>`. E.g. `help nb_graph_ts.set`.

We are now ready to do some plotting, but the `nb_graph_ts` has more graphing methods. These methods will now be described and some examples will be provided.

6.1.1 The method `graph()`

The method `graph` will plot the variables given in the input `nb_ts` object or the variables given by the `variablesToPlot` property in one graph. (If the `nb_ts` object has more pages, each page will be plotted in separate graphs.) The default plot type is line plot. So if we continue on our example above and just type `plotter.graph` the graph given in the figure 1 is plotted.

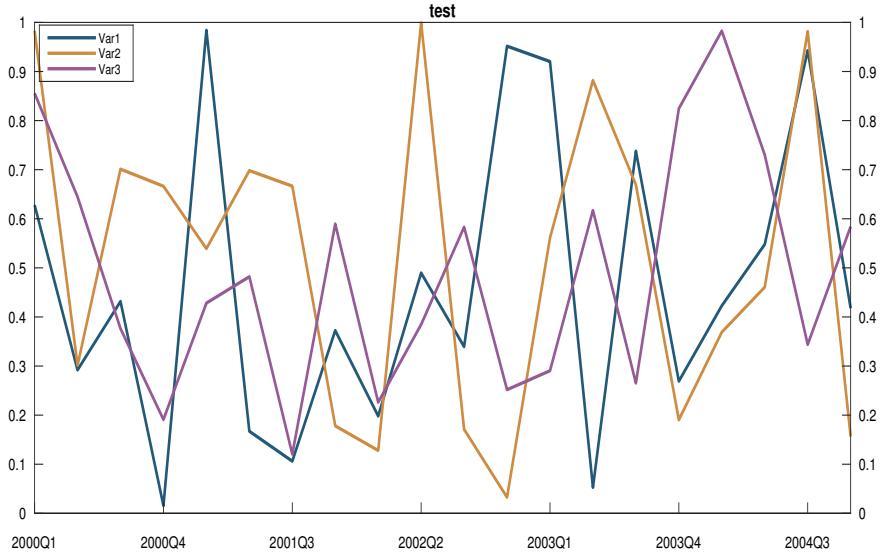

Figure 1: Simple line plot.

6.1.1.1 Different plot types of the graph method The `nb_graph_ts` class supports different plot types, which you can set with the property `plotType`. The supported types are :

- 'area' Area plot(s)
- 'candle' Candle plot(s)
- 'dec' Decomposition plot(s). Which is a bar plot with also a line with the sum of the stacked bars.
- 'grouped' Grouped bar plot(s)
- 'line' Line plot(s)
- 'scatter' Scatter plot(s)
- 'stacked' Stacked bar plot(s)

Here follows examples of the different plot types.

```
% Adding data to an object of class nb_ts
data = nb_ts([2,2;1,3;3,2],'', '2012', {'Var1', 'Var2'});

% Initialize an nb_graph_ts object with the above data
plotter = nb_graph_ts(data);

% Set the plotType to line
plotter.set('plotType', 'line');

% Plot the object
plotter.graph

% Set the plotType to stacked
plotter.set('plotType', 'stacked');

% Plot the object
plotter.graph

% Set the plotType to grouped
plotter.set('plotType', 'grouped');

% Plot the object
plotter.graph

% Set the plotType to dec
plotter.set('plotType', 'dec');

% Plot the object
plotter.graph

% Set the plotType to area
plotter.set('plotType', 'area');

% Plot the object
plotter.graph

% Set the plotType to candle (You must use the
% candleVariables property)
data = nb_ts([1,2,3,4,2.5;1,2,3,4,2.5;1,2,3,4,2.5],'', ...
    '2012', {'var1', 'var2', 'var3', 'var4', 'var5'});
plotter = nb_graph_ts(data);

plotter.set('candleVariables', {'close', 'var2', 'open', 'var3'}, ...
    'plotType', 'candle', ...
```

```

        'yLim',           [0 5]);
plotter.graph();

% Set the plotType to scatter (The default is to use the two
% first variables of the data)
data = nb_ts(rand(10,4),'', '2010', {'var1','var2','var3','var4'});
plotter = nb_graph_ts(data);

plotter.set('plotType','scatter',...
'scatterDates',{'Group1',{'2010','2019'}});
plotter.graph()

```

See the section [6.5](#) for more examples.

6.1.2 The method graphSubPlots()

The method `graphSubPlots` will plot each variable stored in the input data or all variables given by the property `variablesToPlot` in separate subplots. To set the number of subplots on each figure use the `subPlotSize` property. It must be set to a `1x2` double. The first number will be the number of rows of the subplots and the second number will be the number of columns of the subplot. This method is useful when you need a quick view of the data stored in an `nb_ts` object, or when you want to plot different pages (data sets) of the `nb_ts` object against each other quickly. See the examples:

```

% One paged data
data      = nb_ts(rand(20,4), 'Data1', '2012Q1',...
                   {'Var1','Var2','Var3','Var4'});
plotter = nb_graph_ts(data);

% Graph all the variables stored in the data object in separate
% subplots
plotter.graphSubPlots();

% Two paged data
data      = nb_ts(rand(20,4,2), {'Data1','Data2'}, '2012Q1',...
                   {'Var1','Var2','Var3','Var4'});
plotter = nb_graph_ts(data);

% Graph all the variables stored in the data object in separate
% subplots
plotter.graphSubPlots();

```

The plotted two paged data gives the figure [2](#).

6.1.2.1 Different plot types of the graph method The method `graphSubPlots` supports different plot types, which you can set with the property `plotType`. The supported types are:

- 'area' Area plot(s)
- 'line' Line plot(s)
- 'stacked' and 'grouped' Bar plot(s)

6.1.3 The method graphInfoStruct()

This method can be used to set up a graph package. This is especially important when large output from models are plotted. Instead of using `variablesToPlot`, and other properties of the `nb_graph_ts` class you must use the `GraphStruct` property. This property must be either set to a MATLAB struct or a .m file in a specific format. We will start with how to use the struct option. Here is an example:

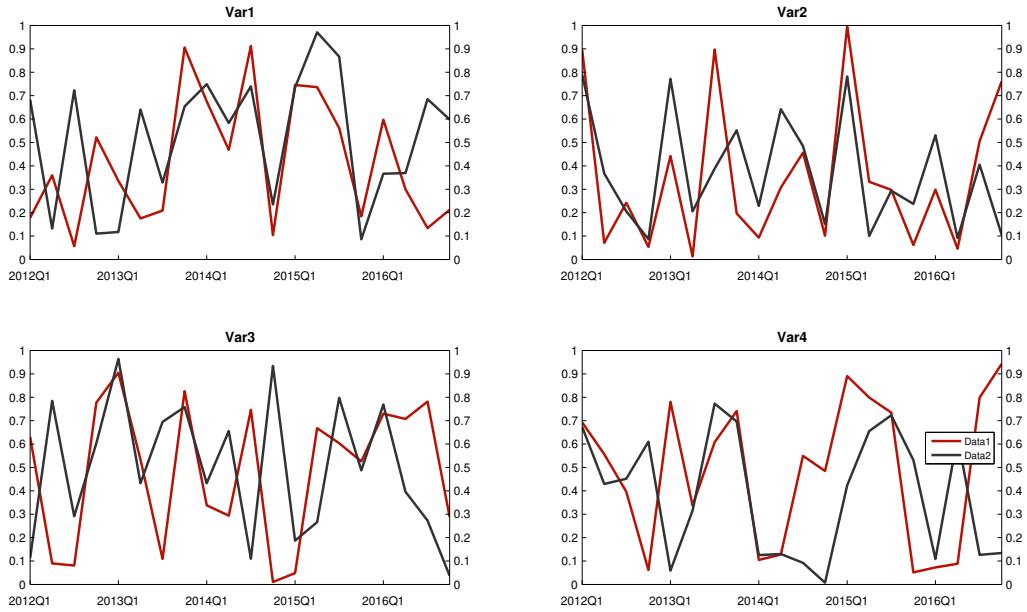

Figure 2: A figure produced by the graphSubPlots method.

```
% Two paged data
data      = nb_ts(rand(20,4,2),{'Data1','Data2'},'2012Q1',...
                  {'Var1','Var2','Var3','Var4'});
plotter = nb_graph_ts(data);

% Set up the graph settings
s = struct();
s.Example = {
    'Var1',      {'ylim', [-1 1],'ySpacing',1};
    'Var3*100',  {'yLabel','Prosent'};
    'Var3./Var4', {'yLabel','Prosent','title','Expression (Var4./Var5)'};
    'Var4',       {}};

% Set the graphStruct property
plotter.set('graphStruct',s);

% Graph given the information given by the GraphStruct property
plotter.graphInfoStruct();
```

We must first initialize the `nb_graph_ts` object in the normal way. Then we construct a variable `s` representing a struct. Then we add a field called `Example`, which will represent one figure. This field must be a cell with size $Z \times 2$. The number of rows (Z) will decide the number of subplots of the produced figure. I.e. each row will result in one subplot. The first element of the row must be the name of the variable or the a mathematical expression to be plotted. Here the expression can include all operators and methods defined by the `nb_math_ts` class.¹⁶ The second element must again be a cell array. Here you can provide the optional inputs of the given subplot (as input name, input value combinations). The following inputs are supported:

¹⁶Inside the method `graphInfoStruct` the `createVariable` method of the `nb_ts` class will be called for each expressions it does not find in the variable names.

- 'colorOrder' Sets the color order of the specific subplot
- 'legends' Sets the legend text of the specific subplot
- 'legLocation' Sets the location of the legend of the specific subplot
- 'legPosition' Sets the position of the legend of the specific subplot
- 'lineStyle' Sets the line style of the specific subplot
- 'plotType' Sets the plot type of the specific subplot
- 'title' Sets the title of the specific subplot
- 'xLabel' Sets the x-axis label of the specific subplot
- 'yLabel' Sets the y-axis label (left) of the specific subplot
- 'yLabelRight' Sets the y-axis label (right) of the specific subplot
- 'yLim' Sets the y-axis (left or both) limits of the specific subplot
- 'yLimRight' Sets the y-axis (right) limits of the specific subplot
- 'ySpacing' Sets the y-axis (left or both) spacing of the specific subplot
- 'ySpacingRight' Sets the y-axis (right) spacing of the specific subplot

If you want the graphInfoStruct method to produce more figures you can add more fields in the same way as described above, but you must give the fields different names. When you are done with constructing the struct (s in our example) you must assign it to the property GraphStruct. This is done with the set method as shown in the example above. When that is done you can create the graph(s) by calling the `graphInfoStruct` method. As already mentioned, it is also possible to set the property GraphStruct to the name of a .m file, as a string without the extension. In the file you must take it for given that the obj.GraphStruct is a struct, so you can add different fields to this "variable" in the .m file you provide. An example of a .m file on this format is provided below:

```
%-----
% Each field gives one figure
%-----
obj.GraphStruct.ExampleI = {
    'Var1',      {'ylim', [-1 1], 'ySpacing', 1};
    'Var3*100',  {'yLabel', 'Prosent'};
    'Var3./Var4', {'yLabel', 'Prosent', 'title', 'Expression (Var3./Var4)'};
    'Var4',       {}};
%-----
obj.GraphStruct.ExampleII = {
    'Var2',      {'ylim', [-1 1], 'ySpacing', 1};
    'Var3*100',  {'yLabel', 'Prosent'};
    'Var2./Var4', {'yLabel', 'Prosent', 'title', 'Expression (Var2./Var4)'};
    'Var4',       {}};
%-----
```

And this code will use the .m file:

```
% Two paged data
data      = nb_ts(rand(20,4,2),{'Data1','Data2'},'2012Q1',...
                  {'Var1','Var2','Var3','Var4'});
plotter = nb_graph_ts(data);

% Set the graphStruct property
plotter.set('graphStruct','graphInfoFile');
```

```
% Graph all the variables stored in the data object in separate
% subplots
plotter.graphInfoStruct();
```

Be aware that many of the properties of the `nb_graph_ts` class are supported by this method. See the archive for more on these properties.

We will now look at some properties which will set the more general settings of the graphs.

6.1.4 Set the spacing between the x-axis tick marks

To set the spacing between the x-axis tick mark labels, you can use the `spacing` property of the `nb_graph_ts` class. The property must be set to an integer. The integer will be the number of periods given in the frequency of the data or the frequency set by the property `xTickFrequency` (See the next paragraph). Here is an example:

```
data      = nb_ts(rand(40,2),'', '2012Q1', {'Var1','Var2'});
plotter = nb_graph_ts(data);

% Uses the property spacing
plotter.set('spacing',4);

% Graph
plotter.graph
```

6.1.5 Set the frequency of the x-axis tick marks

Say you want to plot quarterly data, but want the frequency of the x-axis tick mark labels to be yearly. You can do this using the `xTickFrequency` property of the `nb_graph_ts` class. E.g.

```
data      = nb_ts(rand(40,2),'', '2012Q1', {'Var1','Var2'});
% Initialize an nb_graph_ts object with the above data
plotter = nb_graph_ts(data);

% Uses the property xTickFrequency to do this
plotter.set('xTickFrequency','yearly');

% Graph
plotter.graph
```

Which will produce figure 3. It is only possible to convert the x-axis frequency to a lower one. The supported frequencies are:

- 'daily'
- 'monthly'
- 'quarterly'
- 'semiannually'
- 'yearly'

6.1.6 Set the start date of the x-axis tick marks

To set the start date of the x-axis tick mark labels you can use the `xTickStart` property of the `nb_graph_ts` class. It must either be set to a string with the date or an object which is of an subclass of the `nb_date` class. Here is an example:

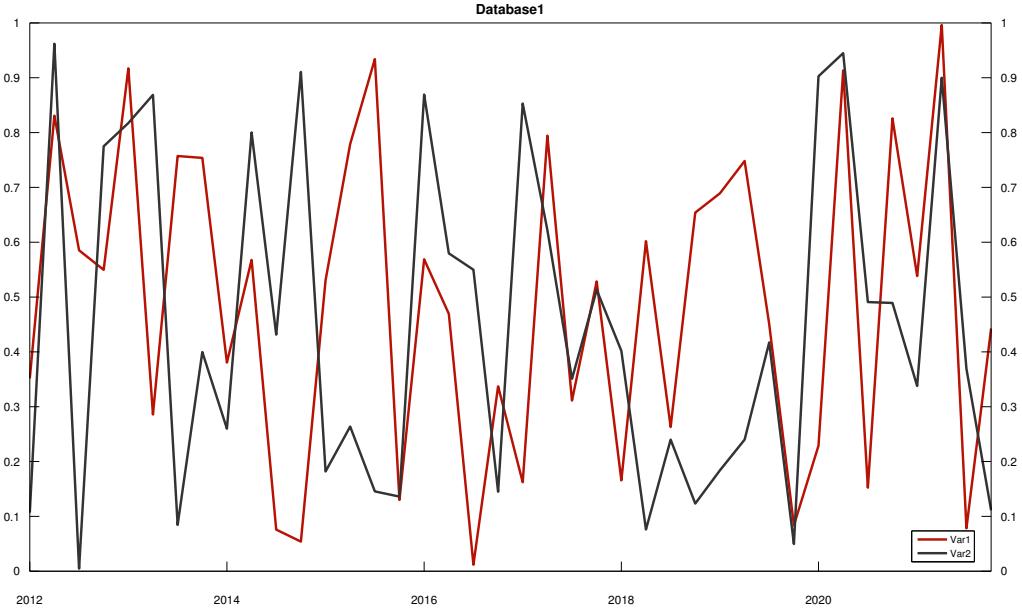

Figure 3: Use of the xTickFrequency property.

```

data      = nb_ts(rand(40,2),'', '2012Q1', {'Var1','Var2'});
plotter = nb_graph_ts(data);

% Uses the property xTickStart to do this
plotter.set('xTickStart','2012Q2', 'spacing', 4);

% Graph
plotter.graph

```

6.1.7 Set how to interpreter the data

You can also set how to interpret the data by setting the property dateInterpreter. I.e. where to place the data points in relation to the tick mark labels. You have the option:

- 'end' The data are given at the end of the period
- 'middle' The data are given at the middle of the period
- 'start' The data are given at the start of the period

6.1.8 Set the alignment of the x-axis tick mark labels

You can set the alignment of the x-axis tick mark labels to move them to be in between the x-axis tick marks. Just set the property xTickLabelAlignment to 'middle' in combination with the dateInterpreter set to 'middle'. E.g:

```

data      = nb_ts([2,2;-1,3;3,-2;3,4;-2,3;1,2],'', '2012Q1',...
                  {'Var1','Var2'});
plotter = nb_graph_ts(data);

% Uses the property xTickLabelAlignment to do this.
plotter.set('dateInterpreter',      'middle',...
            'plotType',           'grouped',...

```

```

    'xTickLabelAlignment', 'middle');

% Graph
plotter.graph

```

This code will result in figure 4.

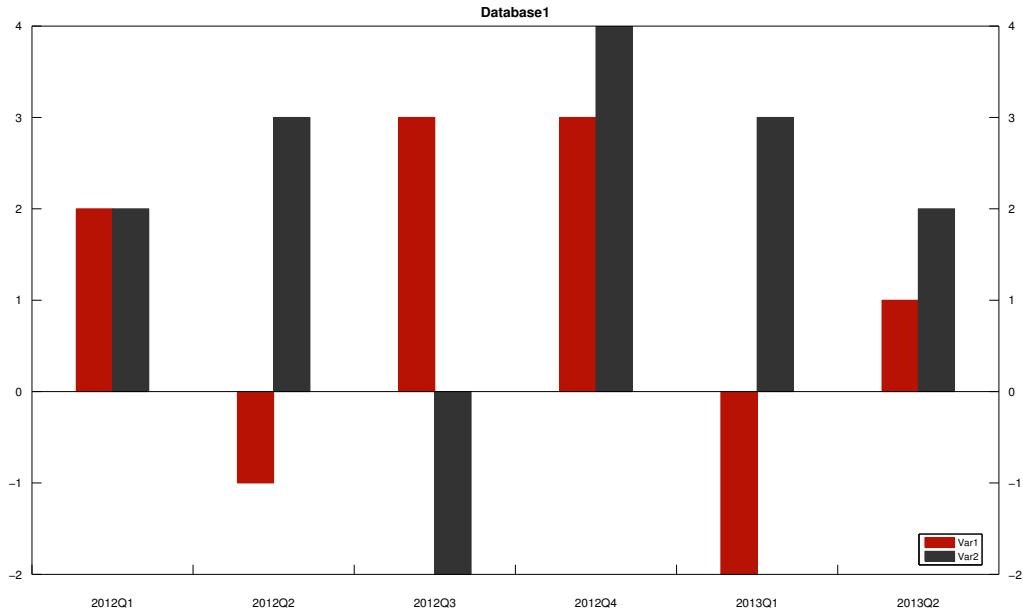

Figure 4: The xTickLabelAlignment property set to 'middle'.

6.1.9 Set the location of the x-axis tick marks

This could be done with setting the property xTickLocation. It can be set to 'bottom', 'top' or a scalar value for where to place the x-axis tick marks. Below is an example where we place the x-axis tick marks on the baseline (which is at zero) of a bar plot:

```

data      = nb_ts([2,2;-1,3;3,-2;3,4;-2,3;1,2], '', '2012Q1',...
                  {'Var1','Var2'});
plotter = nb_graph_ts(data);

% Uses the property xTickLocation to do this
plotter.set('dateInterpreter',      'middle',...
            'plotType',           'grouped',...
            'xTickLabelAlignment', 'middle',...
            'xTickLocation',       0);

% Graph
plotter.graph

```

6.1.10 How to interpret missing data

If you plot data with missing values, the graph can end up looking unsatisfactory. With the missingValues property of the `nb_graph_ts` class you can fix this. I.e. you can set how to interpret the missing values. You have three options:

- 'interpolate' Linearly interpolate the missing values
- 'strip' Strip the missing values
- 'both' First strip up until a date given by the property stopStrip and then interpolate the rest of the missing values. If the stopStrip property is not given this will result in the same as the 'strip' option

Here are some examples:

```
% Create data with missing observations
data = nb_ts.rand('2019M3D1',100,1);
data(2:7:end,:) = nan;
data(3:7:end,:) = nan;
plotter = nb_graph_ts(data);
plotter.graph()

% Interpolate the missing observations
plotter.set('missingValues','interpolate');
plotter.graph()

% Strip the missing observations
plotter.set('missingValues','strip');
plotter.graph()

% Generate data with missing observations (Only workdays)
dataDaily = nb_ts.rand('2016M3D1',1000,1);
dataDaily(2:7:end,:) = nan;
dataDaily(3:7:end,:) = nan;

% Add some artificial forecast
dataQuarterly = nb_ts(rand(3,1),'', '2019Q1', {'Var1'});
data = dataDaily.merge(dataQuarterly);
plotter = nb_graph_ts(data);

% Interpolate the missing observations works fine
plotter.set('missingValues','interpolate');
plotter.graph()

% Strip the missing observations does not
plotter.set('missingValues','strip');
plotter.graph()

% Solution use the 'both' option in combined with the stopStrip
% command
plotter.set('missingValues','interpolate','stopStrip','2013M9D30');
plotter.graph()
```

6.1.11 Creating a fan chart

To create a fan chart you can utilize the fanDatasets property of the `nb_graph_ts` class. To set the percentiles to calculate you can set the fanPercentiles property. Here is an example:

```
% Creating some artificial data
data = nb_ts([ones(20,1,100);ones(16,1,100)*0.5 + ...
rand(16,1,100)],'', '2008Q1', 'Var1');

% Get the mean (which must be given to the nb_graph_ts constructor)
meanData = mean(data,'nb_ts',3);
```

```

meanData = meanData.window('','',{},{},1);
plotter = nb_graph_ts(meanData);

% Set the fanDatasets property
plotter.set('fanDatasets',data);

% Graph the fan chart
plotter.graph();

```

It is also possible to add a fan legend. You can do this by setting the fanLegend property to 1. If you want to change the location of the fan legend you can use the fanLocation property, and if you want to change the text of the fan legend you can use the fanLegendText¹⁷. Here is an example:

```

% Creating some artificial data
data      = nb_ts([ones(20,1,100);ones(16,1,100)*0.5 + ...
    rand(16,1,100)],'', '2008Q1', 'Var1');

% Get the mean (which must be given to the nb_graph_ts constructor)
meanData = mean(data,'nb_ts',3);
meanData = meanData.window('','',{},{},1);
plotter = nb_graph_ts(meanData);

% Set the fanDatasets property
plotter.set('fanDatasets', data, ...
    'fanLegend', 1, ...
    'fanLegendLocation', [0.3,0.7]);

% Graph the fan chart
plotter.graph();

```

6.1.12 Adding highlighted areas

With the use of the highlight property of the `nb_graph_ts` class you can add a colored area behind the plotted variables. It must be set to a cell on the form `{'startDate','endDate'}` if just one highlighted area is wanted or a nested cell `{{'startDate1','endDate1'},...}` if more highlighted areas are wanted. To set the color of the highlighted area(s) you can use the highlightColor property. It must be a cell array with the colors of the highlighted area(s). Each element must either be a string with the color name or a 1x3 double with the RGB color specification. The cell array must match the size of the highlight property, i.e. the number of highlighted areas plotted. The highlightColor property is only optional. The default color of the highlighted areas is light blue. E.g:

```

data      = nb_ts(rand(36,2)*3,'','2008Q1',{'Var1','Var2'});
plotter = nb_graph_ts(data);

% Set some properties of the graph to create one highlighted area
plotter.set('highlight', {'2012Q1','2014Q1'}, ...
    'highlightColor', {'orange'});

plotter.graph()

% Set some properties of the graph to create more highlighted areas
plotter.set('highlight', {'2011Q1','2012Q1'}, ...
    {'2013Q1','2014Q1'}, ...
    'highlightColor', {'orange','light blue'});

plotter.graph()

```

Figure 5 is produced by the second example given above.

¹⁷Default are the percentiles given by the fanPercentiles property.

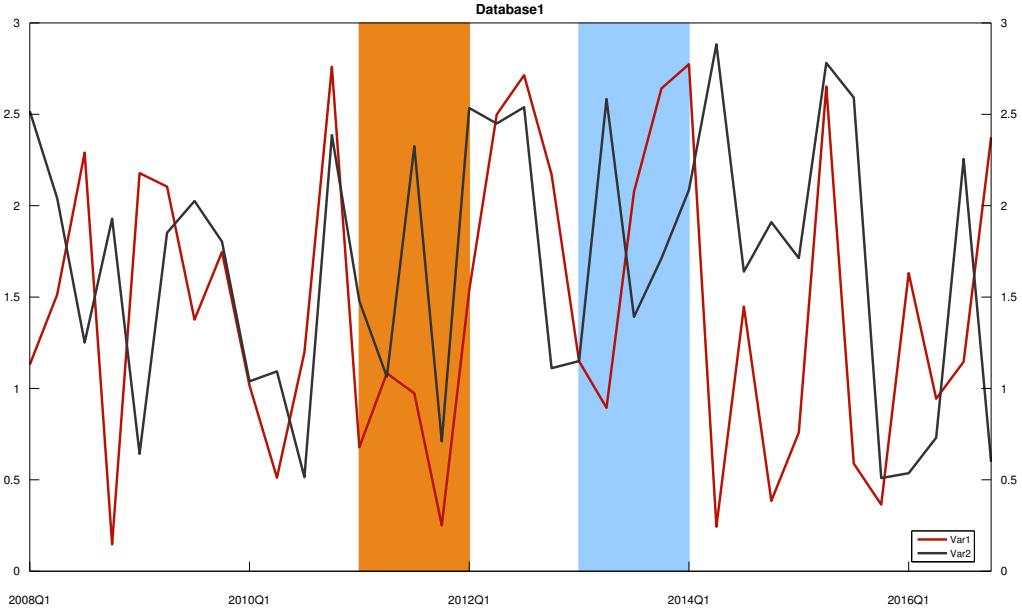

Figure 5: Adding highlighted areas to the figure.

6.2 Cross-sectional data

To plot cross-sectional data you can utilize the `nb_graph_cs` class. To initialize an `nb_graph_cs` class, you first need to provide an object of class `nb_cs` as input to the `nb_graph_cs` command. I.e:

```
% Reading data from a excel spreadsheet to construct a nb_cs object
data = nb_cs('example_cs');

% Initialize a nb_graph_cs object
plotter = nb_graph_cs(data)
```

Be aware that the `nb_graph_cs` object is a handle object. Which means that you do not need to assign changes to the object.

To set the properties of the `nb_graph_cs` object you can use the `set` method of the `nb_graph_cs` class. E.g:

```
% Set one property of an nb_graph_cs object
plotter.set('title','A title');

% Set more properties of an object of class nb_graph_cs
plotter.set('title','A title','titleFontSize',14);
```

In the first example we are assigning the value 'A title' to the property `title` of the `nb_graph_cs` object. As the second example shows, it is also possible to set more properties of an object at the same time. I.e. provide more property name, property value combinations.

To get a list off all the properties of the `nb_graph_cs` class you can type `properties(nb_graph_cs)` in the command line. If you then want help on one property you can type `help nb_graph_cs.<propertyName>`. E.g. `help nb_graph_cs.title`. You can also see the `archive`. To get a list of the methods of the `nb_graph_cs` class type `methods(nb_graph_cs)` in the command line. If you want help on some method you can type `help nb_graph_cs.<methodName>`. E.g. `help nb_graph_cs.set`.

6.2.1 The method graph()

The `graph` method can be used to create graphs. This method can be compared with `graph` method of the `nb_graph_ts` class. We will start with a simple example:

```
% Reading data from a excel spreadsheet to construct a nb_cs object
data = nb_cs('example_cs');

% Initialize a nb_graph_cs object
plotter = nb_graph_cs(data);

% Do the graphing
plotter.graph()
```

Which will result in figure 6.

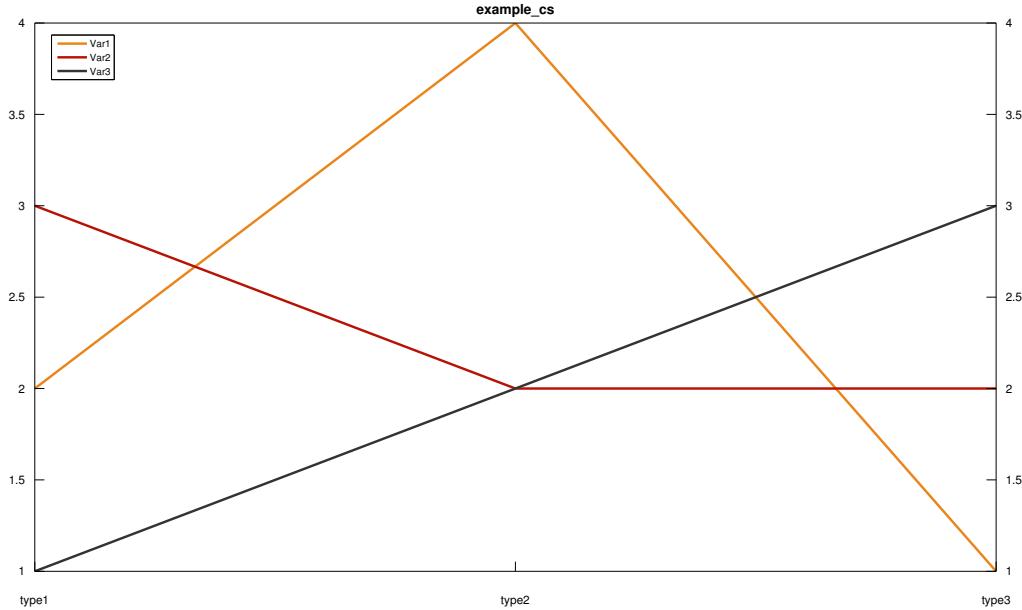

Figure 6: A simple graph using the `nb_graph_cs` class.

6.2.1.1 Different plot types of the graph method The `nb_graph_cs` class supports different plot types, which you can set with the property `plotType`. The supported types are :

- 'area' Area plot(s)
- 'candle' Candle plot(s)
- 'dec' Decomposition plot(s). Which is a bar plot with also a line with the sum of the stacked bars.
- 'grouped' Grouped bar plot(s)
- 'line' Line plot(s)
- 'pie' Pie plot(s)
- 'radar' Radar plot(s)
- 'scatter' Scatter plot(s)
- 'stacked' Stacked bar plot(s)

Here follows examples of the different plot types.

```

%% Line plot
data      = nb_cs([2,2;1,3;3,2],'',{'type1','type2','type3'},...
                  {'Var1','Var2'});
plotter = nb_graph_cs(data);
plotter.graph();

%% Area plot
data      = nb_cs([2,2;1,3;3,2],'',{'type1','type2','type3'},...
                  {'Var1','Var2'});
plotter = nb_graph_cs(data);
plotter.set('plotType', 'area');
plotter.graph();

%% Stacked bar plot
data      = nb_cs([2,2;1,3;3,2],'',{'type1','type2','type3'},...
                  {'Var1','Var2'});
plotter = nb_graph_cs(data);
plotter.set('plotType', 'stacked');
plotter.graph();

%% Grouped bar plot
data      = nb_cs([2,2;1,3;3,2],'',{'type1','type2','type3'},...
                  {'Var1','Var2'});
plotter = nb_graph_cs(data);
plotter.set('plotType', 'grouped');
plotter.graph();

%% Horizontal stacked bar plot
data      = nb_cs([2,2;1,3;3,2],'',{'type1','type2','type3'},...
                  {'Var1','Var2'});
plotter = nb_graph_cs(data);
plotter.set('plotType', 'stacked', 'barOrientation', 'horizontal');
plotter.graph();

%% Pie plot
data      = nb_cs([2,2,3,2],'',{'type1'},...
                  {'Var1','Var2','Var3','Var4'});
plotter = nb_graph_cs(data);
plotter.set('plotType', 'pie');
plotter.graph();

%% Radar plot
data      = nb_cs([1,2; 2,4; 3,5; 2,1; 3,4; 2,5],'',...
                  {'type1','type2','type3','type4','type5','type6'},...

```

```

        {'Var1','Var2'});
plotter = nb_graph_cs(data);
plotter.set('plotType','radar');
plotter.graph();

%% Candle plot
data = nb_cs([1,2,3,4,2.5;1,2,3,4,2.5;1,2,3,4,2.5],'',...
    {'type1','type2','type3'},{'var1','var2','var3','var4','var5'});
plotter = nb_graph_cs(data);

plotter.set('candleVariables',{'low','var1','close','var2',...
    'open','var3','high','var4','indicator','var5'},...
    'plotType',           'candle');
plotter.graph();

%% Scatter plot
data = nb_cs(rand(2,10),'',{'type1','type2'},{'var1','var2',...
    'var3','var4','var5','var6','var7','var8','var9','var10'});

plotter = nb_graph_cs(data);
plotter.set('plotType','scatter',...
    'scatterVariables',{'scatterGroup1',{'var1','var2','var3',...
    'var4','var5','var6','var7','var8','var9','var10'}});
plotter.graph()

```

See the section [6.6](#) for more examples.

6.2.2 The method graphSubPlots()

The method `graphSubPlots` will plot each variable stored in the input data or all variables given by the property `variablesToPlot` in separate subplots. To set the number of subplots on each figure use the `subPlotSize` property. It must be set to a `1x2` double. The first number will be the number of rows of the subplots and the second number will be the number of columns of the subplot. This method is useful when you need a quick view of the data stored in an `nb_cs` object, or when you want to plot different pages (data sets) of the `nb_cs` object against each other quickly. See the examples below:

```

% Initialize multi-paged nb_cs object
data = nb_cs(rand(3,3,3),'',{'type1','type2','type3'},...
    {'var1','var2','var3'});

plotter = nb_graph_cs(data);

% Graph all variables in separate subplots
plotter.graphSubPlots();

```

6.2.2.1 Different plot types of the graph method The method `graphSubPlots` supports different plot types, which you can set with the property `plotType`. The supported types are:

- 'area' Area plot(s)
- 'line' Line plot(s)
- 'stacked' and 'grouped' Bar plot(s)

6.2.3 The method graphInfoStruct()

This method can be used to set up a graph package. This is especially important when large output from models are plotted. Instead of using `variablesToPlot`, and other properties of the `nb_graph_cs` class you must use the `GraphStruct` property. This property

must be either set to a MATLAB struct or a .m file in a specific format. We will start with how to use the struct option. Here is an example:

```
% Three paged data
data = nb_cs(rand(3,3,3),'',{'type1','type2','type3'},...
              {'var1','var2','var3'}); 

plotter = nb_graph_cs(data);

% Set up the graph settings
s = struct();
s.Example = {
    'var1',      {'ylim', [-1 1]}, 'ySpacing', 1;
    'var3*100',  {'yLabel', 'Present'};
    'var3./var2', {'yLabel', 'Present', 'title', 'Expression (Var3./var2)'};
    'var2',      {}};

% Set the graphStruct property
plotter.set('graphStruct',s);

% Graph all the variables stored in the data object in separate
% subplots
plotter.graphInfoStruct();
```

We must first initialize the `nb_graph_cs` object in the normal way. Then we construct a variable `s` representing a struct. Then we add a field called `Example`, which will represent one figure. This field must be a cell with size $Z \times 2$. The number of rows (Z) will decide the number of subplots of the produced figure. I.e. each row will result in one subplot. The first element of the row must be the name of the variable or the a mathematical expression to be plotted. Here the expression can include all operators and methods defined by the MATLAB double class.¹⁸ The second element must again be a cell array. Here you can provide the optional inputs of the given subplot (as input name, input value combinations). The following inputs are supported:

- 'colorOrder' Sets the color order of the specific subplot
- 'legends' Sets the legend text of the specific subplot
- 'legLocation' Sets the location of the legend of the specific subplot
- 'legPosition' Sets the position of the legend of the specific subplot
- 'lineStyle' Sets the line style of the specific subplot
- 'plotType' Sets the plot type of the specific subplot
- 'title' Sets the title of the specific subplot
- 'xLabel' Sets the x-axis label of the specific subplot
- 'yLabel' Sets the y-axis label (left) of the specific subplot
- 'yLabelRight' Sets the y-axis label (right) of the specific subplot
- 'yLim' Sets the y-axis (left or both) limits of the specific subplot
- 'yLimRight' Sets the y-axis (right) limits of the specific subplot
- 'ySpacing' Sets the y-axis (left or both) spacing of the specific subplot
- 'ySpacingRight' Sets the y-axis (right) spacing of the specific subplot

¹⁸Inside the method `graphInfoStruct` the `createVariable` method of the `nb_cs` class will be called for each expressions it does not find in the variable names.

If you want the graphInfoStruct method to produce more figures you can add more fields in the same way as described above, but of course you must give the fields different names. When you are done with constructing the struct (s in our example) you must assign it to the property GraphStruct. This is done with the set method as shown in the example above. When that is done you can create the graph(s) by calling the `graphInfoStruct` method. As already mentioned it is also possible to set the property GraphStruct to a name of a .m file, as a string without the extension. See the section [6.1.3](#) for more on how to set up this file.

Be aware that many of the normal properties of the `nb_graph_cs` class are also supported by this method. See the library for more on this properties.

6.2.4 Multi line x-axis tick mark labels

Sometimes you will end up in a situation where the type names are too long to keep on one line. I.e. they will overlap in the plotted figure. To fix this problem you can use the `xTickLabels` or the `lookUpMatrix` property of the `nb_graph_cs` class.

6.2.4.1 Using the `xTickLabels` property The `xTickLabels` property must be set to a cell array of strings or chars. I.e. each element must either be a string or a multi-row char. Each element with a multi-row char will result in a multi-lined x-axis tick mark label with the same number of lines as the number of rows of the provided char. See the examples below:

```
% Using the xTickLabels property
data      = nb_cs([1,2; 2,4; 3,5; 2,1; 3,4; 2,5; 4,5; 3,4],'',...
                  {'type1','type2','A too long type name',...
                   'Another too long type name','type5','type6',...
                   'type7','type8'},...
                  {'Var1','Var2'});
plotter = nb_graph_cs(data);

% Now the x-axis tick mark labels will overlap
plotter.set('axesFontSize',16);
plotter.graph

plotter.set('xTickLabels',{'type1','type2',...
                           char('A too long','type name'),...
                           char('Another too long','type name'),...
                           'type5','type6','type7','type8'});
plotter.graph
```

6.2.4.2 Using the `lookUpMatrix` property The `lookUpMatrix` property must either be set to a MATLAB cell or a .m file on a specific format. In the example that follows a cell will be used:

```
data      = nb_cs([1,2; 2,4; 3,5; 2,1; 3,4; 2,5; 4,5; 3,4],'',...
                  {'type1','type2','A too long type name',...
                   'Another too long type name','type5','type6',...
                   'type7','type8'},...
                  {'Var1','Var2'});
plotter = nb_graph_cs(data);

% Now the x-axis tick mark labels will overlap
plotter.set('axesFontSize',16);
plotter.graph

% Set the lookUpMatrix property to make the x-axis tick mark labels
% multi-lined
s={'A too long type name',    char('A too long','type name'),''
```

```
'Another too long type name',char('Another too long','type name'),''};  
  
plotter.set('lookUpMatrix',s);  
plotter.graph
```

If you instead want to use a .m file, the file must contain something like:

```
obj.lookUpMatrix = {  
    'A too long type name',    char('A too long','type name'), ''  
    'Another too long type name',char('Another too long','type name'), ''  
};
```

And to use this .m file use the following code (Be aware that the extension should not be provided):

```
data      = nb_cs([1,2; 2,4; 3,5; 2,1; 3,4; 2,5; 4,5; 3,4],'',...  
                  {'type1','type2','A too long type name',...  
                   'Another too long type name','type5','type6',...  
                   'type7','type8'},...  
                  {'Var1','Var2'});  
plotter = nb_graph_cs(data);  
  
% Here the x-axis tick mark labels will overlap  
plotter.set('axesFontSize',16);  
  
% Set the lookUpMatrix property to make the x-axis tick mark labels  
% multi lined  
plotter.set('lookUpMatrix','lookUpMatrixExample');  
plotter.graph
```

Both ways will result in the figure 7.

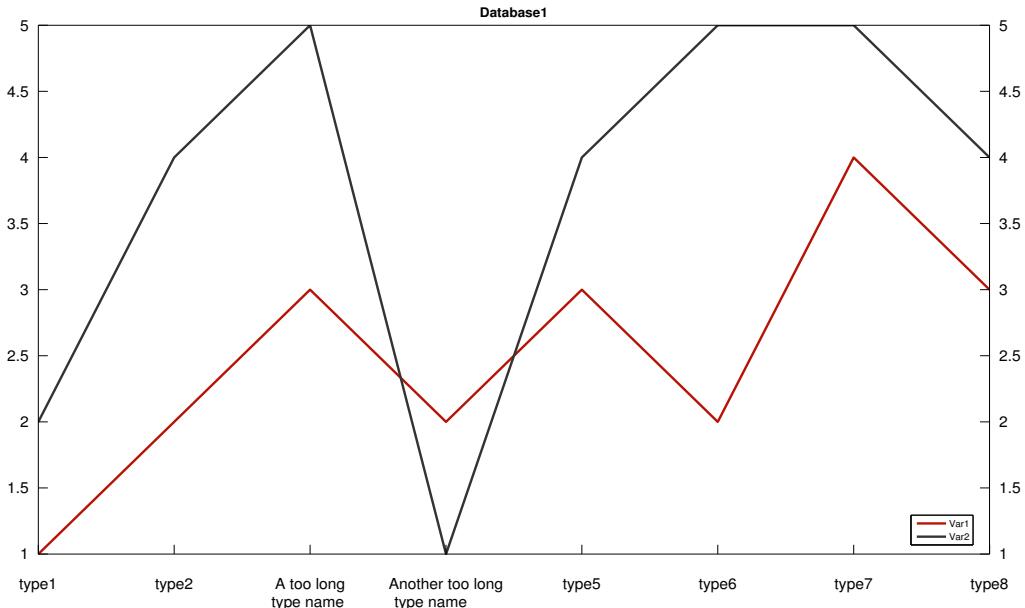

Figure 7: A figure with multi lined x-axis tick mark labels.

This way of creating multi-lined x-axis tick marks must be used if you are producing both an English and a Norwegian version at the same time. I.e. use the last column of the above cell (s or obj.lookUpMatrix) to translate the x-axis tick mark labels to Norwegian.

6.3 Dimensionless data

To plot dimensionless data you can utilize the `nb_graph_data` class. To initialize a `nb_graph_data` class, you first need to provide an object of class `nb_data` as input to the `nb_graph_data` command. I.e:

```
% Reading data from a excel spreadsheet to construct a nb_data object
data = nb_data('example_data');

% Initialize a nb_graph_data object
plotter = nb_graph_cs(data)
```

Be aware that the `nb_graph_data` object is a handle object. Which means that you do not need to assign changes to the object.

To set the properties of the `nb_graph_data` object you can use the `set` method of the `nb_graph_data` class. E.g:

```
% Set one property of an nb_graph_data object
plotter.set('title','A title');

% Set more properties of an object of class nb_graph_data
plotter.set('title','A title','titleFontSize',14);
```

In the first example we are assigning the value 'A title' to the property title of the `nb_graph_data` object. As the second example shows, it is also possible to set more properties of an object at the same time. I.e. provide more property name, property value combinations.

To get a list off all the properties of the `nb_graph_cdata` class you can type `properties(nb_graph_data)` in the command line. If you then want help on one property you can type `help nb_graph_data.<propertyName>`. E.g. `help nb_graph_data.title`. You can also see the [library](#). To get a list of the methods of the `nb_graph_data` class type `methods(nb_graph_cs)` in the command line. If you want help on some method you can type `help nb_graph_data.<methodName>`. E.g. `help nb_graph_data.set`.

6.3.1 The method `graph()`

The `graph` method can be used to create graphs. This method can be compared with `graph` method of the `nb_graph_ts` class. We will start with a simple example:

```
% Reading data from a excel spreadsheet to construct a nb_cs object
data = nb_data('example_data');

% Initialize a nb_graph_cs object
plotter = nb_graph_data(data)

% Do the graphing
plotter.graph()
```

6.3.1.1 Different plot types of the `graph` method The `nb_graph_data` class supports different plot types, which you can set with the property `plotType`. The supported types are :

- 'area' Area plot(s)
- 'candle' Candle plot(s)
- 'dec' Decomposition plot(s). Which is a bar plot with also a line with the sum of the stacked bars.
- 'grouped' Grouped bar plot(s)
- 'line' Line plot(s)
- 'scatter' Scatter plot(s)
- 'stacked' Stacked bar plot(s)

Here follows examples of the different plot types.

```

%% Line plot
data = nb_data([2,2;1,3;3,2],'', '1', {'Var1', 'Var2'});
plotter = nb_graph_data(data);
plotter.graph();

%% Area plot
data = nb_data([2,2;1,3;3,2],'', '1', {'Var1', 'Var2'});
plotter = nb_graph_data(data);
plotter.set('plotType', 'area');
plotter.graph();

%% Stacked bar plot
data = nb_data([2,2;1,3;3,2],'', '1', {'Var1', 'Var2'});
plotter = nb_graph_data(data);
plotter.set('plotType', 'stacked');
plotter.graph();

%% Grouped bar plot
data = nb_data([2,2;1,3;3,2],'', '1', {'Var1', 'Var2'});
plotter = nb_graph_data(data);
plotter.set('plotType', 'grouped');
plotter.graph();

%% Horizontal stacked bar plot
data = nb_data([2,2;1,3;3,2],'', '1', {'Var1', 'Var2'});
plotter = nb_graph_data(data);
plotter.set('plotType', 'stacked', 'barOrientation', 'horizontal');
plotter.graph();

%% Candle plot
data = nb_data([1,2,3,4,2.5;1,2,3,4,2.5;1,2,3,4,2.5],'', ...
    '1', {'var1', 'var2', 'var3', 'var4', 'var5'});
plotter = nb_graph_data(data);

plotter.set('candleVariables', {'low', 'var1', 'close', 'var2', ...
    'open', 'var3', 'high', 'var4', 'indicator', 'var5'}, ...
    'plotType', 'candle');
plotter.graph();

%% Scatter plot
data = nb_data(rand(10,2),'', '1', {'Var1', 'Var2'});
plotter = nb_graph_data(data);
plotter.set('plotType', 'scatter', ...
    'scatterObs', {'Group1', {1,10}});
plotter.graph()

```

See the section [6.7](#) for more examples.

6.3.2 The method graphSubPlots()

The method `graphSubPlots` will plot each variable stored in the input data or all variables given by the property `variablesToPlot` in separate subplots. To set the number of subplots on each figure use the `subPlotSize` property. It must be set to a `1x2 double`. The first number will be the number of rows of the subplots and the second number will be the number of columns of the subplot. This method is useful when you need a quick view of the data stored in an `nb_data` object, or when you want to plot different pages (data sets) of the `nb_data` object against each other quickly. See the examples below:

```
% Initialize multi-paged nb_data object
data      = nb_data(rand(10,2,3), '', '1', {'var1', 'var2'});
plotter = nb_graph_data(data);

% Graph all variables in separate subplots
plotter.graphSubPlots();
```

6.3.2.1 Different plot types of the graph method The method `graphSubPlots` supports different plot types, which you can set with the property `plotType`. The supported types are:

- 'area' Area plot(s)
- 'line' Line plot(s)
- 'stacked' and 'grouped' Bar plot(s)

6.3.3 The method graphInfoStruct()

See the same section for the `nb_graph_ts` class.

6.4 Shared functionality

Now we will return the attention to properties which set some more general settings of the produced graphs.

6.4.1 Plot against different axes

To do this you can use the properties `variablesToPlot` and the `variableToPlotRight` of the `nb_graph_ts`, the `nb_graph_data` or the `nb_graph_cs` class. These properties set the variables to plot against the left and the right axes respectively. Here is an example¹⁹:

```
data      = nb_ts([rand(10,1)*2, rand(10,2), rand(10,1)*2], '', '2012',...
                  {'Var1', 'Var2', 'Var3', 'Var4'});
plotter = nb_graph_ts(data);

% Set which variables to plot against which axes
plotter.set('variablesToPlot',      {'Var1', 'Var4'}, ...
            'variablesToPlotRight', {'Var2', 'Var3'})

plotter.graph()
```

¹⁹This is not supported for radar and pie plot(s). In these cases the property `variableToPlotRight` does nothing.

6.4.2 Set properties of the y-axes

To set the properties of the y-axes you can utilize the yLim, yLimRight, ySpacing, ySpacingRight, yDir, yDirRight, yScale and yScaleRight. All the xxxRight properties sets the properties of the right y-axis. The others sets the properties of both axes if the variablesToPlotRight is empty, otherwise only the left y-axis. The yLim and yLimRight properties sets the limits of the y-axes. Both must be assign a 1x2 double. E.g. [lower, upper]. The ySpacing and ySpacingRight sets the spacing between the y-axis tick marks. Both must be set to a scalar. The yDir and yDirRight properties sets the direction of the graph in the vertical dimension. Either 'normal' or 'reverse'. The properties yScale and yScaleRight sets the scale of the y-axes. Either 'normal' or 'log'. Here are some examples:

```

data      = nb_ts([rand(10,1)*2, rand(10,2), rand(10,1)*2],'', '2012',...
                  {'Var1','Var2','Var3','Var4'});
plotter = nb_graph_ts(data);

% Plot some variables and set the y-axis limits (Here you will
% set the limits of both the left and right y-axis.)
plotter.set('variablesToPlot',      {'Var1','Var4'},...
            'yLim',                [0,2],...
            'ySpacing',             0.5);

plotter.graph()

% Set which variables to plot against which axes and set the
% y-axis limits
plotter.set('variablesToPlot',      {'Var1','Var4'},...
            'yLim',                [0,2],...
            'ySpacing',             0.5,...,
            'variablesToPlotRight', {'Var2','Var3'},...
            'yLimRight',            [0,1],...
            'ySpacingRight',         0.25);

plotter.graph()

```

The yLim and the yLimRight properties can also be given as for example [0,nan], [nan,0] or [nan,nan], where the different examples will result in setting only the lower limit, setting only the upper limit and not set any of the limits respectively.

6.4.3 Colors

To set the colors of the plot you can use the colors, colorOrder or colorOrderRight properties of the `nb_graph_ts`, the `nb_graph_data` or the `nb_graph_cs` class. These must match the number of plotted variables on the left and right axes respectively, if not the default colors will be used. Be aware that you do not specify the color of the horizontal lines, vertical lines, patches or highlighted areas with these properties. The colorOrder and the colorOrderRight must be set to either a cellstr with the color names (size; 1xM) or a double with RGB colors (Size; Mx3). Where M is the number of plotted variables against the left or right axes respectively. While the colors property must be a cellstr assigning each variable a given color. See the example below. The colors property will overload the other color properties. If not all plotted variables are assign by this property, when provided, an error will be given. Both variables plotted on the left and right axes must be given in the colors property. (The colors property is preferred.)

```
% Example of the colors property input
{'Var1',[0 1 0],'Var2','black'}
```

The supported color names are:

- 'black','svart','k' [51 51 51]/255
- 'blue','blå','b' [52 114 166]/255
- 'burgundy','burgunder' [128 0 64]/255
- 'cool grey','kald grå','cgr' [164 172 177]/255
- 'cyan','c' [0 255 255]/255
- 'deep blue','mørk blå','db' [0 60 130]/255
- 'green','grønn','g' [120 165 150]/255
- 'grey','grå','gr' [130 130 130]/255
- 'light blue','lys blå','lb' [153 204 255]/255
- 'magenta','m' [255 0 255]/255
- 'orange','o' [205 140 65]/255
- 'pink','rosa','pi' [150 115 150]/255
- 'purple','lilla','p' [100 50 100]/255
- 'red','rød','r' [221 34 65]/255
- 'sand','s' [195 185 150]/255
- 'sky blue','himmelblå','hb' [44 115 153]/255
- 'turquoise','turkis','t' [0 125 130]/255
- 'water blue','vannblå','vb' [0 60 130]/255
- 'white','hvit','w' [255 255 255]/255
- 'yellow','gul','y' [245 239 5]/255

These color names will be supported as color input to all properties of the graphing classes which have something to do with colors. The same will be the case for the RGB color specification, when given as a 1x3 double. Here are some examples:

```

data      = nb_ts([rand(10,1)*2, rand(10,2), rand(10,1)*2], '', '2012',...
                  {'Var1','Var2','Var3','Var4'});
plotter = nb_graph_ts(data);

% Using color names
plotter.set('variablesToPlot',      {'Var1','Var4'},...
            'colorOrder',        {'purple','green'}); 

plotter.graph()

% Using RGB colors
plotter.set('variablesToPlot',      {'Var1','Var4'},...
            'colorOrder',        [100, 234, 78; 34, 56, 76]/255);

plotter.graph()

% When plotting variables against two axes
plotter.set('variablesToPlot',      {'Var1','Var4'},...
            'colorOrder',        {'purple','green'},...
            'variablesToPlotRight', {'Var2','Var3'},...

```

```

    'colorOrderRight',      {'red','light blue'});
plotter.graph()

% Using the colors property instead
plotter.set('variablesToPlot',     {'Var1','Var4'},...
            'variablesToPlotRight', {'Var2','Var3'},...
            'colors',             {'Var1','purple',...
                                    'Var4','green',...
                                    'Var2','red',...
                                    'Var3','light blue'});
plotter.graph()

```

6.4.4 Edit the legend

The supported properties of the legend are:

- legAuto
- legBox
- legColor
- legColumns
- legColumnWidth
- legends
- legFontColor
- legFontSize
- legInterpreter
- legPosition
- legReorder
- legSpace

To get more information on each of the property type help nb_graph_ts.<propertyName> or nb_graph_cs.<propertyName>, where you must give the name of the property you are interested in after the dot sign.

6.4.5 Adding a fake legend

Sometimes it is needed to add extra legend information. This can be done with the fakeLegend property of the nb_graph_ts, the nb_graph_data or the nb_graph_cs classes. Here is an example:

```

data      = nb_ts(rand(36,2),'', '2008Q1', {'Var1','Var2'});
plotter = nb_graph_ts(data);

% Set some properties of the graph
plotter.set('lineStyles',{'Var1',{'-','2012Q1','--'},...
                        'Var2',{'-','2012Q1','--'}},...
            'colorOrder',{'green','orange'},...
            'legType', 'nb',...
            'legends', {'Var 1','Var 2','','','Anslag'},...
            'fakeLegend',{'Anslag',...
                         {'cData','black','lineStyle','--'}},...

```

```

'yLim', [0 1]);

plotter.graph()

```

Which will give the figure 8. To get more help on this property type `help nb_graph_ts.fakeLegend` on the command line or see the list of the properties of the `nb_graph_ts` in the library.

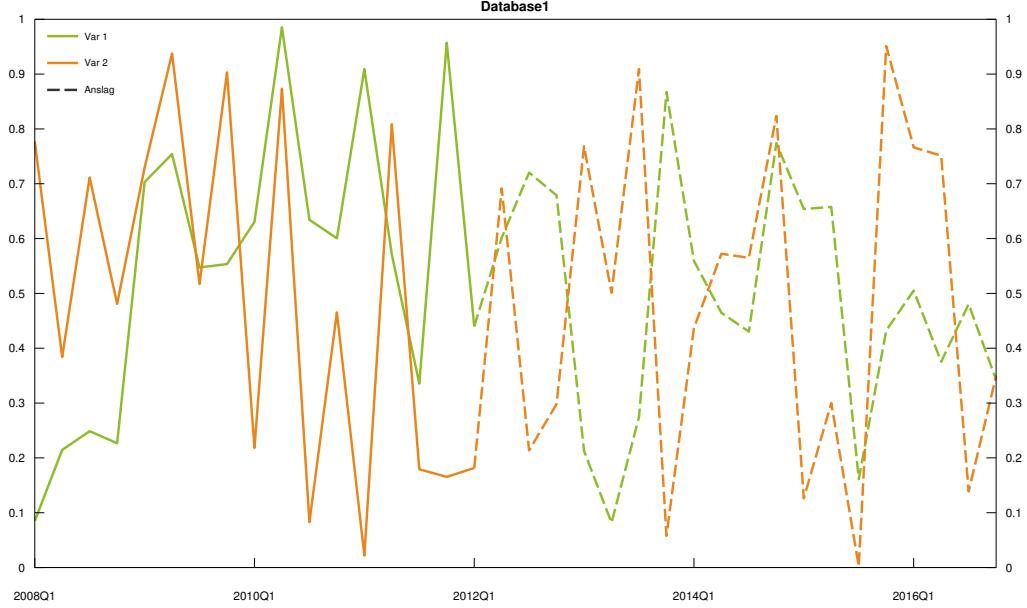

Figure 8: Example of use of the `fakeLegend` property.

6.4.6 Adding labels

It is also possible to add labels to the axes. This could be done with the `xLabel`, `yLabel` and `yLabelRight` properties of the `nb_graph_ts`, the `nb_graph_data` and the `nb_graph_cs` class. Where `xLabel` when set to a string place a label on the x-axis. `yLabel` and `yLabelRight` when set to a string will place a label on the left y-axis and right y-axis respectively. It is also possible to change the font size, font weight and so on with other properties of the `nb_graph_ts`, the `nb_graph_data` and the `nb_graph_cs` class. Please see the library for more on these properties. The example below produces the graph in figure 9.

```

% Adding data to an object of class nb_ts
data      = nb_ts([2,2;1,3;3,2]/1000,'','2012',{'Var1','Var2'});

% Initialize an nb_graph_ts object with the above data
plotter = nb_graph_ts(data);

% Add a x-axis label
plotter.set('xLabel','x-axis');

% Add a y-axis label left
plotter.set('yLabel','y-axis left');

% Add a y-axis label right
plotter.set('yLabelRight','y-axis right');

% Plot the object
plotter.graph

```

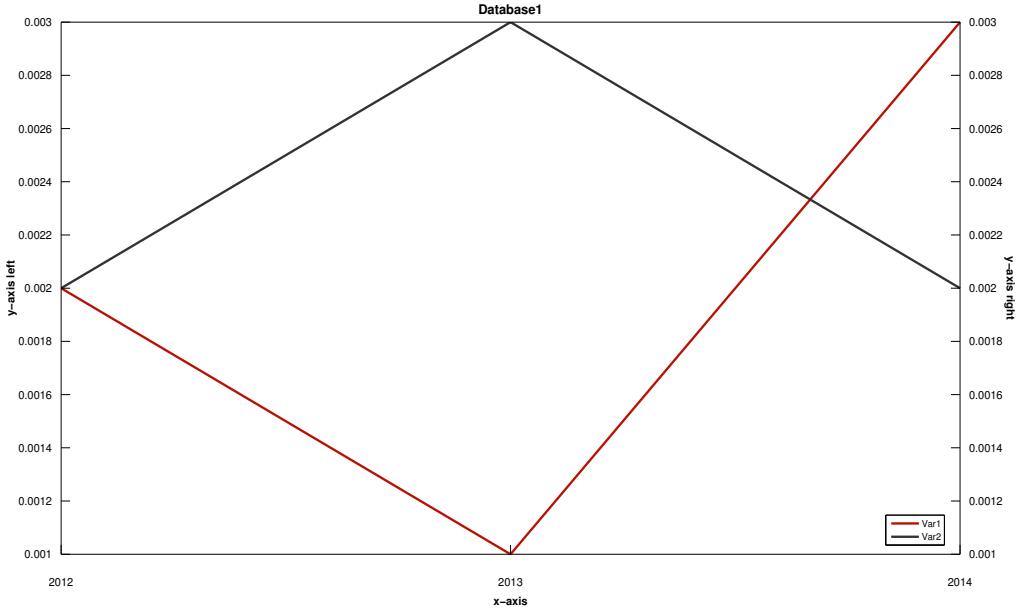

Figure 9: Adding labels to the graph.

6.4.7 Set the graph style

If you are going to produce many graphs and all of them share some of the same settings, the `graphStyle` property of the `nb_graph_ts`, the `nb_graph_data` and the `nb_graph_cs` class can be used.

There are four predefined graph styles for these two classes; 'presentation' and 'presentation_white'. The default graph style used by the `nb_Presentation` class is 'presentation'. Here is an example of the use of the property `graphStyle`:

```
data      = nb_ts([2,2;-1,3;3,-2;3,4;-2,3;1,2],'', '2012Q1',...
                  {'Var1','Var2'});
plotter = nb_graph_ts(data);

% Set the graphStyle property to do this ('presentation' is a predefined
% graph style)
plotter.set('graphStyle', 'presentation');
plotter.graph
```

You can also provide your own settings in a saved .m file. Say you saved your settings to a .m file with the name `exampleStyleFile.m`, you can then set the `graphStyle` property to the string '`exampleStyleFile`'. Be aware that the extension must be excluded from the provided input. Here is an example of using an example file:

```
data      = nb_ts([2,2;-1,3;3,-2;3,4;-2,3;1,2],'', '2012Q1',...
                  {'Var1','Var2'});
plotter = nb_graph_ts(data);

% Set the graphStyle property to do this. Now using a .m file.
% Please don't add the extension!
plotter.set('graphStyle', 'exampleStyleFile');
plotter.graph()
```

Where the format of the provided file is the following:

```
% This is an example file you can provide to the nb_graph_ts
% nb_graph_data and nb_graph_cs classes to set the graph style
% Here we are setting properties inside the method call
obj.noTitle          = 1;
obj.shading           = 'grey';
obj.legBox            = 'off';
obj.axesFontSize      = 17;
obj.legFontSize       = 14;
obj.legSpace          = 0.03;
obj.legInterpreter    = 'tex';
obj.yOffset           = 0.03;
obj.dateInterpreter   = 'middle';
```

6.4.8 Adding horizontal lines

To add a horizontal line you can use the horizontalLine property of the `nb_graph_ts`, the `nb_graph_data` or the `nb_graph_cs` class. This must be set to a $1 \times M$ double. Where M will be the number of added horizontal lines. If you want to change the line color of the horizontal line the `horizontalLineColor` can be used. The default color is black. This input must either be a cell array, where each element must be a color name as a string or a 1×3 doubles with the RGB color of each of the added horizontal lines. E.g. `{'black',[0 0 0]}`. In much the same way you can set the horizontal line style with the property `horizontalLineStyle` property. It must be set to a cell array of the line styles of each horizontal line. E.g. `{'-','--'}`. Lastly it is possible to set the width of the horizontal lines width the property `horizontalLineWidth`. This must be set to a scalar. Default is 1. Here is some examples:

```
data    = nb_ts(rand(36,2)*3,'','2008Q1',{'Var1','Var2'});
plotter = nb_graph_ts(data);

% Set some properties of the graph to create a horizontal line
plotter.set('horizontalLine', 2, ...
            'horizontalLineColor', 'black',...
            'horizontalLineStyle', '-',...
            'horizontalLineWidth', 1);

plotter.graph()

% Set some properties of the graph to create more horizontal lines
plotter.set('horizontalLine', [2, 2.5],...
            'horizontalLineColor', {'orange','blue'},...
            'horizontalLineStyle', {'-','-{-}'},...
            'horizontalLineWidth', 1);

plotter.graph()
```

6.4.9 Adding vertical lines

To add a vertical line you can use the `verticalLine` property of the `nb_graph_ts`, the `nb_graph_data` or the `nb_graph_cs` class. This must be set to a $1 \times M$ cell array. Where M will be the number of added vertical lines. Each element must either be a string with the date or the type for where to place the vertical line or a 1×2 cell array of two dates or types for where to place the vertical line. I.e. between the dates or types given. If you want to change the line color of the vertical line the `verticalLineColor` can be used. The default color is black. This input must either be a cell array, where each element must be a color name as a string or a 1×3 doubles with the RGB color of each of the added vertical lines. E.g. `{'black',[0 0 0]}`. In much the same way you can set the vertical line style with the property `verticalLineStyle` property. It must be set to a cell array of the line styles of each vertical line. E.g. `{'-','--'}`. Lastly it is possible to set the width of

the vertical lines width the property verticalLineWidth. This must be set to a scalar. Default is 1. Here is some examples:

```

data      = nb_ts(rand(36,2)*3,'','2008Q1',{'Var1','Var2'});
plotter = nb_graph_ts(data);

% Set some properties of the graph to create a vertical line
plotter.set('verticalLine',      {'2012Q1'},...
            'verticalLineColor', 'black',...
            'verticalLineStyle', '-',...
            'verticalLineWidth', 1);

plotter.graph()

% Set some properties of the graph to create more vertical lines
plotter.set('verticalLine',      {'2012Q1','2014Q1','2014Q2'},...
            'verticalLineColor', {'orange','blue'},...
            'verticalLineStyle', {'-','{-}{-}'},...
            'verticalLineWidth', 1);

plotter.graph()

```

6.4.10 Normalize the font units

It is possible to normalize the font of the text object of the figure. This could be done with the fontUnits property of the `nb_graph_ts`, the `nb_graph_data` or the `nb_graph_cs` classes. I.e. set it to 'normalized'. This will normalize the current font size properties, i.e. `axesFontSize`, `legFontSize`, `titleFontSize`, `xLabelFontSize` and `yLabelFontSize`, to the size of the font which the former font size would have plotted on the default axes positions and a resolution of the screen of 1680x1050.²⁰

Only set this property with use of the set method of the `nb_graph_ts`, `nb_graph_data` and `nb_graph_cs` class. If not the text will most certainly disappear.

6.4.11 Save the graph(s) to a file

It is also possible to save the produced graphs to a pdf file by setting the property `saveName` of the `nb_graph_ts`, the `nb_graph_data` or the `nb_graph_cs` object. Other formats are supported as well. Just type in `help nb_graph_cs.fileFormat` in the command line to see the file formats supported. Lastly you can resize the printed graph to cover the full paper size by using setting the `crop` property to 1. Default is not to crop. I.e. the size of the graph printed depend on the size of the figure window shown on the screen. E.g:

```

data = nb_ts('example_ts_quarterly');
plotter = nb_graph_ts(data);
plotter.set('title','test','titleFontSize',14);

% Set the saveName property to save it to a pdf
plotter.set('saveName','simpleFigure','crop',1);

% Plot the object
plotter.graph

```

²⁰Be aware that this does not say that the font will relate to the axes exactly in the same way irrespectively of the position of the axes and the resolution of the screen. The reason is that the font size of the text changes discontinuously, and the font size is only normalized to the height of the axes. This will in any case prevent the text to overlap if you switch between screens with different resolution.

If the graphing method produce more figures each figure will be saved down as separate pdf files. If you want to save all figures down to one pdf, you can set the property pdfBook to 1. (This is only an option when saving down the figures to pdf.)

6.4.12 Writing the data of the graph(s) to Excel

If you want to save the data behind a graph you can utilize the method saveData of the nb_graph_ts, the nb_graph_data or the nb_graph_cs class. Here is an example of a time-series graph:

```
% Reading data from a excel spreadsheet
data = nb_ts('example_ts_quarterly');

% Initialize an nb_graph_ts object with the above data
plotter = nb_graph_ts(data);

% Set one property of the object
plotter.set('title','test');

% Set more properties of the object at one function call
plotter.set('variablesToPlot',{'QUA_RNFOLIO','QUA_RNLC_BKF'},...
            'startGraph','1997Q1');

% Plot the object
plotter.graph

% Save the data of the plot to a excel file
plotter.saveData('test')
```

Be aware that only the data of the plotted variables and their time-span is saved to the excel spreadsheet.

An example of the cross-sectional case:

```
data      = nb_cs([1,2; 2,4; 3,5; 2,1; 3,4; 2,5],[],...
                  {'type1','type2','type3','type4','type5','type6'},...
                  {'Var1','Var2'});
plotter = nb_graph_cs(data);
plotter.set('variablesToPlot',{'Var1'},'typesToPlot',{'type1','type2'});
plotter.graph();

% Save the data of the plot to a excel file
plotter.saveData('test')
```

Again be aware that only the data on the types and variables plotted are saved to the excel spreadsheet.

6.5 nb_graph_ts examples

See the example script file found at \\NBTOOLBOX\Examples\Graphics\nb_graph_tsExamples.m

6.6 nb_graph_cs examples

See the example script file found at \\NBTOOLBOX\Examples\Graphics\nb_graph_csExamples.m

6.7 nb_graph_data examples

See the example script file found at \\NBTOOLBOX\Examples\Graphics\nb_graph_dataExamples.m

6.8 Adding annotations

To add annotation you can utilize the annotation property of the `nb_graph_ts`, the `nb_graph_data` or the `nb_graph_cs` class. This property must be assign an object or a cell array of objects which is of a subclass of the `nb_annotation` class. Here is a list of all the subclasses of the `nb_annotation` class²¹:

- `nb_arrow` Adding arrows
- `nb_barAnnotation` Adding text to bar plots
- `nb_drawLine` Plot a line
- `nb_drawPatch` Plot a patch
- `nb_textArrow` Plotting a arrow with a text box
- `nb_textBox` Adding a text box

So to add an annotation object to a graph you can do as follows (ann, ann1 and ann2 is all objects of one of the above listed classes):

```
% One annotation object
plotter.set('annotation',ann);

% More annotation objects
plotter.set('annotation',{ann1,ann2});
```

It is only possible to add annotation using the `graph` method of the `nb_graph_ts`, the `nb_graph_data` or the `nb_graph_cs` class.

6.8.1 More examples

See the example script file found at \\NBTOOLBOX\\Examples\\Graphics\\nb_annotationExamples.m

6.9 Creating subplots

With the use of the `nb_graph_subplot` class you can combine `nb_graph_ts`, `nb_graph_data` and/or `nb_graph_cs` objects in one figure as different subplots. The below code gives an example:

```
% Create objects of the subplots
data1 = nb_ts([2,2,2;1,3,2;3,2,2],'', '2012', {'Var1', 'Var2', 'Var3'});
plotter1 = nb_graph_ts(data1);
plotter1.set('legType','nb', 'legPosition',[0.5 0.5], 'xLabel', 'x-axis');

data2 = nb_ts([2,2,2;1,3,2;3,2,2],'', '2012', {'Var1', 'Var2', 'Var3'});
plotter2 = nb_graph_ts(data2);

data3 = nb_cs([2,2,2;1,3,2;3,2,2],'', {'type1', 'type2', 'type3'}, ...
             {'Var1', 'Var2', 'Var3'});
plotter3 = nb_graph_cs(data3);

data4 = nb_cs([2,2,2;1,3,2;3,2,2],'', {'type1', 'type2', 'type3'}, ...
             {'Var1', 'Var2', 'Var3'});
plotter4 = nb_graph_cs(data4);

% Initialize the nb_graph_subplot object
plotter = nb_graph_subplot(plotter1, plotter2, plotter3, plotter4);
```

²¹To get more information on how to use these classes see the library.

```
% Graph the figure
plotter.graph();
```

Which will result in figure 10.

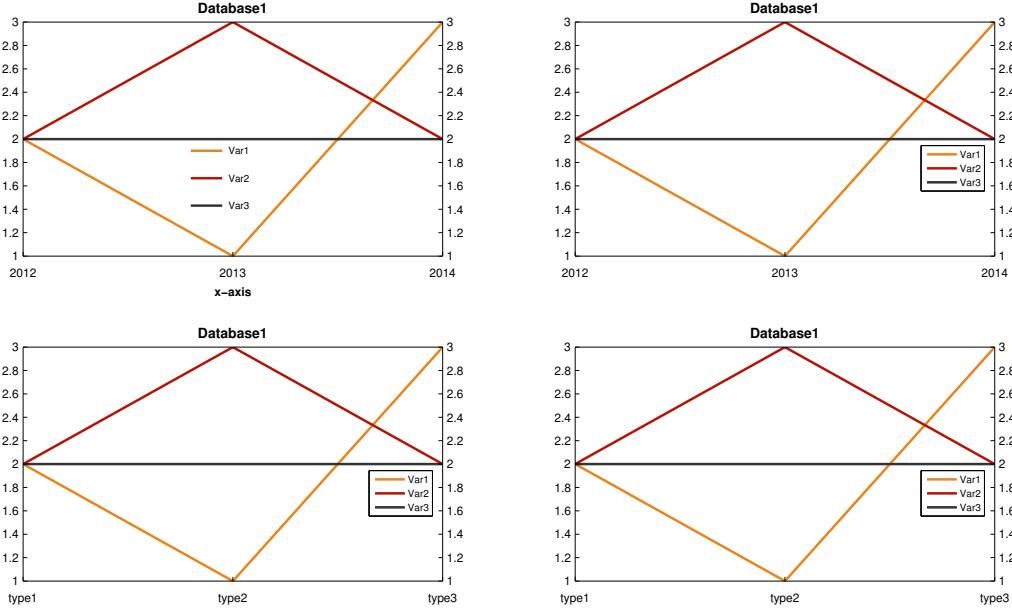

Figure 10: Combing nb_graph_ts and nb_graph_cs objects as subplots in one figure

Also, the `nb_graph_subplot` class has some properties you can set using the `set` method. To find out the properties which are supported, type in `properties(nb_graph_subplot)` on the command line. These properties are mainly font size settings and settings on how to save down the figure to a file. The class also has a method to save down the data of the graph produced to excel. I.e. the `saveData` method.

Objects of this class cannot be included in a graph package, but can be included in a presentation.

6.10 Create a package of graphs

Sometimes its useful to create a package of graphs, so that you have a simple way to produce output in both English and Norwegian. This could be done with the two classes `nb_graph_package` and `nb_graph_adv`. The `nb_graph_adv` is a class for adding figure titles and footers in both English and Norwegian to a `nb_graph_ts`, a `nb_graph_data` or a `nb_graph_cs` object. How this is done will be described first, then it will be described how to incorporate more graphs in one package.

6.10.1 Adding figure title and footer

Sometimes it is easier to first provide an example and then describe what is going on, so:

```
% Reading data from a excel spreadsheet
data = nb_ts('example_ts_quarterly');

% Initialize an nb_graph_ts object with the above data
plotter = nb_graph_ts(data);

plotter.set('graphStyle',      'mpr',...
            'variablesToPlot', {'Var1','Var2'},...
```

```

'legends',           {'FÅ,rste','Andre'},...
'legPosition',      [0.1 0.7],...
'yLim',             [0,1],...
'ySpacing',          1 ...
);

figureTitleNorwegian = {'En tittel til figuren',...
    plotter.timespan('')};

footerNorwegian      = {'1) En fotnote.',...
    'Kilde: En plass.'};

figureTitleEnglish   = {'A title for the graph',...
    plotter.timespan('english')};

footerEnglish         = {'1) A footnote.',...
    'Source: From somewhere.'};

legendsEng           = {'First',...
    'Second'};

plotterAdv = nb_graph_adv(plotter, ...
    'legendsEng', legendsEng, ...
    'figureTitleEng', figureTitleEnglish, ...
    'footerEng', footerEnglish, ...
    'figureTitleNor', figureTitleNorwegian, ...
    'footerNor', footerNorwegian...
);

% Graph Norwegian version
plotterAdv.graphNor()

% Graph English version
plotterAdv.graphEng()

```

As the example shows we must first read the data to a `nb_ts` object, then we initialize the `nb_graph_ts` object. As we want to change how the figure is plotted, we set different properties of the `nb_graph_ts` object `plotter`. Then we are ready to add figure titles and footers in both English and Norwegian. This is done when initializing the `nb_graph_adv` object `plotterAdv` with the inputs given above. Be aware that all the above inputs are cell arrays of strings. For the figure titles and footers (given by the variables `figureTitleNorwegian`, `footerNorwegian`, `figureTitleEnglish` and `footerEnglish`) a new element of the cell will be a new line. Be aware of the square brackets enclosing the two first lines of the variables, this ensures that the two lines of strings are merged into one string. This is the reason that the above code result in only two lines in the figure 11. It is recommended to always let one line of code represent one line of the figure title or footer, but because of space limitation the above example deviated from this. (It is also a good idea to use the comma sign to represent a line break.) The last input above is the translation of the legends to English. This input should always be given if a English version of the figure is produced. **Here you need to be aware that if you use the patch and fakeLegend properties of the nb_graph_ts class you must also provide the legend description for these inputs as well. The translation of the legends for the patch property must be provided first and the translation of the legends provided by the fakeLegend property must be provided last in the legendsEng cell array.**

The `nb_graph_adv` class also have some more properties which affect the excel output file when the `nb_graph_adv` object is included in a graph package. To set the name of the given figure to be included on the index pages in English and Norwegian the properties `figureNameEng` and `figureNameNor` can be used. Both must be set to a string. The `remove` property can be utilized to prevent the data of some variables to be saved to the excel output. This property must be assign a cell array of strings with the names of the variables which are not going to be saved to the excel file. If all variables of the plot is

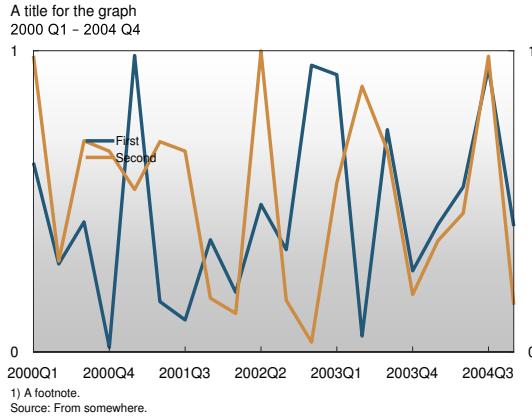

Figure 11: Adding a figure title and footers to an nb_graph_ts object.

being removed, a special message on the worksheet of that figure will be given. I.e. data publiseres ikke/data are not published. Finally, you can use the forecastDate property to color the text of some data to indicate that it is a forecast. It must be assigned as a string with the date the forecast starts (e.g. '2012Q1') or a cellstr with the individual start dates of each variable plotted. (e.g. {'Var1','2012Q1','Var2','2012Q2',...}). If a variable is not given in this cellstr none of the data of that variable will be colored as being forecasts.

The nb_graph_adv class has also some properties which sets the numbering of the figure when included in a graph package. The first is the letter property which when set to 1 will append a letter to the figure number. I.e. Chart 1.1a. And if more graphs which are added to the graph package has this property set to 1 the following graphs will be numbered as Chart 1.1b, 1.1c and so on. The second input is the counter input, this input reset the figure counter. I.e. say you until now have added three graphs, which will mean that next graph you add will normally get the number four. But say you set the property counter to 5 it will of course get the number 5 instead. I.e. Chart 1.5. And the following added graphs will then proceed counting from this number. The last is the jump property which will make the graph counter jump the given number of graphs. E.g. if set to 2 this property will make it jump from Chart 1.1 to Chart 1.3.

6.10.2 Initializing a graph package

To initialize a package you must use the nb_graph_package class. Here is an example:

```
graphNumber = 1;
chapter      = 1;

% Initialize a nb_graph_package object
package = nb_graph_package(graphNumber,chapter);
```

The first input, i.e. graphNumber in the above example, is the starting number of the graph counter. The second input, i.e. chapter int he above example will be the chapter of the graph package. This means in this example the first graph will get the name Chart

1.1 in English and Figur 1.1 in Norwegian.

This class has only one settable property. I.e. lookUpMatrix. The lookUpMatrix property must be set to a string with the name of a .m file on the format (without extension), or a struct:

```
obj.lookUpMatrix = {  
    % mnemonics, English translation Norwegian translation  
    'QUA_VAR1', 'First variable', 'Variabel nummer en'  
    'QUA_VAR2', 'Second variable', 'Variabel nummer to'  
    'QUA_VAR3', 'Third variable', 'Variabel nummer tre'  
    'QUA_VAR4', 'Fourth variable', 'Variabel nummer fire'  
};
```

This property is used to look up the variables names of the data behind the graphs of the graph package and translate them to Norwegian and English. This only applies to the created excel output.

You are now ready to add different graphs to the graph package.

6.10.3 Adding an graph object to the graph package

To add a graph to the graph package you must use the `add` method of the `nb_graph_package` class. Remember that it is only possible to add an `nb_graph_adv` object to the graph package object. So if `plotterAdv` is an object of class `nb_graph_adv` you can use the following code to add the graph to the package object, which is of class `nb_graph_package`:

```
package = package.add(plotterAdv);
```

It is only possible to add one graph object at the time.

6.10.4 Print the graph(s) to a pdf file

When all the graphs are added to the graph package you can use the method `writePDF` to print the figures produced to a pdf file. This method takes two inputs. The first input will be the save name of the pdf file. It must be given as string. The second input must be the language to use. Either 'norsk' or 'english'. An example will follow:

```
% PDF in norwegian  
package.writePDF('test_nor','norsk');  
  
% PDF in english  
package.writePDF('test_eng','english');
```

6.10.5 Writing data of the graph package to Excel

To save the data behind the figures to excel you can use the `saveData` method of the `nb_graph_package` class. This method takes five inputs. The first input will be the name of the saved file, as a string. The second input must be either 'norsk', 'english' or 'both'. This input sets the format of the saved excel spreadsheet, i.e. if should be given in Norwegian, English or in both languages respectively. The third input sets the heading of the Norwegian index page, This must either be a 1x1 cellstr or a 1x2 cellstr. E.g:

```
% A 1x1 cellstr  
firstPageNameNor = {'Et eksempel'};  
  
% A 1x2 cellstr  
firstPageNameNor = {'Et eksempel',...  
    'med masse null'};
```

The fourth input must be the same as the second input only translated to English. I.e. the heading of the English index page. The fifth input will if set to 1 round-off all the save data of the excel spreadsheet to two decimals. Here is an example:

```
firstPageNameNor = {'Et eksempel',...
    'med masse null'};
firstPageNameEng = {'An example',...
    'with a lot of crap'};
roundoff         = 1;

package.saveData('test_excel_output','both',firstPageNameNor,...
    firstPageNameEng,roundoff);
```

Be aware that you must run the writePDF command before the saveData command if default fans are added to a graph of the package.

6.10.6 Full example script

See the example script file found at \\NBTOOLBOX\\Examples\\Graphics\\nb_graph_packageExample.m

6.11 Basic plot classes and functions

All the above classes are calling some basic plot classes and functions under the hood. These are in a sense more general, but are also harder to use. They are also limited in that they only support data as doubles, as the MATLAB plotting functions also do. Here is a list of these classes:²²

²²Follow the links to get more information on the given class

- `nb_area` Area plot
- `nb_axes` Creating a axes to plot on
- `nb_bar` Bar plot
- `nb_candle` Candle plot
- `nb_fanChart` Create a fan chart
- `nb_fanLegend` Create a legend to the fan chart
- `nb_figure` Creating a figure handle add axes to
- `nb_figureTitle` Adding a figure title to the figure
- `nb_footer` Adding footers to the figure
- `nb_graphPanel` Creating a figure handle add axes to
(Fixes aspect ratio)
- `nb_hbar` Horizontal bar plot
- `nb_highlight` Highlighted areas which spans the whole y-axis
- `nb_horizontalLine` A horizontal line which spans the whole x-axis
- `nb_legend` Adding a legend to the plot
- `nb_line` Plotting a line
- `nb_patch` Plotting a patch
- `nb_pie` Pie plot
- `nb_plot` Plotting more lines
- `nb_plotComb` Combine different plot types in one plot
- `nb_radar` Radar plot
- `nb_scatter` Scatter plot
- `nb_title` Adding a title to the plot
- `nb_verticalLine` Adding a vertical line which spans the whole y-axis
- `nb_xlabel` Adding a x-axis label
- `nb_ylabel` Adding a y-axes label

Here is a list of the functions:²³

- `nb_subplot` Create axes in tiled positions
- `nb_subplot_position` Get the position of the tiled axes
- `nb_subplotSpecial` Create axes in tiled positions in a special way

²³Follow the links to get more information on the given function

6.11.1 Examples

See the example script file found at \\NBTOOLBOX\\Examples\\Graphics\\basicPlotClassesExamples.m

7 Basic Econometrics

Throughout this chapter, the data variable will refer to the following time series:

```
% Create time series data
rng(1); % Set seed

draws = randn(100,1);
sim1 = filter(1,[1,-0.8],draws);
sim2 = filter([1,-0.8],1,draws);
sim = [sim1,sim2];

data = nb_ts(sim,'','2012Q1',{'AR','MA'});
```

7.1 Autocorrelation

To compute the autocorrelation of a time series, use the `autocorr` method of the `nb_ts` class:

```
acf = autocorr(data, 5); % 5 lags
acf.plot('graphSubPlots');
```

To calculate confidence bounds, supply the desired calculation method and significance value:

```
acf = autocorr(data, 5, 'asymptotic', 0.05);
acf.plot('graphSubPlots');
```

To compute the partial autocorrelation of a time series, use the `parcorr` method of the `nb_ts` class instead.

7.2 Unit root tests

To test a time series for unit root, use the `nb_unitRootTest` class.

```
test = nb_unitRootTest(data, 'adf'); % or 'pp'.
print(test)
```

For information about optional inputs, look at the documentation for `nb_adf` and `nb_phillipsPeron`.

7.3 Cointegration tests

To test time series for cointegration, use the `nb_cointTest` class.

```
% Engle-Granger
test = nb_cointTest(data, 'eg', 'lagLengthCrit', 'aic');
print(test)

% Johansen
test = nb_cointTest(data, 'jo', 'nLags', 4);
```

```
print(test)
```

For information about optional inputs, look at the documentation for `nb_egoint` and `nb_jcoint`.

7.4 Information Criterion

The different information criterion are calculated using the `nb_infoCriterion` function. For more see the help for this function in MATLAB.

7.5 Frequency zero spectrum estimation

Frequency zero spectrum estimation is done by the `nb_zeroSpectrumEstimation` function. For more see the help for this function in MATLAB.

7.6 Kernel functions

See `nb_bartlettKernel`, `nb_parzenKernel` and `nb_quadraticSpectralKernel`. For more see the help for these functions in MATLAB.

7.7 Bootstrapping

How to bootstrap a model may be very model dependent, but the bootstrapping of residuals is done with the function `nb_bootstrap`. For more see the help for this function in MATLAB.

8 Single equation, time-series

To estimate a single equation model, use the `nb_singleEq` class.

To initialize a `nb_singleEq` object, start by calling the `nb_singleEq.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_singleEq` constructor:

```
% Create some data
EXO1 = randn(100,1);
EXO2 = randn(100,1);
DEP = 0.2*EXO1 + -0.5*EXO2 + randn(100,1);
data = nb_ts([DEP,EXO1,EXO2],'', '1990Q1', {'Dep','Exo1','Exo2'});

% Formulate model
options = nb_singleEq.template();
options.data = data;
options.dependent = {'Dep'};
options.exogenous = {'Exo1', 'Exo2'};
options.nLags = 4;

% Initialize model object
model = nb_singleEq(options);
```

For information about the different options, use the `nb_singleEq.help` method:

```
nb_singleEq.help() % All options
nb_singleEq.help('data') % Specific option
```

To estimate the model, use the `estimate` method:

```

model = estimate(model);
print(model)

```

Where the last statement prints the estimation results to the command line.

8.1 OLS

To estimate the model using OLS, set the 'estim_method' property to 'ols'.

8.2 TSLS

To estimate the model using TSLS, set the 'estim_method' property to 'tsls' and supply endogenous and instrument variables as shown below:

```

% Create some artificial data
sigma = [0.4, 0.1;
          0.1, 0.6];
S      = nb_mvnrnd(100,1,[0,0],sigma);
EXO   = randn(100,1); % Uncorrelated with RES, but correlated with ENDO
ENDO  = S(:,1) + EXO;
RES   = S(:,1);
DEP   = 0.5*ENDO + RES + randn(100,1)*0.5;

data = nb_ts([DEP,ENDO,EXO],'', '1980Q1', {'Dep','Endo','Exo'});

% Formulate model
dep    = {'Dep'};
endo  = {'Endo'};
instr  = {'Endo', {'Exo'}};
modelTS = nb_singleEq...
    'estim_method', 'tsls',...
    'data',        data,...,
    'dependent',  dep,...,
    'endogenous', endo,...,
    'instruments', instr);

% Estimate
modelTS = estimate(modelTS);
print(modelTS)

```

8.3 Estimation results

See corresponding section of [Paulsen \(2021\)](#).

8.4 Automatic model selection

For automatic lag length selection, set the 'modelSelection' property:

```

options.modelSelection      = 'lagLength';
% or 'autometrics'
options.criterion          = 'aic';
options.modelSelectionAlpha = 0.05;
options.maxLagLength       = 10;

```

To indicate which regressors to keep fixed during automatic model selection, set the 'modelSelectionFixed' property to a logical vector:

```

options.modelSelectionFixed = [true, false];

```

The algorithm of the automatic model selection can be found in `nb_automaticModelSelection`. Most models either supports 'lagLength' or 'autometrics'.

8.5 Test statistics

8.5.1 ARCH (Autoregressive conditional heteroskedasticity)

To test for ARCH, use the `nb_archTestStatistic` class:

```
test = nb_archTestStatistic(model, 'nLags', 4);
print(test)
```

For all available options, run `nb_archTestStatistic.template()`.

8.5.2 Autocorrelation

To test for autocorrelation, use the `nb_autocorrTestStatistic` class:

```
test = nb_autocorrTestStatistic(model, 'nLags', 4);
print(test)
```

For all available options, run `nb_autocorrTestStatistic.template()`.

8.5.3 Breusch-Pagan test for heteroskedasticity

To test for heteroskedasticity, use the `nb_breuschPaganTestStatistic` class:

```
test = nb_breuschPaganTestStatistic(model);
print(test)
```

For all available options, run `nb_breuschPaganTestStatistic.template()`.

8.5.4 Chow test for a structural break

To test for a structural break, use the `nb_chowTestStatistic` class:

```
test = nb_chowTestStatistic(model, 'breakpoint', '1970Q1');
print(test)
```

For all available options, run `nb_chowTestStatistic.template()`.

8.5.5 Durbin-Wu-Hausman test for exogeneity

To test for exogeneity, use the `nb_durbinWuHausmanStatistic` class:

```
test = nb_durbinWuHausmanStatistic(model, 'endogenous', {'Var1'}, ...
    'instruments', {'Instr1','Instr2'});
print(test);
```

For all available options, run `nb_durbinWuHausmanStatistic.template()`.

8.5.6 F-test

To perform a F-test, use the `nb_fTestStatistic` class:

```
% Restrictions
A = [1, 0; 0, 1];
c = [1; 0];

test = nb_fTestStatistic(model, 'A', A, 'c', c);
print(test)
```

For all available options, run `nb_fTestStatistic.template()`.

9 Expression model

This model class uses just-in-time evaluation of expression for estimation and forecasting the model. To estimate a expression model, use the `nb_exprModel` class.

To initialize a `nb_exprModel` object, start by calling the `nb_exprModel.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_exprModel` constructor:

```
t          = nb_exprModel.template();
t.constant = true;
t.data     = data;
t.dependent = {'growth(y(t))'};
t.exogenous = {'growth(y(t-1))', 'growth(x(t-1))'};
t.recursive_estim = true;
model      = nb_exprModel(t);

% Initialize model object
model = nb_singleEq(options);
```

Here `data` is a `nb_ts` object storing at least the two time-series y and x . For information about the different options, use the `nb_exprModel.help` method:

```
nb_exprModel.help() % All options
nb_exprModel.help('data') % Specific option
```

To estimate the model, use the `estimate` method:

```
model = estimate(model);
print(model)
```

Where the last statement prints the estimation results to the command line. For more examples go see `NBTOOLBOX\Examples\Econometrics\ExprModel`. Where we also have included an example on how to set up a VAR in this way.

9.1 OLS

To estimate the model using OLS, set the `'estim_method'` property to `'ols'`.

10 Step ahead model

To estimate a step ahead model, use the `nb_sa` class.

To initialize a `nb_sa` object, start by calling the `nb_sa.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_sa` constructor:

```
% Simulate some data
% y_h = a + b*x + e
```

```

y      = nan(100,2);
x1    = nan(100,1);
x2    = nan(100,1);
x1(1) = 1;
x2(1) = 2;
for t = 2:100
    x1(t) = 0.5*x1(t-1) + randn;
    x2(t) = 0.5*x2(t-1) + randn;
end
y(2:100,1) = 0.2 + 0.6*x1(1:99) + 0.4*x2(1:99) + randn(99,1);
y(2:100,2) = 0.3 + 0.1*x1(1:99) + 0.8*x2(1:99) + randn(99,1);
data      = nb_ts([y,x1,x2],'', '1999Q1', {'y', 'y2', 'x1', 'x2'});

% Formulate model
t          = nb_sa.template;
t.data     = data;
t.dependent = {'y'};
t.exogenous = {'x1', 'x2'};
t.constant = 1;
t.nStep    = 4;

% Initialize model object
model = nb_sa(t);

```

As this model is constructed for direct forecast you need to set the nStep options to the number of periods you want to forecast. It is not possible to forecast longer than this option when using the forecast method later on.

For information about the different options, use the `nb_sa.help` method:

```

nb_sa.help() % All options
nb_sa.help('nStep') % Specific option

```

To estimate the model, use the `estimate` method:

```

model = estimate(model);
print(model)

```

Where the last statement prints the estimation results to the command line.

11 ARIMA

To estimate an ARIMA(p,i,q) model, use the `nb_arima` class. Where p is the number of AR terms, i is the level of integration and q is the number of MA terms. Let's first start by generating some artificial data:

```

draws = randn(100,1);
% ARIMA(1,0,0)
sim1 = filter(1,[1,-0.5],draws);
% ARIMA(0,0,1)
sim2 = filter([1,-0.5],1,draws);
% ARIMA(1,0,1)
sim3 = filter([1,-0.5],[1,-0.2],draws);
% ARIMA(1,0,2)
sim4 = filter([1,-0.5,0.2],[1,-0.2],draws);

data  = nb_ts([sim1,sim2,sim3,sim4],'', '2000',...
             {'Sim1','Sim2','Sim3','Sim4'});
dataUR = undiff(data('Sim1'),100,1);
dataUR = rename(dataUR,'variables','Sim1','Sim5');
data  = merge(data,dataUR);

```

So from now on the *data* variable refers to this generated data set. There are two ways to estimate an ARIMA(p,i,q) in NBTOOLBOX, and how to do this is shown in the next two subsections. Please also see section 21 for how to forecast an ARIMA(p,i,q) model.

There are also two ways to initialize a `nb_arima` object. The first way is to use `propertyName`, `PropertyValue` combinations directly to the structure of the `nb_arima` class:

```
model = nb_arima(...  
    'algorithm',      'ml', ...  
    'constant',       0, ...  
    'data',           data, ...  
    'dependent',     {'Sim3'}, ...  
    'AR',             1, ...  
    'MA',             3, ...  
    'integration',   0, ...  
    'estim_start_date', '' , ...  
    'estim_end_date', data.endDate - 11, ...  
    'recursive_estim', 1);
```

Or you can use the static method `nb_arima.template` of the `nb_arima` class to get a struct with the default options:

```
options          = nb_arima.template();  
options.algorithm = 'ml';  
options.constant = 0;  
options.data     = data;  
options.dependent = {'Sim3'};  
options.AR        = 1;  
options.MA        = 3;  
options.integration = 0;  
options.estim_start_date = '';  
options.estim_end_date   = data.endDate - 11;  
options.recursive_estim = 1;  
model            = nb_arima(options);
```

Both will return a `nb_arima` with the same options. To get help on the different options of the `nb_arima` class use the `nb_arima.help` method:

```
h = nb_arima.help('AR')
```

To estimate the model you must use the `estimate` method:

```
model = estimate(model);  
print(model)
```

Where the last statement prints the estimation results to the command line.

11.1 Maximum likelihood

To estimate an ARIMA(p,i,w) model by maximum likelihood set the 'algorithm' option to 'ml'. For more see [Paulsen \(2021\)](#).

11.2 Hannan-Rissan

To estimate an ARIMA(p,i,w) model by the Hannan-Rissan algorithm set the 'algorithm' option to 'hr'. For more see [Paulsen \(2021\)](#).

12 Error-correction model (ECM)

To estimate an ECM, use the `nb_ecm` class. Let's first start by generating some artificial data:

```
% Simulate some data
z      = nan(100,1);
scale = 10;
z(1)  = scale*rand;
for ii = 2:100
    z(ii) = z(ii-1) + scale*rand;
end
x1    = z + randn(100,1);
x2    = z + randn(100,1);
y     = 0.2 + 0.6*x1 + 0.4*x2 + 2*randn(100,1);
w1    = randn(100,1);
w2    = randn(100,1);
data = nb_ts([y,x1,x2,w1,w2],'', '1990Q1', {'y','x1','x2','w1','w2'});
```

To initialize a `nb_ecm` object, start by calling the `nb_ecm.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_ecm` constructor:

```
% Formulate model
t        = nb_ecm.template;
t.data   = data;
t.dependent = {'y'};
t.endogenous = {'x1','x2'};
t.exogenous = {'w1','w2'};
t.constant = 1;

% Initialize model object
model = nb_ecm(t);
```

For information about the different options, use the `nb_ecm.help` method:

```
nb_ecm.help() % All options
nb_ecm.help('constant') % Specific option
```

To estimate the model, use the `estimate` method:

```
model = estimate(model);
print(model)
```

Where the last statement prints the estimation results to the command line.

13 VAR

To estimate a VAR model, use the `nb_var` class.

To initialize a `nb_var` object, start by calling the `nb_var.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_var` constructor:

```
% Generate artificial data
obs     = 100;
lambda  = [0.5, 0.1, 0.3, 0.2, 0.2, -0.1;
           0.5, -0.1, -0.2, 0, 0.1, -0.2;
           0.6, -0.2, 0.1, 0, 0.4, -0.1];
rho     = [1; 1; 1];
```

```

sim      = nb_ts.simulate('2012M1',obs,...
{ 'VAR1','VAR2','VAR3'},1,lambda,rho);

% Formulate model
options          = nb_var.template();
options.data     = data;
options.dependent = { 'VAR1','VAR2','VAR3'};
options.nLags    = 2;
options.constant = 0;

% Initialize model object
model = nb_var(options);

```

For information about the different options, use the `nb_var.help` method:

```

nb_var.help() % All options
nb_var.help('constant') % Specific option

```

To estimate the model, use the `estimate` method:

```

model = estimate(model);
print(model)

```

Where the last statement prints the estimation results to the command line.

13.1 OLS

To estimate the model using OLS, set the 'estim_method' option to 'ols'.

13.2 Ridge

To estimate the model using ridge regression, set the 'estim_method' option to 'ridge'.

13.3 LASSO

To estimate the model using LASSO, set the 'estim_method' option to 'lasso'.

13.4 B-VAR

To estimate the model using Bayesian methods and assign prior probabilities to the parameters, set the 'prior' property of the model object. Suitable values for this property are given by the `nb_var.priorTemplate` method.

```
options.prior = nb_var.priorTemplate('jeffrey');
```

Alternatively, using the `setPrior` method on an existing model object:

```
model = setPrior(model, nb_var.priorTemplate('jeffrey'));
```

For all available prior templates, see the documentation for `nb_var.priorTemplate`.

13.5 Empirical baysian

To estimate the model using Empirical Bayesian methods and assign prior probabilities to the parameters, set the 'prior' property of the model object. Suitable values for this property are given by the `nb_var.priorTemplate` method. You also need to set the 'empirical' option to trye

```
options.prior      = nb_var.priorTemplate('glp');
options.empirical = true;
```

Alternatively, using the `setPrior` method on an existing model object:

```
model = setPrior(model, nb_var.priorTemplate('glp'));
model = set(model, 'empirical',true);
```

Only supported for the priors 'glp', 'dsge' and 'nwishart'.

13.6 Time varying parameter bayesian estimation

To estimate the model using a time-varying parameter Bayesian method, set the 'prior' property of the model object as follows

```
options.prior      = nb_var.priorTemplate('kkse');
```

Alternatively, using the `setPrior` method on an existing model object:

```
model = setPrior(model, nb_var.priorTemplate('kkse'));
```

13.7 Identification

To identify a VAR model, use the the `set_identification` method to set Cholesky restrictions or combinations of sign and zero restrictions.

Cholesky:

```
model = set_identification(model, 'cholesky', 'ordering',...
    {'VAR1','VAR2','VAR3'});
```

Combinations:

```
restrictions = {
% Variable, shock, period, type, magnitude
    'VAR1' , 'E_X',      0,    0, []
    'VAR2' , 'E_X',      0,   '- ', []
    'VAR3' , 'E_X',      0,   '>', 0
};

model = set_identification(model, 'combination', 'restrictions', ...
    restrictions, 'maxDraws', 100000);
```

Here we have added a zero restriction on the 'E_X' shocks impact (period=0) on the variable 'VAR1', a minus restriction on the 'E_X' shocks impact (period=0) on the variable 'VAR2' and a magnitude restriction on the 'E_X' shocks impact (period=0) on the variable 'VAR3'.

Variable

The name of the variable that the restriction should apply to, as a string.

Shock

The name of the shock to be identified, as a string.

Period

The period the restriction should apply. Can also be inf, i.e. cumulative long term restriction. Must be a scalar integer.

Type

The type column can include 0, '+', '-', '>' and '<'.

Magnitude

When type is set to '>' or '<' this will be the restriction the shock impact must satisfy to be accepted.

To get the identified residual from an estimated model, use the `getIdentifiedResidual` method:

```
model = solve(model); % First solve the model!
residual = getIdentifiedResidual(model);
```

If the model is underidentified, and you have set the 'draws' option to a number greater than 1, the residual output will be a multi-paged `nb_ts` object with the distributions of the identified residuals. I.e. the identified residuals for each accepted draw.

13.8 Test the VAR

13.8.1 Test for stationarity

To test a VAR model for stationarity, use the `nb_model_generic.getRoots` method to calculate the roots of the companion form of the model.

```
model = solve(model); % Model must be solved (companion form)
[roots, plotter] = getRoots(model);
disp(roots);
plotter.graph();
```

13.8.2 LM-test for autocorrelation

To test for autocorrelation, use the `nb_LMVARTestStatistic` class:

```
test = nb_LMVARTestStatistic(model, 'lag', 1);
print(test)
```

For all available options, run `nb_LMVARTestStatistic.template()`.

13.8.3 Ljung-Box test for autocorrelation

To test for autocorrelation, use the `nb_ljungBoxTestStatistic` class:

```
test = nb_ljungBoxTestStatistic(model);
print(test)
```

For all available options, run `nb_ljungBoxTestStatistic.template()`.

13.8.4 Granger causality

To test for Granger causality, use the `nb_var.grangerCausalityTest` class:

```
[test, pValue, result] = nb_grangerCausalityTest(model);
disp(result)
```

14 VAR with missing observations

In this example we use a dataset stored in a `nb_ts` object data, which is generated from

```
obs      = 100;
lambda   = [0.5, 0.1, 0.3, 0.2, 0.2, -0.1;
            0.5, -0.1, -0.2, 0, 0.1, -0.2;
            0.6, -0.2, 0.1, 0, 0.4, -0.1];
rho      = [1; 1; 1];
dataQ    = nb_ts.simulate('1990Q1', obs, ...
    {'VAR1', 'VAR2', 'VAR3'}, 1, lambda, rho);
dataA    = convert(dataQ, 1, 'diffAverage');
dataAQ   = convert(dataA, 4, '', 'interpolateDate', 'end');
dataAQ   = addPrefix(dataAQ, 'A_');
data     = [dataAQ, dataQ];

% Make some missing observations
dataM = setValue(data, 'VAR1', nan, data.endDate, data.endDate);
```

The data object then stores the variables 'VAR1' , 'VAR2' and 'VAR3' on quarterly frequency, and 'A_VAR1', 'A_VAR2' and 'A_VAR3' on yearly frequency.

14.1 MO-VAR

If you have some missing observations in your VAR you can either use the methods described in 18, or you can use maximum likelihood estimator or some of the B-VAR priors that handle missing observations. In any case you need to use the `nb_var` class.

14.1.1 Maximum likelihood

To do maximum likelihood estimation with (or without) missing data use

```
% Options
t          = nb_var.template();
t.data     = dataM;
t.estim_method = 'ml';
t.dependent = {'VAR1', 'VAR2', 'VAR3'};
t.constant = true;
t.nLags   = 2;
t.doTests = 1;
t.optimizer = 'fmincon';
t.covrepair = true;

% Create model and estimate
model = nb_var(t);
model = estimate(model);
print(model)
```

For information about the different options, use the `nb_var.help` method:

```
nb_var.help() % All options
nb_var.help('estim_method') % Specific option
```

To get the smoothed point estimate of the missing observation use

```
smoothed = getFiltered(model);
```

To draw from the distribution of the parameters you need to set the 'method' input to 'asymptotic'. So when for example calling `parameterDraws` method

```
param = parameterDraws(models,1000,'asymptotic');
```

14.1.2 Bayesian

To do bayesian estimation with missing data use the prior types ending with MF, e.g.

```
% Prior
prior      = nb_var.priorTemplate('minnesotaMF');
prior.method = 'mci';

% Options
t          = nb_var.template();
t.data     = dataM;
t.dependent = {'VAR1','VAR2','VAR3'};
t.constant = true;
t.nLags    = 2;
t.prior    = prior;
t.draws    = 500;

% Create model and estimate
model = nb_var(t);
model = estimate(model);
print(model)
```

To get the smoothed point estimate of the missing observation use

```
smoothed = getFiltered(model);
```

14.2 MF-VAR

If you want to estimate a mixed frequency VAR, you need to use the `nb_var` class. Both maximum likelihood and Bayesian estimation methods are supported.

14.2.1 Maximum likelihood

To do maximum likelihood estimation of a mixed frequency VAR with (or without) missing data use

```
% Options
t          = nb_mfvar.template();
t.data     = data;
t.estim_method = 'ml';
t.dependent = {'VAR1','A_VAR2'};
t.frequency = {'A_VAR2',1};
t.mapping   = {'A_VAR2','diffAverage'}; % Approximation
t.constant  = true;
t.nLags    = 2;
t.optimizer = 'fmincon';
t.covrepair = true;

% Create model and estimate
model = nb_mfvar(t);
model = estimate(model);
print(model)
```

For information about the different options, use the `nb_mfvar.help` method:

```
nb_mfvar.help() % All options
nb_mfvar.help('estim_method') % Specific option
```

To get the smoothed point estimate of the high frequency and missing observations use

```
smoothed = getFiltered(model);
```

To draw from the distribution of the parameters you need to set the 'method' input to 'asymptotic'. So when for example calling `parameterDraws` method

```
param = parameterDraws(models,1000,'asymptotic');
```

14.2.2 Bayesian

To do bayesian estimation of a mixed frequency VAR use the prior types ending with MF, e.g.

```
% Prior
prior      = nb_mfvar.priorTemplate('minnesotaMF');
prior.method = 'gibbs';
prior.S_scale = 0.00001;

% Options
t          = nb_mfvar.template();
t.data     = data;
t.dependent = {'VAR1','A_VAR2'};
t.frequency = {'A_VAR2',1};
t.mapping   = {'A_VAR2','diffAverage'}; % Approximation
t.constant  = true;
t.nLags    = 2;
t.prior    = prior;
t.draws    = 500;

% Create model and estimate
model = nb_mfvar(t);
model = estimate(model);
print(model)
```

To get the smoothed point estimate of the high frequency and missing observations use

```
smoothed = getFiltered(model);
```

14.3 Time varying parameter bayesian estimation

See the example; NBTOOLBOX\Examples\Econometrics\MixedFrequency\test_nb_mfvar_timeVarying.m.

14.4 Variables observed at different frequencies

14.4.1 Change in frequency

See the example; NBTOOLBOX\Examples\Econometrics\MixedFrequency\test_nb_mfvar_changeFreq.m.

14.4.2 Observed at different frequencies at the same time

See the example; NBTOOLBOX\Examples\Econometrics\MixedFrequency\test_nb_mfvar_combineFreq.m.

14.5 Adding measurement restrictions

See the example; NBTOOLBOX\Examples\Econometrics\VAR\nb_var_measEqRest.m.

15 MIDAS

The data in this example is the same as was the case in section 14. To estimate a single equation MIDAS model, use the `nb_midas` class.

To initialize a `nb_midas` object, start by calling the `nb_midas.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_midas` constructor:

```
% Formulate model
t          = nb_midas.template();
t.data      = data;
t.algorithm = 'unrestricted';
t.dependent = {'A_VAR1'};
t.exogenous = {'VAR2'};
t.constant  = true;
t.frequency = 1;
t.nStep     = 4;
t.nLags     = 4;
t.doTests   = 1;
t.AR        = 0;
t.draws     = 500;

% Initialize model object
model = nb_midas(t);
```

For information about the different options, use the `nb_midas.help` method:

```
nb_midas.help() % All options
nb_midas.help('constant') % Specific option
```

To estimate the model, use the `estimate` method:

```
model = estimate(model);
print_estimation_results(model)
```

Where the last statement prints the estimation results to the command line.

If you want to forecast the model you can follow the same steps as explained in section 21.

16 Factor models using principal component

The dataset (data), which is an object of class `nb_ts`, must in this example include the following variables:

```
dep = {'QSA_PCPI', 'QSA_PCPIJAE'};
obs = {'QSA(CG)', 'QSA(CP)', 'QSA(JC)', 'QSA(JG)', 'QSA(JH)', 'QSA(JOS)', ...
       'QSA(IMN)', 'QSA(WILMN)', 'QSA(XMN)', 'QSA(MMN)', 'QSA(XS)', 'QSA(Y)'},
```

16.1 Principal component

The `pca` method of the `nb_ts` class may be used to do principal component analysis.

```
dataPCA    = window(data, '', '', obs);
[F, lambda] = pca(dataPCA, 2);
```

Where the output F and lambda are the estimated factors and the factor loadings respectively. For more see help on the method `nb_ts.pca`.

16.2 Single equation factor model

To estimate a single equation factor model, use the `nb_fm` class.

To initialize a `nb_fm` object, start by calling the `nb_fm.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_fm` constructor:

```
% Formulate model
t = nb_fm.template();
t.dependent = dep;
t.observables = obs;
t.data = data;
t.nFactors = 4;

% Initialize model object
model = nb_fm(t);
```

For information about the different options, use the `nb_fm.help` method:

```
nb_fm.help() % All options
nb_fm.help('constant') % Specific option
```

To estimate the model, use the `estimate` method:

```
model = estimate(model);
print(model)
```

Where the last statement prints the estimation results to the command line.

16.3 Step ahead factor model

To estimate a step ahead factor model, use the `nb_fmsa` class. This model class can be used to produce direct forecast using factors.

To initialize a `nb_fmsa` object, start by calling the `nb_fmsa.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_fmsa` constructor:

```
% Formulate model
t = nb_fmsa.template();
t.dependent = dep;
t.observables = obs;
t.data = data;
t.nFactors = 4;
t.nStep = 8;

% Initialize model object
model = nb_fmsa(t);
```

As this model is constructed for direct forecast you need to set the `nStep` options to the number of periods you want to forecast. It is not possible to forecast longer than this option when using the `forecast` method later on.

For information about the different options, use the `nb_fmsa.help` method:

```
nb_fmsa.help() % All options
nb_fmsa.help('constant') % Specific option
```

To estimate the model, use the `estimate` method:

```
model = estimate(model);
print(model)
```

Where the last statement prints the estimation results to the command line.

16.4 FA-VAR

To estimate a FA-VAR model, use the `nb_favar` class.

To initialize a `nb_favar` object, start by calling the `nb_favar.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_favar` constructor:

```
% Formulate model
t = nb_favar.template();
t.dependent = dep;
t.observables = obs;
t.data = data;
t.nLags = 2;
t.nFactors = 4;
t.nStep = 8;

% Initialize model object
model = nb_favar(t);
```

For information about the different options, use the `nb_favar.help` method:

```
nb_favar.help() % All options
nb_favar.help('constant') % Specific option
```

To estimate the model, use the `estimate` method:

```
model = estimate(model);
print(model)
```

Where the last statement prints the estimation results to the command line.

17 Dynamic factor model

To estimate a dynamic factor model, use the `nb_fmdyn` class.

To initialize a `nb_fmdyn` object, start by calling the `nb_fmdyn.template()` method. This will return a struct with the default model options. Modify this structure as desired before passing it to the `nb_fmdyn` constructor:

```
% Formulate model
t = nb_fmdyn.template();
t.data = data;
t.nLags = 1;
t.observables = data.variables;
t.transformation = 'standardize';

% Initialize model object
model = nb_fmdyn(t);
```

Here we assume that the data on the observed variables of the model are collected in the `nb_ts` object `data`. For information about the different options, use the `nb_fmdyn.help` method:

```
nb_fmdyn.help() % All options
nb_fmdyn.help('constant') % Specific option
```

17.1 Expected maximum likelihood

To estimate the model using expected maximum likelihood you need to set the 'estim_method' to 'dfmeml':

```
model = set(model, 'estim_method', 'dfmeml');
```

To execute the estimation use the `estimate` method:

```
model = estimate(model);
print(model)
```

Where the last statement prints the estimation results to the command line. A full example can be found at NBTOOLBOX\Examples\Econometrics\FactorModels\Non_stationary. Where we also may allow for a non-stationary dynamic factor model.

17.2 Time varying parameter bayesian estimation

To estimate the model using a baysian method you need to set the 'prior' option:

```
prior = nb_fmdyn.priorTemplate();
model = setPrior(model,prior);
```

To execute the estimation use the `estimate` method:

```
model = estimate(model);
print(model)
```

Where the last statement prints the estimation results to the command line. A full example can be found at NBTOOLBOX\Examples\Econometrics\FactorModels\example_dynFactorModel.m.

18 Missing observations

If there are missing observations in the data, this can be dealt with when estimating VAR-models. We therefore build on the example which was presented in section 14. To initialize a `nb_var` object, start by calling the `nb_var.template()` method:

```
% Formulate model
options          = nb_var.template();
options.data     = dataM; % Data with missing obs
options.dependent = {'Var1', 'Var2', 'Var3'};
options.nLags    = 2;
options.constant = 0;
options.missingMethod = 'forecast';

% Initialize model object
model = nb_var(options);

% Estimate the model
model = estimate(model);
print(model)
```

For information about the options of missing observations, use the `nb_missingEstimator.help` method:

```
nb_missingEstimator.help() % All options
```

Forecasting can be done as documented in section 21, but now also nowcast on the missing observations are produced.

19 DSGE

DSGE models can be solved with use of the `nb_dsge` class. See the corresponding section of the DAG documentation for more on the algorithm used to solve DSGE models.

19.1 Standard 1st order solution

First you need to write down the model in a .nb file. See the DSGE->Model file section in the DAG documentation for more on the model file syntax. In this example we use a simplified version of the Ramirez, Waggoner and Zha (2012) model. The model file is in this case

```
endogenous
PAI,Y,R,RR

exogenous
EPS_R

parameters
betta,eta,kappa,rhor,sigr,mu,psi

model
  1=betta*(1-.5*kappa*(PAI-1)^2)*Y*R(+1)/((1-
  .5*kappa*(PAI(+1)-1)^2)*Y(+1)*exp(mu)*PAI(+1));
  1-eta+eta*(1-.5*kappa*(PAI-1)^2)*Y+betta*kappa*(1-.5*kappa*(PAI-1)^2)*
  (PAI(+1)-1)*PAI(+1)/(1-.5*kappa*(PAI(+1)-1)^2)-kappa*(PAI-1)*PAI;
  (R(-1)/steady_state(R))^rhor*(PAI/steady_state(PAI))^{((1-rhor)*psi)}*
  exp(sigr*EPS_R) - R/steady_state(R);
  RR = R/PAI(+1);
```

To be able to solve the DSGE model, you first need to parse the model file

```
m = nb_dsge('nb_file','frwz_nk.nb');
```

where `frwz_nk.nb` in this case is the name of the model file.

The second thing you need to do is to assign some parameters

```
p.betta = 0.99;
p.kappa = 161;
p.eta   = 10;
p.rhor  = 0.8;
p.sigr  = 0.0025;
p.mu    = 0.03;
p.psi   = 3.1;
m       = assignParameters(m,p);
```

You can get the current assign parameters from the object by using

```
pOut = m.getParameters();
```

When the parameters are assign the next step will be to solve for the steady-state of the model. You need to provide a MATLAB .m file that does solve the steady-state. In our case it must be something like

```
function [ss,param] = frwz_nk_nb_steadystate(~,p)

param = struct();

% Solve steady-state (This is the only part that needs to be changed)
ss.PAI = 1;
ss.Y   = (p.eta - 1)/p.eta;
ss.R   = exp(p.mu)/p.betta*ss.PAI;
ss.RR  = ss.R/ss.PAI;

end
```

See the [Paulsen \(2021\)](#) for more on the steady-state file. Be aware that the endogenous variables of the model with steady-state 0 need not to be assign a value in the steady-state file. Then we can use this file to solve for the steady-state by using

```
m = checkSteadyState(m, 'steady_state_file', 'frwz_nk_nb_steadystate');
```

This method will throw you an error if the .m file does not return the correct steady-state of the model. You can then see the steady-state values of the models by using the [getSteadyState](#) method

```
ss = getSteadyState(m);
```

This method also allows you to get the steady-state value of some user defined expressions of the endogenous variables of the model

```
ss = getSteadyState(m, 'RR*2');
```

If the steady-state is equal to zero for all endogenous variables you do not need to use the [checkSteadyState](#), as the default is to set the steady-state to 0 for all variables.

Then it is time to calculate the derivatives of the model. This can be done using the [derivative](#) method

```
m = derivative(m);
```

The jacobian will be stored in the solution property of the [nb_dsg](#) object at the field jacobian. To get the order of the derivatives use the [getDerivOrder](#) method.

Then to finally solve the model you must use

```
m = solve(m);
```

To print the solution use the [printDecisionRules](#) method. You can also locate the solution of the model on the companion form in the solution property of the [nb_dsg](#) object. Let n be the number of endogenous variables of the model and let the number of innovations (exogenous variables) be given by n^i , then the solution contain the following fields

A

The transition matrix, as a square matrix with size n . The ordering is given by the endo field.

C

The innovation impact matrix with size $n \times n^i$. The ordering is given by the endo and res fields.

endo

Stores the ordering of the endogenous variables in the solution, as a $1 \times n$ cellstr array.

res

Stores the ordering of the innovations (exogenous variables) in the solution, as a $1 \times n^i$ cellstr array.

vcv

The covariance matrix of the innovations. As a identity matrix with size n^i . (To set the standard deviation of some innovation just multiply the innovation in the model file with a parameter.)

ss

A double with size $n \times 1$ storing the steady-state of the model. The ordering is given by the endo field.

obs

The declared observed variables of the model. As a $1 \times O$ cellstr array.

++

Some other fields that is not to useful for the user.

If you do not want to inspect the steady-state or the derivatives of the model, you can call the `solve` method directly without calling `checkSteadyState` and `derivative` first. This will then be done automatically inside the `solve` method instead.

19.2 Optimal monetary policy

When dealing with optimal monetary policy the steps are the same as in the previous section. Here is an example file of a model solved with optimal monetary policy

```
endogenous
DR,PAI,PAI_GAP,PAI_GAP_POL,Y,Y_GAP,R,RR

exogenous
EPS_R

parameters
betta,eta,kappa,sigr,mu,lam_y,lam_dr

model
1 = betta*(1-.5*kappa*(PAI-1)^2)*Y*R(+1)/((1-
.5*kappa*(PAI(+1)-1)^2)*Y(+1)*exp(mu)*PAI(+1));
1-eta+eta*(1-.5*kappa*(PAI-1)^2)*Y+betta*kappa*(1-
.5*kappa*(PAI-1)^2)*(PAI(+1)-1)*PAI(+1)/(1-
.5*kappa*(PAI(+1)-1)^2)-kappa*(PAI-1)*PAI;
```

```

RR = R/PAI(+1);

PAI_GAP      = log(PAI/steady_state(PAI));
PAI_GAP_POL = PAI_GAP + EPS_R;
Y_GAP        = log(Y/steady_state(Y));
DR           = R - R(-1);

planner_objective{discount = 0.99, commitment=1}
.5*(PAI_GAP_POL^2+lam_y*Y_GAP^2+lam_dr*DR^2);

```

It is the planner_objective function that triggers the optimal monetary policy solution, for more on this function see the DSGE->Model file section.

The rest of the steps are unaffected, but now the multipliers are added to the solution so that n in the last section will now be the number of endogenous plus the numbers of multipliers.

19.3 Model file

See corresponding section in [Paulsen \(2021\)](#) or the examples provided in the sections [19.1](#) and [19.2](#).

19.4 Steady-state file

See corresponding section in [Paulsen \(2021\)](#) or the examples provided in the sections [19.1](#) and [19.2](#).

19.5 Calibration

See the sections [19.1](#) and [19.2](#) for how to assign calibrated parameters.

19.6 Estimation

19.6.1 Mode estimation

To do mode estimation you need to first provide some priors.²⁴ It can be given using a struct

```

priors      = struct();
% priors.(paramName) = {start,mean,std,nameOfDist}
priors.theta = {0.5, 0.5, 0.2, 'beta'};
priors.varphi = {0.8, 0.8, 0.1, 'normal'};
priors.phi = {0.5, 0.5, 0.2, 'beta'};
priors.alpha = {0.1, 0, 2}; % Uniform on [0, 2]!
m            = set(m, 'prior', priors);

```

or using the `nb_distribution` class

```

priors(4,1) = nb_distribution();
priors(1,1) = nb_distribution.parameterization(0.5, 0.2^2, 'beta');
set(priors(1,1), 'name', 'theta', 'userData', 0.5);
priors(2,1) = nb_distribution('type', 'normal', 'parameters', {0.8, 0.1}, ...
                             'name', 'varphi', 'userData', 0.8);
priors(3,1) = nb_distribution.parameterization(0.5, 0.2^2, 'beta');
set(priors(3,1), 'name', 'phi', 'userData', 0.5);
priors(4,1) = nb_distribution('type', 'uniform', 'parameters', {0, 2}, ...
                             'name', 'alpha', 'userData', 0.1);
m = set(m, 'prior', priors);

```

²⁴To do Maximum likelihood (ML) estimation specify uniform priors, i.e. do restricted ML estimation.

For more information on how to set the priors see the help on the method `setPrior`. To plot the priors use the `plotPriors` method.

To do the estimation you can use the `estimate` method. To display the estimation results use `print` method. Be aware that you need to call the `solve` method after the estimation to take into account the estimated parameters. A full example follows

```
me = estimate(m);
me.print

% Solve the estimated version (This is not done in
% the estimate method!!)
mes = solve(me);
```

19.6.2 Sampling

To sample from the posterior distribution you can use the `sample` method. The following example illustrate how to use it

```
me = estimate(m);
me.print

% These are the draws made by the sampler!
samplingDraws = 2000;

% This are the number of draws that is kept for IRFs,
% posterior plots, density forecast etc... They are
% randomly selected from the sampled draws from
% chain 1.
usedDraws = 1000;

opt = nb_mcmc.optimset('log',true,'waitbar',true,'thin',2,...
    'draws',samplingDraws,'qFunction','arw','adaptive','recTarget',...
    'accTarget',0.23,'parallel',false,'chains',2);
mp = sample(mes,'draws',usedDraws,'sampler_options',opt);
```

Use the following commands to get more help on the supported sampling options

```
nb_dsge.help('sampler_options')
help nb_mcmc.optimset
```

To check the sampling results you can run some diagnostics, which all uses the full set of sampled draws.

```
% Trace plot and autocorrelation
[~,plotter,pAutocorr] = checkPosterior(mp);
nb_graphSubPlotGUI(plotter);
nb_graphSubPlotGUI(pAutocorr);

% Mean plot
[res,plotter] = meanPlot(mp);
nb_graphSubPlotGUI(plotter);

[res,plotter] = meanPlot(mp,100);
nb_graphSubPlotGUI(plotter);

% Geweke test
res = geweke(mp)

% Gelman Rubin test
[res,plotter] = gelmanRubin(mp);
nb_graphSubPlotGUI(plotter);
```

To plot the posterior against the prior you can use the `plotPosterior` method (which only uses the number of draws selected by the `usedDraws` variable in this example).

```
plotter = plotPosterior(mp,'prior');
nb_graphMultiGUI(plotter);
```

19.6.3 System priors

The system priors implemented are described in the paper Andrle and Benes (2013), "System Priors: Formulating Priors about DSGE Models' Properties. To add system priors, you can use the `setSystemPrior` method or the `systemPrior` option. Remember to first specify the normal priors as described in the section 19.6.1. An example of the first approach is

```
% Parameterize a gamma with mean 0.4 and variance 0.2
[~,param] = nb_distribution.parameterization(0.4,0.2,'invgamma');
yAutoPrior = @(x) log(nb_distribution.invgamma_pdf(x,param{1},param{2}));
ms = setSystemPrior(m,'corr',{'y','y',1,yAutoPrior});
```

while for the second approach you can use

```
ms = set(m,'systemPrior',@yourPriorFunction);
```

where `yourPriorFunction` must be a .m file with the function to call to evaluate your system prior. The function must take two inputs. The `parser` property and the `solution` property (simplified version) of the model object. In this way you can code how to produce any objective from the model and evaluate the prior based on the value of that objective.

In the same way as for the posterior you must sample from the updated priors to get an idea on how your prior and posterior are different. To sample from the updated prior you can use the method `sampleSystemPrior`. Here is an example

```
opt = nb_mcmc.optimset('log',true,'waitbar',true,'thin',2,...
    'draws',2000,'qFunction','arw','adaptive','recTarget',...
    'accTarget',0.23,'parallel',false,'chains',2);
msp = sampleSystemPrior(ms,'sampler_options',opt);
```

To be sure that the sampling has succeeded you need to check that the sampler has converged. This can be done in the same way as for the posterior draws

```
% Trace plot and autocorrelation
[~,plotter,pAutocorr] = checkUpdatedPriors(msp);
nb_graphSubPlotGUI(plotter);
nb_graphSubPlotGUI(pAutocorr);

% Mean plot
[res,plotter] = meanPlot(msp,'updated');
nb_graphSubPlotGUI(plotter);

[res,plotter] = meanPlot(msp,100,'updated');
nb_graphSubPlotGUI(plotter);

% Geweke test
res = geweke(msp,[],'updated');

% Gelman Rubin test
[res,plotter] = gelmanRubin(msp,'updated');
nb_graphSubPlotGUI(plotter);
```

To plot it against the initial prior use

```
plotter = plotUpdatedPriors(msp, 'prior');
nb_graphMultiGUI(plotter);
```

From this you can follow the same steps as for normal estimation, i.e. to do mode estimation and sample from the posterior as described in section 19.6.1 and 19.6.2. To plot the initial prior, the updated prior and the posterior use

```
plotter = plotPosterior(mp, 'updated', 'prior');
nb_graphSubPlotGUI(plotter);
```

19.7 Filtering

To filter the model you must first set the observed variables by using the `set` method

```
m = set(m, 'observables', {'PAI'});
```

Then you need to assign the data to the object, which again can be done by using the `set` method

```
m = set(m, 'data', dataObject);
```

Here the `dataObject` must be a `nb_ts` object at least storing the variables declared as observed.

Then to filter the model you can use the `filter` method

```
m = filter(m);
```

To get more help on the `filter` method write the following in the command window.

```
help nb_dsgc.filter
```

Go to the corresponding section in the DAG documentation for more on the algorithm used.

19.8 DSGE model with break-point

To add a unexpected break-point in the parameter values of the model you can use either the `breakPoint` statement in the model file (see the DSGE->Model file for more on how to do this), or you can use the `breakPoint` method. E.g.

```
m = breakPoint(m, {'kappa'}, 150, '2012Q1');
```

When this method is used you need to call the `solve` method to solve the model. This you need to do even if you have solved the model before calling this method!

19.8.1 Forecast

To forecasting of the model can be done in the same way as in section 21. The state will just follow from the date input you gave to the `breakPoint` method. See the corresponding section in the DAG documentation for more on the algorithm used in the case of a DSGE model with break-points.

19.8.2 IRF

To produce irf you can follow the steps as in section , but you need to use the startingValues and the states input to this method. Default is to use the first state (regime) for both the startingValues and as the state at each period. See the corresponding section in the DAG documentation for more on the algorithm used in the case of a DSGE model with break-points.

19.8.3 Filtering

No changes on how the method is called on the object. See section 19.7. See the corresponding section in the DAG documentation for more on the algorithm used in the case of a DSGE model with break-points.

19.9 Optimal simple rules

This section describes how to find optimal simple rules using the NB toolbox. First we provide you with a simple model which we will use for the examples later.

```
endogenous
y,pie,i,u,e

exogenous
e_u,e_e

parameters
alpha,beta,epsilon,eta,rho_e,rho_u,theta,varphi

model
    y    = y(+1) - eta*(i - pie(+1)) + e;
    pie = beta*pie(+1) + ((1 - alpha/(1 - alpha + alpha*epsilon))
                           *(1 - theta)*(1 - beta*theta)/theta)*(1/eta)
                           + (varphi + alpha)/(1 - alpha)*y + u;
    e   = rho_e*e(-1) + e_e;
    u   = rho_u*u(-1) + e_u;
```

This is the standard 3 equation new keynesian model, but where we for know have left out the interest rate rule. To proceed we need to provide the loss function to minimize. This can be done with the `setLossFunction` method. Remember to also assign all parameters before running the model.

19.9.1 Commitment

If the above model file is stored in the file nk.nb, you can use the following code to find the optimal simple rule under commitment

```
% Parse model
m = nb_dsges('nb_file','nk.nb','silent',false);

% Parameterization
par      = struct();
par.beta = 0.99;
par.eta  = 1;
par.alpha = 0.33;
par.epsilon = 6;
par.theta = 0.67;
par.varphi = 1;
par.rho_u = 0;
```

```

par.rho_e    = 0;
m            = assignParameters(m,par);

% Set loss function
paramL = struct('lambda',0.1);
m      = setLossFunction(m,'0.5*(pie^2 + lambda*y^2)');
m      = assignParameters(m,paramL);

% Optimizer options
opt        = optimset('fmincon');
opt.Display = 'none';

% Initial values of the optimization
init       = struct('gamma_pie',1.2,'gamma_y',0.6, ...
                    'gamma_pie_lag',1.2,'gamma_y_lag',0.6, ...
                    'gamma_e',0,'gamma_u',0);

% Optimal simple rule (commitment)
% This replicate the commitment solution
m_osr_c   = optimalSimpleRules(m, ...
[i = gamma_pie*pie + gamma_y*y + gamma_pie_lag*pie(-1), ...
 ' + gamma_y_lag*y(-1) + gamma_e*e_e + gamma_u*u_e'], ...
'osr_type',      'commitment',...
'init',         init, ...
'lc_discount',  1, ...
'optimset',     opt, ...
'name',         'osr_c');

m_osr_c.print()
m_osr_c.printDecisionRules()

```

Use

```
help nb_dsgc.optimalSimpleRules
```

to get more help on the `optimalSimpleRules` method.

19.9.2 Discretion

Under discretion the rule can only respond to state variables. The first steps are as in the case of the commitment, so given the `nb_dsgc` object `m` we can proceed with

```

% Optimizer options
opt        = optimset('fmincon');
opt.Display = 'none';

% Initial values of the optimization
init       = struct('gamma_pie',1.2,'gamma_y',0.6, ...
                    'gamma_e',0,'gamma_u',0);

% Optimal simple rule (discretion)
% This replicate the discretion solution
m_osr_d   = optimalSimpleRules(m, ...
'i = gamma_pie*pie(-1) + gamma_y*y(-1) + gamma_e*e_e + gamma_u*u_e', ...
'osr_type',      'discretion',...
'init',         init, ...
'lc_discount',  1, ...
'optimset',     opt, ...
'name',         'osr_d');

m_osr_d.print()
m_osr_d.printDecisionRules()

```

19.9.3 Calculate loss

To calculate the loss of any solved `nb_dsge` object m you can use the `calculateLoss` method. If your model is not going to be solved under optimal monetary policy or optimal simple rules, it is important to set a third input to the `setLossFunction` method to false (which must of course be called before `calculateLoss`).

20 Analysis

In this section we use the following example.²⁵

```
% Declare the variables
variables = {'Var1', 'Var1', 'Var3'};

% Formulate model
options          = nb_var.template();
options.data     = data;
options.dependent = variables;
options.nLags    = 2;
options.constant = false;

% Create model object
model = nb_var(options);

% Estimate model
model = estimate(model);

% Identify model
model = set_identification(model, 'cholesky', ...
    'ordering', variables);
model = solve(model);
```

20.1 Impulse response functions

To produce impulse responses, use the `irf` method.

```
[irfs, irfsBand, plotter] = irf(model, 'perc', 0.68, 'replic', 1000);
plotter.graphInfoStruct();
```

20.2 Shock decomposition

To perform shock decomposition, use the `shock_decomposition` method:

```
[decomp, decompBand, decompPlotter] = shock_decomposition(model, ...
    'variables', variables, ...
    'startDate', '', ...
    'endDate',   '', ...
    'Perc',      0.9);
decompPlotter.graph();
```

20.3 Forecast error variance decomposition (FEVD)

To perform FEVD, use the `variance_decomposition` method:

²⁵The data object is the same as that of section 13.

```
% Variance decomposition
[decomp, decompBand, decompPlotter, decompPlotterPerc] = ...
    variance_decomposition(model, 'variables', variables, ...
        'perc', 0.9,
        'output', 'actual');
decompPlotter.graph();

fields = fieldnames(decompPlotterPerc);
for i = 1:length(fields)
    graphSubPlots(decompPlotterPerc.(fields{i}));
end
```

20.4 Model Moments

Model objects have methods for calculating empirical, theoretical and simulated moments, i.e. mean, (auto)covariance and (auto)correlation of the model data.

20.4.1 Empirical moments

To calculate empirical moments of a model, use the [empiricalMoments](#) method:

```
[mean, cov, autoCov1, autoCov2] = empiricalMoments(...  
    model, 'type', 'covariance'); % or 'correlation'
```

The first output is the mean, the second the correlation/-covariance matrix and the following outputs are autocorrelation/-covariance matrices at increasing time lags. The number of output variables you supply decides how many such autocorrelation/-covariance matrices are calculated.

For more information about the available options, see the [empiricalMoments](#) documentation.

20.4.2 Simulated moments

To calculate simulated moments of a model, use the [simulatedMoments](#) method:

```
[mean, cov, autoCov1, autoCov2] = simulatedMoments(...  
    model, ...  
    'type', 'covariance', ...  
    'nSteps', 100, ...  
    'pDraws', 1, ...  
    'draws', 100);
```

The first output is the mean, the second is the correlation/-covariance matrix and the following outputs are autocorrelation/-covariance matrices at increasing time lags. The number of output variables you supply decides how many such autocorrelation/-covariance matrices are calculated.

For more information about the available options, see the [simulatedMoments](#) documentation.

20.4.3 Theoretical moments

To calculate theoretical moments of a model, use the [theoreticalMoments](#) method:

```
[mean, corr, autoCorr1, autoCorr2] = theoreticalMoments(...  
    model, ...  
    'type', 'correlation', ...  
    'maxIter', 1000, ...  
    'pDraws', 1, ...
```

```
'perc', [0.1, 0.3, 0.5, 0.7, 0.9]);
```

The first output is the mean, the second the correlation/-covariance matrix and the following outputs are autocorrelation/-covariance matrices at increasing time lags. The number of output variables you supply decides how many such autocorrelation/-covariance matrices are calculated.

For more information about the available options, see the [theoreticalMoments](#) documentation.

21 Forecasting

21.1 Unconditional forecast

When doing unconditional forecast we can skip the identification part, even for VARs. Instead we just solve it without identification:²⁶

```
model = solve(model);
```

After having the solution of the model we can produce forecast using the [forecast](#) method;

```
model = forecast(model,8);
```

Where the second input is the forecast horizon. To plot the forecast we can use the [plotForecast](#) method:

```
plotter = plotForecast(model);
plotter.graphSubPlots
```

To produce density forecast without parameter uncertainty the following code can be used:

```
model = forecast(model,8,'draws',1000);
```

Here 1000 draws from the residuals/shocks are used to produce density forecast. The forecast can be plotted with the same code as before. If we also want to take parameter uncertainty into account it can be done by:

```
model = forecast(model,8,'draws',100, ...
    'parameterDraws',1000, ...
    'method','bootstrap');
```

Where the 'parameterDraws' are the number of draws from the distribution of the parameters. Be aware that there will be done 100 residual draws per parameter draws in this example. The 'method' option selects the method to draw the parameters from its unknown distribution. For models estimated with classical methods, a bootstrapping method must be used, while models estimated with bayesian methods will sample directly from the posterior distribution.

To do in-sample recursive forecast you need to provided the 'fcstEval' input, here set to calculate squared errors:

```
model = forecast(model,8,'fcstEval','SE');
```

²⁶If the model doesn't need to be identified this amounts to the same.

To plot the recursive forecast the 'hairyplot' option may be used:

```
plotter = plotForecast(model,'hairyplot');  
plotter.graphSubPlots
```

If on the other hand the 'recursive_estim' estimation input is set to 1 when initializing the model, you can produce out-of-sample recursive forecast with the same code as for in-sample recursive forecast.

It is also possible to do recursive density forecast by combining the above options.

21.2 Conditional forecast

See the example script at \\NBTOOLBOX\\Examples\\Econometrics\\VAR\\nb_var_ols_condForecast.m

21.3 Forecast evaluation

See section 21.1

21.3.1 Mincer-Zarnowitz test

To do the Mincer-Zarnowitz test we can use the following code, remember that recursive forecast must have been done

```
[test,pval,printed] = mincerZarnowitzTest(model)
```

21.3.2 Diebold-Mariano test

Let's say we have two models forecasting the same variable. Both being stored as nb_model_generic objects, i.e. being of any type of model which is part of the NBToolbox. Call them model1 and model2. Both must have produced recursive forecast for an overlapping period of time. Then we can run the Diebold-Mariano test for differences in forecast performance as follows:

```
[test,pval,res] = dieboldMarianoTest(model2,model)
```

21.3.3 PIT

If recursive density forecast has been produced by a model we can evaluate it using a PIT graph as follows:

```
[pit,plotter] = getPIT(model);%, '1994Q1', false  
plotter.graph()
```

Where the bars should level up with the plotted line for the density forecast to be performing well.

21.4 Forecast combination

Now we are interested in combining forecast from different models. So first we initialize 4 VARs with different lag lengths:

```
% Formulate model  
options = nb_var.template(4);
```

```

options.data          = data;
options.dependent     = {'Var1', 'Var2', 'Var3'};
options.nLags         = {1,2,3,4};
options.recursive_estim = 1;

% Create model object
models = nb_model_generic.initialize('nb_var',t);

% Estimate and solve model
model = estimate(model);
model = solve(model);

```

Then we want to produce recursive point forecast:

```
models = forecast(models,8,'fcstEval','SE');
```

Before we do the forecast combination we need to create a `nb_model_group` object:

```
modelGroup = nb_model_group(models);
```

At last we use the `combineForecast` method to do the forecast combination:

```
[modelGroup,weights,plotter] = combineForecast(...  
    modelGroup,...  
    'allPeriods', 1,...  
    'fcstEval',   {'SE'},...  
    'type',       'MSE');
```

Here we indicate by the 'allPeriods' input that we want to construct recursive forecast for the combined forecast as well, and not only for the last period. Be aware that if a model does not forecast a series no error will be provided, the model will only be given zero weight. The same goes for a model that hasn't produced forecast at a given period in the recursive sample shared across models.

The 'type' option selects the method to construct the weights. In this example we use mean squared error(MSE).

Using the output we can create a plot of the weights at different horizons, in this example at horizon 1:

```
graph(plotter(1));
```

We can plot the final periods combined forecast with the following code:

```
plotter = plotForecast(modelGroup);  
plotter.graphSubPlots();
```

To compare it to the individual forecast we can plot all of them in the same graph:

```
plotter = plotForecast(models);  
plotter.graphSubPlots();
```

It is also possible to combine density forecast with the use of the 'density' and 'draws' options, but then all the models must have produced density forecast.

21.5 Aggregate forecast

Let's say we want construct an aggregate forecast. I.e. if we have produced forecast on subcomponents of a series and we want to aggregate it to produce a forecast on

the aggregated series. This can be done with the `aggregateForecast` method of the `nb_model_group` class.

First we need some data:

```
% Simulate some artificial data
nDis    = 4;
obs     = 100;
lambda  = [ 0.5,  0.1,  0.3,  0.6,  0.2,  0.2, -0.1, 0;
            0.5, -0.1, -0.2,  0.4,   0,  0.1, -0.2, 0;
            0.6, -0.2,  0.1, -0.2,   0,  0.4, -0.1, 0;
            -0.2, -0.4,   0,  0.7,   0,      0,      0, 0];
rho     = [1;1;1;1];
sim     = nb_ts.simulate('2012M1',obs,{ 'VAR1', 'VAR2', ...
    'VAR3', 'VAR4'},1,lambda,rho);
weights = [0.3,0.2,0.4,0.1];
agg     = sum(bsxfun(@times,weights,double(sim)),2);

% Transform to nb_ts object
data   = nb_ts([double(sim),agg],'', '2000Q1',...
    {'Sim1','Sim2','Sim3','Sim4','Agg'},false);;
```

The data consist of subcomponents of consumption of goods. We want to produce forecast of each subcomponent using an AR(1,0,0) model. So first we set up all the models:

```
% Set options shared by all models
options                     = nb_arima.template;
options.AR                  = 1;
options.MA                  = 0;
options.integration         = 0;
options.constant             = 1;
options.recursive_estim     = 1;
options.recursive_estim_start_date = '2010Q1';
options.data                = data;
models                      = nb_arima(options);

% Replicate the model
models = repmat(models,1,4);
nModels = numel(models);

% Loop through for each variable
variables = data.variables(1:4);
for ii = 1:nModels
    models(ii) = set(models(ii), 'dependent', variables(ii));
end

% Estimate and solve all models
models = estimate(models);
models = solve(models);
```

Secondly we want to produce recursive forecast:

```
models = forecast(models,8,'fcstEval',{'SE'});
```

Then using the known share of each subcomponent we aggregate the forecast:

```
% Construct a nb_model_group object
modelGroup = nb_model_group(models);

% Do the aggregation
modelGroup = aggregateForecast(modelGroup, ...
    'weights',      weights, ...
    'newVar',       'Agg', ...
```

```

    'variables',    variables, ...
    'fcstEval',    {'SE'});

```

The 'variables' input must be a cellstr with the same size as the number of models to aggregate. I.e. it selects which variable to pick from each model to be aggregated. In this example this is trivial, but the forecast may come from models with more than just one variable. The 'newVar' option is the name of the aggregated variable. As you probably have the history of this variable it will be smart to store this in the data property of the different models with the same name. This is to be sure that the forecast evaluation compares to the exact observations of the aggregated variable.

Then we can plot the aggregated forecast and the forecast of each subcomponent as follows:

```

% Plot the aggregated forecast with history
plotter = plotForecast(modelGroup);
nb_graphSubPlotGUI(plotter);

% See the individual forecast
plotter = plotForecast(models);
nb_graphSubPlotGUI(plotter);

```

It is also possible to aggregate density forecast. This is done by:

```

% Density Forecast (recursive)
models = forecast(models,8, ...
    'fcstEval',{'SE'},...
    'draws', 1000, ...
    'perc', []);

% Aggregate models
modelGroup = nb_model_group(models);
modelGroup = aggregateForecast(modelGroup, ...
    'density', true, ...
    'method', 'copula',...
    'weights', weights, ...
    'newVar', 'Agg',...
    'variables', variables, ...
    'fcstEval', {'SE'}, ...
    'nLags', 4, ...
    'perc', []);

% Plot the aggregated forecast with history
plotter = plotForecast(modelGroup);
nb_graphSubPlotGUI(plotter);

% See the individual forecast
for ii = 1:length(models)
    plotter = plotForecast(models(ii));
    nb_graphSubPlotGUI(plotter);
end

```

The important options in this case being 'density', 'method' and 'nLags'. The 'density' option must be set to true, if not only the mean forecast is used to produce an aggregated point forecast. The 'method' option can be used to set the algorithm to make draws from the densities of the subcomponents. The 'copula' option estimate the auto-correlation for the number of needed periods to make draws from the different densities that are consistent with historically observed relation between the subcomponents (cross correlation and cross autocorrelation) and individual autocorrelation. The other option for 'method' is to assume they are perfectly correlated, which may overestimate the variance in the aggregated forecast. When 'method' is set to 'copula' the 'nLags' input sets the number of periods of history to condition on when drawing from the densities of

the subcomponents. A high number here is needed if the subcomponents display high autocorrelation.

21.6 Data transformation and reporting

For point forecast variables may be transformed with any type of expression after the forecast has been produced, this may no longer be true for density forecast. For example when calculating percentiles (for non-linear expressions).

If the forecast should be evaluated based on some transformation of variables it is also important to do them in code, at least it is much easier than to write your own code for it! (Both point and density.)

Here is an example:

```
% Generate some artificial data
obs      = 100;
lambda   = [0.5, 0.1, 0.3, 0.2, 0.2, -0.1;
            0.5, -0.1, -0.2, 0, 0.1, -0.2;
            0.6, -0.2, 0.1, 0, 0.4, -0.1];
rho      = [1; 1; 1];
vars     = {'VAR1', 'VAR2', 'VAR3'};
sim      = nb_ts.simulate('1990Q1', obs, vars, 1, lambda, rho);
data     = igrowth(sim/100+0.01, ones(1, 3)*100, 1);

% VAR Options
t         = nb_var.template();
t.data    = data;
t.constant = 0;
t.nLags   = 2;

% Create model and estimate
model = nb_var(t);

% Do transformations (To store shift/trend)
expressions = {%
    Name, expression, shift/trend, description
'VAR1_growth', 'growth(VAR1)', {'avg'}, ''
'VAR2_growth', 'growth(VAR2)', {'avg'}, ''
'VAR3_growth', 'growth(VAR3)', {'avg'}, ''
};
fcstHor = 8; % The forecast horizon
[model, plotter] = model.createVariables(expressions, ...
                                         fcstHor);
nb_graphInfoStructGUI(plotter);

% Assign inverse transformations
% (shift/trend will be added automatically)
expressions = {%
    Name, expression, description
'VAR1_L', 'igrowth(VAR1_growth, VAR1)', ''
'VAR2_L', 'igrowth(VAR2_growth, VAR2)', ''
'VAR3_L', 'igrowth(VAR3_growth, VAR3)', ''
'VAR1', 'VAR1_L', ''
'VAR2', 'VAR2_L', ''
'VAR3', 'VAR3_L', ''
};
model = set(model, 'reporting', expressions);

% Check reporting
model = checkReporting(model);

% Formulate model
VARvars = {'VAR1_growth', 'VAR2_growth', 'VAR3_growth'};
model   = set(model, 'dependent', VARvars);

% Estimate
model = estimate(model, ...
                  'recursive_estim', true, ...)
```

```

'recursive_estim_start_date','2009Q4');

print(model)

% Solve model and do point forecast
model = solve(model);
model = forecast(model,8, ...
    'fcstEval','SE',...
    'varOfInterest',{'VAR1','VAR2','VAR3'});
plotter = plotForecast(model,'hairyplot');
plotter.set('startGraph','2005Q1');
nb_graphSubPlotGUI(plotter);

```

21.7 Evaluate forecast from model

To evaluate the forecast from the model at specific dates you can use the `evalFcstAtDates` method of the class `nb_model_forecast` (the superclass of all models producing forecast). Here is a full example code for doing this:

```

% Generate some data
draws = randn(100,1);

% ARIMA(1,0,0)
sim1 = filter(1,[1,-0.5],draws);
data = nb_ts(sim1,[],'1995Q1',{'Sim1'});

% Set up model
t = nb_arima.template();
t.data = data;
t.dependent = data.variables;
t.integration = 0;
t.AR = 1;
t.MA = 0;
t.recursive_estim = 1;
t.recursive_estim_start_date = '2001Q1';

% Estimate and forecast model
m = nb_arima(t);
m = estimate(m);
m = solve(m);
m = forecast(m,5,'fcstEval','SE');

% Set the dates for where to evaluate the model
dates = {
    '20170305'
    '20170605'
    '20170905'
    '20171205'
    '20180305'
    '20180605'
    '20180905'
    '20181205'
};

% Get scores from the model
[Mdata,errorD] = evalFcstAtDates(m, ...
    dates,{ 'rmse'},false, false);
if ~isempty(errorD)
    disp(toString(errorD))
end

```

The output is an object of class `nb_data` with the score of the wanted forecast evaluation. For more on this method type `help nb_model_forecast.evalFcstAtDates` in the command window.

22 Model selection

To select the M best VAR/ARIMA models out of a suit of VAR/ARIMA models, use the `nb_model_selection_group` class. To initialize a `nb_model_selection_group` object, start by calling the `nb_model_selection_group()` method. Set class property to 'var' for VAR models and 'arima' for ARIMA models.

```
% Generate some data
obs      = 100;
lambda   = [0.5, 0.1, 0.3, 0.2, 0.2, -0.1;
            0.5, -0.1, -0.2, 0, 0.1, -0.2;
            0.6, -0.2, 0.1, 0, 0.4, -0.1];
rho      = [0.5; 0.5; 0.5];
sim      = nb_ts.simulate('1990Q1', obs, {'VAR1', 'VAR2', ...
                                         'VAR3'}, 1, lambda, rho);
data     = igrowth(sim/100 + 0.01, 100);

% Formulate the model
modelGroup = nb_model_selection_group();
modelGroup = set(modelGroup, ...
                 'data', ...
                 'varOfInterest', ...
                 'modelVarOfInterest', ...
                 'variables', ...
                 { ...
                  'G_VAR1', ...
                  'G_VAR1_GAP', ...
                  {'G_VAR2_GAP', ...
                   'G_VAR3_GAP'}});
```

If you want the forecast to be evaluated on some transformation of the variable, assign the desired transformations and upload the relevant variables to the model group:

```
% Assign desired transformations (shift/trend will be stored)
transformations = {%
    Name, expression, shift/trend, description
    'G_VAR1_GAP', 'pcn(VAR1)', {'avg'}, '% growth gap'
    'G_VAR2_GAP', 'pcn(VAR2)', {'avg'}, '% growth gap'
    'G_VAR3_GAP', 'pcn(VAR3)', {'avg'}, '% growth gap'
};

% Upload data to the model group
modelGroup = createVariables(modelGroup, transformations, 8);
```

If you wish to add the shift/trend from the transformations above when producing forecasts, you can assign the inverse transformation by reporting the variables. This will automatically add the shift/trend to the results:

```
% Report variables
reporting = {%
    Name, expression, description
    'G_VAR1', 'G_VAR1_GAP', '% growth'
};

% Add the reporting to the model group
modelGroup = set(modelGroup, 'reporting', reporting);
modelGroup = checkReporting(modelGroup);
```

Run the model selection and plot the number of times each variable has been chosen for the M best VAR/AR models:

```
% Initialize model object to do model selection
[modelGroups, p] = modelSelection(modelGroup);

% Plot histogram over most selected variables
p.graph
```

23 More examples

More examples can be found in NBTOOLBOX\Examples\Econometrics.

24 Code references

We thank a lot of contributors for making their code open source, as without them we could not have made this toolbox. Here we have to our best effort tried to list the most important once:

Altman, Y and Woodford, Oliver Export_fig. See the [export_fig](#) function.²⁷

Altman, Y Find java objects contained within a specified java container or Matlab GUI handle. See the [findjobj](#) function.

Benes, Jaromir Do x12 Census adjustment to time series using x12awin.exe. See the [x12.x12](#) function, which is a modified version of the corresponding function which is part of the [IRIS toolbox](#). x12awin.exe is a program developed by the U.S. Department of Commerce, U. S. Census Bureau.

Binning, Andrew Identification of VAR model using combination of zero and sign restrictions. Available [here](#). See [nb_var.ABidentification](#).

Chen, S. Samuel Particle Swarm Optimization. Please see the [nb_pso](#) and [pso.do](#) function. Available [here](#).

Dynare NB toolbox makes it possible to use the [nb_dsge](#) class as a overhead of the the [Dynare toolbox](#), so as to make it possible to compare models written in different languages. Parsing and solving is then done with Dynare, but the other analysis, as IRFs, shock decomposition etc. is using code from the NB toolbox. You need to download and add Dynare to the MALTAB run path yourself to able to run Dynare.

Fink, Martin and Ahn, SeHyoun Automatic differentiation of 1st. See the [myAD](#) class.

Gleich, David F. Parts of the Graph Algorithms package GAIMC. Please use [this](#) link to get the original code.

Hoffman, Matthew D. The No-U-Turn-Sampler implementation in MATLAB. See [nb_mcmc.NUTS](#) and [nb_mcmc.dualAveraging](#).

²⁷NB toolbox provide additional functionality. You may flip the PDF with the '-noflip' option, and you may create a portrait PDF using the [portraitPDF](#) function.

25 Library

◆ nb_startup

```
nb_startup(type,silent)
```

Description:

Start up function of the NB toolbox.

This function utilizes a simplified version of the cprintf function made by Yair M. Altman.

Input:

- type : With this input you can specify which functionalities you want
 - 'all' : Add all the functionalities.
 - 'dg' : Only add the data managment and graphics functions and classes.
 - 'full' : Will add all the functionalities of the toolbox except the GUI part.
 - 'g' : Only add the basic plot functions and classes.
 - 'gui' : Add all the functionalities. Same as 'all'.
- silent : If you give 'silent' it will not print anything on the screen.

Output:

- All the wanted function and classes added to the MATLAB path.

Examples:

```
nb_startup  
nb_startup('fg')  
nb_startup('full','silent')
```

■ nb_date

Go to: [Properties](#) | [Methods](#)

The superclass of all the different dates at different frequencies

This class also includes some static functions which are general for all date frequencies.

Subclasses:

`nb_day, nb_week, nb_month, nb_quarter, nb_semiAnnual nb_year`

Constructor:

`obj = nb_date %` Constructs an empty date object

Input:

No inputs

Output:

No outputs

Examples:

`obj = nb_date;`

See also:

`nb_year, nb_semiAnnual, nb_quarter, nb_month, nb_week, nb_day`

Written by Kenneth S. Paulsen

Properties:

- `baseYear`
- `dayOfWeek`
- `leapYear`

- **baseYear** ↑

The base year. 2000.

- **dayOfWeek** ↑

The day which the weekly date represents when converted to or from a weekly frequency. Default is 1, which is sunday.

- **leapYear** ↑

Indicator for leap year. 1 if leap year.

Methods:

- ascensionDay
- colon
- easter
- fromxlsDates2freq
- getFrequencyAsInteger
- getNr
- intersect
- isFirstPeriod
- isempty
- min
- sort
- toString
- unique
- cell2Date
- date2freq
- format2string
- getEarliestDate
- getFrequencyAsString
- holidays
- isDate
- isLeapYear
- ismember
- pentecost
- toDate
- today
- vintage2Date
- christmas
- disp
- freqPlus
- getFreq
- getLatestDate
- initialize
- isEqualFreq
- isPeriod
- max
- setDayOfWeek
- toFormat
- union

► ascensionDay ↑

```
day = ascensionDay(obj,~)
```

Description:

Give the ascension day of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_date.easter](#), [nb_date.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

► cell2Date ↑

```
obj = nb_date.cell2Date(cellstr,freq)
```

Description:

Converts a cellstring of dates into a nb_date object.

Input:

- cellstr : The cellstring of dates that you want to convert.
- freq : The frequency of your data. You can choose between 1, 2, 4, 12, 52, and 365.

Output:

- date : A NumberOfDatesx1 vector containing nb_date objects.

Examples:

```
g = {'2011Q2'
      '2011Q3'
      '2011Q4'
      '2012Q1'
      '2012Q2'
      '2012Q3'
      '2012Q4'
      '2013Q1'
      '2013Q2'}
```

```
a = nb_date.cell2Date(g,4)
```

```
a =
```

```
'2011Q2'
'2011Q3'
'2011Q4'
'2012Q1'
'2012Q2'
'2012Q3'
'2012Q4'
'2013Q1'
'2013Q2'
```

Written by Tobias Ingebrigtsen

► christmas ↑

```
day = christmas(obj,~)
```

Description:

Give the holidays of christmas (25th and 26th) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_date.ascensionDay](#), [nb_date.pentecost](#), [nb_date.easter](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **colon** ↑

cellStr = colon(a,d,b)

Description:

Overload the : operator. The result is a cellstr array of all the dates between the a and b (Including the a and b dates).

Input:

- a : An object of class nb_date or of a subclass of the nb_date class
- d : Increments between the dates
- b : An object of class nb_date or of a subclass of the nb_date class

Output:

- cellStr : A cellstr array of the periods between the dates represented by a and b. (Including the dates a and b). If a and b are nb_date object an empty cell is returned.

Examples:

```
dates = a:b;  
dates = a:2:b;
```

Written by Kenneth S. Paulsen

► **date2freq** ↑

[startDate,frequency,type] = nb_date.date2freq(dates,xls)

Description:

A static method of the nb_date class.

Find out the frequency of the data (also from a xls(x) worksheet)

When trying to figure out the frequency of excel dates, this function must have at least two following dates

```
yearly      : 'yyyy' or 'dd.mm.yyyy'  
semiannually : 'yyyySs' or 'dd.mm.yyyy'  
quarterly   : 'yyyyQq' or 'yyyyKk', 'dd.mm.yyyy'  
monthly     : 'yyyyMm(m)' or 'dd.mm.yyyy'  
weekly       : 'yyyyWw(w)' or 'dd.mm.yyyy'  
daily        : 'yyyyMm(m)Dd(d)', 'ddmonyyyy' or 'dd.mm.yyyy'
```

Input:

- dates : A cellstr of the dates you want to test the frequency of.
- xls : > 'xls' : If you want to test if the dates is on the format 'dd.mm.yyyy' also
> otherwise will not (default)

Output:

- startDate : An object which is a subclass of the class nb_date, with the start date of the input dates. (Either nb_quarter, nb_month, nb_semiAnnual, nb_year, nb_week or nb_day)
- frequency : The frequency of the dates given.
 - > 1 : yearly
 - > 2 : semiannually
 - > 4 : quarterly
 - > 12 : monthly
 - > 52 : weekly
 - > 365 : daily
- type : 1 if the dates input is on the xls format, otherwise 0

Examples:

```
dates = {'01.01.2012','02.01.2012','03.01.2012'};  
[startDate,frequency,type] = nb_date.date2freq(dates,'xls');
```

The output will in this example be:

- startDate : An nb_day object representing the date '01.01.2012'
- frequency : 365
- type : 1

Written by Kenneth S. Paulsen

► **disp** ↑

`disp(obj)`

Description:

Sets how the `nb_date` object is displayed, and all subclasses of the `nb_date` class

Input:

- `obj` : An object of class `nb_date` or of a subclass of the `nb_date` class.

Written by Kenneth S. Paulsen

► **easter** ↑

`day = easter(obj,type)`

Description:

Give the holidays or the sunday of easter of the year the date is located.

Input:

- `obj` : An object of class `nb_date`.
- `type` : 'all' or 'sunday' (default).

Output:

- `days` : All the holidays as a vector of `nb_day` objects.

See also:

[nb_easter](#), [nb_date.ascensionDay](#), [nb_date.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

► **format2string** ↑

```
date = nb_date.format2string(obj,format)
date = nb_date.format2string(obj,format,language,first)
```

Description:

Get date at a given format.

Input:

- obj : An object of a subclass of nb_date.
- format : A string with the format. A combination of the following patterns:

- d : Day of the date. Examples:

```
> 'dd'   : '01', '10'
> 'd'    : '1', '0'
> 'd(d)': '1', '10'
- w : Week of date. Same options as for d.
- m : Month of date. Same options as for d.
```

- q : Quarter of date. Examples:

```
> 'q'   : '1', '4'
- h : Half year of date. Same options as for h.
- y : Year of date.
      > 'yyyy' : '2016'
      > 'yy'   : '16'
      < 'y'    : '6'
```

Caution: To use the actual letter of the patterns use \ in front of the letter. E.g. '\y'.

Extra (see also the language option):

- 'Monthtext' : Month of date as full text. Starting with upper case.
- 'monthtext' : Month of date as full text. Starting with upper case.
- 'Quartertext' : > 'norwegian' : '. kv.'
 > 'english' : 'Q'
- 'Weektext' : > 'norwegian' : 'Uke'
 > 'english' : 'Week'
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- date : A string of the date on the wanted format.

Examples:

```
d      = nb_day.today();
date = nb_date.format2string(d,'dd.mm.yyyy');
date = nb_date.format2string(d,'d(d).m(m).yyyy');
date = nb_date.format2string(d,'d(d) Monthtext yyyy');
date = nb_date.format2string(d,'d(d). monthtext yyyy','norwegian');

m      = nb_month.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'Monthtext yyyy');
date = nb_date.format2string(m,'Monthtext yyyy','norwegian');

q      = nb_quarter.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'qQ yyyy');
date = nb_date.format2string(m,'q. kv. yyyy');

y      = nb_year.today();
date = nb_date.format2string(y,'dd.mm.yyyy');
date = nb_date.format2string(y,'yyyy');
date = nb_date.format2string(y,'\year yyyy');
```

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

► **freqPlus ↑**

```
obj = freqPlus(obj,incr,freq)
```

Description:

Plus the number of periods of another (lower) frequency.

E.g. dayNextYear = freqPlus(day,1,1);

Input:

- obj : An object of class nb_date.
- periods : A scalar integer with the periods to add.
- freq : The frequency of the periods argument.

Output:

- ob : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

► **fromxlsDates2freq** ↑

```
frequency = nb_date.fromxlsDates2freq(dates)
```

Description:

A static method of the nb_date class.

Try to find out the date frequency of the excel dates. I.e. dates on the format 'dd.mm.yyyy'.

Input:

- Dates : A cellstr with at least two dates on the date format 'dd.mm.yyyy'.

Output:

- frequency : The frequency of the input dates given as an integer.
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Examples:

```
dates      = {'01.01.2012','02.01.2012','03.01.2012'};  
frequency = nb_date.fromxlsDates2freq(dates)
```

The output will in this example be:

- frequency : 1

Written by Kenneth S. Paulsen

► **getEarliestDate** ↑

```
date = nb_date.getEarliestDate(c)
```

Description:

Get the earliest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

► **getFreq** ↑

```
freq = nb_date.getFreq(stringDate)
```

Description:

Get the frequency of a string date, given that it is on the nb_ts date format.

Input:

- stringDate :

Supported date formats:

```
> yearly      : 'yyyy'  
> semiannually : 'yyyySs'  
> quarterly   : 'yyyyQq'  
> monthly     : 'yyyyMm(m)'  
> weekly      : 'yyyyWw(w)'  
> daily       : 'yyyyMmDd(d)'
```

Output:

```
- freq      :  
  > yearly    : 1  
  > semiannually : 2  
  > quarterly   : 4  
  > monthly     : 12  
  > weekly      : 52  
  > daily       : 365
```

Examples:

```
freq = nb_date.getFreq('2012'); % Will return 1
```

Written by Kenneth S. Paulsen

► **getFrequencyAsInteger** ↑

```
frequency = nb_date.getFrequencyAsInteger(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as an integer given a frequency as a string

Input:

- frequency : Frequency input as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly', 'annual'

Output:

- frequency : The frequency as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Examples:

```
frequency = nb_date.getFrequencyAsInteger('yearly')
```

Written by Kenneth S. Paulsen

► **getFrequencyAsString** ↑

```
frequency = nb_date.getFrequencyAsString(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as a string given a frequency as an integer

Input:

- frequency : Frequency input as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Output:

- frequency : The frequency as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly'

Examples:

```
frequency = nb_date.getFrequencyAsString(1);
```

Written by Kenneth S. Paulsen

► **getLatestDate** ↑

```
date = nb_date.getLatestDate(c)
```

Description:

Get the latest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

► **getNr** ↑

```
nr = getNr(obj)
```

Description:

Get date number of a nb_date vector.

Input:

- obj : A vector of nb_date objects.

Output:

- nr : A double with the date numbers of each object in the nb_date vector.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

► **holidays** ↑

```
days = holidays(obj)
```

Description:

Find the holidays of the given date object.

Input:

- obj : An object of class nb_month, nb_quarter, nb_semiAnnual or nb_year.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_date.easter](#), [nb_date.ascensionDay](#), [nb_date.pentecost](#)
[nb_date.christmas](#)

Written by Kenneth Sæterhagen Paulsen

► **initialize** ↑

```
obj = nb_date.initialize(freq, dim1, dim2)
```

Description:

Initialize a vector of date objects.

Input:

- freq : The wanted frequency of the date of today. 1,2,4,12,52 or 365.
- dim1 : The size of the first dimension.
- dim2 : The size of the second dimension.

Output:

obj : A vector of nb_date objects.

Written by Kenneth Sæterhagen Paulsen

► **intersect** ↑

```
cout = nb_date.intersect(varargin)
```

Description:

Get the intersection of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

► **isDate** ↑

```
ret = nb_date.isDate(input,freq)
```

Description:

Test if a string or nb_date object is a date. It is also possible to restrict the test to a specific frequency.

Input:

- input : Any object
- freq : 1, 2, 4, 12, 52 or 365. Can also be empty, but then it is slower.
- locVar : A nb_struct/struct with the supported local variables. If the input is a string using the syntax '%#name', this input will be looked up and tested.

Output:

- ret : Either true or false. true if input is a date string or nb_date object.

Written by Kenneth Sæterhagen Paulsen

► **isEqualFreq** ↑

```
ret = isEqualFreq(obj,aObj)
```

Description:

Test if two date objects have the same frequency

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class
- aObj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : 1 if equal frequency, 0 else

Examples:

```
d = nb_day(1,1,2012);
q = nb_quarter(4,2012);
ret = d.isEqualFreq(q); % Will return 0
```

Written by Kenneth S. Paulsen

► **isFirstPeriod** ↑

```
ret = isFirstPeriod(obj,freq)
```

Description:

Return if the obj represent the first period a lower frequency.

Input:

- obj : An object which of a subclass of the nb_date class.
- freq : The lower frequency.

Output:

- ret : True if the object represent the first period of the lower frequency.

Examples:

```
q = nb_quarter(1,2000)
ret = isFirstPeriod(q,1)

m = nb_month(10,2000)
ret = isFirstPeriod(m,4)
```

Written by Kenneth Sætherhagen Paulsen

► **isLeapYear** ↑

```
ret = isLeapYear(obj)
```

Description:

Test if the current year is a leap year

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : Logical. 1 if object is leap year, 0 else

Examples:

```
ret = obj.isLeapYear();
```

Written by Kenneth S. Paulsen

► **isPeriod** ↑

```
ret = isPeriod(obj,period)
```

Description:

Return true if the obj represent the given period, i.e. if you want to test if a nb_quarter object represent the first period of any year you can use isPeriod(obj,1).

Input:

- obj : An object which of a subclass of the nb_date class.
- period : The period to test for.

Output:

- ret : True if the object represent the period to test for, else false.

Examples:

```
q    = nb_quarter(1,2000)
ret = isPeriod(q,1)
```

Written by Kenneth Sæterhagen Paulsen

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if the object is empty, which is always true.

Input:

- obj : An object of class nb_date

Output:

- ret : 1 if empty, 0 else

Examples:

```
ret = objisempty();
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **ismember** ↑

- varargout = ismember(obj1,obj2)

Description:

Utilizes the inbuilt MATLAB function 'ismember' for nb_date objects.

Input:

- obj1 : A nb_date object
- obj2 : A nb_date object

Output:

- varargout : See help on MATLAB function 'ismember'.

See also:

[ismember](#)

Written by Tobias Ingebrigtsen

► **max** ↑

```
obj = nb_date.max(obj1,obj2)
```

Description:

Find the latest date of the two. The frequency must be the same!

Input:

- obj1 : A scalar nb_date object.
- obj2 : A scalar nb_date object.

Output:

- obj : The last of the two dates, as a nb_date object.

Written by Kenneth Sæterhagen Paulsen

► **min** ↑

```
obj = nb_date.min(obj1,obj2)
```

Description:

Find the first date of the two. The frequency must be the same!

Input:

- obj1 : A scalar nb_date object.
- obj2 : A scalar nb_date object.

Output:

- obj : The first of the two dates, as a nb_date object.

Written by Kenneth Sæterhagen Paulsen

► **pentecost** ↑

```
day = pentecost(obj,~)
```

Description:

Give the pentecost (monday) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_date.easter](#), [nb_date.ascensionDay](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **setDayOfWeek** ↑

`obj = setDayOfWeek(obj,dayOfWeek)`

Description:

Set the day of week number of a set of nb_date objects.

Input:

- obj : A nb_date object. May be a vector or matrix.

Output:

- obj : A nb_date object with the same size as the obj input.

See also:

[nb_date.dayOfWeek](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **sort** ↑

`[obj,ind] = sort(obj)`

Description:

Sort a vector of nb_date objects.

Input:

- obj : A vector of nb_date objects.

Output:

- obj : A sorted vector of nb_date objects.
- ind : The index of the sorting.

Written by Kenneth Sæterhagen Paulsen

► **toDate** ↑

```
dObj = nb_date.toDate(date,frequency)
```

Description:

A static method of the nb_date class.

Transform a given date string to the corresponding date object given that the frequency is already known.

If the frequency is not known, use the method date2freq() (handles also excel dates) or getFreq() (Only nb_ts dates).

Input:

- date :

Supported date formats:

> Daily	:	'dd.mm.yyyy' and 'yyyyMm(m)Dd(d)'
> Weekly	:	'dd.mm.yyyy' and 'yyyyWw(w)'
> Monthly	:	'dd.mm.yyyy' and 'yyyyMm(m)'
> Quarterly	:	'dd.mm.yyyy' and 'yyyyQq'
> Semiannually	:	'dd.mm.yyyy' and 'yyyySs'
> Yearly	:	'dd.mm.yyyy' and 'yyyy'
> Secondly	:	'yyyy-mm-dd hh:nn:ss' and 'yyyymmddhhnnss' (only supported if this version of the toolbox includes the nb_second class)

- frequency :

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2

```
> Yearly      : 1  
> Secondly    : 31536000
```

Output:

```
- dObj      :  
  > Daily     : An nb_day object  
  > Weekly    : An nb_week object  
  > Monthly   : An nb_month object  
  > Quarterly : An nb_quarter object  
  > Semiannually : An nb_semiAnnual object  
  > Yearly    : An nb_year object  
  > Secondly   : An nb_second object
```

Examples:

```
dObj = nb_date.toDate('2012M1D1', 365);  
dObj = nb_date.toDate('2012M1', 12);  
dObj = nb_date.toDate('2012Q1', 4);  
dObj = nb_date.toDate('2012S1', 2);  
dObj = nb_date.toDate('2012', 1);
```

Written by Kenneth S. Paulsen

► **toFormat ↑**

```
dates = toFormat(start, finish, format, language, first)
```

Description:

Convert dates vector to a given format.

Input:

```
- start      : An object of a subclass of the nb_date class.  
- finish     : An object of a subclass of the nb_date class.  
- format     : See the format input to the nb_date.format2string  
               method.  
- language   : 'norwegian' or 'english' (default). Only important for the  
               'monthtext' or 'Monthtext' patterns.  
- first      : Give false to return the latest period when converted  
               to a higher frequency. Default is true, i.e. first  
               period.
```

Output:

- vint : A cellstr.

See also:

[nb_date.format2string](#)

Written by Kenneth Sæterhagen Paulsen

► **toString** ↑

date = toString(obj)

Description:

Transform the nb_date object to a string. Will always return 'empty date object'

Input:

- obj : An object of class nb_date

Output:

- string : 'empty date object'

Examples:

Written by Kenneth S. Paulsen

► **today** ↑

obj = nb_date.today(freq)

Description:

Get the current day as a nb_day object.

Input:

- freq : The wanted frequency of the date of today.

1, 2, 4, 12, 52, {365}

Output:

obj : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

► **union** ↑

```
cout = nb_date.union(varargin)
```

Description:

Get the union of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

► **unique** ↑

```
obj = unique(obj)
```

Description:

Get unique elements of a vector of nb_date objects.

Input:

- in : A vector of nb_date objects.

Output:

- out : A unique (sorted) vector of nb_date objects.

- IA : out = in(IA)

- IC : A = C(IC)

Written by Kenneth Sæterhagen Paulsen

► **vintage2Date** ↑

```
date = nb_date.vintage2Date(vintage,freq)
```

Description:

This method converts a vintage date into a nb_date object with the wanted frequency. You can also convert a cellstring containing multiple vintage dates.

Input:

- vintage : Either the vintage date that you want to convert, or a cellstring containing the vintage dates you want to convert.
- freq : The wanted frequency. Your options are 1, 4, 12 or 365.

Output:

- date : A 1xNumberOfVintages vector containing nb_date object(s).

Examples:

```
f = '20110622'  
t = nb_date.vintage2Date(f,4)
```

OR

```
f = {'20110622','20111019','20120314'} |  
t = nb_date.vintage2Date(f,4)
```

Written by Tobias Ingebrigtsen

■ nb_dateInExpr

Go to: [Properties](#) | [Methods](#)

A class representing a date that can be used in nb_eval to get the end dates of time-series used in an expression.

Constructor:

```
obj = nb_dateInExpr(date)
```

Input:

- date : An object of class nb_date or a one line char that can be converted to a nb_date object using nb_date.date2freq.

Output:

- obj : An object of class nb_dateInExpr.

Examples:

```
obj = nb_dateInExpr('2012Q1');
```

See also:

► **abs** ↑

```
obj = abs(obj)
```

Description:

Absolute value

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = abs(in);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acos** ↑

```
obj = acos(obj)
```

Description:

Take inverse cosine, result in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = acos(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acosd** ↑

```
obj = acosd(obj)
```

Description:

acosd(obj) is the inverse cosine, expressed in degrees

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acosd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acosh** ↑

```
obj = acosh(obj)
```

Description:

acosh(obj) is the inverse hyperbolic cosine

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acosh(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acot** ↑

```
obj = acot(obj)
```

Description:

Take inverse cotangent

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = acot(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acotd** ↑

```
obj = acotd(obj)
```

Description:

acotd(obj) is the inverse cotangent, expressed in degrees

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acotd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acoth** ↑

```
obj = acoth(obj)
```

Description:

acoth(obj) is the inverse hyperbolic cotangent of the elements of obj

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acoth(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acsc** ↑

```
obj = acsc(obj)
```

Description:

Take acsc

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = acsc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acsqd** ↑

```
obj = acscd(obj)
```

Description:

acscd(obj) is the inverse cosecant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acscd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **acsch** ↑

```
obj = acsch(obj)
```

Description:

acsch(obj) is the inverse hyperbolic cosecant

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = acsch(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **and** ↑

```
a = and(a,b)
```

Description:

The and operator (&).

Input:

- a : An object of class nb_objectInExpr
- b : An object of class nb_objectInExpr

Output:

- a : An object of class nb_objectInExpr.

Examples:

```
a = a & b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **append ↑**

```
obj = append(obj,aObj)
obj = append(obj,aObj,priority)
```

Description:

Append aObj to obj with a given priority.

Input:

- obj : A nb_objectInExpr object.
- aObj : A nb_objectInExpr object.
- priority : 'first' or 'second'. If 'first' all the observations from obj is used before the observations from aObj, otherwise it is reverse. 'first' is default.

Output:

- obj : A nb_objectInExpr object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asec** ↑

```
obj = asec(obj)
```

Description:

Inverse secant, result in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = asec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asecd** ↑

```
obj = asecd(obj)
```

Description:

asecd(obj) is the inverse secant, expressed in degrees

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = asecd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asech** ↑

```
obj = asech(obj)
```

Description:

asech(obj) is the inverse hyperbolic secant

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = asech(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asin** ↑

```
obj = asin(obj)
```

Description:

Take inverse sine, result in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = asin(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asind** ↑

```
obj = asind(obj)
```

Description:

asind(obj) is the inverse sine, expressed in degrees

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = asind(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **asinh** ↑

```
obj = asinh(obj)
```

Description:

asinh(obj) is the inverse hyperbolic sine

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = asinh(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **atan** ↑

```
obj = atan(obj)
```

Description:

Take the tangent

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = atan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **atand** ↑

```
obj = atand(obj)
```

Description:

atand(obj) is the inverse tangent, expressed in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = atand(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **atanh** ↑

```
obj = atanh(obj)
```

Description:

atanh(obj) is the inverse hyperbolic tangent

Input:

```
- obj : An object of class nb_objectInExpr
```

Output:

```
- obj : An object of class nb_objectInExpr
```

Examples:

```
out = atanh(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **avgOAF** ↑

```
obj = avgOAF(obj,avgFreq)
```

Description:

Take the average over a lower frequency.

Input:

```
- obj : An object of class nb_objectInExpr  
- avgFreq : Any
```

Output:

```
- obj : An object of class nb_objectInExpr
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **bkfilter** ↑

```
obj = bkfilter(obj,low,high)
```

Description:

Do band pass filtering

Input:

- obj : An object of class nb_objectInExpr
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **bkfilterls** ↑

```
obj = bkfilterls(obj,low,high)
```

Description:

Do one sided band pass-filtering.

Input:

- obj : An object of class nb_objectInExpr
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **callfun** ↑

```
obj      = callfun(obj,'func',func)
obj      = callfun(obj,another,'func',func)
obj      = callfun(obj,varargin,'func',func)
varargout = callfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the object.

Input:

- obj : An object of class nb_dateInExpr.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function @(x)x will be used.
- 'frequency' : If the operator should act on the data of the object, as it was on another frequency, you set this option to that frequency. Either 1 (yearly), 2 (semi-annually), 4 (quarterly), 12 (monthly), 52 (weekly) or 365 (daily).

Caution: It will be applied to the obj input as well as all optional inputs being a nb_dateInExpr object.
- 'interpolateDate' : See the nb_dateInExpr.convert method for more on this option. Default is 'start'.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class.

Output:

- varargout : The output will be given as return by the func function when applied to the input objects.

Examples:

```
d1 = callfun(d,'func',@sin); % Same as d1 = sin(d) !
d2 = callfun(d,d,'func','plus') % Same as d2 = d + d !
```

Written by Kenneth Sæterhagen Paulsen

► ceil ↑

```
obj = ceil(obj)
```

Description:

ceil(obj) rounds the elements of obj to the nearest integers towards infinity.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

out = ceil(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **conj** ↑

obj = conj(obj)

Description:

conj(obj) is the complex conjugate

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

out = conj(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **convert** ↑

obj = convert(obj,freq,method,varargin)

Description:

Convert the frequency of the data of the nb_dateInExpr object

Input:

```
- obj      : An object of class nb_dateInExpr  
- freq    : The new frequency of the data. As an integer:  
             > 1    : yearly  
             > 2    : semi annually  
             > 4    : quarterly  
             > 12   : monthly  
             > 52   : weekly  
             > 365  : daily  
- method  : Any
```

Optional input:

```
- 'interpolateDate' : The input after this input must either be  
                      'start' or 'end'.
```

Date of interpolation. Where 'start' means
to interpolate the start date of the
periods of the old frequency, while 'end'
uses the end date of the periods.

Default is 'start'.

Caution : Only when converting to higher
frequency.

Output:

```
- obj : An nb_dateInExpr object.
```

Written by Kenneth S. Paulsen

► **corr ↑**

```
obj = corr(obj)
```

Description:

Correlation

Input:

```
- obj : An object of class nb_objectInExpr
```

Output:

```
- obj : An object of class nb_objectInExpr
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cos** ↑

```
obj = cos(obj)
```

Description:

Cosine

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = cos(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cosd** ↑

```
obj = cosd(obj)
```

Description:

cosd(obj) is the cosine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = cosd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cosh** ↑

obj = cosh(obj)

Description:

cosh(obj) is the hyperbolic cosine.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

out = cosh(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cot** ↑

obj = cot(obj)

Description:

Cotangent

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = cot(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cotd** ↑

```
obj = cotd(obj)
```

Description:

`cotd(obj)` is the cotangent of the elements of `obj`, expressed in degrees.

Input:

- `obj` : An object of class `nb_objectInExpr`

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
out = cotd(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **coth** ↑

```
obj = coth(obj)
```

Description:

`coth(obj)` is the hyperbolic cotangent of the elements of `obj`.

Input:

- `obj` : An object of class `nb_objectInExpr`

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
out = coth(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **cov** ↑

```
obj = cov(obj)
```

Description:

Covariance

Input:

```
obj : An object of class nb_objectInExpr
```

Output:

```
d : An object of class nb_objectInExpr
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **csc** ↑

```
obj = csc(obj)
```

Description:

Cosecant of argument in radians.

Input:

```
- obj : An object of class nb_objectInExpr
```

Output:

```
- obj : An object of class nb_objectInExpr
```

Examples:

```
obj = csc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cscd** ↑

```
obj = cscd(obj)
```

Description:

cscd(obj) is the cosecant, expressed in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = cscd(in);
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **csch** ↑

```
obj = csch(obj)
```

Description:

csch(obj) is the hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = csch(in);
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cumprod** ↑

```
obj = cumprod(obj, dim)
```

Description:

Cumulativ product

Input:

- obj : An object of class nb_objectInExpr
- dim : In which dimension the cumulativ product should be calculated. Default is the first dimension.

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = cumprod(obj,1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **cumsum** ↑

```
obj = cumsum(obj,dim)
```

Description:

Cumulativ sum

Input:

- obj : An object of class nb_objectInExpr
- dim : In which dimension the cumulativ sum should be calculated. Default is the first dimension.

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = cumsum(obj,1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **demean** ↑

```
obj = demean(data,~)
```

Description:

- Demeans along the dimension you choose.

Input:

- obj : A nb_objectInExpr object
- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- obj : A nb_objectInExpr object.

See also:

[sgrowth](#), [subAvg](#).

Written by Tobias Ingebrigtsen

Inherited from superclass NB_OBJECTINEXPR

► **demeanMoving** ↑

```
obj = demeanMoving(obj,backward)
obj = demeanMoving(obj,backward,forward)
```

Description:

- Demeans data with a moving average process.

Input:

- obj : A nb_objectInExpr object
- backward : Number of periods backward in time to calculate the moving average
- forward : Number of periods forward in time to calculate the moving average

Output:

- obj : A nb_objectInExpr object.

See also:

[nb_dateInExpr.demean](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **denton** ↑

obj = denton(obj,z,k,type,d)

Description:

The Denton method of transforming a series from low to high frequency.

See Denton (1971), Adjustment of Monthly or Quarterly Series to Annual Totals: An Approach Based on Quadratic Minimization.

Input:

- obj : A nb_dateInExpr object.
- z : Any
- k : The number intra low frequency observations. If you have annual data and want out quarterly data use 4.
- type : Any
- d : Any

Output:

- x : A nb_dateInExpr object.

See also:

[nb_ts.convert](#), [nb_denton](#)

Written by Kenneth Sæterhagen Paulsen

► **deptcat** ↑

obj = deptcat(a,b,varargin)

Description:

Depth concatenation (add pages of different nb_objectInExpr objects)
(No short hand notation)

Input:

```
- a : An object of class nb_objectInExpr  
- b : An object of class nb_objectInExpr  
- varargin : Optional number of nb_objectInExpr objects
```

Output:

```
obj : An object of class nb_objectInExpr.
```

Examples:

```
obj = deptcat(a,b);  
obj = deptcat(a,b,c);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **detrend** ↑

```
obj = detrend(obj,method,output,varargin)
```

Description:

De-trend.

Input:

```
- obj : A nb_objectInExpr object.  
- method : Any  
- output : Any
```

Optional input:

Any

Output:

```
- obj : A nb_objectInExpr object.
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **diff** ↑

```
obj = diff(obj)
obj = diff(obj,lag)
obj = diff(obj,lag,skipNaN)
```

Description:

Diff method.

Input:

- obj : An object of class nb_objectInExpr
- lag : Any
- skipNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = diff(obj);
obj = diff(obj,4);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **disp ↑**

```
disp(obj)
```

Description:

Display object (On the commandline)

Input:

obj : An object of class nb_dateInExpr

Output:

The object display on the command line. (When not ending the command with an semicolon)

Examples:

```
obj
```

Written by Kenneth S. Paulsen

► **egrowth** ↑

```
obj = egrowth(obj,lag,stripNaN)
```

Description:

Calculate exact growth, using the formula: $(x(t) - x(t-1))/x(t-1)$.

Input:

- obj : An object of class nb_objectInExpr
- lag : Any
- stripNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = egrowth(obj);  
obj = egrowth(obj,4);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **epcn** ↑

```
obj = epcn(obj,lag,stripNaN)
```

Description:

Calculate exact percentage growth, using the formula:
 $100 * (x(t) - x(t-1))/x(t-1)$.

Input:

- obj : An object of class nb_objectInExpr
- lag : Any
- stripNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = epcn(obj); % period-on-period growth  
obj = epcn(obj,4); % 4-periods growth
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **eq** ↑

```
a = eq(a,b)
```

Description:

This method is intended to test if two nb_math_ts objects are equal. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar.
- b : An object of class nb_objectInExpr or a scalar.

Output:

- a : An object of class nb_objectInExpr

Examples:

```
obj = a == b;  
obj = 2 == b;  
obj = a == 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **exp** ↑

```
obj = exp(obj)
```

Description:

Exponential function.

Input:

- obj : An object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr.

Examples:

```
obj = exp(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **expand** ↑

```
obj = expand(obj,newStartDate,newEndDate,type,warningOff)
```

Description:

This method expands a nb_math_ts object, which means we need to take max of existing end date and the new end date.

Input:

- obj : An object of class nb_dateInExpr
- newStartDate : Any
- newEndDate : The wanted new end date of the data.
- type : Any
- warningOff : Any

Output:

- obj : An nb_dateInExpr object.

Examples:

```
obj = expand(obj,'1900Q1','2050Q1');  
obj = expand(obj,'1900Q1','2050Q1','zeros');
```

Written by Kenneth S. Paulsen

► **expml** ↑

```
obj = expml(obj)
```

Description:

```
expml(obj) computes exp(obj)-1, compensating for the roundoff in  
exp(obj).  
(For small real X, expml(X) should be approximately X, whereas the  
computed value of EXP(X)-1 can be zero or have high relative error.)
```

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = expml(obj);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **extrapolate** ↑

```
obj = extrapolate(obj,toDate)  
obj = extrapolate(obj,toDate,varargin)
```

Description:

Extrapolate the time-series.

Input:

- obj : An object of class nb_dateInExpr
- toDate : Extrapolate to the given date. If the date is before the end date of the given variable no changes will be made, and with no warning. Can also be a integer with the number of periods to extrapolate.

Optional inputs:

- Any

Output:

- obj : An nb_dateInExpr object.

Examples:

```
obj = nb_dateInExpr('2000M1');
obj = extrapolate(obj,'2004M3');
obj = extrapolate(obj,'2004M3','method','ar');
obj = extrapolate(obj,'low','method','ar','freq',4);
```

Written by Kenneth S. Paulsen

► **fillNaN** ↑

```
obj = fillNaN(obj)
obj = fillNaN(obj,date)
```

Description:

Fill in for nan values with last valid observation.

Input:

- obj : An object of class nb_dateInExpr.
- date : The end date of the returned dataset. Either a nb_date object or string with the date, or a number indicating how many periods back in time from the date today, i.e. 0 is today, -1 is past period and 1 is next period. Default is to use the end date of the object.

Caution : If the given date is before the date of the object nothing will be done to the returned object.

Output:

- obj : An object of class nb_dateInExpr.

Examples:

```
d2 = fillNaN(d);
```

Written by Kenneth Sæterhagen Paulsen

► **floor** ↑

```
obj = floor(obj)
```

Description:

floor(obj) rounds the data elements of obj to the nearest integers towards minus infinity

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = floor(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ge** ↑

```
a = ge(a,b)
```

Description:

This method is intended to test if a nb_math_ts object is greater than or equal to another. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- a : An nb_objectInExpr object.

Examples:

```
obj = a >= b;  
obj = 2 >= b;  
obj = a >= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **growth** ↑

```
obj = growth(obj)  
obj = growth(obj,lag,stripNaN)
```

Description:

Calculate approx growth, using the formula: $\log(x(t)) - \log(x(t-1))$.

Input:

- obj : An object of class nb_objectInExpr
- lag : Any
- stripNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = growth(obj);
obj = growth(obj, 4);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► gt ↑

```
a = gt(a,b)
```

Description:

This method is intended to test if a nb_math_ts object is greater than another. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- a : An nb_objectInExpr object.

Examples:

```
obj = a > b;
obj = 2 > b;
obj = a > 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **h21** ↑

```
obj = h21(obj,freq,type)
```

Description:

Map high 2 low frequency observation with converting the frequency of the object.

Input:

- obj : An object of class nb_objectInExpr
- freq : Any
- type : Any

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **horzcat** ↑

```
obj = horzcat(a,b,varargin)
```

Description:

Horizontal concatenation ([a,b])

Input:

- a : An object of class nb_objectInExpr
- b : An object of class nb_objectInExpr
- varargin : Optional number of nb_objectInExpr objects

Output:

obj : An object of class nb_objectInExpr

Examples:

```
obj = [a,b];  
obj = [a,b,c];
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **horzcatfast** ↑

```
obj = horzcatfast(varargin)
```

Description:

Horizontal concatenation

Input:

- a : An object of class nb_objectInExpr
- b : An object of class nb_objectInExpr
- varargin : Optional number of nb_objectInExpr objects

Output:

```
obj : An object of class nb_objectInExpr
```

See also

`nb_dateInExpr.horzcat`

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **hpfilter** ↑

```
obj = hpfilter(obj,lambda)
```

Description:

HP-filtering.

Input:

- obj : An object of class nb_objectInExpr
- lambda : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
gap = hpfilter(data,3000);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **hpfilter1s** ↑

```
obj = hpfilter1s(obj,lambda)
```

Description:

Do one-sided hp-filtering.

Input:

- obj : An object of class nb_objectInExpr
- lambda : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
gap = hpfilter1s(data,3000)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **iegrowth** ↑

```
obj = iegrowth(obj,initialValues,periods)
```

Description:

Inverse of exact growth, i.e. the inverse method of the egrowth method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = iegrowth(obj);
obj = iegrowth(obj,100);
obj = iegrowth(obj,[78,89]);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **iegrowthnan** ↑

```
obj = iegrowthnan(obj)
obj = iegrowthnan(obj,initialValues,periods)
```

Description:

Inverse of exact growth, i.e. the inverse method of the egrowth method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **iepcn** ↑

```
obj = iepcn(obj,initialValues,periods)
```

Description:

Inverse of exact percentage growth, i.e. the inverse method of the epcn method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = iepcn(obj);
obj = iepcn(obj,100);
obj = iepcn(obj,[78,89]);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **iepcnnan** ↑

```
obj = iepcnnan(obj)
obj = iepcnnan(obj,initialValues,periods)
```

Description:

Inverse of exact percentage growth, i.e. the inverse method of the epcn method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **igrowth** ↑

```
obj = igrowth(obj,initialValues,periods)
```

Description:

Inverse of log approx. growth, i.e. the inverse method of the growth method

Input:

```
- obj : An object of class nb_objectInExpr  
- InitialValues : Any  
- periods : Any
```

Output:

```
- obj : An nb_objectInExpr object.
```

Examples:

```
obj = igrowth(obj);  
obj = igrowth(obj,100);  
obj = igrowth(obj,[78,89]);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **igrowthnan** ↑

```
obj = igrowthnan(obj)  
obj = igrowthnan(obj,initialValues,periods)
```

Description:

Inverse of log approx. growth, i.e. the inverse method of the growth method

Input:

```
- obj : An object of class nb_objectInExpr  
- InitialValues : Any  
- periods : Any
```

Output:

```
- obj : An nb_objectInExpr object.
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **interpolate** ↑

```
obj = interpolate(obj,method)
```

Description:

Interpolate.

Input:

- data : A nb_objectInExpr object.
- method : Any

Output:

- data : A nb_objectInExpr object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ipcn** ↑

```
obj = ipcn(obj)
obj = ipcn(obj,initialValues,periods,startAtNaN)
```

Description:

Inverse of percentage log approx. growth, i.e. the inverse method of the pcn method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any
- startAtNaN : Any

Output:

- obj : An nb_objectInExpr object.

Examples:

```
obj = ipcn(obj);
obj = ipcn(obj,100);
obj = ipcn(obj,[78,89]);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ipcnnan** ↑

```
obj = ipcnnan(obj)
obj = ipcnnan(obj,initialValues,periods)
```

Description:

Inverse of percentage log approx. growth, i.e. the inverse method of the pcn method

Input:

- obj : An object of class nb_objectInExpr
- InitialValues : Any
- periods : Any

Output:

- obj : An nb_objectInExpr object.

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **isfinite** ↑

```
obj = isfinite(obj)
```

Description:

Is finite.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = isfinite(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **isnan** ↑

```
obj = isnan(obj)
```

Description:

Is nan.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = isnan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **kurtosis** ↑

```
obj = kurtosis(obj,flag,dim,outputType)
```

Description:

Calculate the kurtosis.

Input:

- obj : An object of class nb_objectInExpr

- flag : Any

- dim : Any

- outputType : - 'nb_math_ts': The result will be an object
of class nb_objectInExpr.

- 'double': The result will be an empty object
of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **lag** ↑

obj = lag(obj,periods)

Description:

Lag method.

Input:

- obj : An object of class nb_objectInExpr

- periods : Any

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = lag(obj,1);

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ldivide** ↑

obj = ldivide(a,b)

Description:

Left element-wise division (.\ \backslash). Same as right element-wise (./) division. See rdivide for more.

Input:

- a : An object of class nb_objectInExpr or a scalar

- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = a.\b;  
obj = 2.\b;  
obj = a.\2;
```

See also:

[rdivide](#), [mldivide](#), [mrdivide](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **le ↑**

```
a = le(a,b)
```

Description:

This method is intended to test if a nb_math_ts object is less than or equal to another. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- a : An nb_objectInExpr object.

Examples:

```
obj = a <= b;  
obj = 2 <= b;  
obj = a <= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **lead ↑**

```
obj = lead(obj,periods)
```

Description:

Lead method.

Input:

- obj : An object of class nb_objectInExpr
- periods : Any

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = lead(obj,1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **log ↑**

```
obj = log(obj)
```

Description:

Log operator

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = log(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **log10 ↑**

```
obj = log10(obj)
```

Description:

Take the common (base 10) log

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = log(obj);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **log1p** ↑

```
obj = log1p(obj)
```

Description:

log1p(obj) computes $\text{LOG}(1+xi)$, where xi are the elements of obj. Complex results are produced if $xi < -1$.

For small real xi, log1p(xi) should be approximately xi, whereas the computed value of $\text{LOG}(1+xi)$ can be zero or have high relative error.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = log1p(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **log2** ↑

```
obj = log2(obj)
```

Description:

log2(obj) is the base 2 logarithm of the elements of obj.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = log2(obj);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **lt ↑**

```
a = lt(a,b)
```

Description:

This method is intended to test if a nb_math_ts object is less than another. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- a : An nb_objectInExpr object.

Examples:

```
obj = a < b;
obj = 2 < b;
obj = a < 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mavg** ↑

```
obj = mavg(obj,backward,forward,flag)
```

Description:

Taking moving avarage

Input:

- obj : An object of class nb_objectInExpr
- backward : Any
- forward : Any
- flag : Any

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **max** ↑

```
obj = max(obj,dim,outputType)
```

Description:

Max

Input:

- obj : An object of class nb_objectInExpr
- dim : Any
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mean** ↑

```
obj = mean(obj,dim,outputType)
```

Description:

Mean

Input:

- obj : An object of class nb_objectInExpr
- dim : Any
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **median** ↑

```
obj = median(obj,dim,outputType)
```

Description:

Median.

Input:

- obj : An object of class nb_objectInExpr
- dim : Any
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an empty object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **merge2Series** ↑

obj = merge2Series(obj,other,method,varargin)

Description:

Merge 2 series.

Input:

- obj : An object of class nb_objectInExpr.

- other : An object of class nb_objectInExpr.

- method : Any

Optional input:

- Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **min** ↑

obj = min(obj,dim,outputType)

Description:

Min

Input:

- obj : An object of class nb_objectInExpr

- dim : Any

- `outputType` : - 'nb_math_ts': The result will be an object of class `nb_objectInExpr`.
 - 'double': The result will be an empty object of class `nb_objectInExpr`.

Output:

- `obj` : An object of class `nb_objectInExpr`

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **minus** ↑

`obj = minus(a,b)`

Description:

Binary subtraction (-).

Input:

- `a` : An object of class `nb_objectInExpr` or a scalar
- `b` : An object of class `nb_objectInExpr` or a scalar

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
obj = a-b;
obj = 2-b;
obj = a-2;
```

See also:

[plus](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **mldivide** ↑

`obj = mldivide(a,b)`

Description:

Matrix left division (\).

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = 2\obj;  
obj = obj\2;
```

See also:

[rdivide](#), [ldivide](#), [mrdivide](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mpower** ↑

```
obj = power(a,b)
```

Description:

Element-wise power (.^)

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = 2^b;  
obj = a^2;
```

See also:

[power](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **mrdivide** ↑

`obj = mrdivide(a,b)`

Description:

Matrix left division (/).

Input:

- `a` : An object of class `nb_objectInExpr` or a scalar
- `b` : An object of class `nb_objectInExpr` or a scalar

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
obj = 2/obj;  
obj = obj/2;
```

See also:

[rdivide](#), [ldivide](#), [mldivide](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **mstd** ↑

`obj = mstd(obj,backward,forward)`

Description:

Moving standard deviation

Input:

- obj : An object of class nb_objectInExpr
- backward : Number of periods backward in time to calculate the moving std
- forward : Number of periods forward in time to calculate the moving std

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **mtimes** ↑

obj = power(a,b)

Description:

Matrix multiplication (*).

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = 2*b;
obj = a*2;

See also:

[times](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ne** ↑

a = ne(a,b)

Description:

This method is intended to test if two nb_math_ts objects are not equal. We therefore just return the a object here as the date the objects represent does not change in this case.

Input:

- a : An object of class nb_objectInExpr or a scalar.
- b : An object of class nb_objectInExpr or a scalar.

Output:

- a : An object of class nb_objectInExpr

Examples:

```
obj = a ~= b;  
obj = 2 ~= b;  
obj = a ~= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **not** ↑

```
obj = not(obj)
```

Description:

The not operator (~)

Input:

- a : An object of class nb_objectInExpr

Output:

- a : An object of class nb_objectInExpr

Examples:

```
obj = ~obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **or** ↑

```
a = or(a,b)
```

Description

The `or` operator (`||`)

Input:

- `a` : An object of class `nb_objectInExpr`
- `b` : An object of class `nb_objectInExpr`

Output:

- `a` : An object of class `nb_objectInExpr`

Examples:

```
a = a | b;
```

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **pca ↑**

```
F = pca(obj)
[F,LAMBDA,R,varF,expl,c,sigma,e,Z] = pca(obj,r,method,varargin)
```

Description:

Principal Component Analysis.

Input:

- `obj` : An object of class `nb_objectInExpr`.
- The rest not important

Output:

- `F` : A `nb_objectInExpr` object.
- `LAMBDA` : A empty `nb_objectInExpr` object.
- `R` : A empty `nb_objectInExpr` object.
- `varF` : A empty `nb_objectInExpr` object.
- `expl` : A empty `nb_objectInExpr` object.
- `c` : A empty `nb_objectInExpr` object.

- sigma : A empty nb_objectInExpr object.
- e : A nb_objectInExpr object.
- Z : A nb_objectInExpr object.

See also:

[nb_pca](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **pca_func** ↑

factors = pca_func(varargin)

Description:

Principal Component of selected number of series represented by a set of nb_objectInExpr.

Optional input:

- varargin : Optional number of nb_objectInExpr objects.
- 'numFactors' : Determine number of Factors to report. Standard is first factor only.
- 'unbalanced' : true or false.
- 'whichFactor' : Select the factor to return.

Output:

- factors : An object of class nb_objectInExpr.

See also:

[nb_dateInExpr.pca](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **pcn** ↑

obj = pcn(obj,lag,stripNaN)

Description:

Calculate log approximated percentage growth. Using the formula
 $(\log(t+lag) - \log(t)) * 100$

Input:

- obj : An object of class nb_objectInExpr
- lag : The number of lags. Default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = pcn(obj); % period-on-period log approx. growth
obj = pcn(obj,4); % 4-periods log approx. growth
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **plus ↑**

```
obj = plus(a,b)
```

Description:

Binary addition (+).

Input:

- a : An object of class nb_objectInExpr or a scalar
- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = a+b;
obj = 2+b;
obj = a+2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **pow2** ↑

```
obj = pow2(obj)
```

Description:

pow2(obj) raises the number 2 to the object

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = pow2(obj);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **power** ↑

```
obj = power(a,b)
```

Description:

Element-wise power (.^)

Input:

- a : An object of class nb_objectInExpr or a scalar

- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = a.^b;
obj = 2.^b;
obj = a.^2;
```

See also:

[mpower](#)

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **q2y** [↑](#)

`obj = q2y(obj)`

Description:

Cumulative sum over the last 4 periods.

Input:

- `obj` : An object of class `nb_objectInExpr`

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

`obj = q2y(obj)`

Written by Kenneth S. Paulsen

Inherited from superclass `NB_OBJECTINEXPR`

► **rdivide** [↑](#)

`obj = rdivide(a,b)`

Description:

Right element-wise division (`./`)

Input:

- `a` : An object of class `nb_objectInExpr` or a scalar
- `b` : An object of class `nb_objectInExpr` or a scalar

Output:

- `obj` : An object of class `nb_objectInExpr`

Examples:

```
obj = a./b;  
obj = 2./b;  
obj = a./2;
```

See also:

[mrdivide](#), [mldivide](#), [ldivide](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **reIndex** ↑

```
obj = reIndex(obj,date)
```

Description:

Reindex the data of the object to a new date.

Input:

- obj : An object of class nb_objectInExpr
- date : Any

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **real** ↑

```
obj = real(obj)
```

Description:

real(obj) returns the real part

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **reallog** ↑

obj = reallog(obj)

Description:

The real natural logarithm

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

obj = reallog(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **realpow** ↑

obj = realpow(a,b)

Description:

Real power.

Input:

- a : An object of class nb_objectInExpr or a scalar

- b : An object of class nb_objectInExpr or a scalar

Output:

- obj : An object of class nb_objectInExpr

See also:

mpower, power

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **realsqrt** ↑

obj = realsqrt(obj)

Description:

realsqrt(obj) is the the real square root

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

out = realsqrt(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **ret** ↑

obj = ret(obj)
obj = ret(obj,nlag)
obj = ret(obj,nlag,skipNaN)

Description:

Calculate return, using the formula: $x(t)/x(t-lag)$.

Input:

- obj : An object of class nb_objectInExpr
- nlag : Any
- skipNaN : Any

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = ret(obj);  
obj = ret(obj,4);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **rlag** ↑

```
obj = rlag(obj,lags)  
obj = rlag(obj,lags,periods)
```

Description:

Roll a pattern in the data forward with a given lag.

Input:

- obj : An object of class nb_objectInExpr
- lags : Any
- periods : The extrapolated periods. The end date of the object will be the current end date plus these number of periods. Be aware that trailing nan values in the data will be filled in for even if periods == 0, which is the default.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **round** ↑

```
obj = round(obj,value,startDate,endDate,pages)
```

Description:

Round to closes value. I.e. if value is 0.25 it will round to the closes 0.25. E.g. 0.67 will be rounded to 0.75.

Input:

```
- obj : A nb_objectInExpr object  
- value : Any  
- startDate : Any  
- endDate : Any  
- variables : Any
```

Output:

```
- obj : A nb_objectInExpr object
```

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sec ↑**

```
obj = sec(obj)
```

Description:

Secant of argument in radians.

Input:

```
- obj : An object of class nb_objectInExpr
```

Output:

```
- obj : An object of class nb_objectInExpr.
```

Examples:

```
obj = sec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **secd ↑**

```
obj = secd(obj)
```

Description:

Secant of argument in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

out = secd(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sech** ↑

obj = sech(obj)

Description:

Hyperbolic secant.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

out = sech(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **set2Value** ↑

obj = set2Value(obj, func, value)

Description:

Set all values applying to the restriction given by the input func to the provided value.

Input:

- obj : An object of class nb_objectInExpr.
- func : Any
- value : Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► setNan2Zero ↑

obj = setNan2Zero(obj)

Description:

Set all nan values of the data of the object to 0.

Input:

- obj : An object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► sgrowth ↑

obj = sgrowth(obj,horizon)

Description:

Calculates smoothed 12 or 6 months growth.

$x(*) = ((x13+x14+x15)/(x1+x2+x3)-1)*100$

$x(*) = ((x7+x8+x9)/(x1+x2+x3)-1)*100$

Input:

- obj : A nb_objectInExpr object
- horizon : Any

Output:

- out : A nb_objectInExpr object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sin** ↑

obj = sin(obj)

Description:

Sine of argument in radians.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr.

Examples:

obj = sin(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sind** ↑

obj = sind(obj)

Description:

Sine of argument in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = sind(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► sinh ↑

```
obj = sinh(obj)
```

Description:

Hyperbolic sine.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = sinh(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► skewness ↑

```
obj = skewness(obj,flag,dim,outputType)
```

Description:

Calculate the skewness

Input:

- obj : An object of class nb_objectInExpr

- flag : Any

- dim : Any

- outputType : - 'nb_math_ts': The result will be an object
of class nb_objectInExpr.

- 'double': The result will be an empty object
of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sqrt** ↑

obj = sqrt(obj)

Description:

Square root.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

out = sqrt(in);

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **std** ↑

obj = std(obj,flag,dim,outputType)

Description:

Standard deviation

Input:

- obj : An object of class nb_objectInExpr

- flag : Any

- dim : Any

- outputType : - 'nb_math_ts': The result will be an object
of class nb_objectInExpr.

- 'double': The result will be an empty object
of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **stdise** ↑

obj = stdise(obj,flag)

Description:

Standardise

Input :

- obj : An object of class nb_objectInExpr

- flag : Any

Output:

- obj : An nb_objectInExpr object

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **subAvg** ↑

obj = subAvg(obj,k,w)

Description:

- Will for the last k periods (including the present) calculate the cumulative sum and then divide by the amount of periods, which gives you the average over those periods.

Input:

- obj : An object of class nb_objectInExpr.

- k : Any

- w : Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **subSum** ↑

obj = subSum(obj, k, w)

Description:

Calculates the cumulative sum over the last k periods (including the present period).

Input:

- obj : An object of class nb_objectInExpr.
- k : Any
- w : Any

Output:

- obj : An object of class nb_objectInExpr.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sum** ↑

obj = sum(obj, dim)

Description:

Takes the sum of the object data in the wanted dimension

Input:

- obj : An object of class nb_objectInExpr
- dim : Any

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = sum(obj,1)
obj = sum(obj,2)
obj = sum(obj,3)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **sumOAF** ↑

```
obj = sumOAF(obj,sumFreq)
```

Description:

Take the sum over a lower frequency.

Input:

- obj : An object of class nb_objectInExpr
- sumFreq : Any

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **tan** ↑

```
obj = tan(obj)
```

Description:

Tangent

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr.

Examples:

```
obj = tan(obj);  
  
Written by Kenneth S. Paulsen  
  
Inherited from superclass NB_OBJECTINEXPR
```

► **tand** ↑

```
obj = tand(obj)
```

Description:

tand(obj) is the tangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = tand(in);
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **tanh** ↑

```
obj = tanh(obj)
```

Description:

Hyperbolic tangent.

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
out = tanh(in);  
  
Written by Kenneth Sæterhagen Paulsen  
  
Inherited from superclass NB_OBJECTINEXPR
```

► **times** ↑

```
obj = times(a,b)
```

Description:

Element-wise multiplication (.*)

Input:

- a : An object of class nb_objectInExpr or a scalar double
- b : An object of class nb_objectInExpr or a scalar double

Output:

- obj : An object of class nb_objectInExpr

See also:

[mtimes](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **uminus** ↑

```
obj = uminus(obj)
```

Description

Unary minus

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = -obj;

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR
```

► **undiff** ↑

```
obj = undiff(obj,initialValues,periods)
```

Description:

Inverse of the diff method.

Input:

- obj : An object of class nb_objectInExpr.
- initialValues : Any.
- periods : Any.

Output:

- Output : An object of class nb_objectInExpr.

See also
nb_dateInExpr.diff

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **uplus** ↑

```
obj = uplus(obj)
```

Description:

Unary plus

Input:

- obj : An object of class nb_objectInExpr

Output:

- obj : An object of class nb_objectInExpr

Examples:

```
obj = +obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **var** ↑

```
obj = var(obj,dim,outputType)
```

Description:

Variance

Input:

- obj : An object of class nb_objectInExpr
- dim : Any
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_objectInExpr.
 - 'double': The result will be an object of class nb_objectInExpr.

Output:

- obj : An object of class nb_objectInExpr

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **vertcat** ↑

```
obj = vertcat(a,b,varargin)
```

Description:

Vertical concatenation ([a;b])

Input:

- a : An object of class nb_objectInExpr
- b : An object of class nb_objectInExpr
- varargin : Optional numbers of objects of class nb_objectInExpr

Output:

- a : An nb_objectInExpr object

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **window** ↑

```
obj = window(obj,startDateWin,endDateWin, pages)
```

Description:

Narrow down window

Input:

- obj : An object of class nb_dateInExpr

- startDateWin : Any

- endDateWin : The new wanted end date of the data of the object. Must be a string on the format. 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the end date of the data.

Can also be an object which is a subclass of the nb_date class.

- pages : Any

Output:

- obj : An object of class nb_dateInExpr

Written by Kenneth S. Paulsen

► **x12** ↑

```
obj = x12(obj,range,varargin)
```

Description:

Seasonally adjust

Input:

```
- obj : An object of class nb_objectInExpr.  
- range : Any  
  
Optional input (..., 'propertyName', propertyName, ...):  
Any
```

Output:

```
- obj : An object of class nb_objectInExpr.
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_OBJECTINEXPR

► **x12Census** ↑

```
obj = x12Census(obj)  
[obj,x,outputfile,errorfile,model] = x12Census(obj)  
[obj,x,outputfile,errorfile,model] = x12Census(obj,varargin)
```

Description:

Do x12 Census

Input:

```
- obj : An object of class nb_objectInExpr.  
  
Optional input (..., 'propertyName', propertyName, ...):  
  
Any.
```

Output:

```
- obj : An object of class nb_objectInExpr.  
- x : An object of class nb_objectInExpr.  
- outputfile : ''  
- errorfile : {}  
- mdl : []
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_OBJECTINEXPR

■ **nb_day**
Go to: [Properties](#) | [Methods](#)

A class representing a daily date.

Superclasses:

`nb_date`

Constructor:

```
obj = nb_day(day)
obj = nb_day(day,month,year)
```

Input:

- day : A string on one of the following date formats:

```
> 'yyyyMm(m)Dd(d)', e.g. '2012M1D10'
> 'dd.mm.yyyy', e.g. '10.01.2012'
> 'ddmonyyyy', e.g. '10jan2012'
> 'yyyymmdd', e.g. '20121231'
```

Or an integer with the day. (Must be combined with the month and year arguments)

- month : Must be an integer with the month.

- year : Must be an integer with the year.

Output:

- obj : An `nb_day` object.

Examples:

```
obj = nb_day('2012M1D10');
obj = nb_day(1,1,2012);
```

See also:

[nb_date](#), [nb_year](#), [nb_semiAnnual](#), [nb_quarter](#), [nb_month](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- `baseYear`
- `day`
- `dayNr`
- `dayOfWeek`
- `frequency`
- `leapYear`
- `month`
- `quarter`
- `year`

- **baseYear** ↑

The base year. 2000.

Inherited from superclass `NB_DATE`

- **day** ↑

The given day as a double

- **dayNr** ↑

The number of days since the base year, which is 1.1.2000

- **dayOfWeek** ↑

The day which the weekly date represents when converted to or from a weekly frequency. Default is 1, which is sunday.

Inherited from superclass NB_DATE

- **frequency** ↑

The frequency of the date. Must be 365.

- **leapYear** ↑

Indicator for leap year. 1 if leap year.

Inherited from superclass NB_DATE

- **month** ↑

The month of the given day

- **quarter** ↑

The quarter of the given day

- **year** ↑

The year of the given day

► **ascensionDay** ↑

```
day = ascensionDay(obj,~)
```

Description:

Give the ascension day of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

[nb_easter](#), [nb_day.easter](#), [nb_day.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **cell2Date** ↑

```
obj = nb_date.cell2Date(cellstr,freq)
```

Description:

Converts a cellstring of dates into a nb_date object.

Input:

- cellstr : The cellstring of dates that you want to convert.

- freq : The frequency of your data. You can choose between 1, 2, 4, 12, 52, and 365.

Output:

- date : A NumberOfDatesx1 vector containing nb_date objects.

Examples:

```
g = {'2011Q2'
      '2011Q3'
      '2011Q4'
      '2012Q1'
      '2012Q2'
```

```
'2012Q3'  
'2012Q4'  
'2013Q1'  
'2013Q2'}  
  
a = nb_date.cell2Date(g,4)  
  
a =  
  
'2011Q2'  
'2011Q3'  
'2011Q4'  
'2012Q1'  
'2012Q2'  
'2012Q3'  
'2012Q4'  
'2013Q1'  
'2013Q2'
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **christmas** ↑

```
day = christmas(obj,~)
```

Description:

Give the holidays of christmas (25th and 26th) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_day.ascensionDay](#), [nb_day.pentecost](#), [nb_day.easter](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **colon** ↑

```
cellStr = colon(a,d,b)
```

Description:

Overload the : operator. The result is a cellstr array of all the dates between the a and b (Including the a and b dates).

Input:

- a : An object of class nb_date or of a subclass of the nb_date class
- d : Increments between the dates
- b : An object of class nb_date or of a subclass of the nb_date class

Output:

- cellStr : A cellstr array of the periods between the dates represented by a and b. (Including the dates a and b). If a and b are nb_date object an empty cell is returned.

Examples:

```
dates = a:b;
dates = a:2:b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► convert ↑

```
obj = convert(obj,frequency,first)
```

Description:

Convert the nb_day object ot the wanted frequency. The return variable will be an object which is of an subclass of the nb_date class.

Input:

- obj : An object of class nb_day
- frequency : The frequency to convert to. As a scalar.
- first : Does nothing. Just to make the code general for all frequencies.

Output:

- obj : An object of subclass of the nb_date class with the frequency given by the frequency input.

Examples:

```
obj = nb_day(1,1,2012);
obj = obj.convert(1);
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **date2freq ↑**

```
[startDate,frequency,type] = nb_date.date2freq(dates,xls)
```

Description:

A static method of the nb_date class.

Find out the frequency of the data (also from a xls(x) worksheet)

When trying to figure out the frequency of excel dates, this function must have at least two following dates

```
yearly      : 'yyyy' or 'dd.mm.yyyy'
semiannually : 'yyyySs' or 'dd.mm.yyyy'
quarterly   : 'yyyyQq' or 'yyyyKk', 'dd.mm.yyyy'
monthly     : 'yyyyMm(m)' or 'dd.mm.yyyy'
weekly       : 'yyyyWw(w)' or 'dd.mm.yyyy'
daily        : 'yyyyMm(m)Dd(d)', 'ddmonyyyy' or 'dd.mm.yyyy'
```

Input:

- dates : A cellstr of the dates you want to test the frequency of.
- xls : > 'xls' : If you want to test if the dates is on the format 'dd.mm.yyyy' also
> otherwise will not (default)

Output:

- startDate : An object which is a subclass of the class nb_date, with the start date of the input dates. (Either nb_quarter, nb_month, nb_semiAnnual, nb_year, nb_week or nb_day)
- frequency : The frequency of the dates given.
> 1 : yearly

```
> 2    : semiannually  
> 4    : quarterly  
> 12   : monthly  
> 52   : weekly  
> 365  : daily  
  
- type      : 1 if the dates input is on the xls format,  
               otherwise 0
```

Examples:

```
dates = {'01.01.2012','02.01.2012','03.01.2012'};  
[startDate,frequency,type] = nb_date.date2freq(dates,'xls');
```

The output will in this example be:

- startDate : An nb_day object representing the date '01.01.2012'
- frequency : 365
- type : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **disp** ↑

```
disp(obj)
```

Description:

Sets how the nb_date object is displayed, and all subclasses of the nb_date class

Input:

- obj : An object of class nb_date or of a subclass of the nb_date class.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **easter** ↑

```
day = easter(obj,type)
```

Description:

Give the holidays or the sunday of easter of the year the date is located.

Input:

- obj : An object of class nb_date.
- type : 'all' or 'sunday' (default).

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_day.ascensionDay](#), [nb_day.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **eq** ↑

```
ret = eq(obj,aObj)
```

Description:

Tests if the two objects represent the same dates

Input:

- obj : An object of class nb_day
- aObj : Another object of class nb_day

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj == aObj;
```

Written by Kenneth S. Paulsen

► **format2string** ↑

```
date = nb_date.format2string(obj,format)
date = nb_date.format2string(obj,format,language,first)
```

Description:

Get date at a given format.

Input:

- obj : An object of a subclass of nb_date.
- format : A string with the format. A combination of the following patterns:

- d : Day of the date. Examples:

```
> 'dd'   : '01', '10'  
> 'd'    : '1', '0'  
> 'd(d)': '1', '10'  
- w : Week of date. Same options as for d.  
- m : Month of date. Same options as for d.
```

- q : Quarter of date. Examples:

```
> 'q'   : '1', '4'  
- h : Half year of date. Same options as for h.  
- y : Year of date.  
    > 'yyyy' : '2016'  
    > 'yy'   : '16'  
    < 'y'    : '6'
```

Caution: To use the actual letter of the patterns use \ in front of the letter. E.g. '\y'.

Extra (see also the language option):

- 'Monthtext' : Month of date as full text. Starting with upper case.
- 'monthtext' : Month of date as full text. Starting with upper case.
- 'Quartertext' : > 'norwegian' : '. kv.'
 > 'english' : 'Q'
- 'Weektext' : > 'norwegian' : 'Uke'
 > 'english' : 'Week'
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- date : A string of the date on the wanted format.

Examples:

```
d      = nb_day.today();  
date = nb_date.format2string(d,'dd.mm.yyyy');
```

```

date = nb_date.format2string(d,'d(d).m(m).yyyy');
date = nb_date.format2string(d,'d(d) Monthtext yyyy');
date = nb_date.format2string(d,'d(d). monthtext yyyy','norwegian');

m     = nb_month.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'Monthtext yyyy');
date = nb_date.format2string(m,'Monthtext yyyy','norwegian');

q     = nb_quarter.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'qQ yyyy');
date = nb_date.format2string(m,'q. kv. yyyy');

y     = nb_year.today();
date = nb_date.format2string(y,'dd.mm.yyyy');
date = nb_date.format2string(y,'yyyy');
date = nb_date.format2string(y,'\year yyyy');

```

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► [freqPlus ↑](#)

obj = freqPlus(obj,incr,freq)

Description:

Plus the number of periods of another (lower) frequency.

E.g. dayNextYear = freqPlus(day,1,1);

Input:

- obj : An object of class nb_date.
- periods : A scalar integer with the periods to add.
- freq : The frequency of the periods argument.

Output:

- ob : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **fromxlsDates2freq** ↑

```
frequency = nb_date.fromxlsDates2freq(dates)
```

Description:

A static method of the nb_date class.

Try to find out the date frequency of the excel dates. I.e. dates on the format 'dd.mm.yyyy'.

Input:

- Dates : A cellstr with at least two dates on the date format 'dd.mm.yyyy'.

Output:

- frequency : The frequency of the input dates given as an integer.

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2
> Yearly	:	1

Examples:

```
dates      = {'01.01.2012','02.01.2012','03.01.2012'};  
frequency = nb_date.fromxlsDates2freq(dates)
```

The output will in this example be:

- frequency : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **ge** ↑

```
ret = ge(obj,aObj)
```

Description:

Tests if an object is greater than or equal to another object.
Which will mean that the first input is after or the same
as the second input in the calendar

Input:

- obj : An object of class nb_day
- aObj : Another object of class nb_day

Output:

- ret : 1 if obj >= aObj, 0 else

Examples:

```
ret = obj >= aObj;
```

Written by Kenneth S. Paulsen

► **getDate** ↑

```
date = getDate(obj, freq)
```

Description:

Get the date of the object at another frequency.

Input:

- obj : An object of class nb_day
- freq : The frequency you want to convert to.
 - 1 : nb_year
 - 2 : nb_semiAnnual
 - 4 : nb_quarter
 - 12 : nb_month
 - 52 : nb_week
 - 365 : nb_day

Output:

- date : The date of the object at the new frequency. As an object which is a subclass of the nb_date class.

Examples:

```
date = obj.getDate(4); % Will return a nb_quarter object
```

See also:

[nb_day.convert](#)

Written by Kenneth S. Paulsen

► **getEarliestDate** ↑

```
date = nb_date.getEarliestDate(c)
```

Description:

Get the earliest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getFreq** ↑

```
freq = getFreq(obj)
```

Description:

Gets the frequency of the object.

Input:

- obj : An object of class nb_day

Output:

- freq : 365

Examples:

```
freq = obj.getFreq();
```

Written by Kenneth S. Paulsen

► **getFrequencyAsInteger** ↑

```
frequency = nb_date.getFrequencyAsInteger(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as an integer given a frequency as a string

Input:

- frequency : Frequency input as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly', 'annual'

Output:

- frequency : The frequency as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Examples:

```
frequency = nb_date.getFrequencyAsInteger('yearly')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getFrequencyAsString** ↑

```
frequency = nb_date.getFrequencyAsString(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as a string given a frequency as an integer

Input:

- frequency : Frequency input as an integer

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2
> Yearly	:	1

Output:

- frequency : The frequency as a string

> Daily	:	'daily'
> Weekly	:	'weekly'
> Monthly	:	'monthly'
> Quarterly	:	'quarterly'
> Semiannually	:	'semiannually'
> Yearly	:	'yearly'

Examples:

```
frequency = nb_date.getFrequencyAsString(1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getHalfYear** ↑

```
halfYear = getHalfYear(obj)
```

Description:

```
Get the half year of the day, given as an nb_semiAnnual object
```

Input:

- obj : An object of class nb_day

Output:

- halfYear : An nb_semiAnnual object

Examples:

```
halfYear = obj.getHalfYear(); % Will return the half year
```

Written by Kenneth S. Paulsen

► **getLatestDate** ↑

```
date = nb_date.getLatestDate(c)
```

Description:

Get the latest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATE

► **getMonth** ↑

```
month = getMonth(obj)
```

Description:

Get the month of the day, given as a nb_month object

Input:

- obj : An object of class nb_day

Output:

- month : An nb_month object

Examples:

```
month = obj.getMonth(); % Will return the month
```

Written by Kenneth S. Paulsen

► **getNr** ↑

```
nr = getNr(obj)
```

Description:

Get date number of a nb_date vector.

Input:

- obj : A vector of nb_date objects.

Output:

- nr : A double with the date numbers of each object in the nb_date vector.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getNumberOfDaysInMonth** ↑

```
numberOfDays = nb_day.getNumberOfDaysInMonth(month, leapYear)
```

Description:

A static method of the class nb_day.

Get the number of days in the given month

Input:

```
- month      : An object of the class nb_day  
- leapYear  : 1 if leapYear, 0 else
```

Output:

```
- numberOfDaysInMonth : Returns the number of days in the current  
month
```

Examples:

```
numberOfDays = nb_day.getNumberOfDaysInMonth(2,1); % returns 29  
numberOfDays = nb_day.getNumberOfDaysInMonth(2,0); % returns 28  
numberOfDays = nb_day.getNumberOfDaysInMonth(3,1); % returns 31
```

Written by Kenneth S. Paulsen

► **getNumberOfDaysUntilNowInMonth ↑**

```
numberOfDaysUntilNowInMonth = getNumberOfDaysUntilNowInMonth(obj)
```

Description:

Get the number of days in the current month

Input:

```
- obj : An object of class nb_day
```

Output:

```
- numberOfDaysUntilNowInMonth : Number of days of the current  
month of the date object.
```

Examples:

```
ret = obj.getNumberOfDaysUntilNowInMonth();
```

Written by Kenneth S. Paulsen

► **getNumberOfDaysUntilNowInYear ↑**

```
numberOfDaysUntilNowInYear = getNumberOfDaysUntilNowInYear(obj)
```

Description:

Get the number of days until now in the current year

Input:

- obj : An nb_day object

Output:

- `numberOfDaysUntilNowInYear` : Number of days until now in the current year as a double.

Examples:

```
ret = obj.getNumberOfDaysUntilNowInYear();
```

Written by Kenneth S. Paulsen

► **getQuarter** ↑

```
quarter = getQuarter(obj)
```

Description:

Get the quarter of the day, given as a nb_quarter object

Input:

- obj : An object of class nb_day

Output:

- quarter : An nb_quarter object

Examples:

```
quarter = obj.getQuarter(); % Will return the current quarter
```

Written by Kenneth S. Paulsen

► **getWeek** ↑

```
week = getWeek(obj,dayOfWeek)
```

Description:

Get the week of the day, given as an nb_week object

Input:

- obj : An object of class nb_day
- dayOfWeek : The weekday the given week represents when converted to a day. (1-7 (Monday-Sunday)). Default is to use the weekday(obj).

Output:

- week : An nb_week object

Examples:

```
week = obj.getWeek();      % Will return the week of the day
```

Written by Kenneth S. Paulsen

► **getWeekNumber ↑**

```
[weekNum,weekDay,yearN] = getWeekNumber(obj)
```

Description:

Get week number and weekday of a nb_day object.

Input:

- obj : A nb_day object.

Output:

- weekNum : The week number that the day is in. As a double.
- weekDay : The weekday of the day. As an integer. Sun: 1, Mon: 2, Tue: 3, Wed: 4, Thu: 5, Fri: 6, Sat: 7.
- yearN : The year of the day, as a double.

Written by Kenneth Sæterhagen Paulsen

► **getYear ↑**

```
year = getYear(obj)
```

Description:

Get the year of the day, given as a nb_year object

Input:

- obj : An object of class nb_day

Output:

- year : A nb_Year object

Examples:

```
day = nb_day(1,1,2020);
year = day.getYear(); % Will return the current year
```

Written by Kenneth S. Paulsen

► gt ↑

```
ret = gt(obj,aObj)
```

Description:

Tests if an object is greater than another object. Which will mean that the first input is after the second input in the calendar

Input:

- obj : An object of class nb_day
- aObj : An object of class nb_day

Output:

- ret : 1 if obj > aObj, 0 else

Examples:

```
ret = obj > aObj;
```

Written by Kenneth S. Paulsen

► holidays ↑

```
days = holidays(obj)
```

Description:

Find the holidays of the given date object.

Input:

- obj : An object of class nb_month, nb_quarter, nb_semiAnnual or nb_year.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_day.easter](#), [nb_day.ascensionDay](#), [nb_day.pentecost](#)
[nb_day.christmas](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **initialize** ↑

```
obj = nb_date.initialize(freq, dim1, dim2)
```

Description:

Initialize a vector of date objects.

Input:

- freq : The wanted frequency of the date of today. 1,2,4,12,52 or 365.
- dim1 : The size of the first dimension.
- dim2 : The size of the second dimension.

Output:

obj : A vector of nb_date objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **intersect** ↑

```
cout = nb_date.intersect(varargin)
```

Description:

Get the intersection of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **isDate** ↑

```
ret = nb_date.isDate(input,freq)
```

Description:

Test if a string or nb_date object is a date. It is also possible to restrict the test to a specific frequency.

Input:

- input : Any object
- freq : 1, 2, 4, 12, 52 or 365. Can also be empty, but then it is slower.
- locVar : A nb_struct/struct with the supported local variables. If the input is a string using the syntax '%#name', this input will be looked up and tested.

Output:

- ret : Either true or false. true if input is a date string or nb_date object.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **isEqualFreq** ↑

```
ret = isEqualFreq(obj,aObj)
```

Description:

Test if two date objects have the same frequency

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class
- aObj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : 1 if equal frequency, 0 else

Examples:

```
d = nb_day(1,1,2012);
q = nb_quarter(4,2012);
ret = d.isEqualFreq(q); % Will return 0
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isFirstPeriod** ↑

```
ret = isFirstPeriod(obj,freq)
```

Description:

Return if the obj represent the first period a lower frequency.

Input:

- obj : An object which of a subclass of the nb_date class.
- freq : The lower frequency.

Output:

- ret : True if the object represent the first period of the lower frequency.

Examples:

```
q = nb_quarter(1,2000)
ret = isFirstPeriod(q,1)

m = nb_month(10,2000)
ret = isFirstPeriod(m,4)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isLeapYear** ↑

```
ret = isLeapYear(obj)
```

Description:

Test if the current year is a leap year

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : Logical. 1 if object is leap year, 0 else

Examples:

```
ret = obj.isLeapYear();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isPeriod** ↑

```
ret = isPeriod(obj,period)
```

Description:

Return true if the obj represent the given period, i.e. if you want to test if a nb_quarter object represent the first period of any year you can use isPeriod(obj,1).

Input:

- obj : An object which of a subclass of the nb_date class.
- period : The period to test for.

Output:

- ret : True if the object represent the period to test for, else false.

Examples:

```
q    = nb_quarter(1,2000)
ret = isPeriod(q,1)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE
```

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if the object is empty

Input:

- obj : An object of class nb_day

Output:

- ret : 1 if empty, 0 else. Always false for vectors of objects.

Examples:

```
ret = obj.isempty();
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **isequal** ↑

```
ret = isequal(obj,aObj)
```

Description:

Tests if the two objects representing the same date

Input:

- obj : An object of class nb_day
- aObj : Another object of class nb_day

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj.isequal(aObj);
ret = isequal(obj,aObj);
```

Written by Kenneth S. Paulsen

► **ismember** ↑

- varargout = ismember(obj1,obj2)

Description:

Utilizes the inbuilt MATLAB function 'ismember' for nb_date objects.

Input:

- obj1 : A nb_date object
- obj2 : A nb_date object

Output:

- varargout : See help on MATLAB function 'ismember'.

See also:

[ismember](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **le** ↑

ret = le(obj,aObj)

Description:

Tests if an object is less then or equal to another object.
Which will mean that the first input is before or the same as
the second input in the calendar.

Input:

- obj : An object of class nb_day
- aObj : An object of class nb_day

Output:

- ret : 1 if obj <= aObj, 0 else

Examples:

ret = obj <= aObj;

Written by Kenneth S. Paulsen

► **lt** ↑

ret = lt(obj,aObj)

Description:

Tests if an object is less than another object. Which will mean that the first input is before the second input in the calendar

Input:

- obj : An object of class nb_day
- aObj : An object of class nb_day

Output:

- ret : 1 if obj < aObj, 0 else

Examples:

ret = obj < aObj;

Written by Kenneth S. Paulsen

► **max** ↑

d = max(obj)
[d,ind] = max(obj)
d = max(obj,aObj)

Description:

Find the max date.

Input:

One input:

- obj : A vector of nb_day objects.

Two inputs:

- obj : A scalar nb_day object.

- aObj : A scalar nb_day object.

Output:

- d : A scalar nb_day object.

- ind : The index of the last date.

Written by Kenneth Sæterhagen Paulsen

► **min ↑**

```
d      = min(obj)
[d,ind] = min(obj)
d      = min(obj,aObj)
```

Description:

Find the min date.

Input:

One input:

- obj : A vector of nb_day objects.

Two inputs:

- obj : A scalar nb_day object.

- aObj : A scalar nb_day object.

Output:

- d : A scalar nb_day object.

- ind : The index of the first date.

Written by Kenneth Sæterhagen Paulsen

► **minus ↑**

```
output = minus(obj,aObj)
```

Description:

Makes it possible to take an nb_day object minus another nb_day object and get the number of days between them.

It makes it also possible to take the difference between an nb_day object and a string one one of the following formats:
'yyyyMm(m)Dd(d)', 'dd.mm.yyyy'

And last it makes it possible to subtract the number of days from an nb_day object and receive an nb_day representing the day the given number of days backward in time.

Input:

- obj : A date string, an nb_day object or an integer.
- aObj : A date string, an nb_day object or an integer.

Output:

- output : The number of days between the given days. As a double

or

An nb_day object representing the date the given number of days backwards in time.

Examples:

```
output = obj - aObj;           % (both objects). Returns a double
output = obj - '2012M1D1';    % Returns a double
output = '2012M12D23' - obj;  % Returns a double
output = obj - 1;              % Returns an object
same as
output = 1 - obj;             % Returns an object
```

Written by Kenneth S. Paulsen

► **ne ↑**

```
ret = ne(obj,aObj)
```

Description:

Tests if the two objects not representing the same date

Input:

- obj : An object of class nb_day
- aObj : An object of class nb_day

Output:

- ret : 1 if obj is not equal to aObj, 0 else

Examples:

```
ret = obj ~= aObj;
```

Written by Kenneth S. Paulsen

► **pentecost** ↑

```
day = pentecost(obj,~)
```

Description:

Give the pentecost (monday) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_day.easter](#), [nb_day.ascensionDay](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **plus** ↑

```
out = plus(obj,aObj)
```

Description:

Makes it possible to add a given number of days to an nb_day and receive a nb_day object which represents the day the given numbers of days ahead

Input:

- obj : A nx1 double or a nx1 nb_day object
- aObj : A nx1 double or a nx1 nb_day object

Output:

- out : A nx1 nb_day object with the given number of years ahead

Examples:

```
obj = obj + 1;
```

same as

```
obj = 1 + obj;
```

Written by Kenneth S. Paulsen

► **setDayOfWeek** ↑

```
obj = setDayOfWeek(obj,dayOfWeek)
```

Description:

Set the day of week number of a set of nb_date objects.

Input:

- obj : A nb_date object. May be a vector or matrix.

Output:

- obj : A nb_date object with the same size as the obj input.

See also:

[nb_day.dayOfWeek](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **sort** ↑

```
[obj,ind] = sort(obj)
```

Description:

Sort a vector of nb_date objects.

Input:

- obj : A vector of nb_date objects.

Output:

- obj : A sorted vector of nb_date objects.

- ind : The index of the sorting.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **toDate ↑**

```
dObj = nb_date.toDate(date,frequency)
```

Description:

A static method of the nb_date class.

Transform a given date string to the corresponding date object given that the frequency is already known.

If the frequency is not known, use the method date2freq() (handles also excel dates) or getFreq() (Only nb_ts dates).

Input:

- date :

Supported date formats:

- > Daily : 'dd.mm.yyyy' and 'yyyyMm(m)Dd(d)'
- > Weekly : 'dd.mm.yyyy' and 'yyyyWw(w)'
- > Monthly : 'dd.mm.yyyy' and 'yyyyMm(m)'
- > Quarterly : 'dd.mm.yyyy' and 'yyyyQq'
- > Semiannually : 'dd.mm.yyyy' and 'yyyySs'
- > Yearly : 'dd.mm.yyyy' and 'yyyy'
- > Secondly : 'yyyy-mm-dd hh:nn:ss' and 'yyyymmddhhnnss'

(only supported if this version of the toolbox
includes the nb_second class)

- frequency :

```
> Daily      : 365
> Weekly     : 52
> Monthly    : 12
> Quarterly  : 4
> Semiannually : 2
> Yearly     : 1
> Secondly   : 31536000
```

Output:

- dObj :

```
> Daily      : An nb_day object
> Weekly     : An nb_week object
> Monthly    : An nb_month object
> Quarterly  : An nb_quarter object
> Semiannually : An nb_semiAnnual object
> Yearly     : An nb_year object
> Secondly   : An nb_second object
```

Examples:

```
dObj = nb_date.toDate('2012M1D1',365);
dObj = nb_date.toDate('2012M1',12);
dObj = nb_date.toDate('2012Q1',4);
dObj = nb_date.toDate('2012S1',2);
dObj = nb_date.toDate('2012',1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **toDates ↑**

```
varargout = toDates(obj,periods,format,newFreq,first)
```

Description:

Get a cellstr array of the dates ahead

Input:

- obj : An object of class nb_day
- periods : The periods wanted, must be given as a double array.
E.g. 1:20.
- format : Set the format of the cellstr of dates:
 - > 'nb_date' : The output will be a vector of nb_date objects.
 - > 'default' : 'yyyyMm(m)Dd(d)'
 - > 'fame' : 'ddmonyyyy', e.g. '10jan2012'
 - > 'xls' : 'dd.mm.yyyy'
 - > 'vintage' : 'yyyymmdd'

Formats which is dependent on the 'newFreq' input

> 'NBNorsk' ('NBNorwegian'):

```
newFreq;  
> 1 : 'YYYY'  
> 2 : 'mmm. yy', e.g. 'jan. 08' and 'jul. 08'  
> 4 : 'q.kv.yy'  
> 12 : 'mmm. yy', e.g. mmm = 'jan'  
> 52 : 'Ukew(w)-yy'  
> 365 : 'dd.mm.yyyy'
```

(Date strings are only given for the days which ends the periods)

> 'NBEnglish' ('NBEngelsk'):

```
newFreq;  
> 1 : 'YYYY'  
> 2 : 'mmm-yy', e.g. 'jan. 08' and 'jul. 08'  
> 4 : 'yyyyQq'  
> 12 : 'mmm-yy', e.g. mmm = 'jan'  
> 52 : 'Weekw(w)-yy'  
> 365 : 'dd.mm.yyyy'
```

(Date strings are only given for the days which ends the periods)

- newFreq : > 1 : yearly
> 2 : semiannually
> 4 : quarterly
> 12 : monthly
> 365 : daily
- first : When converting to a lower frequency you must set if you want to use the first date or the last date as the location of the returned date. The default is to use the first.

```
1 = first  
0 = last
```

Output:

- varargout{1} : A cell array of the wanted dates.
- varargout{2} : Locations of the returned dates. Of interest when converting to lower frequencies

Examples:

```
obj          = nb_day(1,1,2000);  
dates        = obj.toDates(0:2000);  
dates        = obj.toDates(0:2000,'xls');  
dates        = obj.toDates(0:2000,'nb_date',12)  
[dates,locations] = obj.toDates(0:2000,'NBNorsk',1);
```

Written by Kenneth S. Paulsen

► **toFormat ↑**

```
dates = toFormat(start,finish,format,language,first)
```

Description:

Convert dates vector to a given format.

Input:

- start : An object of a subclass of the nb_date class.
- finish : An object of a subclass of the nb_date class.
- format : See the format input to the nb_date.format2string method.
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- vint : A cellstr.

See also:

[nb_day.format2string](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **toString** ↑

```
date = toString(obj,format,first)
```

Description:

Transform the nb_day object to a string representing the date.

Input:

- obj : An object of class nb_day
- format :
 - > 'xls' : 'dd.mm.yyyy'
 - > 'pprnorsk' or 'mprnorwegian' : 'd(d). monthtext yyyy'
 - > 'pprengelsk' or 'mprenglish' : 'd(d) Monthtext yyyy'
 - > 'default' (otherwise) : 'yyyyMm(m)Dd(d)'
 - > 'vintage' : 'yyyymmdd'
- first :
 - 'xls' : If 1 is given, the first day of the current month will be returned. Default is not.

Output:

- date : A string with the date on the wanted format

Examples:

```
obj = nb_day(1,1,2012);
date = obj.toString(); % Will give '2012M1D1'
date = obj.toString('xls'); % Will give '01.01.2012'
date = obj.toString('xls',0); % Will give '01.01.2012'
date = obj.toString('nborsk'); % Will give '2012M1D1'
date = obj.toString('nbengelsk'); % Will give '2012M1D1'
date = obj.toString('pprnorsk'); % Will give '1. januar 2012'
date = obj.toString('pprnorsk',0); % Will give '1. januar 2012'
date = obj.toString('pprengelsk'); % Will give '1 January 2012'
```

Written by Kenneth S. Paulsen

► **today** ↑

```
obj = nb_day.today()
```

Description:

Get the current day as a nb_day object.

Output:

obj : An object of class nb_day.

Written by Kenneth SÃ¶terhagen Paulsen

► **union** ↑

```
cout = nb_date.union(varargin)
```

Description:

Get the union of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **unique** ↑

```
obj = unique(obj)
```

Description:

Get unique elements of a vector of nb_date objects.

Input:

- in : A vector of nb_date objects.

Output:

```
- out : A unique (sorted) vector of nb_date objects.  
- IA : out = in(IA)  
- IC : A = C(IC)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **vec** ↑

```
out = vec(obj,endD)
```

Description:

A method to create a vector of dates between two dates.

Input:

```
obj : A nb_day object which represents the start date of the vector  
end : A nb_day object or a double, representing the end date or the  
number of periods you want in your vector
```

Output:

```
obj : A nPeriods*1 vector of nb_day objects.
```

Examples:

```
f = nb_day(1,1,2010);  
g = nb_day(10,1,2010);  
vector = f.vec(g)
```

See also:

[nb_day](#)

Written by Tobias Ingebrigtsen

► **vintage2Date** ↑

```
date = nb_date.vintage2Date(vintage,freq)
```

Description:

This method converts a vintage date into a nb_date object with the wanted frequency. You can also convert a cellstring containing multiple vintage dates.

Input:

- vintage : Either the vintage date that you want to convert, or a cellstring containing the vintage dates you want to convert.
- freq : The wanted frequency. Your options are 1, 4, 12 or 365.

Output:

- date : A 1xNumberOfVintages vector containing nb_date object(s).

Examples:

```
f = '20110622'  
t = nb_date.vintage2Date(f,4)
```

OR

```
f = {'20110622','20111019','20120314'} |  
t = nb_date.vintage2Date(f,4)
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► weekday ↑

```
[dayNum,dayName] = weekday(obj)
```

Description:

Get weekday of daily date.

Input:

- obj : An object of class nb_day.
- language : 'english' (default) or 'norwegian'.

Output:

- dayNum : As an integer. Sun: 1, Mon: 2, Tue: 3, Wed: 4, Thu: 5, Fri: 6, Sat: 7
- dayName : As a string. (A cellstr if numel(obj) > 1)

Written by Kenneth Sæterhagen Paulsen

■ nb_month

Go to: [Properties](#) | [Methods](#)

A class representing a monthly date.

Superclasses:

[nb_date](#)

Constructor:

`obj = nb_month(month,year)`

Input:

- month : A string on one of the following date formats:

> 'yyyyMm(m)'

> 'dd.mm.yyyy'

Or an integer with the month. (Must be combined with the year argument)

- year : Must be an integer with the year.

Output:

- obj : An nb_month object.

Examples:

```
obj = nb_month('2012M1');
obj = nb_month('01.01.2012');
obj = nb_month(1,2012);
```

Properties:

- [baseYear](#)
- [dayOfWeek](#)
- [frequency](#)
- [leapYear](#)
- [month](#)
- [monthNr](#)
- [quarter](#)
- [year](#)

- **baseYear** ↑

The base year. 2000.

Inherited from superclass NB_DATE

- **dayOfWeek** ↑

The day which the weekly date represents when converted to or from a weekly frequency. Default is 1, which is sunday.

Inherited from superclass NB_DATE

- **frequency** ↑

The frequency of the date. Must be 12.

- **leapYear** ↑

Indicator for leap year. 1 if leap year.

Inherited from superclass NB_DATE

- **month** ↑

The given month as a double

- **monthNr** ↑

The number of months since the base.
Which is the first month of 2000.

- **quarter** ↑

The given quarter as a double.

- **year** ↑

The given year as a double.

► **ascensionDay** ↑

```
day = ascensionDay(obj,~)
```

Description:

Give the ascension day of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_month.easter](#), [nb_month.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **cell2Date** ↑

```
obj = nb_date.cell2Date(cellstr,freq)
```

Description:

Converts a cellstring of dates into a nb_date object.

Input:

- cellstr : The cellstring of dates that you want to convert.

- freq : The frequency of your data. You can choose between 1, 2, 4, 12, 52, and 365.

Output:

- date : A NumberOfDatesx1 vector containing nb_date objects.

Examples:

```
g = {'2011Q2'  
     '2011Q3'  
     '2011Q4'  
     '2012Q1'  
     '2012Q2'  
     '2012Q3'  
     '2012Q4'  
     '2013Q1'  
     '2013Q2' }  
  
a = nb_date.cell2Date(g,4)
```

a =

```
'2011Q2'  
'2011Q3'  
'2011Q4'  
'2012Q1'  
'2012Q2'  
'2012Q3'  
'2012Q4'  
'2013Q1'  
'2013Q2'
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **christmas** ↑

```
day = christmas(obj,~)
```

Description:

Give the holidays of christmas (25th and 26th) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_month.ascensionDay](#), [nb_month.pentecost](#), [nb_month.easter](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **colon** ↑

```
cellStr = colon(a,d,b)
```

Description:

Overload the : operator. The result is a cellstr array of all the dates between the a and b (Including the a and b dates).

Input:

- a : An object of class nb_date or of a subclass of the nb_date class
- d : Increments between the dates
- b : An object of class nb_date or of a subclass of the nb_date class

Output:

- cellStr : A cellstr array of the periods between the dates represented by a and b. (Including the dates a and b). If a and b are nb_date object an empty cell is returned.

Examples:

```
dates = a:b;  
dates = a:2:b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **convert** ↑

```
obj = convert(obj,frequency,first)
```

Description:

Convert the nb_month object ot the wanted frequency. The return variable will be an object which is of an subclass of the nb_date class.

Input:

- obj : An object of class nb_month
- frequency : The frequency to convert to. As a scalar.

```
- first      : 1 : first period  
              0 : last period  
  
Only when converting the object to a higher  
frequency.
```

Output:

```
- obj      : An object of subclass of the nb_date class with the  
frequency given by the frequency input.
```

Examples:

```
obj = nb_month(1,2012);  
obj = obj.convert(1);
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **date2freq** ↑

```
[startDate,frequency,type] = nb_date.date2freq(dates,xls)
```

Description:

A static method of the nb_date class.

Find out the frequency of the data (also from a xls(x) worksheet)

When trying to figure out the frequency of excel dates, this
function must have at least two following dates

```
yearly      : 'yyyy' or 'dd.mm.yyyy'  
semiannually : 'yyyySs' or 'dd.mm.yyyy'  
quarterly   : 'yyyyQq' or 'yyyyKk', 'dd.mm.yyyy'  
monthly     : 'yyyyMm(m)' or 'dd.mm.yyyy'  
weekly       : 'yyyyWw(w)' or 'dd.mm.yyyy'  
daily        : 'yyyyMm(m)Dd(d)', 'ddmonyyyy' or 'dd.mm.yyyy'
```

Input:

```
- dates      : A cellstr of the dates you want to test the  
frequency of.  
  
- xls        : > 'xls' : If you want to test if the dates is on  
                  the format 'dd.mm.yyyy' also  
  
                  > otherwise will not (default)
```

Output:

- startDate : An object which is a subclass of the class nb_date, with the start date of the input dates. (Either nb_quarter, nb_month, nb_semiAnnual, nb_year, nb_week or nb_day)
- frequency : The frequency of the dates given.
 - > 1 : yearly
 - > 2 : semiannually
 - > 4 : quarterly
 - > 12 : monthly
 - > 52 : weekly
 - > 365 : daily
- type : 1 if the dates input is on the xls format, otherwise 0

Examples:

```
dates = {'01.01.2012','02.01.2012','03.01.2012'};
[startDate,frequency,type] = nb_date.date2freq(dates,'xls');
```

The output will in this example be:

- startDate : An nb_day object representing the date '01.01.2012'
- frequency : 365
- type : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **disp** ↑

disp(obj)

Description:

Sets how the nb_date object is displayed, and all subclasses of the nb_date class

Input:

- obj : An object of class nb_date or of a subclass of the nb_date class.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **easter** ↑

```
day = easter(obj,type)
```

Description:

Give the holidays or the sunday of easter of the year the date is located.

Input:

- obj : An object of class nb_date.
- type : 'all' or 'sunday' (default).

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_month.ascensionDay](#), [nb_month.pentecost](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATE

► [eq](#) ↑

```
ret = eq(obj,aObj)
```

Description:

Tests if the two objects representing the same dates

Input:

- obj : An object of class nb_month
- aObj : Another object of class nb_month

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj == aObj;
```

Written by Kenneth S. Paulsen

► **format2string** ↑

```
date = nb_date.format2string(obj,format)
date = nb_date.format2string(obj,format,language,first)
```

Description:

Get date at a given format.

Input:

- obj : An object of a subclass of nb_date.
- format : A string with the format. A combination of the following patterns:

- d : Day of the date. Examples:

- > 'dd' : '01', '10'
- > 'd' : '1', '0'
- > 'd(d)' : '1', '10'
- w : Week of date. Same options as for d.
- m : Month of date. Same options as for d.

- q : Quarter of date. Examples:

- > 'q' : '1', '4'
- h : Half year of date. Same options as for h.
- y : Year of date.
 - > 'yyyy' : '2016'
 - > 'yy' : '016'
 - > 'yy' : '16'
 - < 'y' : '6'

Caution: To use the actual letter of the patterns use \ in front of the letter. E.g. '\y'.

Extra (see also the language option):

- 'Monthtext' : Month of date as full text. Starting with upper case.
- 'monthtext' : Month of date as full text. Starting with upper case.
- 'Quartertext' : > 'norwegian' : '. kv.'
- > 'english' : 'Q'
- 'Weektext' : > 'norwegian' : 'Uke'
- > 'english' : 'Week'
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- date : A string of the date on the wanted format.

Examples:

```
d      = nb_day.today();
date = nb_date.format2string(d,'dd.mm.yyyy');
date = nb_date.format2string(d,'d(d).m(m).yyyy');
date = nb_date.format2string(d,'d(d) Monthtext yyyy');
date = nb_date.format2string(d,'d(d). monthtext yyyy','norwegian');

m      = nb_month.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'Monthtext yyyy');
date = nb_date.format2string(m,'Monthtext yyyy','norwegian');

q      = nb_quarter.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'qQ yyyy');
date = nb_date.format2string(m,'q. kv. yyyy');

y      = nb_year.today();
date = nb_date.format2string(y,'dd.mm.yyyy');
date = nb_date.format2string(y,'yyyy');
date = nb_date.format2string(y,'\year yyyy');
```

See also:[toString](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► freqPlus ↑

```
obj = freqPlus(obj,incr,freq)
```

Description:

Plus the number of periods of another (lower) frequency.

E.g. dayNextYear = freqPlus(day,1,1);

Input:

- obj : An object of class nb_date.
- periods : A scalar integer with the periods to add.
- freq : The frequency of the periods argument.

Output:

- ob : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **fromxlsDates2freq ↑**

frequency = nb_date.fromxlsDates2freq(dates)

Description:

A static method of the nb_date class.

Try to find out the date frequency of the excel dates. I.e. dates on the format 'dd.mm.yyyy'.

Input:

- Dates : A cellstr with at least two dates on the date format 'dd.mm.yyyy'.

Output:

- frequency : The frequency of the input dates given as an integer.

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2
> Yearly	:	1

Examples:

```
dates      = {'01.01.2012','02.01.2012','03.01.2012'};  
frequency = nb_date.fromxlsDates2freq(dates)
```

The output will in this example be:

- frequency : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **ge ↑**

```
ret = ge(obj,aObj)
```

Description:

Tests if an object is greater then or equal to another object.
Which will mean that the first input is after or the same
as the second input in the calendar

Input:

- obj : An object of class nb_month
- aObj : Another object of class nb_month

Output:

- ret : 1 if obj >= aObj, 0 else

Examples:

```
ret = obj >= aObj;
```

Written by Kenneth S. Paulsen

► **getDate ↑**

```
date = getDate(obj,freq)
```

Description:

Get the date of the object at another frequency. If the frequency
is higher the first period is returned

Input:

- obj : An object of class nb_month
- freq : The frequency you want to convert to.
 - 1 : nb_year
 - 2 : nb_semiAnnual
 - 4 : nb_quarter
 - 12 : nb_month
 - 52 : nb_week
 - 365 : nb_day

Output:

- date : The date of the object at the new frequency. As an
object which is a subclass of the nb_date class.

Examples:

```
date = obj.getDate(4); % Will return a nb_quarter object
```

See also:

[nb_month.convert](#)

Written by Kenneth S. Paulsen

► **getDay** ↑

```
day = getDay(obj,first)
```

Description:

Get the first or last day of the month, given as an nb_day object

Input:

- obj : An object of class nb_month
- first : 1 : First day (always 1)
0 : Last day (Either 28, 29, 30 or 31)
2 : The first day that match the dayOfWeek property.
3 : The last day that match the dayOfWeek property.

Output:

- day : An nb_day object

Examples:

```
day = obj.getDay();      % Will return the first day of the year  
day = obj.getDay(0);    % Will return the last day of the year
```

Written by Kenneth S. Paulsen

► **getDays** ↑

```
days = getDays(obj)
```

Description:

Get all the days of the given month as a cell of nb_day objects

Input:

- obj : An object of class nb_month

Output:

- days : A cell array of nb_day objects

Examples:

```
days = obj.getDays();
```

Written by Kenneth S. Paulsen

► **getEarliestDate** ↑

```
date = nb_date.getEarliestDate(c)
```

Description:

Get the earliest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getFreq** ↑

```
freq = getFreq(obj)
```

Description:

Gets the frequency of the object.

Input:

- obj : An object of class nb_month

Output:

- freq : 12

Examples:

```
freq = obj.getFreq();
```

Written by Kenneth S. Paulsen

► **getFrequencyAsInteger ↑**

```
frequency = nb_date.getFrequencyAsInteger(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as an integer given a frequency as a string

Input:

- frequency : Frequency input as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly', 'annual'

Output:

- frequency : The frequency as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Examples:

```
frequency = nb_date.getFrequencyAsInteger('yearly')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getFrequencyAsString** ↑

```
frequency = nb_date.getFrequencyAsString(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as a string given a frequency as an integer

Input:

- frequency : Frequency input as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Output:

- frequency : The frequency as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly'

Examples:

```
frequency = nb_date.getFrequencyAsString(1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getHalfYear** ↑

```
halfYear = getHalfYear(obj)
```

Description:

Get the current half year of the month, given as an nb_semiAnnual object

Input:

- obj : An object of class nb_year

Output:

- halfYear : An nb_semiAnnual object

Examples:

```
halfYear = obj.getHalfYear();
```

Written by Kenneth S. Paulsen

► **getLatestDate** ↑

```
date = nb_date.getLatestDate(c)
```

Description:

Get the latest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getNr** ↑

```
nr = getNr(obj)
```

Description:

Get date number of a nb_date vector.

Input:

- obj : A vector of nb_date objects.

Output:

- nr : A double with the date numbers of each object in the nb_date vector.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getNumberOfDays** ↑

numberOfDays = getNumberOfDays(obj)

Description:

Get the number of days in the given month

Input:

- obj : An object of class nb_month

Output:

- numberOfDays : The number of days, given as double

Examples:

numberOfDays = obj.getNumberOfDays();

Written by Kenneth S. Paulsen

► **getNumberOfWeeks** ↑

numberOfWeeks = getNumberOfWeeks(obj)

Description:

Get the number of weeks in the given month

Input:

- obj : An object of class nb_month

Output:

- numberOfWeeks : The number of weeks, given as double

Written by Kenneth S. Paulsen

► **getQuarter** ↑

```
quarter = getQuarter(obj,first)
```

Description:

Get the current quarter of the month, given as an nb_quarter object

Input:

- obj : An object of class nb_mont

Output:

- quarter : An nb_quarter object

Examples:

```
quarter = obj.getQuarter();
```

Written by Kenneth S. Paulsen

► **getWeek** ↑

```
week = getWeek(obj,first,dayOfWeek)
```

Description:

Get the first or last week of the month, given as a nb_week object.

Input:

```
- obj : An object of class nb_month

- first : 1 : First week
          0 : Last week

- dayOfWeek : The weekday the given week represents when
               converted to a day. (1-7 (Monday-Sunday)). Default
               is to use the dayOfWeek property.
```

Output:

```
- week : An nb_week object
```

Examples:

```
week = obj.getWeek();      % Will return the first week of the year
week = obj.getWeek(0);    % Will return the last week of the year
```

Written by Kenneth S. Paulsen

► **getWeeks** ↑

```
weeks = getWeeks(obj,dayOfWeek)
```

Description:

Get all the weeks of the given month as a cell of nb_week objects.

Input:

```
- obj : An object of class nb_month

- dayOfWeek : The weekday the given week represents when
               converted to a day. (1-7 (Monday-Sunday)). Default
               is to use the dayOfWeek property.
```

Output:

```
- weeks : A cell array of nb_week objects
```

Examples:

```
month = nb_month(1,2020);
weeks = month.getWeeks();
```

Written by Kenneth S. Paulsen

► **getYear** ↑

```
year = getYear(obj)
```

Description:

Get the year of the month, given as a nb_year object

Input:

- obj : The object itself

Output:

- year : A nb_year object

Examples:

```
month = nb_month(1,2020);
year = month.getYear();
```

Written by Kenneth S. Paulsen

► **gt** ↑

```
ret = gt(obj,aObj)
```

Description:

Tests if an object is greater then another object. Which will mean that the first input is after the second input in the calendar

Input:

- obj : An object of class nb_month

- aObj : An object of class nb_month

Output:

- ret : 1 if obj > aObj, 0 else

Examples:

```
ret = obj > aObj;
```

Written by Kenneth S. Paulsen

► **holidays** ↑

```
days = holidays(obj)
```

Description:

Find the holidays of the given date object.

Input:

- obj : An object of class nb_month, nb_quarter, nb_semiAnnual or nb_year.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_month.easter](#), [nb_month.ascensionDay](#), [nb_month.pentecost](#)
[nb_month.christmas](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **initialize ↑**

```
obj = nb_date.initialize(freq, dim1, dim2)
```

Description:

Initialize a vector of date objects.

Input:

- freq : The wanted frequency of the date of today. 1,2,4,12,52 or 365.
- dim1 : The size of the first dimension.
- dim2 : The size of the second dimension.

Output:

obj : A vector of nb_date objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **intersect ↑**

```
cout = nb_date.intersect(varargin)
```

Description:

Get the intersection of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isDate** ↑

```
ret = nb_date.isDate(input,freq)
```

Description:

Test if a string or nb_date object is a date. It is also possible to restrict the test to a specific frequency.

Input:

- input : Any object
- freq : 1, 2, 4, 12, 52 or 365. Can also be empty, but then it is slower.
- locVar : A nb_struct/struct with the supported local variables. If the input is a string using the syntax '%#name', this input will be looked up and tested.

Output:

- ret : Either true or false. true if input is a date string or nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isEqualFreq** ↑

```
ret = isEqualFreq(obj,aObj)
```

Description:

Test if two date objects have the same frequency

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class
- aObj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : 1 if equal frequency, 0 else

Examples:

```
d = nb_day(1,1,2012);
q = nb_quarter(4,2012);
ret = d.isEqualFreq(q); % Will return 0
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isFirstPeriod ↑**

```
ret = isFirstPeriod(obj,freq)
```

Description:

Return if the obj represent the first period a lower frequency.

Input:

- obj : An object which of a subclass of the nb_date class.
- freq : The lower frequency.

Output:

- ret : True if the object represent the first period of the lower frequency.

Examples:

```
q = nb_quarter(1,2000)
ret = isFirstPeriod(q,1)

m = nb_month(10,2000)
ret = isFirstPeriod(m,4)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isLeapYear** ↑

```
ret = isLeapYear(obj)
```

Description:

Test if the current year is a leap year

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : Logical. 1 if object is leap year, 0 else

Examples:

```
ret = obj.isLeapYear();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isPeriod** ↑

```
ret = isPeriod(obj,period)
```

Description:

Return true if the obj represent the given period, i.e. if you want to test if a nb_quarter object represent the first period of any year you can use isPeriod(obj,1).

Input:

- obj : An object which of a subclass of the nb_date class.
- period : The period to test for.

Output:

- ret : True if the object represent the period to test for, else false.

Examples:

```
q    = nb_quarter(1,2000)
ret = isPeriod(q,1)
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if the object is empty

Input:

- obj : An object of class nb_month

Output:

- ret : 1 if empty, 0 else. Always false for vectors of objects.

Examples:

```
ret = objisempty();
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **isequal** ↑

```
ret = isequal(obj,aObj)
```

Description:

Tests if the two objects representing the same date

Input:

- obj : an object of class nb_month
- aObj : another object of class nb_month

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj.isequal(aObj);
ret = isequal(obj,aObj);
```

Written by Kenneth S. Paulsen

► **ismember** ↑

- varargout = ismember(obj1,obj2)

Description:

Utilizes the inbuilt MATLAB function 'ismember' for nb_date objects.

Input:

- obj1 : A nb_date object
- obj2 : A nb_date object

Output:

- varargout : See help on MATLAB function 'ismember'.

See also:

[ismember](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **le** ↑

ret = le(obj,aObj)

Description:

Tests if an object is less then or equal to another object.
Which will mean that the first input is before or the same as
the second input in the calendar.

Input:

- obj : An object of class nb_month
- aObj : An object of class nb_month

Output:

- ret : 1 if obj <= aObj, 0 else

Examples:

ret = obj <= aObj;

Written by Kenneth S. Paulsen

► **lt** ↑

ret = lt(obj,aObj)

Description:

Tests if an object is less than another object. Which will mean that the first input is before the second input in the calendar

Input:

- obj : An object of class nb_month
- aObj : An object of class nb_month

Output:

- ret : 1 if obj < aObj, 0 else

Examples:

ret = obj < aObj;

Written by Kenneth S. Paulsen

► **max** ↑

d = max(obj)
[d,ind] = max(obj)
d = max(obj,aObj)

Description:

Find the max date.

Input:

One input:

- obj : A vector of nb_month objects.

Two inputs:

- obj : A scalar nb_month object.

- aObj : A scalar nb_month object.

Output:

- d : A scalar nb_month object.

- ind : The index of the last date.

Written by Kenneth Sæterhagen Paulsen

► **min ↑**

```
d      = min(obj)
[d,ind] = min(obj)
d      = min(obj,aObj)
```

Description:

Find the min date.

Input:

One input:

- obj : A vector of nb_month objects.

Two inputs:

- obj : A scalar nb_month object.

- aObj : A scalar nb_month object.

Output:

- d : A scalar nb_month object.

- ind : The index of the first date.

Written by Kenneth Sæterhagen Paulsen

► **ne ↑**

```
ret = ne(obj,aObj)
```

Description:

Tests if the two objects not representing the same date

Input:

- obj : An object of class nb_month
- aObj : An object of class nb_month

Output:

- ret : 1 if obj is not equal to aObj, 0 else

Examples:

```
ret = obj ~= aObj;
```

Written by Kenneth S. Paulsen

► **pentecost** ↑

```
day = pentecost(obj,~)
```

Description:

Give the pentecost (monday) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_month.easter](#), [nb_month.ascensionDay](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **plus** ↑

```
out = plus(obj,aObj)
```

Description:

Makes it possible to add a given number of months to an nb_month object and receive an nb_month object which represents the month the given numbers of months ahead

Input:

- obj : A nx1 double or a nx1 nb_month object
- aObj : A nx1 double or a nx1 nb_month object

Output:

- out : A nx1 nb_year object the given number of years ahead

Examples:

```
obj = obj + 1;
```

same as

```
obj = 1 + obj;
```

Written by Kenneth S. Paulsen

► **setDayOfWeek** ↑

```
obj = setDayOfWeek(obj,dayOfWeek)
```

Description:

Set the day of week number of a set of nb_date objects.

Input:

- obj : A nb_date object. May be a vector or matrix.

Output:

- obj : A nb_date object with the same size as the obj input.

See also:

[nb_month.dayOfWeek](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **sort** ↑

```
[obj,ind] = sort(obj)
```

Description:

Sort a vector of nb_date objects.

Input:

- obj : A vector of nb_date objects.

Output:

- obj : A sorted vector of nb_date objects.

- ind : The index of the sorting.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **toDate** ↑

```
dObj = nb_date.toDate(date,frequency)
```

Description:

A static method of the nb_date class.

Transform a given date string to the corresponding date object given that the frequency is already known.

If the frequency is not known, use the method date2freq() (handles also excel dates) or getFreq() (Only nb_ts dates).

Input:

- date :

Supported date formats:

> Daily : 'dd.mm.yyyy' and 'yyyyMm(m)Dd(d)'

> Weekly : 'dd.mm.yyyy' and 'yyyyWw(w)'

> Monthly : 'dd.mm.yyyy' and 'yyyyMm(m)'

> Quarterly : 'dd.mm.yyyy' and 'yyyyQq'

> Semiannually : 'dd.mm.yyyy' and 'yyyySs'

```

> Yearly      : 'dd.mm.yyyy' and 'yyyy'
> Secondly    : 'yyyy-mm-dd hh:nn:ss' and 'yyyymmddhhnnss'
                (only supported if this version of the toolbox
                 includes the nb_second class)

- frequency :

> Daily       : 365
> Weekly      : 52
> Monthly     : 12
> Quarterly   : 4
> Semiannually : 2
> Yearly      : 1
> Secondly    : 31536000

```

Output:

```

- dObj      :

> Daily      : An nb_day object
> Weekly     : An nb_week object
> Monthly    : An nb_month object
> Quarterly  : An nb_quarter object
> Semiannually : An nb_semiAnnual object
> Yearly     : An nb_year object
> Secondly   : An nb_second object

```

Examples:

```

dObj = nb_date.toDate('2012M1D1',365);
dObj = nb_date.toDate('2012M1',12);
dObj = nb_date.toDate('2012Q1',4);
dObj = nb_date.toDate('2012S1',2);
dObj = nb_date.toDate('2012',1);

```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **toDates ↑**

```
varargout = toDates(obj,periods,format,newFreq,first)
```

Description:

Get a cellstr array of the dates ahead

Input:

- obj : An object of class nb_month
 - periods : The periods wanted, must be given as a double array.
E.g. 1:20.
 - format : Set the format of the cellstr of dates:
 - > 'nb_date' : The output will be a vector of nb_date objects.
 - > 'default' : 'yyyyMm(m)'
 - > 'fame' : 'yyyyMm(m)'
 - > 'xls' : 'dd.mm.yyyy'
 - > 'vintage' : 'yyyymmdd'
- Formats which is dependent on the 'newFreq' input
- > 'NBNorsk' ('NBNorwegian'):
 - newFreq:
 - > 1 : 'YYYY'
 - > 2 : 'mmm. yy', e.g. 'jan. 08' and 'jul. 08'
 - > 4 : 'q.kv.yy'
 - > 12 : 'mmm. yy', e.g. mmm = 'jan'
 - > 52 : Not possible
 - > 365 : Not possible
 - (Date strings are only given for the days which ends the periods)
 - > 'NBEnglish' ('NBEngelsk'):
 - newFreq:
 - > 1 : 'YYYY'
 - > 2 : 'mmm-yy', e.g. 'jan. 08' and 'jul. 08'
 - > 4 : 'yyyyQq'
 - > 12 : 'mmm-yy', e.g. mmm = 'jan'
 - > 52 : Not possible
 - > 365 : Not possible
 - (Date strings are only given for the days which ends the periods)
 - newFreq : > 1 : yearly
> 2 : semiannually
> 4 : quarterly
> 12 : monthly
> 52 : weekly (Not possible)
> 365 : daily (Not possible)
 - first : When converting to a lower frequency you must set if you want to use the first date or the last date as

the location of the returned date. The default is to use the first.

```
1 : first  
0 : last
```

Output:

- varargout{1} : A cell array of the wanted dates.
- varargout{2} : Locations of the returned dates. Of interest when converting to lower frequencies

Examples:

```
dates          = obj.toDates(0:20);  
dates          = obj.toDates(0:20,'xls');  
[dates,locations] = obj.toDates(0:20,'NBNorsk',1);
```

Written by Kenneth S. Paulsen

► **toFormat ↑**

```
dates = toFormat(start,finish,format,language,first)
```

Description:

Convert dates vector to a given format.

Input:

- start : An object of a subclass of the nb_date class.
- finish : An object of a subclass of the nb_date class.
- format : See the format input to the nb_date.format2string method.
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- vint : A cellstr.

See also:

[nb_month.format2string](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **toString** ↑

```
date = toString(obj,format,extra)
```

Description:

Transform the nb_month object to a string representing the date.
It will be given in the format: 'yyyyMm(m)'.

Input:

- obj : The object itself

Optional input:

```
- format : > 'xls' : 'dd.mm.yyyy'  
> 'nbnorwegian' : 'mmm. yy'  
> 'nbengelsk' or 'nbenglish' : 'Mmm-yy'  
> 'pprnorsk' or 'mprnorwegian' : 'monthtext yyyy'  
> 'pprengelsk' or 'mprenglish' : 'Monthtext yyyy'  
> 'default' : 'yyyyMm(m)'  
> 'vintage' : 'yyyymmdd'
```

- extra :

```
> 'xls':
```

Give 1 if you want the date string to represent the
first day of the month ('01.01.yyyy'), otherwise last
day of the month will be given ('31.01.yyyy'). Only
when format is given as 'xls'

```
> 'pprnorsk', 'mprnorwegian', 'pprengelsk', 'mprenglish' :
```

Give 0 if you want the month text in lowercase only.
Default is that the month text starts with an uppercase.

Output:

- date : A string with the date on the wanted format

Examples:

```
obj = nb_month(1,2012);  
date = obj.toString(); % Will give '2012M1'  
date = obj.toString('xls'); % Will give '01.01.2012'  
date = obj.toString('xls',0); % Will give '31.01.2012'  
date = obj.toString('nbnorwegian'); % Will give 'jan. 12'  
date = obj.toString('nbengelsk'); % Will give 'Jan-12'
```

```
date = obj.toString('pprnorsk'); % Will give 'Januar 2012'  
date = obj.toString('pprnorsk',0); % Will give 'januar 2012'  
date = obj.toString('pprengelsk'); % Will give 'January 2012'
```

Written by Kenneth S. Paulsen

► **today** ↑

```
obj = nb_month.today()
```

Description:

Get the current month as a nb_month object.

Output:

obj : An object of class nb_month.

Written by Kenneth Sæterhagen Paulsen

► **union** ↑

```
cout = nb_date.union(varargin)
```

Description:

Get the union of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **unique** ↑

```
obj = unique(obj)
```

Description:

Get unique elements of a vector of nb_date objects.

Input:

- in : A vector of nb_date objects.

Output:

- out : A unique (sorted) vector of nb_date objects.

- IA : out = in(IA)

- IC : A = C(IC)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **vec** ↑

out = vec(obj,endD)

Description:

A method to create a vector of dates between two dates.

Input:

obj : An nb_month object which represents the start date of the vector

end : An nb_month object or a double, representing the end date or the number of periods you want in your vector

Output:

obj : A nPeriods*1 vector of nb_month objects.

Examples:

```
f = nb_month(1,1,2010);
g = nb_month(10,1,2010);
vector = f.vec(g)
```

See also:

[nb_month](#)

Written by Tobias Ingebrigtsen

► **vintage2Date** ↑

```
date = nb_date.vintage2Date(vintage,freq)
```

Description:

This method converts a vintage date into a nb_date object with the wanted frequency. You can also convert a cellstring containing multiple vintage dates.

Input:

- vintage : Either the vintage date that you want to convert, or a cellstring containing the vintage dates you want to convert.
- freq : The wanted frequency. Your options are 1, 4, 12 or 365.

Output:

- date : A 1xNumberOfVintages vector containing nb_date object(s).

Examples:

```
f = '20110622'  
t = nb_date.vintage2Date(f,4)
```

OR

```
f = {'20110622','20111019','20120314'} |  
t = nb_date.vintage2Date(f,4)
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

■ nb_quarter

Go to: [Properties](#) | [Methods](#)

A class representing a quarterly date.

Superclasses:

nb_date

Constructor:

```
obj = nb_quarter(quarter,year)
```

Input:

- quarter : A string on one of the following date formats:

```
> 'yyyyQq'  
> 'dd.mm.yyyy'
```

Or an integer with the quarter. (Must be combined

with the year argument)

- year : Must be an integer with the year.

Output:

- obj : An nb_quarter object

Examples:

```
obj = nb_quarter('2012Q1');
obj = nb_quarter(1,2012);
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- [baseYear](#)
- [dayOfWeek](#)
- [frequency](#)
- [leapYear](#)
- [quarter](#)
- [quarterNr](#)
- [year](#)

- **baseYear** ↑

The base year. 2000.

Inherited from superclass NB_DATE

- **dayOfWeek** ↑

The day which the weekly date represents when converted to or from a weekly frequency. Default is 1, which is sunday.

Inherited from superclass NB_DATE

- **frequency** ↑

The frequency of the date. Must be 4.

- **leapYear** ↑

Indicator for leap year. 1 if leap year.

Inherited from superclass NB_DATE

- **quarter** ↑

The given quarter as a double

- **quarterNr** ↑

The number of quarters since the base, which is first quarter of 2000.

- **year** ↑

The year of the given quarter

► **ascensionDay** ↑

```
day = ascensionDay(obj,~)
```

Description:

Give the ascension day of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_quarter.easter](#), [nb_quarter.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► cell2Date ↑

```
obj = nb_date.cell2Date(cellstr,freq)
```

Description:

Converts a cellstring of dates into a nb_date object.

Input:

- cellstr : The cellstring of dates that you want to convert.
- freq : The frequency of your data. You can choose between 1, 2, 4, 12, 52, and 365.

Output:

- date : A NumberOfDatesx1 vector containing nb_date objects.

Examples:

```
g = {'2011Q2'  
     '2011Q3'  
     '2011Q4'  
     '2012Q1'  
     '2012Q2'  
     '2012Q3'  
     '2012Q4'  
     '2013Q1'  
     '2013Q2'}
```

```
a = nb_date.cell2Date(g,4)
```

```
a =
```

```
'2011Q2'  
'2011Q3'  
'2011Q4'  
'2012Q1'  
'2012Q2'  
'2012Q3'  
'2012Q4'
```

```
'2013Q1'  
'2013Q2'
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **christmas** ↑

```
day = christmas(obj, ~)
```

Description:

Give the holidays of christmas (25th and 26th) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_quarter.ascensionDay](#), [nb_quarter.pentecost](#), [nb_quarter.easter](#)

Written by Kenneth SÅ!terhagen Paulsen

Inherited from superclass NB_DATE

► **colon** ↑

```
cellStr = colon(a, d, b)
```

Description:

Overload the : operator. The result is a cellstr array of all the dates between the a and b (Including the a and b dates).

Input:

- a : An object of class nb_date or of a subclass of the nb_date class
- d : Increments between the dates
- b : An object of class nb_date or of a subclass of the nb_date class

Output:

- cellStr : A cellstr array of the periods between the dates represented by a and b. (Including the dates a and b). If a and b are nb_date object an empty cell is returned.

Examples:

```
dates = a:b;  
dates = a:2:b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► convert ↑

```
obj = convert(obj,frequency,first)
```

Description:

Convert the nb_quarter object ot the wanted frequency. The return variable will be an object which is of an subclass of the nb_date class.

Input:

- obj : An object of class nb_quarter
- frequency : The frequency to convert to. As a scalar.
- first : 1 : first period (default)
0 : last period

Only when converting the object to a higher frequency.

Output:

- obj : An object of subclass of the nb_date class with the frequency given by the frequency input.

Examples:

```
obj = nb_quarter(1,2012);  
obj = obj.convert(1);
```

See also:

Written by Kenneth Sæterhagen Paulsen

► date2freq ↑

```
[startDate,frequency,type] = nb_date.date2freq(dates,xls)
```

Description:

A static method of the nb_date class.

Find out the frequency of the data (also from a xls(x) worksheet)

When trying to figure out the frequency of excel dates, this function must have at least two following dates

```
yearly      : 'yyyy' or 'dd.mm.yyyy'  
semiannually : 'yyyySs' or 'dd.mm.yyyy'  
quarterly   : 'yyyyQq' or 'yyyyKk', 'dd.mm.yyyy'  
monthly     : 'yyyyMm(m)' or 'dd.mm.yyyy'  
weekly       : 'yyyyWw(w)' or 'dd.mm.yyyy'  
daily        : 'yyyyMm(m)Dd(d)', 'ddmonyyyy' or 'dd.mm.yyyy'
```

Input:

- dates : A cellstr of the dates you want to test the frequency of.
- xls : > 'xls' : If you want to test if the dates is on the format 'dd.mm.yyyy' also
> otherwise will not (default)

Output:

- startDate : An object which is a subclass of the class nb_date, with the start date of the input dates. (Either nb_quarter, nb_month, nb_semiAnnual, nb_year, nb_week or nb_day)
- frequency : The frequency of the dates given.
 - > 1 : yearly
 - > 2 : semiannually
 - > 4 : quarterly
 - > 12 : monthly
 - > 52 : weekly
 - > 365 : daily
- type : 1 if the dates input is on the xls format, otherwise 0

Examples:

```
dates = {'01.01.2012','02.01.2012','03.01.2012'};  
[startDate,frequency,type] = nb_date.date2freq(dates,'xls');
```

The output will in this example be:

- startDate : An nb_day object representing the date '01.01.2012'
- frequency : 365
- type : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **disp** ↑

disp(obj)

Description:

Sets how the nb_date object is displayed, and all subclasses of the nb_date class

Input:

- obj : An object of class nb_date or of a subclass of the nb_date class.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **easter** ↑

day = easter(obj,type)

Description:

Give the holidays or the sunday of easter of the year the date is located.

Input:

- obj : An object of class nb_date.
- type : 'all' or 'sunday' (default).

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

`nb_easter, nb_quarter.ascensionDay, nb_quarter.pentecost`

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_DATE`

► **eq** ↑

```
ret = eq(obj, aObj)
```

Description:

Tests if the two objects represent the same date

Input:

- `obj` : An object of class `nb_quarter`
- `aObj` : Another object of class `nb_quarter`

Output:

- `ret` : 1 if equal, 0 else

Examples:

```
ret = obj == aObj;
```

Written by Kenneth S. Paulsen

► **format2string** ↑

```
date = nb_date.format2string(obj, format)
date = nb_date.format2string(obj, format, language, first)
```

Description:

Get date at a given format.

Input:

- `obj` : An object of a subclass of `nb_date`.
- `format` : A string with the format. A combination of the following patterns:
 - **d** : Day of the date. **Examples:**

```

        > 'dd'   : '01', '10'
        > 'd'    : '1', '0'
        > 'd(d)' : '1', '10'
- w : Week of date. Same options as for d.
- m : Month of date. Same options as for d.

```

- q : Quarter of date. Examples:

```

        > 'q'   : '1', '4'
- h : Half year of date. Same options as for h.
- y : Year of date.
        > 'yyyy' : '2016'
        > 'yy'   : '016'
        > 'y'    : '16'
        < 'y'    : '6'

```

Caution: To use the actual letter of the patterns use \ in front of the letter. E.g. '\y'.

Extra (see also the language option):

```

- 'Monthtext'   : Month of date as full text. Starting with
                  upper case.
- 'monthtext'   : Month of date as full text. Starting with
                  upper case.

- 'Quartertext' : > 'norwegian' : '. kv.'
                  > 'english'   : 'Q'

- 'Weektext'     : > 'norwegian' : 'Uke'
                  > 'english'   : 'Week'

- language : 'norwegian' or 'english' (default). Only important for the
             'monthtext' or 'Monthtext' patterns.

- first      : Give false to return the latest period when converted to a
                  higher frequency. Default is true, i.e. first period.

```

Output:

- date : A string of the date on the wanted format.

Examples:

```

d      = nb_day.today();
date = nb_date.format2string(d,'dd.mm.yyyy');
date = nb_date.format2string(d,'d(d).m(m).yyyy');
date = nb_date.format2string(d,'d(d) Monthtext yyyy');
date = nb_date.format2string(d,'d(d). monthtext yyyy','norwegian');

m      = nb_month.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'Monthtext yyyy');
date = nb_date.format2string(m,'Monthtext yyyy','norwegian');

q      = nb_quarter.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'qQ yyyy');

```

```
date = nb_date.format2string(m,'q. kv. yyyy');

y      = nb_year.today();
date = nb_date.format2string(y,'dd.mm.yyyy');
date = nb_date.format2string(y,'yyyy');
date = nb_date.format2string(y,'\year yyyy');
```

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **freqPlus** ↑

```
obj = freqPlus(obj,incr,freq)
```

Description:

Plus the number of periods of another (lower) frequency.

E.g. dayNextYear = freqPlus(day,1,1);

Input:

- obj : An object of class nb_date.
- periods : A scalar integer with the periods to add.
- freq : The frequency of the periods argument.

Output:

- ob : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **fromxlsDates2freq** ↑

```
frequency = nb_date.fromxlsDates2freq(dates)
```

Description:

A static method of the nb_date class.

Try to find out the date frequency of the excel dates. I.e. dates on the format 'dd.mm.yyyy'.

Input:

- Dates : A cellstr with at least two dates on the date format 'dd.mm.yyyy'.

Output:

- frequency : The frequency of the input dates given as an integer.

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2
> Yearly	:	1

Examples:

```
dates      = {'01.01.2012','02.01.2012','03.01.2012'};  
frequency = nb_date.fromxlsDates2freq(dates)
```

The output will in this example be:

- frequency : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► ge ↑

```
ret = ge(obj,aObj)
```

Description:

Tests if an object is greater than or equal to another object.
Which will mean that the first input is after or the same
as the second input in the calendar

Input:

- obj : An object of class nb_quarter
- aObj : Another object of class nb_quarter

Output:

```
- ret : 1 if obj >= aObj, 0 else
```

Examples:

```
ret = obj >= aObj;
```

Written by Kenneth S. Paulsen

► **getDate** ↑

```
date = getDate(obj,freq)
```

Description:

Get the date of the object at another frequency. If the frequency is higher the first period is returned

Input:

- obj : An object of class nb_quarter
- freq : The frequency you want to convert to.
 - 1 : nb_year
 - 2 : nb_semiAnnual
 - 4 : nb_quarter
 - 12 : nb_month
 - 52 : nb_week
 - 365 : nb_day

Output:

- date : The date of the object at the new frequency. As an object which is a subclass of the nb_date class.

Examples:

```
date = obj.getDate(2); % Will return a nb_semiAnnual object
```

See also:

[nb_quarter.convert](#)

Written by Kenneth S. Paulsen

► **getDay** ↑

```
day = getDay(obj,first)
```

Description:

Get the first or last day of the quarter, given as a nb_day object

Input:

- obj : An object of class nb_quarter
- first :
 - 1 : First day (always 1)
 - 0 : Last day (Either 28, 29, 30 or 31)
 - 2 : The first day that match the dayOfWeek property.
 - 3 : The last day that match the dayOfWeek property.

Output:

- day : An nb_day object

Examples:

```
day = obj.getDay(); % Will return the first day of the quarter  
day = obj.getDay(1); % Will return the last day of the quarter
```

Written by Kenneth S. Paulsen

► getDays ↑

```
days = getDays(obj)
```

Description:

Get all the days of the given quarter as a cell of nb_day objects

Input:

- obj : An object of class nb_quarter

Output:

- days : A cell array of nb_day objects

Examples:

```
days = obj.getDays();
```

Written by Kenneth S. Paulsen

► getEarliestDate ↑

```
date = nb_date.getEarliestDate(c)
```

Description:

Get the earliest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getFreq ↑**

```
freq = getFreq(obj)
```

Description:

Gets the frequency of the object.

Input:

- obj : An object of class nb_quarter

Output:

- freq : 4

Examples:

```
freq = obj.getFreq();
```

Written by Kenneth S. Paulsen

► **getFrequencyAsInteger ↑**

```
frequency = nb_date.getFrequencyAsInteger(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as an integer given a frequency as a string

Input:

- frequency : Frequency input as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly', 'annual'

Output:

- frequency : The frequency as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Examples:

```
frequency = nb_date.getFrequencyAsInteger('yearly')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getFrequencyAsString ↑**

```
frequency = nb_date.getFrequencyAsString(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as a string given a frequency as an integer

Input:

- frequency : Frequency input as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Output:

- frequency : The frequency as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly'

Examples:

```
frequency = nb_date.getFrequencyAsString(1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► getHalfYear ↑

```
halfYear = getHalfYear(obj)
```

Description:

Get the half year of the quarter, given as an nb_semiAnnual object

Input:

- obj : An object of class nb_quarter

Output:

- halfYear : An nb_semiAnnual object

Examples:

```
halfYear = obj.getHalfYear(); % Will return the half year
```

Written by Kenneth S. Paulsen

► **getLatestDate** ↑

```
date = nb_date.getLatestDate(c)
```

Description:

Get the latest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getMonth** ↑

```
month = getMonth(obj,first)
```

Description:

Get the first or last month of the quarter, given as a nb_month object

Input:

- obj : An object of class nb_quarter
- first : 1 : first month
 0 : last month

Output:

- month : An nb_month object

Examples:

```
month = obj.getMonth();    % Will return the first month  
month = obj.getMonth(0);  % Will return the last month
```

Written by Kenneth S. Paulsen

► **getMonths** ↑

```
months = getMonths(obj)
```

Description:

Get all the months of the given quarter as a cell array of nb_month objects

Input:

- obj : An object of class nb_quarter

Output:

- months : A cell array of nb_month objects

Examples:

```
months = obj.getMonths();
```

Written by Kenneth S. Paulsen

► **getNr** ↑

```
nr = getNr(obj)
```

Description:

Get date number of a nb_date vector.

Input:

- obj : A vector of nb_date objects.

Output:

- nr : A double with the date numbers of each object in the nb_date vector.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getNumberOfDays** ↑

```
numberOfDaysInQuarter = getNumberOfDaysInMonth(obj)
```

Description:

Get the number of days in the given quarter

Input:

- obj : An object of the class nb_quarter

Output:

- numberOfDaysInQuarter : Returns the number of days in the current quarter

Examples:

```
numberOfDays = obj.getNumberOfDaysInMonth();
```

Written by Kenneth S. Paulsen

► **getNumberOfWeeks** ↑

```
numberOfWeeks = getNumberOfWeeks(obj)
```

Description:

Get the number of weeks in the given quarter

Input:

- obj : An object of class nb_quarter

Output:

- numberOfWeeks : The number of weeks, given as double

Written by Kenneth S. Paulsen

► **getWeek** ↑

```
week = getWeek(obj,first,dayOfWeek)
```

Description:

Get the first or last week of the quarter, given as an nb_week object

Input:

- obj : An object of class nb_quarter
- first : 1 : first week
0 : last week
- dayOfWeek : The weekday the given week represents when converted to a week. (1-7 (Monday-Sunday)). Default is to use the dayOfWeek property.

Output:

- week : An nb_week object

Examples:

```
week = obj.getWeek();      % Will return the first week of the year
week = obj.getWeek(0);    % Will return the last week of the year
```

Written by Kenneth S. Paulsen

► **getWeeks** ↑

```
weeks = getWeeks(obj,dayOfWeek)
```

Description:

Get all the weeks of the given quarter as a cell of nb_week objects

Input:

- obj : An object of class nb_quarter
- dayOfWeek : The weekday the given week represents when converted to a day. (1-7 (Monday-Sunday)). Default is to use the dayOfWeek property.

Output:

- weeks : A cell array of nb_week objects

Examples:

```
quarter = nb_quarter(1,2020);
weeks = quarter.getWeeks();
```

Written by Kenneth S. Paulsen

► getYear ↑

```
year = getYear(obj)
```

Description:

Get the year of the quarter, given as a nb_year object

Input:

- obj : An object of class nb_quarter

Output:

- year : A nb_year object

Examples:

```
quarter = nb_quarter(1,2020);
year = quarter.getYear(); % Will return the current year
```

Written by Kenneth S. Paulsen

► gt ↑

```
ret = gt(obj,aObj)
```

Description:

Tests if an object is greater than another object. Which will mean that the first input is after the second input in the calendar

Input:

- obj : An object of class nb_quarter
- aObj : An object of class nb_quarter

Output:

- ret : 1 if obj > aObj, 0 else

Examples:

```
ret = obj > aObj;
```

Written by Kenneth S. Paulsen

► **holidays** ↑

```
days = holidays(obj)
```

Description:

Find the holidays of the given date object.

Input:

- obj : An object of class nb_month, nb_quarter, nb_semiAnnual or nb_year.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_quarter.easter](#), [nb_quarter.ascensionDay](#), [nb_quarter.pentecost](#)
[nb_quarter.christmas](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **initialize** ↑

```
obj = nb_date.initialize(freq, dim1, dim2)
```

Description:

Initialize a vector of date objects.

Input:

- freq : The wanted frequency of the date of today. 1,2,4,12,52 or 365.
- dim1 : The size of the first dimension.
- dim2 : The size of the second dimension.

Output:

obj : A vector of nb_date objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► intersect ↑

```
cout = nb_date.intersect(varargin)
```

Description:

Get the intersection of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► isDate ↑

```
ret = nb_date.isDate(input,freq)
```

Description:

Test if a string or nb_date object is a date. It is also possible to restrict the test to a specific frequency.

Input:

- input : Any object
- freq : 1, 2, 4, 12, 52 or 365. Can also be empty, but then it is slower.
- locVar : A nb_struct/struct with the supported local variables. If the input is a string using the syntax '%#name', this input will be looked up and tested.

Output:

- ret : Either true or false. true if input is a date string or nb_date object.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **isEqualFreq** ↑

ret = isEqualFreq(obj,aObj)

Description:

Test if two date objects have the same frequency

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class
- aObj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : 1 if equal frequency, 0 else

Examples:

```
d = nb_day(1,1,2012);
q = nb_quarter(4,2012);
ret = d.isEqualFreq(q); % Will return 0
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isFirstPeriod** ↑

ret = isFirstPeriod(obj,freq)

Description:

Return if the obj represent the first period a lower frequency.

Input:

- obj : An object which of a subclass of the nb_date class.
- freq : The lower frequency.

Output:

- ret : True if the object represent the first period of the lower frequency.

Examples:

```
q    = nb_quarter(1,2000)
ret = isFirstPeriod(q,1)
```

```
m    = nb_month(10,2000)
ret = isFirstPeriod(m,4)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isLeapYear** ↑

```
ret = isLeapYear(obj)
```

Description:

Test if the current year is a leap year

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : Logical. 1 if object is leap year, 0 else

Examples:

```
ret = obj.isLeapYear();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isPeriod** ↑

```
ret = isPeriod(obj,period)
```

Description:

Return true if the obj represent the given period, i.e. if you want to test if a nb_quarter object represent the first period of any year you can use isPeriod(obj,1).

Input:

- obj : An object which of a subclass of the nb_date class.
- period : The period to test for.

Output:

- ret : True if the object represent the period to test for, else false.

Examples:

```
q    = nb_quarter(1,2000)
ret = isPeriod(q,1)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if the object is empty

Input:

- obj : An object of class nb_quarter

Output:

- ret : 1 if empty, 0 else. Always false for vectors of objects.

Examples:

```
ret = objisempty();
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **isequal** ↑

```
ret = isequal(obj,aObj)
```

Description:

Tests if the two objects representing the same date

Input:

- obj : An object of class nb_quarter
- aObj : Another object of class nb_quarter

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj.isequal(aObj);
ret = isequal(obj,aObj);
```

Written by Kenneth S. Paulsen

► **ismember** ↑

```
- varargout = ismember(obj1,obj2)
```

Description:

Utilizes the inbuilt MATLAB function 'ismember' for nb_date objects.

Input:

- obj1 : A nb_date object
- obj2 : A nb_date object

Output:

- varargout : See help on MATLAB function 'ismember'.

See also:

[ismember](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **le** ↑

```
ret = le(obj,aObj)
```

Description:

Tests if an object is less then or equal to another object.
Which will mean that the first input is before or the same as
the second input in the calendar.

Input:

- obj : An object of class nb_quarter
- aObj : An object of class nb_quarter

Output:

- ret : 1 if obj <= aObj, 0 else

Examples:

```
ret = obj <= aObj;
```

Written by Kenneth S. Paulsen

► **lt** ↑

```
ret = lt(obj,aObj)
```

Description:

Tests if an object is less then an another object. Which
will mean that the first input is before the second input in the
calendar

Input:

- obj : An object of class nb_quarter
- aObj : An object of class nb_quarter

Output:

- ret : 1 if obj < aObj, 0 else

Examples:

ret = obj < aObj;

Written by Kenneth S. Paulsen

► **max** ↑

```
d      = max(obj)
[d,ind] = max(obj)
d      = max(obj,aObj)
```

Description:

Find the max date.

Input:

One input:

- obj : A vector of nb_quarter objects.

Two inputs:

- obj : A scalar nb_quarter object.

- aObj : A scalar nb_quarter object.

Output:

- d : A scalar nb_quarter object.

- ind : The index of the last date.

Written by Kenneth Sæterhagen Paulsen

► **min** ↑

```
d      = min(obj)
[d,ind] = min(obj)
d      = min(obj,aObj)
```

Description:

Find the min date.

Input:

One input:

- obj : A vector of nb_quarter objects.

Two inputs:

- obj : A scalar nb_quarter object.
- aObj : A scalar nb_quarter object.

Output:

- d : A scalar nb_quarter object.
- ind : The index of the first date.

Written by Kenneth Sæterhagen Paulsen

► minus ↑

```
output = minus(obj,aObj)
```

Description:

Makes it possible to take an nb_quarter object minus another nb_quarter object and get the number of quarters between them.

It makes it also possible to take the difference between an nb_quarter object and a string one one of the following formats: 'yyyyQq', 'dd.mm.yyyy'

And last it makes it possible to subtract the number of quarters from an nb_quarter object and receive an nb_quarter representing the quarter the given number of quarters backward in time.

Input:

- obj : A date string, an nb_quarter object or an integer.
- aObj : A date string, an nb_quarter object or an integer.

Output:

- output : The number of quarters between the given quarters. As a double

or

An nb_quarter object representing the date the given number of quarter backwards in time.

Examples:

```
output = obj - aObj;           % (both objects). Returns a double  
output = obj - '2012Q2';      % Returns a double  
output = '2012Q3' - obj;      % Returns a double  
output = obj - 1;             % Returns an object  
  
same as  
  
output = 1 - obj;             % Returns an object
```

Written by Kenneth S. Paulsen

► **ne** ↑

```
ret = ne(obj,aObj)
```

Description:

Tests if the two objects not representing the same date

Input:

- obj : An object of class nb_quarter
- aObj : An object of class nb_quarter

Output:

- ret : 1 if obj is not equal to aObj, 0 else

Examples:

```
% ret = obj ~= aObj;
```

Written by Kenneth S. Paulsen

► **pentecost** ↑

```
day = pentecost(obj,~)
```

Description:

Give the pentecost (monday) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_quarter.easter](#), [nb_quarter.ascensionDay](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **plus** ↑

out = plus(obj,aObj)

Description:

Makes it possible to add a given number of quarters to an nb_quarter and receive a nb_quarter object which represents the quarter the given numbers of quarters ahead

Input:

- obj : A nx1 double or a nx1 nb_quarter object
- aObj : A nx1 double or a nx1 nb_quarter object

Output:

- out : A nx1 nb_quarter object with the given number of years ahead

Examples:

obj = obj + 1;

same as

obj = 1 + obj;

Written by Kenneth S. Paulsen

► **setDayOfWeek** ↑

```
obj = setDayOfWeek(obj,dayOfWeek)
```

Description:

Set the day of week number of a set of nb_date objects.

Input:

- obj : A nb_date object. May be a vector or matrix.

Output:

- obj : A nb_date object with the same size as the obj input.

See also:

[nb_quarter.dayOfWeek](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **sort ↑**

```
[obj,ind] = sort(obj)
```

Description:

Sort a vector of nb_date objects.

Input:

- obj : A vector of nb_date objects.

Output:

- obj : A sorted vector of nb_date objects.

- ind : The index of the sorting.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **toDate ↑**

```
dObj = nb_date.toDate(date,frequency)
```

Description:

A static method of the nb_date class.

Transform a given date string to the corresponding date object given that the frequency is already known.

If the frequency is not known, use the method date2freq() (handles also excel dates) or getFreq() (Only nb_ts dates).

Input:

- date :

Supported date formats:

> Daily : 'dd.mm.yyyy' and 'yyyyMm(m)Dd(d)'
> Weekly : 'dd.mm.yyyy' and 'yyyyWw(w)'
> Monthly : 'dd.mm.yyyy' and 'yyyyMm(m)'
> Quarterly : 'dd.mm.yyyy' and 'yyyyQq'
> Semiannually : 'dd.mm.yyyy' and 'yyyySs'
> Yearly : 'dd.mm.yyyy' and 'yyyy'
> Secondly : 'yyyy-mm-dd hh:nn:ss' and 'yyyymmddhhnnss'
(only supported if this version of the toolbox includes the nb_second class)

- frequency :

> Daily : 365
> Weekly : 52
> Monthly : 12
> Quarterly : 4
> Semiannually : 2
> Yearly : 1
> Secondly : 31536000

Output:

- dObj :

> Daily : An nb_day object
> Weekly : An nb_week object
> Monthly : An nb_month object
> Quarterly : An nb_quarter object

```

> Semiannually : An nb_semiAnnual object
> Yearly      : An nb_year object
> Secondly     : An nb_second object

```

Examples:

```

dObj = nb_date.toDate('2012M1D1',365);
dObj = nb_date.toDate('2012M1',12);
dObj = nb_date.toDate('2012Q1',4);
dObj = nb_date.toDate('2012S1',2);
dObj = nb_date.toDate('2012',1);

```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **toDates ↑**

```
varargout = toDates(obj,periods,format,newFreq,first)
```

Description:

Get a cellstr array of the dates ahead

Input:

- obj : An object of class nb_quarter
- periods : The periods wanted, must be given as a double array.
E.g. 1:20.
- format : Set the format of the cellstr of dates:
 - > 'nb_date' : The output will be a vector of nb_date objects.
 - > 'default' : 'yyyyQq'
 - > 'fame' : 'yyyyQq'
 - > 'xls' : 'dd.mm.yyyy'
 - > 'vintage' : 'yyyymmdd'

Formats which is dependent on the 'newFreq' input
> 'NBNorsk' ('NBNorwegian'):

```

newFreq:
> 1   : 'YYYY'
> 2   : 'mmmm. yy', e.g. 'jan. 08' and 'jul. 08'
> 4   : 'q.kv.yy'
> 12  : Not possible
> 52  : Not possible
> 365 : Not possible

```

```

(Date strings are only given for the days which
ends the periods)

> 'NBEnglish' ('NBEngelsk'):

newFreq:
> 1    : 'YYYY'
> 2    : 'mmm-yy', e.g. 'Jan-08' and 'Jul-08'
> 4    : 'yyyyQq'
> 12   : Not possible
> 52   : Not possible
> 365  : Not possible

(Date strings are only given for the days which
ends the periods)

- newFreq : > 1    : yearly
             > 2    : semiannually
             > 4    : quarterly
             > 12   : monthly (Not possible)
             > 52   : weekly  (Not possible)
             > 365  : daily   (Not possible)

- first   : When converting to a lower frequency you must set if
you want to use the first date or the last date as
the location of the returned date. The default is to
use the first.

1 : first
0 : last

```

Output:

- varargout{1} : A cell array of the wanted dates.
- varargout{2} : Locations of the returned dates. Of interest
when converting to lower frequencies

Examples:

```

dates      = obj.toDates(0:20);
dates      = obj.toDates(0:20,'xls');
[dates,locations] = obj.toDates(0:20,'NBNorsk',1);

```

Written by Kenneth S. Paulsen

► **toFormat ↑**

```
dates = toFormat(start,finish,format,language,first)
```

Description:

Convert dates vector to a given format.

Input:

- start : An object of a subclass of the nb_date class.
- finish : An object of a subclass of the nb_date class.
- format : See the format input to the nb_date.format2string method.
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- vint : A cellstr.

See also:

[nb_quarter.format2string](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► [toString ↑](#)

date = toString(obj,format,first)

Description:

Transforms the nb_quarter object to a string representing the date. It will be given in the format: 'yyyyQq'.

Input:

- obj : An object of class nb_quarter
- format : > 'xls' : 'dd.mm.yyyy'
> 'nborsk' or 'nbnorwegian' : 'q.kv.yy'
> 'nbengelsk' or 'nbenglish' : 'yyyyQq'
> 'pprnorsk' or 'mprnorwegian' : 'q.kv. yyyy'
> 'pprengelsk' or 'mprenglish' : 'yyyy Qq'
> 'default' : 'yyyyQq'
> 'vintage' : 'yyyymmdd'
- first : If you want the 'xls' type date string to begin with first or last day of the month. Will only have an effect when format is set to 'xls'. Default is 1 (first day). Give any other number to get the last day.

Output:

- date : A string with the date on the wanted format

Examples:

```
obj = nb_quarter(1,2012);
date = obj.toString();                                % Will give '2012Q1'
date = obj.toString('xls');                           % Will give '01.01.2012'
date = obj.toString('xls',0);                         % Will give '31.03.2012'
date = obj.toString('nbnorsk');                      % Will give '1.kv.12'
date = obj.toString('nbengelsk');                    % Will give '2012Q1'
date = obj.toString('pprnorsk');                     % Will give '1.kv. 2012'
date = obj.toString('pprengelsk');                   % Will give '2012 Q1'
```

Written by Kenneth S. Paulsen

► today ↑

```
obj = nb_quarter.today()
```

Description:

Get the current quarter as a nb_quarter object.

Output:

- obj : An object of class nb_quarter.

Written by Kenneth Sæterhagen Paulsen

► union ↑

```
cout = nb_date.union(varargin)
```

Description:

Get the union of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **unique** ↑

```
obj = unique(obj)
```

Description:

Get unique elements of a vector of nb_date objects.

Input:

- in : A vector of nb_date objects.

Output:

- out : A unique (sorted) vector of nb_date objects.

- IA : out = in(IA)

- IC : A = C(IC)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATE

► **vec** ↑

```
out = vec(obj,endD)
```

Description:

A method to create a vector of dates between to dates.

Input:

obj : An nb_quarter object which represents the start date of the vector

end : An nb_quarter object or a double, representing the end date or the number of periods you want in your vector

Output:

obj : A nPeriods*1 vector of nb_quarter objects.

Examples:

```
f = nb_quarter(1,2010);
g = nb_quarter(4,2010);
vector = f.vec(g)
```

See also:

[nb_quarter](#)

Written by Tobias Ingebrigtsen

► **vintage2Date** ↑

```
date = nb_date.vintage2Date(vintage,freq)
```

Description:

This method converts a vintage date into a nb_date object with the wanted frequency. You can also convert a cellstring containing multiple vintage dates.

Input:

- vintage : Either the vintage date that you want to convert, or a cellstring containing the vintage dates you want to convert.
- freq : The wanted frequency. Your options are 1, 4, 12 or 365.

Output:

- date : A 1xNumberOfVintages vector containing nb_date object(s).

Examples:

```
f = '20110622'  
t = nb_date.vintage2Date(f,4)
```

OR

```
f = {'20110622','20111019','20120314'} |  
t = nb_date.vintage2Date(f,4)
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

■ **nb_semiAnnual**

Go to: [Properties](#) | [Methods](#)

A class representing a semiannual date.

Superclasses:

nb_date

Constructor:

```
obj = nb_semiAnnual(halfYear,year)
```

Input:

- halfYear : A string on one of the following date formats:

> 'yyyySq'

> 'dd.mm.yyyy'

Or an integer with the half year. (Must be combined with the year argument)

- year : Must be an integer with the year.

Output:

- obj : An nb_year object.

Examples:

```
obj = nb_year('2012');
obj = nb_year(2012);
```

See also:

[nb_date](#), [nb_year](#), [nb_quarter](#), [nb_month](#), [nb_day](#), [nb_week](#)

Properties:

- [baseYear](#)
- [dayOfWeek](#)
- [frequency](#)
- [halfYear](#)
- [halfYearNr](#)
- [leapYear](#)
- [year](#)

- **baseYear** ↑

The base year. 2000.

Inherited from superclass NB_DATE

- **dayOfWeek** ↑

The day which the weekly date represents when converted to or from a weekly frequency. Default is 1, which is sunday.

Inherited from superclass NB_DATE

- **frequency** ↑

The frequency of the date. Must be 1.

- **halfYear** ↑

The given half year as a double.

- **halfYearNr** ↑

The number of half years since the base.
Which is the first half year of 2000

- **leapYear** ↑

Indicator for leap year. 1 if leap year.

Inherited from superclass NB_DATE

- **year** ↑

The given year as a double

► **ascensionDay** ↑

day = ascensionDay(obj, ~)

Description:

Give the ascension day of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_semiannual.easter](#), [nb_semiannual.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► cell2Date ↑

```
obj = nb_date.cell2Date(cellstr,freq)
```

Description:

Converts a cellstring of dates into a nb_date object.

Input:

- cellstr : The cellstring of dates that you want to convert.
- freq : The frequency of your data. You can choose between 1, 2, 4, 12, 52, and 365.

Output:

- date : A NumberOfDatesx1 vector containing nb_date objects.

Examples:

```
g = {'2011Q2'  
     '2011Q3'  
     '2011Q4'  
     '2012Q1'  
     '2012Q2'  
     '2012Q3'  
     '2012Q4'  
     '2013Q1'  
     '2013Q2'}
```

```
a = nb_date.cell2Date(g,4)
```

```
a =
```

```
'2011Q2'  
'2011Q3'  
'2011Q4'  
'2012Q1'  
'2012Q2'  
'2012Q3'  
'2012Q4'  
'2013Q1'  
'2013Q2'
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **christmas** ↑

```
day = christmas(obj,~)
```

Description:

Give the holidays of christmas (25th and 26th) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_semiAnnual.ascensionDay](#), [nb_semiannual.pentecost](#), [nb_semiannual.easter](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **colon** ↑

```
cellStr = colon(a,d,b)
```

Description:

Overload the : operator. The result is a cellstr array of all the dates between the a and b (Including the a and b dates).

Input:

- a : An object of class nb_date or of a subclass of the nb_date class
- d : Increments between the dates
- b : An object of class nb_date or of a subclass of the nb_date class

Output:

- cellStr : A cellstr array of the periods between the dates represented by a and b. (Including the dates a and b). If a and b are nb_date object an empty cell is returned.

Examples:

```
dates = a:b;  
dates = a:2:b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► convert ↑

```
obj = convert(obj,frequency,first)
```

Description:

Convert the nb_semiAnnual object ot the wanted frequency. The return variable will be an object which is of an subclass of the nb_date class.

Input:

- obj : An object of class nb_semiAnnual
- frequency : The frequency to convert to. As a scalar.
- first : 1 : first period
0 : last period

Only when converting the object to a higher frequency.

Output:

- obj : An object of subclass of the nb_date class with the frequency given by the frequency input.

Examples:

```
obj = nb_semiAnnual(1,2012);
obj = obj.convert(1);
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **date2freq ↑**

```
[startDate,frequency,type] = nb_date.date2freq(dates,xls)
```

Description:

A static method of the nb_date class.

Find out the frequency of the data (also from a xls(x) worksheet)

When trying to figure out the frequency of excel dates, this function must have at least two following dates

```
yearly      : 'yyyy' or 'dd.mm.yyyy'
semiannually : 'yyyySs' or 'dd.mm.yyyy'
quarterly   : 'yyyyQq' or 'yyyyKk', 'dd.mm.yyyy'
monthly     : 'yyyyMm(m)' or 'dd.mm.yyyy'
weekly       : 'yyyyWw(w)' or 'dd.mm.yyyy'
daily        : 'yyyyMm(m)Dd(d)', 'ddmonyyyy' or 'dd.mm.yyyy'
```

Input:

- dates : A cellstr of the dates you want to test the frequency of.
- xls : > 'xls' : If you want to test if the dates is on the format 'dd.mm.yyyy' also
 > otherwise will not (default)

Output:

- startDate : An object which is a subclass of the class nb_date, with the start date of the input dates. (Either nb_quarter, nb_month, nb_semiAnnual, nb_year, nb_week or nb_day)
- frequency : The frequency of the dates given.
 - > 1 : yearly
 - > 2 : semiannually
 - > 4 : quarterly
 - > 12 : monthly
 - > 52 : weekly

```
> 365 : daily  
- type      : 1 if the dates input is on the xls format,  
               otherwise 0
```

Examples:

```
dates = {'01.01.2012','02.01.2012','03.01.2012'};  
[startDate,frequency,type] = nb_date.date2freq(dates,'xls');
```

The output will in this example be:

- startDate : An nb_day object representing the date '01.01.2012'
- frequency : 365
- type : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **disp** ↑

```
disp(obj)
```

Description:

Sets how the nb_date object is displayed, and all subclasses of the nb_date class

Input:

- obj : An object of class nb_date or of a subclass of the nb_date class.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **easter** ↑

```
day = easter(obj,type)
```

Description:

Give the holidays or the sunday of easter of the year the date is located.

Input:

```
- obj : An object of class nb_date.  
- type : 'all' or 'sunday' (default).
```

Output:

```
- days : All the holidays as a vector of nb_day objects.
```

See also:

[nb_easter](#), [nb_semiAnnual.ascensionDay](#), [nb_semiannual.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **eq** ↑

```
ret = eq(obj,aObj)
```

Description:

Tests if the two objects representing the same dates

Input:

```
- obj : An object of class nb_semiAnnual  
- aObj : Another object of class nb_semiAnnual
```

Output:

```
- ret : 1 if equal, 0 else
```

Examples:

```
ret = obj == aObj;
```

Written by Kenneth S. Paulsen

► **format2string** ↑

```
date = nb_date.format2string(obj,format)  
date = nb_date.format2string(obj,format,language,first)
```

Description:

Get date at a given format.

Input:

- obj : An object of a subclass of nb_date.
- format : A string with the format. A combination of the following patterns:

- d : Day of the date. Examples:

```
> 'dd'   : '01', '10'  
> 'd'    : '1', '0'  
> 'd(d)' : '1', '10'  
- w : Week of date. Same options as for d.  
- m : Month of date. Same options as for d.
```

- q : Quarter of date. Examples:

```
> 'q'   : '1', '4'  
- h : Half year of date. Same options as for h.  
- y : Year of date.  
    > 'yyyy' : '2016'  
    > 'yyy'  : '016'  
    > 'yy'   : '16'  
    < 'y'    : '6'
```

Caution: To use the actual letter of the patterns use \ in front of the letter. E.g. '\y'.

Extra (see also the language option):

- 'Monthtext' : Month of date as full text. Starting with upper case.
- 'monthtext' : Month of date as full text. Starting with upper case.
- 'Quartertext' : > 'norwegian' : '. kv.'
 > 'english' : 'Q'
- 'Weektext' : > 'norwegian' : 'Uke'
 > 'english' : 'Week'
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- date : A string of the date on the wanted format.

Examples:

```
d      = nb_day.today();  
date = nb_date.format2string(d,'dd.mm.yyyy');  
date = nb_date.format2string(d,'d(d).m(m).yyyy');  
date = nb_date.format2string(d,'d(d) Monthtext yyyy');  
date = nb_date.format2string(d,'d(d). monthtext yyyy','norwegian');
```

```

m      = nb_month.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'Monthtext yyyy');
date = nb_date.format2string(m,'Monthtext yyyy','norwegian');

q      = nb_quarter.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'qQ yyyy');
date = nb_date.format2string(m,'q. kv. yyyy');

y      = nb_year.today();
date = nb_date.format2string(y,'dd.mm.yyyy');
date = nb_date.format2string(y,'yyyy');
date = nb_date.format2string(y,'\year yyyy');

```

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **freqPlus** ↑

obj = freqPlus(obj,incr,freq)

Description:

Plus the number of periods of another (lower) frequency.

E.g. dayNextYear = freqPlus(day,1,1);

Input:

- obj : An object of class nb_date.
- periods : A scalar integer with the periods to add.
- freq : The frequency of the periods argument.

Output:

- ob : An object of class nb_date.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **fromxlsDates2freq** ↑

```
frequency = nb_date.fromxlsDates2freq(dates)
```

Description:

A static method of the nb_date class.

Try to find out the date frequency of the excel dates. I.e. dates on the format 'dd.mm.yyyy'.

Input:

- Dates : A cellstr with at least two dates on the date format 'dd.mm.yyyy'.

Output:

- frequency : The frequency of the input dates given as an integer.

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2
> Yearly	:	1

Examples:

```
dates      = {'01.01.2012','02.01.2012','03.01.2012'};  
frequency = nb_date.fromxlsDates2freq(dates)
```

The output will in this example be:

- frequency : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **ge ↑**

```
ret = ge(obj,aObj)
```

Description:

Tests if an object is greater then or equal to another object. Which will mean that the first input is after or the same as the second input in the calendar

Input:

- obj : An object of class nb_semiAnnual
- aObj : Another object of class nb_semiAnnual

Output:

- ret : 1 if obj >= aObj, 0 else

Examples:

```
ret = obj >= aObj;
```

Written by Kenneth S. Paulsen

► **getDate ↑**

```
date = getDate(obj, freq)
```

Description:

Get the date of the object at another frequency. If the frequency is higher the first period is returned

Input:

- obj : An object of class nb_semiAnnual
- freq : The frequency you want to convert to.
 - 1 : nb_year
 - 2 : nb_semiAnnual
 - 4 : nb_quarter
 - 12 : nb_month
 - 52 : nb_week
 - 365 : nb_day

Output:

- date : The date of the object at the new frequency. As an object which is a subclass of the nb_date class.

Examples:

```
date = obj.getDate(4); % Will return a nb_quarter object
```

See also:

[nb_semiAnnual.convert](#)

► **getDay** ↑

```
day = getDay(obj,first)
```

Description:

Get the first or last day of the year, given as an nb_day object

Input:

- obj : An object of class nb_semiAnnual
- first : 1 : first day
0 : last day
2 : The first day that match the dayOfWeek property.
3 : The last day that match the dayOfWeek property.

Output:

- day : An nb_day object

Examples:

```
obj = nb_semiAnnual(1,2020);  
day = obj.getDay();      % Will return the first day of the year  
day = obj.getDay(0);    % Will return the last day of the year
```

Written by Kenneth S. Paulsen

► **getDays** ↑

```
days = getDays(obj)
```

Description:

Get all the days of the given half year as a cell of nb_day objects

Input:

- obj : An object of class nb_semiAnnual

Output:

- days : A cell array of nb_day objects

Examples:

```
days = obj.getDays();
```

Written by Kenneth S. Paulsen

► **getEarliestDate** ↑

```
date = nb_date.getEarliestDate(c)
```

Description:

Get the earliest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getFreq** ↑

```
freq = getFreq(obj)
```

Description:

Gets the frequency of the object.

Input:

- obj : An object of class nb_semiAnnual

Output:

- freq : 1

Examples:

```
freq = obj.getFreq();
```

Written by Kenneth S. Paulsen

► **getFrequencyAsInteger** ↑

```
frequency = nb_date.getFrequencyAsInteger(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as an integer given a frequency as a string

Input:

- frequency : Frequency input as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly', 'annual'

Output:

- frequency : The frequency as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Examples:

```
frequency = nb_date.getFrequencyAsInteger('yearly')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getFrequencyAsString** ↑

```
frequency = nb_date.getFrequencyAsString(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as a string given a frequency as an integer

Input:

- frequency : Frequency input as an integer

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2
> Yearly	:	1

Output:

- frequency : The frequency as a string

> Daily	:	'daily'
> Weekly	:	'weekly'
> Monthly	:	'monthly'
> Quarterly	:	'quarterly'
> Semiannually	:	'semiannually'
> Yearly	:	'yearly'

Examples:

```
frequency = nb_date.getFrequencyAsString(1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getLatestDate ↑**

```
date = nb_date.getLatestDate(c)
```

Description:

Get the latest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getMonth** ↑

```
month = getMonth(obj,first)
```

Description:

Get the first or last month of the half year, given as a nb_month object

Input:

- obj : An object of class nb_semiAnnual
- first : 1 : first month
0 : last month

Output:

- month : An nb_month object

Examples:

```
month = obj.getMonth(); % Will return the first month
month = obj.getMonth(1); % Will return the last month
```

Written by Kenneth S. Paulsen

► **getMonths** ↑

```
months = getMonths(obj)
```

Description:

Get all the months of the given half year as a cell of nb_month objects

Input:

- obj : An object of class nb_semiAnnual

Output:

- months : A cell array of nb_month objects

Examples:

```
months = obj.getMonths();
```

Written by Kenneth S. Paulsen

► **getNr ↑**

```
nr = getNr(obj)
```

Description:

Get date number of a nb_date vector.

Input:

- obj : A vector of nb_date objects.

Output:

- nr : A double with the date numbers of each object in the nb_date vector.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getNumberOfDays ↑**

```
numberOfDays = getNumberOfDays(obj)
```

Description:

Get the number of days in the given year

Input:

- obj : An object of class nb_semiAnnual

Output:

- numberOfDays : The number of days, given as double

Examples:

```
numberOfDays = obj.getNumberOfDays();
```

Written by Kenneth S. Paulsen

► **getNumberOfWeeks ↑**

```
numberOfWeeks = getNumberOfWeeks(obj)
```

Description:

Get the number of weeks in the given half year

Input:

- obj : An object of class nb_semiAnnual

Output:

- numberOfWeeks : The number of weeks, given as double

Written by Kenneth S. Paulsen

► **getQuarter ↑**

```
quarter = getQuarter(obj,first)
```

Description:

Get the first or last quarter of the half year, given as an nb_quarter object

Input:

- obj : An object of class nb_semiAnnual

Output:

- quarter : An nb_quarter object
- first : 1 : first quarter
0 : last quarter

Examples:

```
quarter = obj.getQuarter(); % Will return the first quarter
quarter = obj.getQuarter(1); % Will return the last quarter
```

Written by Kenneth S. Paulsen

► **getQuarters** ↑

```
quarters = getQuarters(obj)
```

Description:

Get all the quarters of the given half year as a cell of nb_quarter objects

Input:

- obj : An object of class nb_semiAnnual

Output:

```
quarters : A cell array of nb_quarter objects
```

Examples:

```
quarters = obj.getQuarters();
```

Written by Kenneth S. Paulsen

► **getWeek** ↑

```
week = getWeek(obj,first,dayOfWeek)
```

Description:

Get the first or last week of the half year, given as an nb_week object

Input:

```
- obj : An object of class nb_semiAnnual  
- first : 1 : first day  
          0 : last day  
  
- dayOfWeek : The weekday the given week represents when  
               converted to a day. (1-7 (Monday-Sunday)). Default  
               is to use the dayOfWeek property.
```

Output:

```
- week : An nb_week object
```

Examples:

```
week = obj.getWeek();      % Will return the first week of the year  
week = obj.getWeek(0);    % Will return the last week of the year
```

Written by Kenneth S. Paulsen

► **getWeeks** ↑

```
weeks = getWeeks(obj,dayOfWeek)
```

Description:

Get all the weeks of the given half year as a cell of nb_week objects

Input:

```
- obj : An object of class nb_semiAnnual  
  
- dayOfWeek : The weekday the given week represents when  
               converted to a day. (1-7 (Monday-Sunday)). Default  
               is to use the dayOfWeek property.
```

Output:

```
- weeks : A cell array of nb_week objects
```

Examples:

```
sAnnual = nb_semiAnnual(1,2020);  
weeks = sAnnual.getWeeks();
```

Written by Kenneth S. Paulsen

► **getYear** ↑

```
year = getYear(obj)
```

Description:

Get the year of the half year, given as a nb_year object

Input:

- obj : An object of class nb_semiAnnual

Output:

- year : A object of class nb_year

Examples:

```
sAnnual = nb_semiAnnual(1,2020);
year      = sAnnual.getYear();
```

Written by Kenneth S. Paulsen

► **gt** ↑

```
ret = gt(obj,aObj)
```

Description:

Tests if an object is greater than another object. Which will mean that the first input is after the second input in the calendar

Input:

- obj : An object of class nb_semiAnnual

- aObj : An object of class nb_semiAnnual

Output:

- ret : 1 if obj > aObj, 0 else

Examples:

```
ret = obj > aObj;
```

Written by Kenneth S. Paulsen

► **holidays** ↑

```
days = holidays(obj)
```

Description:

Find the holidays of the given date object.

Input:

- obj : An object of class nb_month, nb_quarter, nb_semiAnnual or nb_year.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_semiannual.easter](#), [nb_semiAnnual.ascensionDay](#), [nb_semiannual.pentecost](#)
[nb_semiannual.christmas](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **initialize ↑**

```
obj = nb_date.initialize(freq, dim1, dim2)
```

Description:

Initialize a vector of date objects.

Input:

- freq : The wanted frequency of the date of today. 1,2,4,12,52 or 365.
- dim1 : The size of the first dimension.
- dim2 : The size of the second dimension.

Output:

obj : A vector of nb_date objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **intersect ↑**

```
cout = nb_date.intersect(varargin)
```

Description:

Get the intersection of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isDate** ↑

```
ret = nb_date.isDate(input,freq)
```

Description:

Test if a string or nb_date object is a date. It is also possible to restrict the test to a specific frequency.

Input:

- input : Any object
- freq : 1, 2, 4, 12, 52 or 365. Can also be empty, but then it is slower.
- locVar : A nb_struct/struct with the supported local variables. If the input is a string using the syntax '%#name', this input will be looked up and tested.

Output:

- ret : Either true or false. true if input is a date string or nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isEqualFreq** ↑

```
ret = isEqualFreq(obj,aObj)
```

Description:

Test if two date objects have the same frequency

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class
- aObj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : 1 if equal frequency, 0 else

Examples:

```
d = nb_day(1,1,2012);
q = nb_quarter(4,2012);
ret = d.isEqualFreq(q); % Will return 0
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isFirstPeriod ↑**

```
ret = isFirstPeriod(obj,freq)
```

Description:

Return if the obj represent the first period a lower frequency.

Input:

- obj : An object which of a subclass of the nb_date class.
- freq : The lower frequency.

Output:

- ret : True if the object represent the first period of the lower frequency.

Examples:

```
q = nb_quarter(1,2000)
ret = isFirstPeriod(q,1)

m = nb_month(10,2000)
ret = isFirstPeriod(m,4)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isLeapYear** ↑

```
ret = isLeapYear(obj)
```

Description:

Test if the current year is a leap year

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : Logical. 1 if object is leap year, 0 else

Examples:

```
ret = obj.isLeapYear();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isPeriod** ↑

```
ret = isPeriod(obj,period)
```

Description:

Return true if the obj represent the given period, i.e. if you want to test if a nb_quarter object represent the first period of any year you can use isPeriod(obj,1).

Input:

- obj : An object which of a subclass of the nb_date class.
- period : The period to test for.

Output:

- ret : True if the object represent the period to test for, else false.

Examples:

```
q    = nb_quarter(1,2000)
ret = isPeriod(q,1)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE
```

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if the object is empty

Input:

- obj : An object of class nb_semiAnnual

Output:

- ret : 1 if empty, 0 else. Always false for vectors of objects.

Examples:

```
ret = objisempty();
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **isequal** ↑

```
ret = isequal(obj,aObj)
```

Description:

Tests if the two objects representing the same date

Input:

- obj : An object of class nb_semiAnnual
- aObj : Another object of class nb_semiAnnual

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj.isequal(aObj);
ret = isequal(obj,aObj);
```

Written by Kenneth S. Paulsen

► **ismember** ↑

- varargout = ismember(obj1,obj2)

Description:

Utilizes the inbuilt MATLAB function 'ismember' for nb_date objects.

Input:

- obj1 : A nb_date object
- obj2 : A nb_date object

Output:

- varargout : See help on MATLAB function 'ismember'.

See also:

[ismember](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **le** ↑

ret = le(obj,aObj)

Description:

Tests if an object is less then or equal to another object.
Which will mean that the first input is before or the same as
the second input in the calendar.

Input:

- obj : An object of class nb_semiAnnual
- aObj : An object of class nb_semiAnnual

Output:

- ret : 1 if obj <= aObj, 0 else

Examples:

ret = obj <= aObj;

Written by Kenneth S. Paulsen

► **lt** ↑

ret = lt(obj,aObj)

Description:

Tests if an object is less than another object. Which will mean that the first input is before the second input in the calendar

Input:

- obj : An object of class nb_semiAnnual
- aObj : An object of class nb_semiAnnual

Output:

- ret : 1 if obj < aObj, 0 else

Examples:

ret = obj < aObj;

Written by Kenneth S. Paulsen

► **max** ↑

d = max(obj)
[d,ind] = max(obj)
d = max(obj,aObj)

Description:

Find the max date.

Input:

One input:

- obj : A vector of nb_semiAnnual objects.

Two inputs:

- obj : A scalar nb_semiAnnual object.

- aObj : A scalar nb_semiAnnual object.

Output:

- d : A scalar nb_semiAnnual object.

- ind : The index of the last date.

Written by Kenneth Sæterhagen Paulsen

► **min ↑**

```
d      = min(obj)
[d,ind] = min(obj)
d      = min(obj,aObj)
```

Description:

Find the min date.

Input:

One input:

- obj : A vector of nb_semiAnnual objects.

Two inputs:

- obj : A scalar nb_semiAnnual object.

- aObj : A scalar nb_semiAnnual object.

Output:

- d : A scalar nb_semiAnnual object.

- ind : The index of the first date.

Written by Kenneth Sæterhagen Paulsen

► **minus ↑**

```
output = minus(obj,aObj)
```

Description:

Makes it possible to take an nb_semiAnnual object minus another nb_semiAnnual object and get the number of half years between them.

It makes it also possible to take the difference between an nb_semiAnnual object and a string on one of the following formats: 'yyyySs', 'dd.mm.yyyy'

And last it makes it possible to subtract the number of half years from an nb_semiAnnual object and receive an nb_semiAnnual representing the half year the given number of half years backward in time.

Input:

- obj : A date string, an nb_semiAnnual object or an integer.
- aObj : A date string, an nb_semiAnnual object or an integer.

Output:

- output : The number of years between the given half years. As a double

or

An nb_semiAnnual object representing the date the given number of half years backwards in time.

Examples:

```
output = obj - aObj;      % (both objects). Returns a double
```

```
output = obj - '2012';   % Returns a double
```

```
output = '2012' - obj;  % Returns a double
```

```
output = obj - 1;        % Returns an object
```

same as

```
output = 1 - obj;       % Returns an object
```

Written by Kenneth S. Paulsen

► ne ↑

```
ret = ne(obj,aObj)
```

Description:

Tests if the two objects not representing the same date

Input:

- obj : An object of class nb_semiAnnual
- aObj : An object of class nb_semiAnnual

Output:

- ret : 1 if obj is not equal to aObj, 0 else

Examples:

```
% ret = obj ~= aObj;
```

Written by Kenneth S. Paulsen

► **pentecost** ↑

```
day = pentecost(obj,~)
```

Description:

Give the pentecost (monday) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_semiannual.easter](#), [nb_semiAnnual.ascensionDay](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **plus** ↑

```
out = plus(obj,aObj)
```

Description:

Makes it possible to add a given number of half years to an nb_semiAnnual object and receive an nb_semiAnnual object which represents the half year the given numbers of half years ahead

Input:

- obj : A nx1 double or a nx1 nb_semiAnnual object
- aObj : A nx1 double or a nx1 nb_semiAnnual object

Output:

- out : A nx1 nb_semiAnnual object the given number of half years ahead

Examples:

```
obj = obj + 1;
```

same as

```
obj = 1 + obj;
```

Written by Kenneth S. Paulsen

► **setDayOfWeek ↑**

```
obj = setDayOfWeek(obj,dayOfWeek)
```

Description:

Set the day of week number of a set of nb_date objects.

Input:

- obj : A nb_date object. May be a vector or matrix.

Output:

- obj : A nb_date object with the same size as the obj input.

See also:

[nb_semiAnnual.dayOfWeek](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **sort** ↑

```
[obj,ind] = sort(obj)
```

Description:

Sort a vector of nb_date objects.

Input:

- obj : A vector of nb_date objects.

Output:

- obj : A sorted vector of nb_date objects.

- ind : The index of the sorting.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **toDate** ↑

```
dObj = nb_date.toDate(date,frequency)
```

Description:

A static method of the nb_date class.

Transform a given date string to the corresponding date object given that the frequency is already known.

If the frequency is not known, use the method date2freq() (handles also excel dates) or getFreq() (Only nb_ts dates).

Input:

- date :

Supported date formats:

> Daily : 'dd.mm.yyyy' and 'yyyyMm(m)Dd(d)'

> Weekly : 'dd.mm.yyyy' and 'yyyyWw(w)'

> Monthly : 'dd.mm.yyyy' and 'yyyyMm(m)'

> Quarterly : 'dd.mm.yyyy' and 'yyyyQq'

> Semiannually : 'dd.mm.yyyy' and 'yyyySs'

```

> Yearly      : 'dd.mm.yyyy' and 'yyyy'
> Secondly    : 'yyyy-mm-dd hh:nn:ss' and 'yyyymmddhhnnss'
                (only supported if this version of the toolbox
                 includes the nb_second class)

- frequency :

> Daily       : 365
> Weekly      : 52
> Monthly     : 12
> Quarterly   : 4
> Semiannually : 2
> Yearly      : 1
> Secondly    : 31536000

```

Output:

```

- dObj      :

> Daily      : An nb_day object
> Weekly     : An nb_week object
> Monthly    : An nb_month object
> Quarterly  : An nb_quarter object
> Semiannually : An nb_semiAnnual object
> Yearly     : An nb_year object
> Secondly   : An nb_second object

```

Examples:

```

dObj = nb_date.toDate('2012M1D1',365);
dObj = nb_date.toDate('2012M1',12);
dObj = nb_date.toDate('2012Q1',4);
dObj = nb_date.toDate('2012S1',2);
dObj = nb_date.toDate('2012',1);

```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **toDates ↑**

```
varargout = toDates(obj,periods,format,newFreq,first)
```

Description:

Get a cellstr array of the dates ahead

Input:

- obj : The object itself
 - periods : The periods wanted, must be given as a double array.
E.g. 1:20.
 - format : Set the format of the cellstr of dates:
 - > 'nb_date' : The output will be a vector of nb_date objects.
 - > 'default' : 'yyyySs'
 - > 'fame' : 'yyyySs'
 - > 'xls' : 'dd.mm.yyyy'
 - > 'vintage' : 'yyyymmdd'
- Formats which is dependent on the 'newFreq' input
- > 'NBNorsk' ('NBNorwegian'):
 - newFreq:
 - > 1 : 'YYYY'
 - > 2 : 'mmmm. yy', e.g. 'jan. 08' and 'jul. 08'
 - > 4 : Not possible
 - > 12 : Not possible
 - > 52 : Not possible
 - > 365 : Not possible
 - (Date strings are only given for the days which ends the periods)
 - > 'NBEnglish' ('NBEngelsk'):
 - newFreq:
 - > 1 : 'YYYY'
 - > 2 : 'mmmm-yy', e.g. 'Jan-08' and 'Jul-08'
 - > 4 : Not possible
 - > 12 : Not possible
 - > 52 : Not possible
 - > 365 : Not possible
 - (Date strings are only given for the days which ends the periods)
- newFreq : > 1 : yearly
 - > 2 : semiannually
 - > 4 : quarterly (Not possible)
 - > 12 : monthly (Not possible)
 - > 52 : weekly (Not possible)
 - > 365 : daily (Not possible)
- first : When converting to a lower frequency you must set if you want to use the first date or the last date as

the location of the returned date. The default is to use the first.

```
1 : first  
0 : last
```

Output:

- varargout{1} : A cell array of the wanted dates.
- varargout{2} : Locations of the returned dates. Of interest when converting to lower frequencies

Examples:

```
dates          = obj.toDates(0:20);  
dates          = obj.toDates(0:20,'xls');  
[dates,locations] = obj.toDates(0:20,'NBNorsk',1);
```

Written by Kenneth S. Paulsen

► **toFormat ↑**

```
dates = toFormat(start,finish,format,language,first)
```

Description:

Convert dates vector to a given format.

Input:

- start : An object of a subclass of the nb_date class.
- finish : An object of a subclass of the nb_date class.
- format : See the format input to the nb_date.format2string method.
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- vint : A cellstr.

See also:

[nb_semiannual.format2string](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **toString** ↑

```
date = toString(obj, format, extra)
```

Description:

Transform the nb_semiAnnual object to a string representing the date. It will be given in the format: 'yyyyQq'.

Input:

- obj : AN object of class nb_semiAnnual

Optional input:

- format : > 'xls' : 'dd.mm.yyyy'
> 'nborsk' or 'nbnorwegian' : 'mmm. yy'
> 'nbengelsk' or 'nbenglish' : 'Mmm. yy'
> 'pprnorsk' or 'mprnorwegian' : 'Monthtext yyyy'
> 'pprengelsk' or 'mprenglish' : 'Monthtext yyyy'
> 'default' : 'yyyySs'
> 'vintage' : 'yyyymmdd'

- extra :

> 'xls':

Give 1 if you want the date string to represent the first day of the half year ('01.01.yyyy'), otherwise last day of the half year will be given ('31.06.yyyy'). Only when format is given as 'xls'

> 'pprnorsk', 'mprnorwegian', 'pprengelsk', 'mprenglish' :

Give 0 if you want the month text in lowercase only.
Default is that the month text starts with an uppercase.

Output:

- date : A string with the date on the wanted format

Written by Kenneth S. Paulsen

► **today** ↑

```
obj = nb_semiAnnual.today()
```

Description:

Get the current half year as a nb_semiAnnual object.

Output:

obj : An object of class nb_semiAnnual.

Written by Kenneth SÃ¶terhagen Paulsen

► **union** ↑

```
cout = nb_date.union(varargin)
```

Description:

Get the union of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **unique** ↑

```
obj = unique(obj)
```

Description:

Get unique elements of a vector of nb_date objects.

Input:

- in : A vector of nb_date objects.

Output:

- out : A unique (sorted) vector of nb_date objects.

- IA : out = in(IA)

- IC : A = C(IC)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **vec** ↑

```
out = vec(obj,endD)
```

Description:

A method to create a vector of dates between to dates.

Input:

obj : An nb_semiAnnual object which represents the start date of the vector
end : An nb_semiAnnual object or a double, representing the end date or the number of periods you want in your vector

Output:

```
obj : A nPeriods*1 vector of nb_semiAnnual objects.
```

Examples:

```
f = nb_semiAnnual(1,2010);  
g = nb_semiAnnual(2,2011);  
vector = f.vec(g)
```

See also:

[nb_semiAnnual](#)

Written by Tobias Ingebrigtsen

► **vintage2Date** ↑

```
date = nb_date.vintage2Date(vintage,freq)
```

Description:

This method converts a vintage date into a nb_date object with the wanted frequency. You can also convert a cellstring containing multiple vintage dates.

Input:

- vintage : Either the vintage date that you want to convert, or a cellstring containing the vintage dates you want to convert.
- freq : The wanted frequency. Your options are 1, 4, 12 or 365.

Output:

```
- date : A 1xNumberOfVintages vector containing nb_date object(s).
```

Examples:

```
f = '20110622'  
t = nb_date.vintage2Date(f, 4)
```

OR

```
f = {'20110622', '20111019', '20120314'} |  
t = nb_date.vintage2Date(f, 4)
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

■ nb_week

Go to: [Properties](#) | [Methods](#)

A class representing a weekly date.

Superclasses:

nb_date

Constructor:

```
obj = nb_week(week)  
obj = nb_week(week, dayOfWeek)  
obj = nb_week(week, year)  
obj = nb_week(week, year, dayOfWeek)
```

Input:

```
- week : A string on one of the following date formats:  
        > 'yyyyWw(w)', e.g. '2012W1'  
        > 'dd.mm.yyyy', e.g. '10.01.2012', '17.01.2012'  
        Or an integer with the week. (Must be combined  
        with the year arguments)  
- year : Must be an integer with the year.  
- dayOfWeek : Should only be provided with the date format 'yyyyWw(w)'  
    or when week and year inputs are both doubles. Default  
    is 1, which is sunday.
```

Output:

```
- obj : An nb_week object.
```

Examples:

```
obj = nb_week('01.01.2001');
```

```
obj = nb_week('2001W1');
obj = nb_week('2001W1',1);
obj = nb_week(1,2001);
obj = nb_week(1,2001,1);
```

Properties:

- [baseYear](#)
- [dayOfWeek](#)
- [frequency](#)
- [leapYear](#)
- [specialYear](#)
- [week](#)
- [weekNr](#)
- [year](#)

- [baseYear](#) ↑

The base year. 2000.

Inherited from superclass NB_DATE

- [dayOfWeek](#) ↑

The day which the weekly date represents when converted to or from a weekly frequency. Default is 1, which is sunday.

Inherited from superclass NB_DATE

- [frequency](#) ↑

The frequency of the date. Must be 52.

- [leapYear](#) ↑

Indicator for leap year. 1 if leap year.

Inherited from superclass NB_DATE

- [specialYear](#) ↑

Indicator. Is 1 if the year has 53 weeks, otherwise 0.

- [week](#) ↑

The given day as a double

- [weekNr](#) ↑

The number of weeks since the base year, which is the first week of 2000

- [year](#) ↑

The year of the given week

► ascensionDay ↑

```
day = ascensionDay(obj,~)
```

Description:

Give the ascension day of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_week.easter](#), [nb_week.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **cell2Date** ↑

```
obj = nb_date.cell2Date(cellstr,freq)
```

Description:

Converts a cellstring of dates into a nb_date object.

Input:

- cellstr : The cellstring of dates that you want to convert.
- freq : The frequency of your data. You can choose between 1, 2, 4, 12, 52, and 365.

Output:

- date : A NumberOfDatesx1 vector containing nb_date objects.

Examples:

```
g = {'2011Q2'  
     '2011Q3'  
     '2011Q4'  
     '2012Q1'  
     '2012Q2'  
     '2012Q3'  
     '2012Q4'  
     '2013Q1'  
     '2013Q2'}
```

```
a = nb_date.cell2Date(g,4)
```

```
a =
```

```
'2011Q2'  
'2011Q3'  
'2011Q4'  
'2012Q1'  
'2012Q2'  
'2012Q3'  
'2012Q4'  
'2013Q1'  
'2013Q2'
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **christmas** ↑

```
day = christmas(obj,~)
```

Description:

Give the holidays of christmas (25th and 26th) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_week.ascensionDay](#), [nb_week.pentecost](#), [nb_week.easter](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **colon** ↑

```
cellStr = colon(a,d,b)
```

Description:

Overload the : operator. The result is a cellstr array of all the dates between the a and b (Including the a and b dates).

Input:

- a : An object of class nb_date or of a subclass of the nb_date class
- d : Increments between the dates
- b : An object of class nb_date or of a subclass of the nb_date class

Output:

- cellStr : A cellstr array of the periods between the dates represented by a and b. (Including the dates a and b). If a and b are nb_date object an empty cell is returned.

Examples:

```
dates = a:b;  
dates = a:2:b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **convert ↑**

```
obj = convert(obj,frequency,first)
```

Description:

Convert the nb_week object ot the wanted frequency. The returned variable will be an object which is of an subclass of the nb_date class.

Input:

- obj : An object of class nb_week
- frequency : The frequency to convert to. As a scalar.
- first : Does nothing. Just to make the code general for all frequencies.

Output:

- obj : An object of subclass of the nb_date class with the frequency given by the frequency input.

Examples:

```
obj = nb_week(1,2012);  
obj = obj.convert(1);
```

Written by Kenneth Sæterhagen Paulsen

► **date2freq ↑**

```
[startDate,frequency,type] = nb_date.date2freq(dates,xls)
```

Description:

A static method of the nb_date class.

Find out the frequency of the data (also from a xls(x) worksheet)

When trying to figure out the frequency of excel dates, this function must have at least to following dates

```
yearly      : 'yyyy' or 'dd.mm.yyyy'  
semiannually : 'yyyySs' or 'dd.mm.yyyy'  
quarterly   : 'yyyyQq' or 'yyyyKk', 'dd.mm.yyyy'  
monthly     : 'yyyyMm(m)' or 'dd.mm.yyyy'  
weekly       : 'yyyyWw(w)' or 'dd.mm.yyyy'  
daily        : 'yyyyMm(m)Dd(d)', 'ddmonyyyy' or 'dd.mm.yyyy'
```

Input:

- dates : A cellstr of the dates you want to test the frequency of.
- xls : > 'xls' : If you want to test if the dates is on the format 'dd.mm.yyyy' also
 - > otherwise will not (default)

Output:

- startDate : An object which is a subclass of the class nb_date, with the start date of the input dates. (Either nb_quarter, nb_month, nb_semiAnnual, nb_year, nb_week or nb_day)
- frequency : The frequency of the dates given.
 - > 1 : yearly
 - > 2 : semiannually
 - > 4 : quarterly
 - > 12 : monthly
 - > 52 : weekly
 - > 365 : daily
- type : 1 if the dates input is on the xls format, otherwise 0

Examples:

```
dates = {'01.01.2012','02.01.2012','03.01.2012'};  
[startDate,frequency,type] = nb_date.date2freq(dates,'xls');
```

The output will in this example be:

- startDate : An nb_day object representing the date '01.01.2012'
- frequency : 365
- type : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **disp ↑**

```
disp(obj)
```

Description:

Sets how the nb_date object is displayed, and all subclasses of the nb_date class

Input:

- obj : An object of class nb_date or of a subclass of the nb_date class.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **easter** ↑

```
day = easter(obj,type)
```

Description:

Give the holidays or the sunday of easter of the year the date is located.

Input:

- obj : An object of class nb_date.
- type : 'all' or 'sunday' (default).

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_week.ascensionDay](#), [nb_week.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **eq** ↑

```
ret = eq(obj,aObj)
```

Description:

Tests if the two objects represent the same date

Input:

- obj : An object of class nb_week
- aObj : Another object of class nb_week

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj == aObj;
```

Written by Kenneth S. Paulsen

► **format2string ↑**

```
date = nb_date.format2string(obj,format)
date = nb_date.format2string(obj,format,language,first)
```

Description:

Get date at a given format.

Input:

- obj : An object of a subclass of nb_date.
- format : A string with the format. A combination of the following patterns:

- d : Day of the date. Examples:

```
> 'dd'   : '01', '10'
> 'd'    : '1', '0'
> 'd(d)': '1', '10'
- w : Week of date. Same options as for d.
- m : Month of date. Same options as for d.
```

- q : Quarter of date. Examples:

```
> 'q'    : '1', '4'
- h : Half year of date. Same options as for h.
- y : Year of date.
    > 'yyyy' : '2016'
    > 'yyy'  : '016'
    > 'yy'   : '16'
    < 'y'    : '6'
```

Caution: To use the actual letter of the patterns use \ in front of the letter. E.g. '\y'.

Extra (see also the language option):

- 'Monthtext' : Month of date as full text. Starting with upper case.
- 'monthtext' : Month of date as full text. Starting with upper case.
- 'Quartertext' : > 'norwegian' : '. kv.'
 > 'english' : 'Q'
- 'Weektext' : > 'norwegian' : 'Uke'
 > 'english' : 'Week'
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- date : A string of the date on the wanted format.

Examples:

```
d = nb_day.today();
date = nb_date.format2string(d,'dd.mm.yyyy');
date = nb_date.format2string(d,'d(d).m(m).yyyy');
date = nb_date.format2string(d,'d(d) Monthtext yyyy');
date = nb_date.format2string(d,'d(d). monthtext yyyy','norwegian');

m = nb_month.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'Monthtext yyyy');
date = nb_date.format2string(m,'Monthtext yyyy','norwegian');

q = nb_quarter.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'qQ yyyy');
date = nb_date.format2string(m,'q. kv. yyyy');

y = nb_year.today();
date = nb_date.format2string(y,'dd.mm.yyyy');
date = nb_date.format2string(y,'yyyy');
date = nb_date.format2string(y,'\year yyyy');
```

See also:

[toString](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **freqPlus** ↑

```
obj = freqPlus(obj,incr,freq)
```

Description:

Plus the number of periods of another (lower) frequency.

E.g. dayNextYear = freqPlus(day,1,1);

Input:

- obj : An object of class nb_date.
- periods : A scalar integer with the periods to add.
- freq : The frequency of the periods argument.

Output:

- ob : An object of class nb_date.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATE

► **fromxlsDates2freq** ↑

```
frequency = nb_date.fromxlsDates2freq(dates)
```

Description:

A static method of the nb_date class.

Try to find out the date frequency of the excel dates. I.e. dates on the format 'dd.mm.yyyy'.

Input:

- Dates : A cellstr with at least two dates on the date format 'dd.mm.yyyy'.

Output:

- frequency : The frequency of the input dates given as an integer.

> Daily : 365

> Weekly : 52

```
> Monthly      : 12
> Quarterly    : 4
> Semiannually : 2
> Yearly       : 1
```

Examples:

```
dates      = {'01.01.2012','02.01.2012','03.01.2012'};
frequency = nb_date.fromxlsDates2freq(dates)
```

The output will in this example be:

- frequency : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **ge** ↑

```
ret = ge(obj,aObj)
```

Description:

Tests if an object is greater than or equal to another object.
Which will mean that the first input is after or the same
as the second input in the calendar

Input:

- obj : An object of class nb_week
- aObj : Another object of class nb_week

Output:

- ret : 1 if obj >= aObj, 0 else

Examples:

```
ret = obj >= aObj;
```

Written by Kenneth S. Paulsen

► **getDate** ↑

```
date = getDate(obj,freq)
```

Description:

Get the date of the object at another frequency.

Input:

- obj : An object of class nb_day
- freq : The frequency you want to convert to.
 - 1 : nb_year
 - 2 : nb_semiAnnual
 - 4 : nb_quarter
 - 12 : nb_month
 - 52 : nb_week
 - 365 : nb_day

Output:

- date : The date of the object at the new frequency. As an object which is a subclass of the nb_date class.

Examples:

```
date = obj.getDate(4); % Will return a nb_quarter object
```

See also:

[nb_week.convert](#)

Written by Kenneth S. Paulsen

► **getDay** ↑

```
day = getDay(obj,first)
```

Description:

Get the day of the week, given as a nb_day object

Input:

- obj : An object of class nb_week
- first : 2 : Uses the dayOfWeek property.
 - 1 : first day of the week (Monday)
 - 0 : last day of the week (Sunday)

Output:

- day : An nb_day object

Examples:

```
month = obj.getDay(); % Will return the day
```

Written by Kenneth S. Paulsen

► **getDays** ↑

```
days = getDays(obj)
```

Description:

Get all the days of the given week as a cell of nb_day objects

Input:

- obj : An object of class nb_week

Output:

- days : A cell array of nb_day objects

Examples:

```
days = obj.getDays();
```

Written by Kenneth S. Paulsen

► **getEarliestDate** ↑

```
date = nb_date.getEarliestDate(c)
```

Description:

Get the earliest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

```
- date : A nb_date object.  
Written by Kenneth Sæterhagen Paulsen  
Inherited from superclass NB_DATE
```

► **getFreq ↑**

```
freq = getFreq(obj)
```

Description:

Gets the frequency of the object.

Input:

```
- obj : An object of class nb_week
```

Output:

```
- freq : 52
```

Examples:

```
freq = obj.getFreq();
```

Written by Kenneth S. Paulsen

► **getFrequencyAsInteger ↑**

```
frequency = nb_date.getFrequencyAsInteger(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as an integer given a frequency as a string

Input:

```
- frequency : Frequency input as a string
```

```
> Daily : 'daily'  
> Weekly : 'weekly'  
> Monthly : 'monthly'  
> Quarterly : 'quarterly'  
> Semiannually : 'semiannually'  
> Yearly : 'yearly', 'annual'
```

Output:

```
- frequency : The frequency as an integer

> Daily      : 365
> Weekly     : 52
> Monthly    : 12
> Quarterly   : 4
> Semiannually : 2
> Yearly     : 1
```

Examples:

```
frequency = nb_date.getFrequencyAsInteger('yearly')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getFrequencyAsString** ↑

```
frequency = nb_date.getFrequencyAsString(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as a string given a frequency as an integer

Input:

```
- frequency : Frequency input as an integer

> Daily      : 365
> Weekly     : 52
> Monthly    : 12
> Quarterly   : 4
> Semiannually : 2
> Yearly     : 1
```

Output:

```
- frequency : The frequency as a string
```

```
> Daily           : 'daily'  
> Weekly          : 'weekly'  
> Monthly         : 'monthly'  
> Quarterly       : 'quarterly'  
> Semiannually    : 'semiannually'  
> Yearly          : 'yearly'
```

Examples:

```
frequency = nb_date.getFrequencyAsString(1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getHalfYear ↑**

```
halfYear = getHalfYear(obj)
```

Description:

Get the half year of the week, given as an nb_semiAnnual object

Input:

```
- obj      : An object of class nb_week
```

Output:

```
- halfYear : An nb_semiAnnual object
```

Examples:

```
halfYear = obj.getHalfYear(); % Will return the half year
```

Written by Kenneth S. Paulsen

► **getLatestDate ↑**

```
date = nb_date.getLatestDate(c)
```

Description:

Get the latest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getMonth** ↑

month = getMonth(obj)

Description:

Get the month of the week, given as a nb_month object

Input:

- obj : An object of class nb_week

Output:

- month : An nb_month object

Examples:

month = obj.getMonth(); % Will return the month

Written by Kenneth S. Paulsen

► **getNr** ↑

nr = getNr(obj)

Description:

Get date number of a nb_date vector.

Input:

- obj : A vector of nb_date objects.

Output:

- nr : A double with the date numbers of each object in the nb_date vector.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getNumberOfDays** ↑

numberOfDays = getNumberOfDays(obj)

Description:

Get the number of days in the given week (always 7)

Input:

- obj : An object of class nb_week

Output:

- numberOfDays : The number of days, given as double

Examples:

numberOfDays = obj.getNumberOfDays();

Written by Kenneth S. Paulsen

► **getQuarter** ↑

quarter = getQuarter(obj)

Description:

Get the quarter of the day, given as a nb_quarter object

Input:

- obj : An object of class nb_day

Output:

- quarter : An nb_quarter object

Examples:

```
quarter = obj.getQuarter(); % Will return the current quarter
```

Written by Kenneth S. Paulsen

► **getYear** ↑

```
year = getYear(obj)
```

Description:

Get the year of the week, given as a nb_year object

Input:

- obj : An object of class nb_week

Output:

- year : A nb_year object

Examples:

```
week = nb_week(1,2020);
year = week.getYear(); % Will return the current year
```

Written by Kenneth S. Paulsen

► **gt** ↑

```
ret = gt(obj,aObj)
```

Description:

Tests if an object is greater than another object. Which will mean that the first input is after the second input in the calendar

Input:

- obj : An object of class nb_week
- aObj : An object of class nb_week

Output:

```
- ret : 1 if obj > aObj, 0 else
```

Examples:

```
ret = obj > aObj;
```

Written by Kenneth S. Paulsen

► **holidays** ↑

```
days = holidays(obj)
```

Description:

Find the holidays of the given date object.

Input:

```
- obj : An object of class nb_month, nb_quarter, nb_semiAnnual or  
nb_year.
```

Output:

```
- days : All the holidays as a vector of nb_day objects.
```

See also:

[nb_week.easter](#), [nb_week.ascensionDay](#), [nb_week.pentecost](#)
[nb_week.christmas](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **initialize** ↑

```
obj = nb_date.initialize(freq, dim1, dim2)
```

Description:

Initialize a vector of date objects.

Input:

- freq : The wanted frequency of the date of today. 1,2,4,12,52 or 365.
- dim1 : The size of the first dimension.
- dim2 : The size of the second dimension.

Output:

obj : A vector of nb_date objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **intersect** ↑

cout = nb_date.intersect(varargin)

Description:

Get the intersection of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isDate** ↑

ret = nb_date.isDate(input,freq)

Description:

Test if a string ot nb_date object is a date. It is also possible to restrict the test to a specific frequency.

Input:

- input : Any object
- freq : 1, 2, 4, 12, 52 or 365. Can also be empty, but then it is slower.
- locVar : A nb_struct/struct with the supported local variables. If the input is a string using the syntax '%#name', this input will be looked up and tested.

Output:

- ret : Either true or false. true if input is a date string or nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isEqualFreq** ↑

```
ret = isEqualFreq(obj,aObj)
```

Description:

Test if two date objects have the same frequency

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class
- aObj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : 1 if equal frequency, 0 else

Examples:

```
d = nb_day(1,1,2012);
q = nb_quarter(4,2012);
ret = d.isEqualFreq(q); % Will return 0
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isFirstPeriod** ↑

```
ret = isFirstPeriod(obj,freq)
```

Description:

Return if the obj represent the first period a lower frequency.

Input:

- obj : An object which of a subclass of the nb_date class.
- freq : The lower frequency.

Output:

- ret : True if the object represent the first period of the lower frequency.

Examples:

```
q = nb_quarter(1,2000)
ret = isFirstPeriod(q,1)
```

```
m = nb_month(10,2000)
ret = isFirstPeriod(m,4)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isLeapYear ↑**

```
ret = isLeapYear(obj)
```

Description:

Test if the current year is a leap year

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : Logical. 1 if object is leap year, 0 else

Examples:

```
ret = obj.isLeapYear();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isPeriod ↑**

```
ret = isPeriod(obj,period)
```

Description:

Return true if the obj represent the given period, i.e. if you want to test if a nb_quarter object represent the first period of any year you can use isPeriod(obj,1).

Input:

- obj : An object which of a subclass of the nb_date class.
- period : The period to test for.

Output:

- ret : True if the object represent the period to test for, else false.

Examples:

```
q    = nb_quarter(1,2000)
ret = isPeriod(q,1)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if the object is empty

Input:

- obj : An object of class nb_day

Output:

- ret : 1 if empty, 0 else. Always false for vectors of objects.

Examples:

```
ret = obj.isempty();
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **isequal** ↑

```
ret = isequal(obj,aObj)
```

Description:

Tests if the two objects representing the same date

Input:

- obj : An object of class nb_week
- aObj : Another object of class nb_week

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj.isequal(aObj);  
ret = isequal(obj,aObj);
```

Written by Kenneth S. Paulsen

► **ismember** ↑

- varargout = ismember(obj1,obj2)

Description:

Utilizes the inbuilt MATLAB function 'ismember' for nb_date objects.

Input:

- obj1 : A nb_date object
- obj2 : A nb_date object

Output:

- varargout : See help on MATLAB function 'ismember'.

See also:

[ismember](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **le** ↑

```
ret = le(obj,aObj)
```

Description:

Tests if an object is less then or equal to another object.
Which will mean that the first input is before or the same as
the second input in the calendar.

Input:

- obj : An object of class nb_week
- aObj : An object of class nb_week

Output:

- ret : 1 if obj <= aObj, 0 else

Examples:

```
ret = obj <= aObj;
```

Written by Kenneth S. Paulsen

► **lt** ↑

```
ret = lt(obj,aObj)
```

Description:

Tests if an object is less then an another object. Which
will mean that the first input is before the second input in the
calendar

Input:

- obj : An object of class nb_week
- aObj : An object of class nb_week

Output:

- ret : 1 if obj < aObj, 0 else

Examples:

```
ret = obj < aObj;
```

Written by Kenneth S. Paulsen

► **max** ↑

```
d      = max(obj)
[d,ind] = max(obj)
d      = max(obj,aObj)
```

Description:

Find the max date.

Input:

One input:

- obj : A vector of nb_week objects.

Two inputs:

- obj : A scalar nb_week object.

- aObj : A scalar nb_week object.

Output:

- d : A scalar nb_week object.

- ind : The index of the last date.

Written by Kenneth Sætherhagen Paulsen

► **min** ↑

```
d      = min(obj)
[d,ind] = min(obj)
d      = min(obj,aObj)
```

Description:

Find the min date.

Input:

One input:

- obj : A vector of nb_week objects.

Two inputs:

- obj : A scalar nb_week object.
- aObj : A scalar nb_week object.

Output:

- d : A scalar nb_week object.
- ind : The index of the first date.

Written by Kenneth Sæterhagen Paulsen

► **minus ↑**

```
output = minus(obj,aObj)
```

Description:

Makes it possible to take an nb_week object minus another nb_week object and get the number of days between them.

It makes it also possible to take the difference between an nb_week object and a string one one of the following formats:
'yyyyWw(w)', 'dd.mm.yyyy'

And last it makes it possible to subtract the number of days from an nb_week object and receive an nb_week representing the week the given number of weeks backward in time.

Input:

- obj : A date string, an nb_week object or an integer.
- aObj : A date string, an nb_week object or an integer.

Output:

- output : The number of days between the given days. As a double

or

An nb_week object representing the date the given number of days backwards in time.

Examples:

```
output = obj - aObj; % (both objects). Returns a double
```

```
output = obj - '2012W1';           % Returns a double  
output = '2012W12' - obj;          % Returns a double  
output = obj - 1;                  % Returns an object  
  
same as  
  
output = 1 - obj;                 % Returns an object
```

Written by Kenneth S. Paulsen

► ne ↑

```
ret = ne(obj,aObj)
```

Description:

Tests if the two objects not representing the same date

Input:

- obj : An object of class nb_week
- aObj : An object of class nb_week

Output:

- ret : 1 if obj is not equal to aObj, 0 else

Examples:

```
ret = obj ~= aObj;
```

Written by Kenneth S. Paulsen

► pentecost ↑

```
day = pentecost(obj,~)
```

Description:

Give the pentecost (monday) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_week.easter](#), [nb_week.ascensionDay](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **plus** ↑

out = plus(obj,aObj)

Description:

Makes it possible to add a given number of weeks to an nb_week and receive a nb_week object which represents the week the given numbers of weeks ahead

Input:

- obj : A nx1 double or a nx1 nb_week object.
- aObj : A nx1 double or a nx1 nb_week object.

Output:

- out : A nx1 nb_week object with the given number of years ahead

Examples:

obj = obj + 1;

same as

obj = 1 + obj;

Written by Kenneth S. Paulsen

► **setDayOfWeek** ↑

obj = setDayOfWeek(obj,dayOfWeek)

Description:

Set the day of week number of a set of nb_date objects.

Input:

- obj : A nb_date object. May be a vector or matrix.

Output:

- obj : A nb_date object with the same size as the obj input.

See also:

[nb_week.dayOfWeek](#)

Written by Kenneth Sølterhagen Paulsen

Inherited from superclass NB_DATE

► **sort ↑**

```
[obj,ind] = sort(obj)
```

Description:

Sort a vector of nb_date objects.

Input:

- obj : A vector of nb_date objects.

Output:

- obj : A sorted vector of nb_date objects.

- ind : The index of the sorting.

Written by Kenneth Sølterhagen Paulsen

Inherited from superclass NB_DATE

► **toDate ↑**

```
dObj = nb_date.toDate(date,frequency)
```

Description:

A static method of the nb_date class.

Transform a given date string to the corresponding date object given that the frequency is already known.

If the frequency is not known, use the method date2freq() (handles also excel dates) or getFreq() (Only nb_ts dates).

Input:

- date :

Supported date formats:

> Daily : 'dd.mm.yyyy' and 'yyyyMm(m)Dd(d)'
> Weekly : 'dd.mm.yyyy' and 'yyyyWw(w)'
> Monthly : 'dd.mm.yyyy' and 'yyyyMm(m)'
> Quarterly : 'dd.mm.yyyy' and 'yyyyQq'
> Semiannually : 'dd.mm.yyyy' and 'yyyySs'
> Yearly : 'dd.mm.yyyy' and 'yyyy'
> Secondly : 'yyyy-mm-dd hh:nn:ss' and 'yyyymmdhhnnss'
(only supported if this version of the toolbox
includes the nb_second class)

- frequency :

> Daily : 365
> Weekly : 52
> Monthly : 12
> Quarterly : 4
> Semiannually : 2
> Yearly : 1
> Secondly : 31536000

Output:

- dObj :

> Daily : An nb_day object
> Weekly : An nb_week object
> Monthly : An nb_month object
> Quarterly : An nb_quarter object
> Semiannually : An nb_semiAnnual object
> Yearly : An nb_year object
> Secondly : An nb_second object

Examples:

```
dObj = nb_date.toDate('2012M1D1',365);
dObj = nb_date.toDate('2012M1',12);
dObj = nb_date.toDate('2012Q1',4);
dObj = nb_date.toDate('2012S1',2);
dObj = nb_date.toDate('2012',1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **toDates** ↑

```
varargout = toDates(obj,periods,format,newFreq,first)
```

Description:

Get a cellstr array of the dates ahead

Input:

- obj : An object of class nb_week
- periods : The periods wanted, must be given as a double array.
E.g. 1:20.
- format : Set the format of the cellstr of dates:
 - > 'nb_date' : The output will be a vector of nb_date objects.
 - > 'default' : 'yyyyWw(w)'
 - > 'xls' : 'dd.mm.yyyy'
 - > 'vintage' : 'yyyymmdd'

Formats which is dependent on the 'newFreq' input
> 'NBNorsk' ('NBNorwegian'):

```
newFreq;
> 1   : 'YYYY'
> 2   : 'mmm. yy', e.g. 'jan. 08' and 'jul. 08'
> 4   : 'q.kv.yy'
> 12  : 'mmm. yy', e.g. mmm = 'jan'
> 52  : 'Uke w(w)-yy'
> 365 : 'dd.mm.yyyy'
```

(Date strings are only given for the days which ends the periods)

> 'NBEnglish' ('NBEngelsk'):

```
newFreq;
> 1   : 'YYYY'
> 2   : 'mmm-yy', e.g. 'jan. 08' and 'jul. 08'
> 4   : 'yyyyQq'
```

```

> 12   : 'mmm-yy', e.g. mmm = 'jan'
> 52   : 'Week w(w)-yy'
> 365  : 'dd.mm.yyyy'

(Date strings are only given for the days which
ends the periods)

- newFreq : > 1   : yearly
             > 2   : semiannually
             > 4   : quarterly
             > 12  : monthly
             > 52  : weekly
             > 365 : daily

- first   : When converting to a lower frequency you must set if
            you want to use the first date or the last date as
            the location of the returned date. The default is to
            use the first.

    1 = first
    0 = last

```

Output:

- varargout{1} : A cell array of the wanted dates.
- varargout{2} : Locations of the returned dates. Of interest
 when converting to lower frequencies

Examples:

```

dates          = obj.toDates(0:2000);
dates          = obj.toDates(0:2000,'xls');
[dates,locations] = obj.toDates(0:2000,'NBNorsk',1);

```

Written by Kenneth S. Paulsen

► **toFormat ↑**

```
dates = toFormat(start,finish,format,language,first)
```

Description:

Convert dates vector to a given format.

Input:

- start : An object of a subclass of the nb_date class.
- finish : An object of a subclass of the nb_date class.
- format : See the format input to the nb_date.format2string
 method.

- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- vint : A cellstr.

See also:

[nb_week.format2string](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **toString** ↑

date = toString(obj,format,first)

Description:

Transform the nb_day object to a string representing the date.

Input:

- obj : An object of class nb_day
- format :
 - > 'xls' : 'dd.mm.yyyy'
 - > 'pprnorsk' or 'mprnorwegian' : 'Uke w(w) yyyy'
 - > 'pprengelsk' or 'mprenglish' : 'Week w(w) yyyy'
 - > 'default' (otherwise) : 'yyyyWw(w)'
 - > 'vintage' : 'yyyymmdd'
- extra :
 - > 'xls' :
Give 1 if you want the date string to represent the first day of the week, otherwise last day of the week will be given. Only when format is given as 'xls'. Default is 0 when 'xls'.
 - > 'pprnorsk', 'mprnorwegian', 'pprengelsk', 'mprenglish' :
Give 0 if you want the week text in lowercase only.
Default is 1, i.e. that the week text starts with an uppercase.

Output:

- date : A string with the date on the wanted format

Examples:

```
obj = nb_week(1,2012);
date = obj.toString();                      % Will give '2012W1'
date = obj.toString('xls');                  % Will give '08.01.2012'
date = obj.toString('xls',1);                % Will give '02.01.2012'
date = obj.toString('nborsk');               % Will give '2012W1'
date = obj.toString('nbengelsk');            % Will give '2012W1'
date = obj.toString('pprnorsk');             % Will give 'Uke 1 2012'
date = obj.toString('pprnorsk',0);           % Will give 'uke 1 2012'
date = obj.toString('pprengelsk');            % Will give 'Week 1 2012'
date = obj.toString('pprengelsk',0);          % Will give 'week 1 2012'
```

Written by Kenneth S. Paulsen

► today ↑

```
obj = nb_week.today()
obj = nb_week.today(dayOfWeek)
```

Description:

Get the current week as a nb_week object.

Input:

- dayOfWeek : The weekday the given week represents when converted to a day. (1-7 (Monday-Sunday)). Default is 7 (Sunday).

Output:

obj : An object of class nb_week.

Written by Kenneth Sæterhagen Paulsen

► union ↑

```
cout = nb_date.union(varargin)
```

Description:

Get the union of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► unique ↑

```
obj = unique(obj)
```

Description:

Get unique elements of a vector of nb_date objects.

Input:

- in : A vector of nb_date objects.

Output:

- out : A unique (sorted) vector of nb_date objects.

- IA : out = in(IA)

- IC : A = C(IC)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► vec ↑

```
out = vec(obj,endD)
```

Description:

A method to create a vector of dates between two dates.

Input:

obj : An nb_week object which represents the start date of the vector

end : An nb_week object or a double, representing the end date or the number of periods you want in your vector

Output:

```
obj : A nPeriods*1 vector of nb_week objects.
```

Examples:

```
f = nb_week(1,2010);
g = nb_week(10,2010);
vector = f.vec(g)
```

See also:

[nb_week](#)

Written by Tobias Ingebrigtsen

► vintage2Date ↑

```
date = nb_date.vintage2Date(vintage,freq)
```

Description:

This method converts a vintage date into a nb_date object with the wanted frequency. You can also convert a cellstring containing multiple vintage dates.

Input:

- vintage : Either the vintage date that you want to convert, or a cellstring containing the vintage dates you want to convert.
- freq : The wanted frequency. Your options are 1, 4, 12 or 365.

Output:

- date : A 1xNumberOfVintages vector containing nb_date object(s).

Examples:

```
f = '20110622'
t = nb_date.vintage2Date(f,4)
```

OR

```
f = {'20110622','20111019','20120314'} |
t = nb_date.vintage2Date(f,4)
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

■ nb_year

Go to: [Properties](#) | [Methods](#)

A class representing a yearly date.

Superclasses:

`nb_date`

Constructor:

`obj = nb_year(year)`

Input:

- `year` : Either a string or an integer representing the year. I.e. '`yyyy`', '`yyyyY01`', '`yyyyY1`' or `yyyy`.

Output:

- `obj` : An `nb_year` object.

Examples:

```
obj = nb_year('2012');
obj = nb_year(2012);
```

See also:

`nb_date`, `nb_semiAnnual`, `nb_quarter`, `nb_month`, `nb_day`

Written by Kenneth Sæterhagen Paulsen

Properties:

- `baseYear`
- `dayOfWeek`
- `frequency`
- `leapYear`
- `year`
- `yearNr`

- **`baseYear`** ↑

The base year. 2000.

Inherited from superclass `NB_DATE`

- **`dayOfWeek`** ↑

The day which the weekly date represents when converted to or from a weekly frequency. Default is 1, which is sunday.

Inherited from superclass `NB_DATE`

- **`frequency`** ↑

The frequency of the date. Must be 1.

- **`leapYear`** ↑

Indicator for leap year. 1 if leap year.

Inherited from superclass `NB_DATE`

- **year** ↑

The given year as a double

- **yearNr** ↑

The number of years since the base year. Which is
2000

► **ascensionDay** ↑

day = ascensionDay(obj, ~)

Description:

Give the ascension day of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_year.easter](#), [nb_year.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **cell2Date ↑**

```
obj = nb_date.cell2Date(cellstr,freq)
```

Description:

Converts a cellstring of dates into a nb_date object.

Input:

- cellstr : The cellstring of dates that you want to convert.
- freq : The frequency of your data. You can choose between 1, 2, 4, 12, 52, and 365.

Output:

- date : A NumberOfDatesx1 vector containing nb_date objects.

Examples:

```
g = {'2011Q2'
      '2011Q3'
      '2011Q4'
      '2012Q1'
      '2012Q2'
      '2012Q3'
      '2012Q4'
      '2013Q1'
      '2013Q2' }

a = nb_date.cell2Date(g,4)
```

```
a =
```

```
'2011Q2'  
'2011Q3'  
'2011Q4'  
'2012Q1'  
'2012Q2'  
'2012Q3'  
'2012Q4'  
'2013Q1'  
'2013Q2'
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **christmas** ↑

```
day = christmas(obj,~)
```

Description:

Give the holidays of christmas (25th and 26th) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_easter](#), [nb_year.ascensionDay](#), [nb_year.pentecost](#), [nb_year.easter](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **colon** ↑

```
cellStr = colon(a,d,b)
```

Description:

Overload the : operator. The result is a cellstr array of all the dates between the a and b (Including the a and b dates).

Input:

- a : An object of class nb_date or of a subclass of the nb_date class
- d : Increments between the dates
- b : An object of class nb_date or of a subclass of the nb_date class

Output:

- cellStr : A cellstr array of the periods between the dates represented by a and b. (Including the dates a and b). If a and b are nb_date object an empty cell is returned.

Examples:

```
dates = a:b;
dates = a:2:b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **convert ↑**

```
obj = convert(obj,frequency,first)
```

Description:

Convert the nb_year object ot the wanted frequency. The return variable will be an object which is of an subclass of the nb_date class.

Input:

- obj : An object of class nb_year
- frequency : The frequency to convert to. As a scalar.
- first : 1 : first period
0 : last period

Only when converting the object to a higher frequency.

Output:

- obj : An object of subclass of the nb_date class with the frequency given by the frequency input.

Examples:

```
obj = nb_year(2012);
obj = obj.convert(1);
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **date2freq** ↑

```
[startDate,frequency,type] = nb_date.date2freq(dates,xls)
```

Description:

A static method of the nb_date class.

Find out the frequency of the data (also from a xls(x) worksheet)

When trying to figure out the frequency of excel dates, this function must have at least two following dates

```
yearly      : 'yyyy' or 'dd.mm.yyyy'
semiannually : 'yyyySs' or 'dd.mm.yyyy'
quarterly   : 'yyyyQq' or 'yyyyKk', 'dd.mm.yyyy'
monthly     : 'yyyyMm(m)' or 'dd.mm.yyyy'
weekly       : 'yyyyWw(w)' or 'dd.mm.yyyy'
daily        : 'yyyyMm(m)Dd(d)', 'ddmonyyyy' or 'dd.mm.yyyy'
```

Input:

- dates : A cellstr of the dates you want to test the frequency of.
- xls : > 'xls' : If you want to test if the dates is on the format 'dd.mm.yyyy' also
 - > otherwise will not (default)

Output:

- startDate : An object which is a subclass of the class nb_date, with the start date of the input dates. (Either nb_quarter, nb_month, nb_semiAnnual, nb_year, nb_week or nb_day)
- frequency : The frequency of the dates given.
 - > 1 : yearly
 - > 2 : semiannually
 - > 4 : quarterly
 - > 12 : monthly
 - > 52 : weekly
 - > 365 : daily
- type : 1 if the dates input is on the xls format, otherwise 0

Examples:

```
dates = {'01.01.2012','02.01.2012','03.01.2012'};  
[startDate,frequency,type] = nb_date.date2freq(dates,'xls');
```

The output will in this example be:

- startDate : An nb_day object representing the date '01.01.2012'
- frequency : 365
- type : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **disp** ↑

```
disp(obj)
```

Description:

Sets how the nb_date object is displayed, and all subclasses of the nb_date class

Input:

- obj : An object of class nb_date or of a subclass of the nb_date class.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **easter** ↑

```
day = easter(obj,type)
```

Description:

Give the holidays or the sunday of easter of the year the date is located.

Input:

- obj : An object of class nb_date.
- type : 'all' or 'sunday' (default).

Output:

```
- days : All the holidays as a vector of nb_day objects.
```

See also:

[nb_easter](#), [nb_year.ascensionDay](#), [nb_year.pentecost](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **eq** ↑

```
ret = eq(obj,aObj)
```

Description:

Tests if the two objects representing the same dates

Input:

- obj : An object of class nb_year
- aObj : Another object of class nb_year

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj == aObj;
```

Written by Kenneth S. Paulsen

► **format2string** ↑

```
date = nb_date.format2string(obj,format)
date = nb_date.format2string(obj,format,language,first)
```

Description:

Get date at a given format.

Input:

- obj : An object of a subclass of nb_date.
- format : A string with the format. A combination of the following patterns:

- **d** : Day of the date. Examples:

```
> 'dd'   : '01', '10'
> 'd'    : '1', '0'
> 'd(d)': '1', '10'
```
- **w** : Week of date. Same options as for d.
- **m** : Month of date. Same options as for d.

- **q** : Quarter of date. Examples:

```
> 'q'   : '1', '4'
- h : Half year of date. Same options as for h.
- y : Year of date.
> 'yyyy' : '2016'
> 'yy'   : '016'
> 'yy'   : '16'
< 'y'   : '6'
```

Caution: To use the actual letter of the patterns use \ in front of the letter. E.g. '\y'.

Extra (see also the language option):

- 'Monthtext' : Month of date as full text. Starting with upper case.
- 'monthtext' : Month of date as full text. Starting with upper case.
- 'Quartertext' : > 'norwegian' : '. kv.'

```
> 'english' : 'Q'
```
- 'Weektext' : > 'norwegian' : 'Uke'

```
> 'english' : 'Week'
```
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- date : A string of the date on the wanted format.

Examples:

```
d      = nb_day.today();
date = nb_date.format2string(d,'dd.mm.yyyy');
date = nb_date.format2string(d,'d(d).m(m).yyyy');
date = nb_date.format2string(d,'d(d) Monthtext yyyy');
date = nb_date.format2string(d,'d(d). monthtext yyyy','norwegian');

m      = nb_month.today();
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'Monthtext yyyy');
date = nb_date.format2string(m,'Monthtext yyyy','norwegian');

q      = nb_quarter.today();
```

```
date = nb_date.format2string(m,'dd.mm.yyyy');
date = nb_date.format2string(m,'qQ yyyy');
date = nb_date.format2string(m,'q. kv. yyyy');

y     = nb_year.today();
date = nb_date.format2string(y,'dd.mm.yyyy');
date = nb_date.format2string(y,'yyyy');
date = nb_date.format2string(y,'\year yyyy');
```

See also:

[toString](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **freqPlus** ↑

```
obj = freqPlus(obj,incr,freq)
```

Description:

Plus the number of periods of another (lower) frequency.

E.g. dayNextYear = freqPlus(day,1,1);

Input:

- obj : An object of class nb_date.
- periods : A scalar integer with the periods to add.
- freq : The frequency of the periods argument.

Output:

- ob : An object of class nb_date.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **fromxlsDates2freq** ↑

```
frequency = nb_date.fromxlsDates2freq(dates)
```

Description:

A static method of the nb_date class.

Try to find out the date frequency of the excel dates. I.e. dates on the format 'dd.mm.yyyy'.

Input:

- Dates : A cellstr with at least two dates on the date format 'dd.mm.yyyy'.

Output:

- frequency : The frequency of the input dates given as an integer.

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2
> Yearly	:	1

Examples:

```
dates      = {'01.01.2012','02.01.2012','03.01.2012'};  
frequency = nb_date.fromxlsDates2freq(dates)
```

The output will in this example be:

- frequency : 1

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **ge ↑**

```
ret = ge(obj,aObj)
```

Description:

Tests if an object is greater then or equal to another object.
Which will mean that the first input is after or the same
as the second input in the calendar

Input:

- obj : An object of class nb_year
- aObj : Another object of class nb_year

Output:

- ret : 1 if obj >= aObj, 0 else

Examples:

```
ret = obj >= aObj;
```

Written by Kenneth S. Paulsen

► **getDate ↑**

```
date = getDate(obj, freq)
```

Description:

Get the date of the object at another frequency. If the frequency is higher the first period is returned

Input:

- obj : An object of class nb_year
- freq : The frequency you want to convert to.
 - 1 : nb_year
 - 2 : nb_semiAnnual
 - 4 : nb_quarter
 - 12 : nb_month
 - 52 : nb_week
 - 365 : nb_day

Output:

- date : The date of the object at the new frequency. As an object which is a subclass of the nb_date class.

Examples:

```
date = obj.getDate(4); % Will return a nb_quarter object
```

See also:

[nb_year.convert](#)

Written by Kenneth S. Paulsen

► **getDay** ↑

```
day = getDay(obj,first)
```

Description:

Get the first or last day of the year, given as an nb_day object

Input:

- obj : An object of class nb_year
- first : 1 : The first day
0 : The last day
2 : The first day that match the dayOfWeek property.
3 : The last day that match the dayOfWeek property.
4 : The first business day.

Output:

- day : An nb_day object

Examples:

```
obj = nb_year(2020);  
day = obj.getDay();      % Will return the first day of the year  
day = obj.getDay(0);    % Will return the last day of the year  
day = obj.getDay(2);    % Will return the first sunday of the year  
day = obj.getDay(3);    % Will return the last sunday of the year
```

Written by Kenneth S. Paulsen

► **getDays** ↑

```
days = getDays(obj)
```

Description:

Get all the days of the given year as a cell of nb_day objects

Input:

- obj : An object of class nb_year

Output:

- days : A cell array of nb_day objects

Examples:

```
days = obj.getDays();
```

Written by Kenneth S. Paulsen

► **getEarliestDate** ↑

```
date = nb_date.getEarliestDate(c)
```

Description:

Get the earliest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getFreq** ↑

```
freq = getFreq(obj)
```

Description:

Gets the frequency of the object.

Input:

- obj : An object of class nb_year

Output:

- freq : 1

Examples:

```
freq = obj.getFreq();
```

Written by Kenneth S. Paulsen

► **getFrequencyAsInteger** ↑

```
frequency = nb_date.getFrequencyAsInteger(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as an integer given a frequency as a string

Input:

- frequency : Frequency input as a string
 - > Daily : 'daily'
 - > Weekly : 'weekly'
 - > Monthly : 'monthly'
 - > Quarterly : 'quarterly'
 - > Semiannually : 'semiannually'
 - > Yearly : 'yearly', 'annual'

Output:

- frequency : The frequency as an integer
 - > Daily : 365
 - > Weekly : 52
 - > Monthly : 12
 - > Quarterly : 4
 - > Semiannually : 2
 - > Yearly : 1

Examples:

```
frequency = nb_date.getFrequencyAsInteger('yearly')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getFrequencyAsString** ↑

```
frequency = nb_date.getFrequencyAsString(frequency)
```

Description:

A static method of the nb_date class.

Get the frequency as a string given a frequency as an integer

Input:

- frequency : Frequency input as an integer

> Daily	:	365
> Weekly	:	52
> Monthly	:	12
> Quarterly	:	4
> Semiannually	:	2
> Yearly	:	1

Output:

- frequency : The frequency as a string

> Daily	:	'daily'
> Weekly	:	'weekly'
> Monthly	:	'monthly'
> Quarterly	:	'quarterly'
> Semiannually	:	'semiannually'
> Yearly	:	'yearly'

Examples:

```
frequency = nb_date.getFrequencyAsString(1);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **getHalfYear** ↑

```
halfYear = getHalfYear(obj,first)
```

Description:

Get the first or last half year of the year, given as an nb_semiAnnual object

Input:

- obj : An object of class nb_year
- first : 1 : first half year
0 : last half year

Output:

- halfYear : An nb_semiAnnual object

Examples:

```
halfYear = obj.getHalfYear(); % Will return first half year
halfYear = obj.getHalfYear(1); % Will return last half year
```

Written by Kenneth S. Paulsen

► **getHalfYears** ↑

```
halfYears = getHalfYears(obj)
```

Description:

Get all the half years of the given year as a cell of nb_semiAnnual objects

Input:

- obj : An object of class nb_year

Output:

- halfYears : A cell array of nb_semiAnnual objects

Examples:

```
halfYears = obj.getHalfYears();
```

Written by Kenneth S. Paulsen

► **getLatestDate** ↑

```
date = nb_date.getLatestDate(c)
```

Description:

Get the latest date among the dates in c.

Input:

- c : A cellstr of dates.

Output:

- date : A nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getMonth** ↑

```
month = getMonth(obj,first)
```

Description:

Get the first or last month of the year, given as a nb_month object

Input:

- obj : An object of class nb_year
- first : 1 : first month
0 : last month

Output:

- month : An nb_month object

Examples:

```
month = obj.getMonth(); % Will return the first month
month = obj.getMonth(1); % Will return the last month
```

Written by Kenneth S. Paulsen

► **getMonths** ↑

```
months = getMonths(obj)
```

Description:

Get all the months of the given year as a cell of nb_month objects

Input:

- obj : An object of class nb_year

Output:

- months : A cell array of nb_month objects

Examples:

```
months = obj.getMonths();
```

Written by Kenneth S. Paulsen

► **getNr** ↑

```
nr = getNr(obj)
```

Description:

Get date number of a nb_date vector.

Input:

- obj : A vector of nb_date objects.

Output:

- nr : A double with the date numbers of each object in the nb_date vector.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **getNumberOfDays** ↑

```
numberOfDays = getNumberOfDays(obj)
```

Description:

Get the number of days in the given year

Input:

- obj : An object of class nb_year

Output:

- numberOfDays : The number of days, given as double

Examples:

```
numberOfDays = obj.getNumberOfDays();
```

Written by Kenneth S. Paulsen

► **getNumberOfWeeks ↑**

```
numberOfWeeks = getNumberOfWeeks(obj)
```

Description:

Get the number of weeks in the given year

Input:

- obj : An object of class nb_year

Output:

- numberOfWeeks : The number of weeks, given as double

Written by Kenneth S. Paulsen

► **getQuarter ↑**

```
quarter = getQuarter(obj,first)
```

Description:

Get the first or last quarter of the year, given as an nb_quarter object

Input:

- obj : An object of class nb_year

Output:

- quarter : An nb_quarter object
- first : 1 : first quarter
0 : last quarter

Examples:

```
quarter = obj.getQuarter(); % Will return the first quarter
quarter = obj.getQuarter(1); % Will return the last quarter
```

Written by Kenneth S. Paulsen

► getQuarters ↑

```
quarters = getQuarters(obj)
```

Description:

Get all the quarters of the given year as a cell of nb_quarter objects

Input:

- obj : An object of class nb_year

Output:

```
quarters : A cell array of nb_quarter objects
```

Examples:

```
quarters = obj.getQuarters();
```

Written by Kenneth S. Paulsen

► getWeek ↑

```
week = getWeek(obj,first,dayOfWeek)
```

Description:

Get the first or last week of the year, given as an nb_week object

Input:

```
- obj : An object of class nb_year  
  
- first : 1 : first day  
          0 : last day  
  
- dayOfWeek : The weekday the given week represents when  
               converted to a day. (1-7 (Monday-Sunday)). Default  
               is to use the dayOfWeek property.
```

Output:

```
- week : An nb_week object
```

Examples:

```
week = obj.getWeek();      % Will return the first week of the year  
week = obj.getWeek(0);    % Will return the last week of the year
```

Written by Kenneth S. Paulsen

► **getWeeks** ↑

```
weeks = getWeeks(obj,dayOfWeek)
```

Description:

Get all the weeks of the given year as a cell of nb_week objects

Input:

```
- obj : An object of class nb_year  
  
- dayOfWeek : The weekday the given week represents when  
               converted to a day. (1-7 (Monday-Sunday)). Default  
               is to use the dayOfWeek property.
```

Output:

```
- weeks : A cell array of nb_week objects
```

Examples:

```
year = nb_year(2020);  
weeks = year.getWeeks();
```

Written by Kenneth S. Paulsen

► **gt** ↑

```
ret = gt(obj,aObj)
```

Description:

Tests if an object is greater than another object. Which will mean that the first input is after the second input in the calendar

Input:

- obj : An object of class nb_year
- aObj : An object of class nb_year

Output:

- ret : 1 if obj > aObj, 0 else

Examples:

```
ret = obj > aObj;
```

Written by Kenneth S. Paulsen

► **holidays** ↑

```
days = holidays(obj)
```

Description:

Find the holidays of the given date object.

Input:

- obj : An object of class nb_month, nb_quarter, nb_semiAnnual or nb_year.

Output:

- days : All the holidays as a vector of nb_day objects.

See also:

[nb_year.easter](#), [nb_year.ascensionDay](#), [nb_year.pentecost](#)
[nb_year.christmas](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **initialize** ↑

```
obj = nb_date.initialize(freq,dim1,dim2)
```

Description:

Initialize a vector of date objects.

Input:

- freq : The wanted frequency of the date of today. 1,2,4,12,52 or 365.
- dim1 : The size of the first dimension.
- dim2 : The size of the second dimension.

Output:

obj : A vector of nb_date objects.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **intersect** ↑

```
cout = nb_date.intersect(varargin)
```

Description:

Get the intersection of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isDate** ↑

```
ret = nb_date.isDate(input,freq)
```

Description:

Test if a string or nb_date object is a date. It is also possible to restrict the test to a specific frequency.

Input:

- input : Any object
- freq : 1, 2, 4, 12, 52 or 365. Can also be empty, but then it is slower.
- locVar : A nb_struct/struct with the supported local variables. If the input is a string using the syntax '%#name', this input will be looked up and tested.

Output:

- ret : Either true or false. true if input is a date string or nb_date object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► isEqualFreq ↑

```
ret = isEqualFreq(obj,aObj)
```

Description:

Test if two date objects have the same frequency

Input:

- obj : An object which is of class nb_date or a subclass of the nb_date class
- aObj : An object which is of class nb_date or a subclass of the nb_date class

Output:

- ret : 1 if equal frequency, 0 else

Examples:

```
d = nb_day(1,1,2012);
q = nb_quarter(4,2012);
ret = d.isEqualFreq(q); % Will return 0
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **isFirstPeriod** ↑

```
ret = isFirstPeriod(obj,freq)
```

Description:

Return if the obj represent the first period a lower frequency.

Input:

- obj : An object which of a subclass of the nb_date class.
- freq : The lower frequency.

Output:

- ret : True if the object represent the first period of the lower frequency.

Examples:

```
q    = nb_quarter(1,2000)
ret = isFirstPeriod(q,1)
```

```
m    = nb_month(10,2000)
ret = isFirstPeriod(m,4)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isPeriod** ↑

```
ret = isPeriod(obj,period)
```

Description:

Return true if the obj represent the given period, i.e. if you want to test if a nb_quarter object represent the first period of any year you can use isPeriod(obj,1).

Input:

- obj : An object which of a subclass of the nb_date class.
- period : The period to test for.

Output:

- ret : True if the object represent the period to test for, else false.

Examples:

```
q = nb_quarter(1,2000)
ret = isPeriod(q,1)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if the object is empty

Input:

- obj : An object of class nb_year

Output:

- ret : 1 if empty, 0 else. Always false for vectors of objects.

Examples:

```
ret = obj.isempty();
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **isequal** ↑

```
ret = isequal(obj,aObj)
```

Description:

Tests if the two objects representing the same date

Input:

- obj : An object of class nb_year
- aObj : Another object of class nb_year

Output:

- ret : 1 if equal, 0 else

Examples:

```
ret = obj.isequal(aObj);  
ret = isequal(obj,aObj);
```

Written by Kenneth S. Paulsen

► **ismember** ↑

- varargout = ismember(obj1,obj2)

Description:

Utilizes the inbuilt MATLAB function 'ismember' for nb_date objects.

Input:

- obj1 : A nb_date object
- obj2 : A nb_date object

Output:

- varargout : See help on MATLAB function 'ismember'.

See also:

[ismember](#)

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

► **le** ↑

ret = le(obj,aObj)

Description:

Tests if an object is less then or equal to another object.
Which will mean that the first input is before or the same as
the second input in the calendar.

Input:

```
- obj    : An object of class nb_year  
- aObj   : An object of class nb_year
```

Output:

```
- ret    : 1 if obj <= aObj, 0 else
```

Examples:

```
ret = obj <= aObj;
```

Written by Kenneth S. Paulsen

► **lt** ↑

```
ret = lt(obj,aObj)
```

Description:

Tests if an object is less than another object. Which will mean that the first input is before the second input in the calendar

Input:

```
- obj    : An object of class nb_year  
- aObj   : An object of class nb_year
```

Output:

```
- ret    : 1 if obj < aObj, 0 else
```

Examples:

```
ret = obj < aObj;
```

Written by Kenneth S. Paulsen

► **max** ↑

```
d      = max(obj)  
[d,ind] = max(obj)  
d      = max(obj,aObj)
```

Description:

Find the max date.

Input:

One input:

- obj : A vector of nb_year objects.

Two inputs:

- obj : A scalar nb_year object.
- aObj : A scalar nb_year object.

Output:

- d : A scalar nb_year object.
- ind : The index of the last date.

Written by Kenneth Sæterhagen Paulsen

► **min ↑**

```
d      = min(obj)
[d,ind] = min(obj)
d      = min(obj,aObj)
```

Description:

Find the min date.

Input:

One input:

- obj : A vector of nb_year objects.

Two inputs:

- obj : A scalar nb_year object.
- aObj : A scalar nb_year object.

Output:

- d : A scalar nb_year object.
- ind : The index of the first date.

Written by Kenneth Sæterhagen Paulsen

► **minus** ↑

```
output = minus(obj,aObj)
```

Description:

Makes it possible to take an nb_year object minus another nb_year object and get the number of years between them.

It makes it also possible to take the difference between an nb_year object and a string on one of the following formats:
'yyyy', 'dd.mm.yyyy'

And last it makes it possible to subtract the number of years from an nb_year object and receive an nb_year representing the year the given number of years backward in time.

Input:

- obj : A date string, an nb_year object or an integer.
- aObj : A date string, an nb_year object or an integer.

Output:

- output : The number of years between the given years. As a double
or

An nb_year object representing the date the given number of years backwards in time.

Examples:

```
output = obj - aObj;      % (both objects). Returns a double
output = obj - '2012';    % Returns a double
output = '2012' - obj;   % Returns a double
output = obj - 1;         % Returns an object
same as
output = 1 - obj;        % Returns an object
```

Written by Kenneth S. Paulsen

► **ne** ↑

```
ret = ne(obj,aObj)
```

Description:

Tests if the two objects not representing the same date

Input:

- obj : An object of class nb_year
- aObj : An object of class nb_year

Output:

- ret : 1 if obj is not equal to aObj, 0 else

Examples:

```
ret = obj ~= aObj;
```

Written by Kenneth S. Paulsen

► **pentecost** ↑

```
day = pentecost(obj,~)
```

Description:

Give the pentecost (monday) of the year the date is located.

Input:

- obj : An object of class nb_date.

Output:

- days : The holiday as a nb_day object.

See also:

[nb_easter](#), [nb_year.easter](#), [nb_year.ascensionDay](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **plus** ↑

```
out = plus(obj,aObj)
```

Description:

Makes it possible to add a given number of years to an nb_year object and receive an nb_year object which represents the year the given numbers of years ahead

Input:

- obj : An nx1 double or a nx1 nb_year object.
- aObj : An nx1 double or a nx1 nb_year object.

Output:

- out : A nx1 nb_year object the given number of years ahead.

Examples:

```
obj = obj + 1;
```

same as

```
obj = 1 + obj;
```

Written by Kenneth S. Paulsen

► **setDayOfWeek** ↑

```
obj = setDayOfWeek(obj,dayOfWeek)
```

Description:

Set the day of week number of a set of nb_date objects.

Input:

- obj : A nb_date object. May be a vector or matrix.

Output:

- obj : A nb_date object with the same size as the obj input.

See also:

[nb_year.dayOfWeek](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **sort ↑**

```
[obj,ind] = sort(obj)
```

Description:

Sort a vector of nb_date objects.

Input:

- obj : A vector of nb_date objects.

Output:

- obj : A sorted vector of nb_date objects.

- ind : The index of the sorting.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATE

► **toDate ↑**

```
dObj = nb_date.toDate(date,frequency)
```

Description:

A static method of the nb_date class.

Transform a given date string to the corresponding date object given that the frequency is already known.

If the frequency is not known, use the method date2freq() (handles also excel dates) or getFreq() (Only nb_ts dates).

Input:

- date :

Supported date formats:

> Daily : 'dd.mm.yyyy' and 'yyyyMm(m)Dd(d)'

> Weekly : 'dd.mm.yyyy' and 'yyyyWw(w)'

> Monthly : 'dd.mm.yyyy' and 'yyyyMm(m)'

```

> Quarterly      : 'dd.mm.yyyy' and 'yyyyQq'
> Semiannually   : 'dd.mm.yyyy' and 'yyyySs'
> Yearly        : 'dd.mm.yyyy' and 'yyyy'
> Secondly       : 'yyyy-mm-dd hh:nn:ss' and 'yyyymmddhhnnss'
                  (only supported if this version of the toolbox
                  includes the nb_second class)

- frequency :

> Daily          : 365
> Weekly         : 52
> Monthly        : 12
> Quarterly      : 4
> Semiannually   : 2
> Yearly         : 1
> Secondly       : 31536000

```

Output:

```

- dObj      :

> Daily      : An nb_day object
> Weekly     : An nb_week object
> Monthly    : An nb_month object
> Quarterly  : An nb_quarter object
> Semiannually : An nb_semiAnnual object
> Yearly     : An nb_year object
> Secondly   : An nb_second object

```

Examples:

```

dObj = nb_date.toDate('2012M1D1',365);
dObj = nb_date.toDate('2012M1',12);
dObj = nb_date.toDate('2012Q1',4);
dObj = nb_date.toDate('2012S1',2);
dObj = nb_date.toDate('2012',1);

```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATE

► **toDates** ↑

```
varargout = toDates(obj, periods, format, newFreq, first)
```

Description:

Get a cellstr array of the dates ahead

Input:

- obj : An object of class nb_year
- periods : The periods wanted, must be given as a double array.
E.g. 1:20.
- format : > 'xls' : 'dd.mm.yyyy'
> 'vintage' : 'yyyymmdd'
> 'nb_date' : Vector of nb_year
> otherwise : 'yyyy'
- newFreq : Give a error if you are trying to change the frequency. 1 is the only appropriate input value.
- first : Give 1 if you want the date strings to represent the first day of the year ('01.01.yyyy'), otherwise last day of the year will be given ('31.12.yyyy'). Only when format is given as 'xls'

Output:

- varargout{1} : A cell array of the wanted dates.
- varargout{2} : Locations of the returned dates.

Examples:

```
dates      = obj.toDates(0:20);
dates      = obj.toDates(0:20,'xls');
```

Written by Kenneth S. Paulsen

► **toFormat** ↑

```
dates = toFormat(start, finish, format, language, first)
```

Description:

Convert dates vector to a given format.

Input:

- start : An object of a subclass of the nb_date class.
- finish : An object of a subclass of the nb_date class.
- format : See the format input to the nb_date.format2string method.
- language : 'norwegian' or 'english' (default). Only important for the 'monthtext' or 'Monthtext' patterns.
- first : Give false to return the latest period when converted to a higher frequency. Default is true, i.e. first period.

Output:

- vint : A cellstr.

See also:

[nb_year.format2string](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **toString** ↑

date = toString(obj,format,first)

Description:

Transform the nb_year object to a string representing the date.

Input:

- obj : An object of class nb_year
- format : > 'xls' : 'dd.mm.yyyy'
 > 'vintage' : 'yyyymmdd'
 > otherwise : 'yyyy'
- first : Give 1 if you want the date string to represent the first day of the year ('01.01.yyyy'), otherwise last day of the year will be given ('31.12.yyyy'). Only when format is given as 'xls'

Output:

- date : A string on the wanted format

Examples:

```
obj = nb_year(2012);
date = obj.toString();           % Will give '2012'
date = obj.toString('xls');     % Will give '31.12.2012'
date = obj.toString('xls',1);   % Will give '01.01.2012'
```

Written by Kenneth S. Paulsen

► **today** ↑

```
obj = nb_year.today()
```

Description:

Get the current year as a nb_year object.

Output:

obj : An object of class nb_year.

Written by Kenneth Sæterhagen Paulsen

► **union** ↑

```
cout = nb_date.union(varargin)
```

Description:

Get the union of dates.

Input:

- varargin : Each input must be a cellstr of dates.

Output:

- cout : A cellstr of dates.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **unique** ↑

```
obj = unique(obj)
```

Description:

Get unique elements of a vector of nb_date objects.

Input:

- in : A vector of nb_date objects.

Output:

- out : A unique (sorted) vector of nb_date objects.

- IA : out = in(IA)

- IC : A = C(IC)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATE

► **vec** ↑

out = vec(obj, endD)

Description:

A method to create a vector of dates between two dates.

Input:

obj : An nb_year object which represents the start date of the vector

end : An nb_year object or a double, representing the end date or the number of periods you want in your vector

Output:

obj : A nPeriods*1 vector of nb_year objects.

Examples:

```
f = nb_year(2010);
g = nb_year(2014);
vector = f.vec(g)
```

See also:

[nb_year](#)

Written by Tobias Ingebrigtsen

► **vintage2Date** ↑

```
date = nb_date.vintage2Date(vintage,freq)
```

Description:

This method converts a vintage date into a nb_date object with the wanted frequency. You can also convert a cellstring containing multiple vintage dates.

Input:

- vintage : Either the vintage date that you want to convert, or a cellstring containing the vintage dates you want to convert.
- freq : The wanted frequency. Your options are 1, 4, 12 or 365.

Output:

- date : A 1xNumberOfVintages vector containing nb_date object(s).

Examples:

```
f = '20110622'  
t = nb_date.vintage2Date(f,4)
```

OR

```
f = {'20110622','20111019','20120314'} |  
t = nb_date.vintage2Date(f,4)
```

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATE

◆ **nb_dateminus**

```
diff = nb_dateminus(date1,date2)
```

Description:

This function calculates how many quarters or months there is between two dates (given as strings).

Inputs:

- date1 : Must be on one of the following date formats:

- > 'yyyyQq', e.g. '2011Q1'
- > 'yyyyMm(m)', e.g. '2011M1'
- > 'yyyy', e.g. 2011

- date2 : Must be on one of the following date formats:

- > 'yyyyQq', e.g. '2011Q1'

```
> 'yyyyMm(m)', e.g. '2011M1'  
> 'yyyy', e.g. 2011
```

Output:

- diff : Number of quarters/months/years between date1 and date2
(date1 minus date2)

Examples:

```
diff = nb_dateminus('2012Q4','2012Q1');  
diff = nb_dateminus('2012M4','2012M1');  
diff = nb_dateminus('2014','2012');
```

See also:

[nb_quarter](#), [nb_month](#), [nb_year](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_dateplus**

```
date = nb_dateplus(datein,plus)
```

Description:

You can specify a date and get the date "plus" period(s) ahead.

Input:

- datein : A date string on one of the following formats
 - > 'yyyyQq', e.g. '2011Q1'.
 - > 'yyyyMm', e.g. '2011M1'.
 - > 'yyyy', e.g. '2011'
- added : An integer with the number of added months, quarters or years ahead

Output:

date : A date string at the same date format as the input, but with the added periods.

Example of use of function:

```
dateString = dateplus('2011Q1',1);      % '2011Q2'  
dateString = dateplus('2011Q1',-1);      % '2010Q4'
```

See also:

[nb_quarter](#), [nb_month](#), [nb_year](#)

Written by Kenneth Sætherhagen Paulsen

◆ **nb_easter**

easter = nb_easter(years)

Description:

A function to identify the date of easter for a given year. Utilizes Gauss' Easter Algorithm.

https://en.wikipedia.org/wiki/Computus#Gauss's_Easter_algorithm

Input:

- years : A double vector of years

Output:

- easter : A cellstring with the dates of easter corresponding to each year

Examples:

```
years = 1950:2050;
easter = nb_easter(years)
```

Written by Tobias Ingebrigtsen

◆ **nb_isDate**

[ret,date] = nb_isDate(in)

Description:

Check if any type of input is a date as a one line char or a nb_date object.

Input:

- in : Any input.

Output:

```
- ret   : true or false
- date : An object of class nb_date.
```

See also:

[nb_date](#), [nb_date.date2freq](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_sameDateFormat**

returned = nb_sameDateFormat(date1,date2)

Description

Compares two string, and test if the dates are of the same frequency. Return true if the two dates have the same frequency. The following date formats are supported by this function:

- Daily : 'yyyyMm(m)Dd(dd)'
- Weekly : 'yyyyW(w)'
- Monthly : 'yyyyMm(m)'
- Quarterly : 'yyyyQq'
- Semiannually : 'yyyySs'
- Yearly : 'yyyy'

Input:

- date1 : A string with the date.
- date2 : A string with the date.

Output:

- returned : Logical. 1 if both dates have same frequency, otherwise 0.

Examples:

returned = nb_sameDateFormat('2013Q4','2012Q1'); % true

See also:

[nb_date.date2freq](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_xlsDates2FAMEVintage**

```
d          = nb_xlsDates2FAMEVintage(dates)
[d,years,months,days] = nb_xlsDates2FAMEVintage(dates)
```

Description:

Convert dates from the format 'dd.mm.yyyy' to 'yyyymmdd'.

Input:

- dates : A cellstr or char array where each element is on the format 'dd.mm.yyyy'.

Output:

- d : A cellstr where each element is on the format 'yyyymmdd'.
- years : A double with the years of the provided dates.
- months : A double with the months of the provided dates.
- days : A double with the days of the provided dates.

■ nb_DataCollection

Go to: [Properties](#) | [Methods](#)

A class for storing nb_ts, nb_cs and/or nb_data objects

Constructor:

obj = nb_DataCollection(filename)

Input:

- filename : A string with the names of an excel spreadsheet.

If given this input will be given to the nb_readExcelMoreSheets, so see the documentation of this function for more one the needed format of the excel spreadsheet.

If this input is not given, a empty nb_DataCollection object is constructed.

Output:

- obj : An object of class nb_DataCollection

Examples:

```
obj = nb_DataCollection();
obj = nb_DataCollection('excelFileName');
```

See also:

[nb_ts](#), [nb_cs](#), [nb_readExcelMoreSheets](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [list](#)
- [objectsID](#)

- [list](#)

An object of class nb_List storing the data objects

- [objectsID](#)

A cellstr with the identifiers of the stored objects.

Methods:

- [add](#)
- [convert](#)
- [disp](#)
- [get](#)
- [getVariables](#)
- [merge](#)
- [remove](#)
- [reset](#)
- [saveData](#)

► [add](#)

```
obj = add(obj,dataObject,id)
```

Description:

Adding an object of class nb_ts or nb_cs to a nb_DataCollection object.

Caution : The added object can only have one page (dataset)

Input:

- obj : An object of class nb_DataCollection
- dataObject : An nb_ts or nb_cs object with only one page (dataset).
- id : A string with the identifier of the provided object.

Output:

- obj : An object of class nb_DataCollection with the added data object.

Examples:

```
obj      = nb_DataCollection();
dataObject = nb_ts([2,2],'', '2012Q1', 'Var1');
obj      = obj.add(dataObject,'Dataset1');
```

Written by Kenneth S. Paulsen

► convert ↑

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert all the nb_ts object of the object. I.e. use their convert method with the same inputs as given to this method.

Input:

- obj : An object of class nb_DataCollection
- freq : The new frequency of the data. As an integer:
 - 1 : yearly
 - 4 : quarterly
 - 12 : monthly
 - 365 : daily
- method : The method to use. Either:

From a high frequency to a low:

- 'avarage' : Takes averages over the subperiods
- 'sum' : Takes sums over the subperiods
- 'discrete' : Takes last observation in each subperiod (Default)

From a low frequency to a high:

- 'linear' : linear interpolation (Default)
- 'cubic' : shape-preserving piecewise cubic interpolation
- 'spline' : piecewise cubic spline interpolation
- 'none' : no interpolation. All data in between is given by nans (missing values)

Caution: This input must be given if you provide some of the optional inputs.

Optional input:

- 'includeLast' : Give this string as input if you want to include the last period, even if it is not finished. Only when converting to lower frequencies
 - E.g: `obj = obj.convert(1,'average',...
'includeLast');`
- 'rename' : Changes the postfixes of the variables names.
 - E.g. If you covert from the frequency 12 to 4 the prefixes of the variable names changes from 'MUA' to 'QUA', if the postfix exist.
 - E.g: `obj = obj.convert('yearly','average',...
'rename');`

Optional input `obj.convert(...,'inputName','inputValue',...)`:

- 'interpolateDate' : The input after this input must either be 'start' or 'end'.
 - Date of interpolation. Where 'start' means to interpolate the start date of the periods of the old frequency, while 'end' uses the end date of the periods.
 - Default is 'start'.
 - Caution : Only when converting to higher frequency.
 - E.g: `obj = obj.convert(365,'linear',...
'interpolateDate','end');`

Output:

- obj : An object of class nb_DataCollection with all the stored nb_ts object converted to the new freqency.

Examples:

```
obj = obj.convert(4,'average');
obj = obj.convert(365,'linear','interpolateDate','end');
obj = obj.convert(1,'average','includeLast');
obj = obj.convert(1,'average','rename');
```

Written by Kenneth S. Paulsen

► **disp** ↑

```
disp(obj)
```

Description:

Overrun how the object is displayed in MATLAB (On the command line)

Input:

- obj : An object of class nb_DataCollection

Output:

The object displayed on the command line

Examples:

```
obj
```

Written by Kenneth S. Paulsen

► **get** ↑

```
obj = get(obj,id)
```

Description:

Get the object with the given identifier

Input:

- obj : An object of class nb_DataCollection
- id : The identifier of the object you want to get. As a string.

Output:

- dataObject : The data object which match the identifier.
Either a nb_cs, nb_ts or nb_data

Examples:

```
dataObject = get(obj,'Dataset1');
```

Written by Kenneth S. Paulsen

► **getVariables ↑**

```
obj = getVariables(obj,vars,interpolateDate,method,rename)
```

Description:

Get the variables given by the vars input stored in the nb_DataCollection object.

Caution : Be aware that the variables you try to get can only represent time series or cross-sectional data.

Caution : If the variables represent different frequencies the lowest frequencies will be converted to the highest frequency.

Input:

- obj : An object of class nb_DataCollection
- vars : A cellstr array of the variable you want to load.
- interpolateDate :
 - How to transform the database with the lowest frequency.
 - 'start' : The interpolated data are taken as given at the start of the periods. I.e. use 01.01.2012 and 01.01.2013 when interpolating data on yearly frequency. (Default)
 - 'end' : The interpolated data are taken as given at the end of the periods. I.e. use 31.12.2012 and 31.12.2013 when interpolating data on yearly frequency.
- method : The method to use when converting:
 - 'linear' : Linear interpolation
 - 'cubic' : Shape-preserving piecewise cubic interpolation

```

        - 'spline'    : Piecewise cubic spline
                         interpolation
        - 'none'      : No interpolation. All data in
                         between is given by nans
                         (missing values) (Default)

- rename          : > 'on'   : Renames the prefixes (default)
                     > 'off'  : Do not rename the prefixes

For more see the 'rename' option of the
convert method.

```

Output:

- obj : An object of class nb_ts or nb_cs.

Examples:

Written by Kenneth S. Paulsen

► **merge** ↑

obj = merge(obj,aObj)

Description:

Merge two objects of class nb_DataCollection

Collect each object stored in the two input objects of class nb_DataCollection and store it in one nb_DataCollection object.

Input:

- obj : An object of class nb_DataCollection
- aObj : An object of class nb_DataCollection

Output:

- obj : An object of class nb_DataCollection, where all the data objects of the two input objects of class nb_DataCollection are stored.

Examples:

obj = merge(obj,aObj)

Written by Kenneth S. Paulsen

► **remove** ↑

```
obj = remove(obj,id)
```

Description:

Remove a data object from the given object. (Using the objects identifier)

Input:

- obj : An object of class nb_DataCollection
- id : The identifier of the object you want to remove. As a string.

Output:

- obj : An object of class nb_DataCollection with the data object with the given identifier removed.

Examples:

```
obj = obj.remove('Dataset1');
```

Written by Kenneth S. Paulsen

► **reset ↑**

```
obj = reset(obj,dataObject,id)
```

Description:

Resetting an object of class nb_ts or nb_cs of an nb_DataCollection object.

Caution : The reset object can only have one page (dataset)

Input:

- obj : An object of class nb_DataCollection
- dataObject : An nb_ts or nb_cs object with only one page (dataset).
- id : A string with the identifier of the reset object.

Output:

- obj : An object of class nb_DataCollection with the reset data object.

Examples:

```
obj      = obj.reset(dataObject,'Dataset1');
```

Written by Kenneth S. Paulsen

► **saveData** ↑

```
saveData(obj,saveName,descriptionPage)
```

Description:

Write object to excel, where each stored object is saved in
seperate worksheets

Input:

- obj : An object of class nb_DataCollection
- saveName : A string with the wanted name of the saved
excel file
- descriptionPage : Give 1 if you want a description page.
Default is 0.

Output:

The data of the object is saved to excel with the given save
name. Each worksheet is saved with the names of the objects
identifiers.

Examples:

```
obj      = nb_DataCollection();  
dataObject = nb_ts([2,2],'', '2012Q1', 'Var1');  
obj      = obj.add(dataObject,'Dataset1');  
saveData(obj,'test')  
saveData(obj,'test',1)
```

Written by Kenneth S. Paulsen

■ **nb_bd**

Go to: [Properties](#) | [Methods](#)

A class for storing vintage / business-day data or simply time-series
with a large share of missing values.

Constructor:

```
obj = nb_bd(datasets, nameOfDatasets, startDate, variables)
obj = nb_bd(datasets, nameOfDatasets, startDate, variables, sorted)
```

Input:

- datasets:

Input can be one of the data types listed below:

- xls(x) : A name of the excel spreadsheet to import. (With or without extension.). As a string.

Caution : If you read a specific worksheet, and want the object to be updateable you must provide the extension.

- mat : Name(s) of the .mat file(s) to import. (With or without extension.) As a string. This .mat file must store a struct where each field stores the data of a variable. The data stored at each field must be doubles with same size. The only exception is that you must include a field called 'dates', storing a cellstr with the dates of the data. (This cellstr must have the same size as the provided data (size of the first dimension)).

Caution : The data stored as seperate field could have more pages (size of the third dimension could be lager then 1). Again All the data of the variables must be of the same size.

- double : As a double matrix. Each page of the matrix will be added as separate datasets.

- struct : As a structure of double matrices. Each field is added as a separate datasets.

You can also give a cell array consisting of one or a combination of the data types mentioned above. Each cell will be added as a new dataset.

Extra: Use the method structure2nb_bd function to add all the fields of the structure as variables in an nb_bd object. (If each field has more page then 1, then each page will be a new datasets). See the method structure2nb_bd for more on the supported format of the structure you can provide as input.

- nameOfDatasets :

Input will depend on the data type provided to the datasets input:

- xls(x) : A string with the wanted dataset name. Default is the excel file name. If the provided string is a sheet of the read spreadsheet that specific worksheet will be read.

- mat : A string with the wanted dataset name. Default is the .mat file name.

- double : A string with the wanted dataset name. Default is 'Dataset1'.

Caution: When you give double matrices which has more pages than one, either directly or through a struct. Each of the pages will be added as a dataset. The name of this datasets will, if the input nameOfDatasets has the same size as the input datasets, get the name nameOfDatasets{jj}<jj>, where jj is the page number, or else get the name 'Database<jj>'.

- struct : This input has no consequence. The dataset names will be given by the fieldnames.

- A cell array of the listed types above:

If you give a cell array to the datasets input, this input must be a cell array of strings. If you give a cell array which doesn't have the same size as the cell array given to the datasets input, the datasets which is left gets the name 'Database<jj>', where <jj> stands for this added datasets number.

If you give an empty cell array, i.e. {} all the datasets get the names; 'Database<jj>', where <jj> stands for the added datasets number. Except when the datasets input are given by a cellstr with the excel file names or .mat file names, then the default dataset names will be set to the same cellstr. Or if some elements of the cell is a struct, then the datasets provided through the struct will get their fieldnames as the dataset names.

- dates :

A cell array of the type names of the data, as strings. Only needed when you give a double or a struct of doubles as the datasets input. The number of dates must be the same as the size of the data (1- dimension).

- variables :

A cell array of the variable names of the data, as strings. Only needed when you give a double or a struct of doubles as the datasets input. The number of variables must be the same as the size of the data (2- dimension).

- sorted : true or false. Default is true.

Output:

- obj : An object of class nb_bd.

Examples:

```

- xls(x):

    One excel spreadsheet

    obj = nb_bd('test1')

    More excel spreadsheets

    obj = nb_bd({'test1','test2',...})

- mat:

    One .mat file:

    obj = nb_bd('test1')

    More .mat files:

    obj = nb_bd({'test1','test2',...})

    same as

    obj = nb_bd({'test1','test2',...},{'test1','test2',...})

- double matrix:

    One matrix

    obj = nb_bd(double1,'','2000Q1',{'Var1','Var2',...})

    obj = nb_bd(double1,'test1','2000Q1',{'Var1','Var2',...})

```

[nb_graph_bd](#), [nb_ts](#), [nb_graph_ts](#)

Written by Per Bjarne Bye

Properties:

- [data](#)
- [ignorenan](#)
- [numberOfDatasets](#)
- [userData](#)
- [dataNames](#)
- [indicator](#)
- [numberOfObservations](#)
- [variables](#)
- [endDate](#)
- [localVariables](#)
- [numberOfVariables](#)
- [frequency](#)
- [locations](#)
- [startDate](#)

- **data** ↑

The data of the object. As a double or logical.

Inherited from superclass NB_DATASOURCE

- **dataNames** ↑

The names of the different dataset. As a cellstr.

Inherited from superclass NB_DATASOURCE

- **endDate** ↑

The end date of the data. Given as an object which is of a subclass of the nb_date class. Either: nb_day, nb_week, nb_month, nb_quarter, nb_semiAnnual or nb_year.

- **frequency** ↑

Frequency of data:
1 : yearly (also used for integers)
2 : semiannually
4 : quarterly
12 : monthly
52 : weekly
365 : daily

- **ignorenan** ↑

A boolean indicating if we should (1) (default) ignore NaNs when doing calculations on the dataset or (0) take NaNs into account when doing these calculations. Note that taking NaNs into account require the dataset to be expanded prior to the operation and will consequently take more time. Also, this will behave like a nb_ts calculation.

- **indicator** ↑

A boolean indicating if either (1) the locations where we do have an observation should be saved as 1 or (0) the locations where we do not have an observation should be saved as 1. This affects the memory required to save the sparse <locations> double. By default this will be set to the "best" option, that is the option that requires the least memory.

indicator = 1 : observation = 1, missing value = 0
Indicator = 0 : observation = 0, missing value = 1

- **localVariables** ↑

A nb_struct with the local variables of the nb_ts object.
I.e. a field with name 'test' can be reach with the string input %#test. Only for dates and vintage inputs.

Inherited from superclass NB_DATASOURCE

- **locations** ↑

Sparse logical keeping track of where we have observations or not. NaN is counted as a missing observation.

- **numberOfDatasets** ↑

Number of datasets stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **numberOfObservations** ↑

Number of observation of the data stored in the object. As a double.

- **numberOfVariables** ↑

Number of variables stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **startDate** ↑

The start date of the data. Given as an object which is of a subclass of the nb_date class. Either: nb_day, nb_week, nb_month, nb_quarter, nb_semiAnnual or nb_year.

- **userData** ↑

Add user data. Can be of any type.

Inherited from superclass NB_DATASOURCE

- **variables** ↑

Variables of the object. As a cellstr.

Inherited from superclass NB_DATASOURCE

► **abs** ↑

```
obj = abs(obj)
```

Description:

Take the absolute value of each data elements of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = abs(in);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acos** ↑

obj = acos(obj)

Description:

Take acos of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acos(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acosd** ↑

obj = acosd(obj)

Description:

acosd(obj) is the inverse cosine, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acosd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acosh** ↑

obj = acosh(obj)

Description:

acosh(obj) is the inverse hyperbolic cosine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acosh(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acot** ↑

obj = acot(obj)

Description:

Take acotangent of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acot(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acotd** ↑

obj = acotd(obj)

Description:

acotd(obj) is the inverse cotangent, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acotd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acoth** ↑

obj = acoth(obj)

Description:

acoth(obj) is the inverse hyperbolic cotangent of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acoth(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acsc** ↑

obj = acsc(obj)

Description:

Take inverse csc of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acsc(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acscl** ↑

obj = acscl(obj)

Description:

acscl(obj) is the inverse cosecant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acscd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acsch** ↑

obj = acsch(obj)

Description:

acsch(obj) is the inverse hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acsch(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **addDataset** ↑

obj = addDataset(obj,dataset,nameOfDataset,startDate,locations,...
indicator,variables)

Description:

Makes it possible to add a dataset to an existing nb_bd object

Caution : If more than one dataset is added to an object the link to the data source is broken!

Input:

- obj : An object of class nb_bd
- dataset : Either a string with the name of excel spreadsheet or a .mat file (no extension needed), or a numerical matrix.
- nameOfDataset : Must be a string with the dataset name. If not given (or given as '') the default name Database<jj> is given. Where jj is the number of added datasets of the object, including dataset you add with this method.
- dates : A cell array of string with the dates you want to add. Only needed when numerical matrix of data is added to the object. Must have the same size as the data you add.
- variables : A cell array of string with the names of the variables you want to add. Only needed when numerical matrix of data is added to the object. Must have the same size as the data you add.

Output:

- obj : The object itself with the added dataset.

Written by Per Bjarne Bye

► addDatasets ↑

```
obj = addDatasets(datasets,nameOfDatasets,dates,variables)
```

Makes it possible to add more datasets to a existing nb_bd object

Input:

Same input as of the constructor but only cell arrays are supported for the inputs 'datasets' and 'nameOfDatasets'. 'nameOfDatasets' could be given as a empty cell; {};

Output:

- obj : An object of class nb_bd, now including the new datasets provided

Examples:

```
obj = addDatasets({'2019Q1','2019Q2'},{},{'First'},...  
{'Var1','Var2'})
```

Written by Kenneth S. Paulsen

► **addPageCopies** ↑

Description:

Add copies of the data of an object of class nb_bd and append it as new datasets of the object. Only possible if an object has only one page.

Input:

- obj : An object of class nb_bd
- num : Number of copies to be appended

Output:

- obj : An object of class nb_bd with the added copies of the first dataset in the object.

Examples:

```
obj = nb_bd([2,2],'test','2012Q1',{'Var1','Var2'});  
obj = addPageCopies(obj,2);
```

Written by Kenneth S. Paulsen

► **addPages** ↑

```
obj = addPages(obj,DB)
```

Description:

Add all pages from a different nb_bd object with the current one

Caution : This method will break the link to the data source of updateable objects!

Input:

- obj : An object of class nb_bd
- DB : An object of class nb_bd
- varargin : Optional number of objects of class nb_bd

Output:

- obj : An object of class nb_bd with all the datasets from the objects obj and varargin.

Be aware: If the added datasets does not contain the same variables or dates, the data of the nb_bd object with the tightest window will be expanded automatically to include all the same dates and variables. (The added data will be set as nan when expanded to full representation.)

Examples:

```
obj = addPages(obj,DB);
```

Written by Per Bjarne Bye

► **addPostfix** ↑

```
obj = addPostfix(obj,postfix)
obj = addPostfix(obj,postfix,vars)
```

Description:

Add a postfix to all the variables in the nb_ts, nb_cs or nb_data object, or a a provided variable group.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- postfix : The postfix to add to all the variables of the object. Must be a string
- vars : A cellstr of the variable to add the prefix to. Default is all variable of the object.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data with the postfix added to the variables selected

Examples:

```
obj = obj.addPostfix('_NEW');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **addPrefix** ↑

```
obj = addPrefix(obj,prefix)
obj = addPrefix(obj,prefix,vars)
```

Description:

Add a prefix to all the variables in the nb_ts, nb_cs or nb_data object, or a provided variable group.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- prefix : The prefix to add to all the variables of the object.
Must be a string
- vars : A cellstr of the variable to add the prefix to.
Default is all variable of the object.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data with a prefix added to the selected variables

Example:

```
obj = obj.addPrefix('NEMO.');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **addVariable ↑**

```
obj = addVariable(obj,startDateOfData,Data,Variable)
```

Description:

Add a new variable to a existing nb_bd object (including all pages)

Input:

- obj : An object of class nb_bd
- startDate : The start date of the data of the added variable. Must be a string or a date object. Cannot be outside the window of the dates of the object.
- data : The data of the added variable. Cannot be outside the window of the data of the object. Must be a n x 1 or 1 x n double.
- varname : A string with the added variable name. Cannot be the same as a existing variable. (Then use setValue instead)

Output:

- obj : An object of class nb_bd with the added variable

Examples:

```
obj = addVariable(obj,'2012Q1',[2;2;2;2],'newVariable');
```

Written by Per Bjarne Bye

► and ↑

```
a = and(a,b)
```

Description:

The and operator (&).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the and operator has evaluated all the data elements of the object.
The data will be a logical matrix

Examples:

```
a = a & b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► appendFromAnotherPage ↑

```
obj = appendFromAnotherPage(obj,page)
```

Description:

Append data from another page where the rest has missing data.

Input:

- obj : A nObs1 x nVar x nPages nb_dataSource object.
- page : The page to append data from.

Output:

- obj : A nObs x nVar x nPages nb_dataSource object.

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **asCell ↑**

```
cellMatrix = asCell(obj,page,strip)
```

Description:

Return the nb_bd objects data as a cell matrix.

Input:

- obj : An object of class nb_bd
- page : Which pages of the expanded dataset should be transformed to a cell. Must be a double (vector) with the indicies.
- strip : Set to false to not strip all the nan observations.

Output:

- cellMatrix : The objects data transformed to a cell. (With types and variable names)

Examples:

```
obj      = nb_bd([2,2],'test','2000Q1',{'Var1','Var2'});  
cellMatrix = obj.asCell();
```

Written by Per Bjarne Bye

► **asec ↑**

```
obj = asec(obj)
```

Description:

Take inverse sec of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Examples:

```
obj = asec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **asecd** ↑

```
obj = asecd(obj)
```

Description:

asecd(obj) is the inverse secant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asecd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asech** ↑

```
obj = asech(obj)
```

Description:

```
asech(obj) is the inverse hyperbolic secant of the elements of obj
```

Input:

```
- obj : An object of class nb_ts, nb_cs or nb_data
```

Output:

```
- obj : An object of class nb_ts, nb_cs or nb_data
```

Examples:

```
out = asech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asin ↑**

```
obj = asin(obj)
```

Description:

Take inverse sin of the data stored in the nb_ts, nb_cs or nb_data object

Input:

```
- obj : An object of class nb_ts, nb_cs or nb_data
```

Output:

```
- obj : An object of class nb_ts, nb_cs or nb_data
```

Examples:

```
obj = asin(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **asind ↑**

```
obj = asind(obj)
```

Description:

asind(obj) is the inverse sine, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asinh** ↑

```
obj = asinh(obj)
```

Description:

asinh(obj) is the inverse hyperbolic sine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asinh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **assignNan** ↑

```
obj = expand(obj,variables,value)
```

Description:

Assign all the nan observation to the value input.

Input:

- obj : An object of class nb_dataSource.
- variables : A char or a cellstr with the variables to assign nan values.
- value : A scalar number.

Output:

- obj : An nb_ts object with expanded timespan

Examples:

```
obj      = nb_ts.rand('2012Q1',10,2,3);
obj(1:2,1,:) = nan;
obj      = assignNan(obj,'Var1',0)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atan** ↑

```
obj = atan(obj)
```

Description:

Take the inverse tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = atan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atand** ↑

```
obj = atand(obj)
```

Description:

atand(obj) is the inverse tangent, expressed in degrees, of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = atand(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **atanh** ↑

```
obj = atanh(obj)
```

Description:

atanh(obj) is the inverse hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = atanh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **breakLink** ↑

```
obj = breakLink(obj)
```

Description:

Break link to source

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callfun ↑**

```
obj      = callfun(obj,'func',func)
obj      = callfun(obj,another,'func',func)
obj      = callfun(obj,varargin,'func',func)
varargout = callfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the data of the nb_dataSource object(s). The data of the object is normally of class double, but may also be of class logical or nb_distribution. Use nb_dataSource.getClassOfData to find the class of the data of the object.

Input:

- obj : An object of class nb_dataSource.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function @(x)x will be used.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class. nb_dataSource objects are converted to a matrix with elements of class double, logical or nb_distribution.

Output:

```
- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb.DataSource object. The rest will be given as return by the func function when applied to the data of the object.
```

Examples:

```
d      = nb_ts.rand('2012Q1',10,3);
d1     = callfun(d,'func',@sin); % Same as d1 = sin(d) !
d2     = callfun(d,d,'func','plus') % Same as d2 = d + d !
[s1,s2] = callfun(d,'func',@size) % Same as [s1,s2] = size(d)
```

See also:

[nb_bd.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callop** ↑

```
obj = callop(obj,another,func)
obj = callop(obj,another,func,type)
```

Description:

Call mathematical operator on the data of the object. In contrast to calling the operator itself on the object, this method does not try to match the same variables from the two inputs, but instead operate in the same way as mathematical operators do on double matrices (bsxfun). The time domain is matched though!

Caution: The following operators are supported:

```
> @plus or 'plus'
> @minus or 'minus'
> @times or 'times'
> @rdivide or 'rdivide'
> @power or 'power'
```

Input:

```
- obj      : An object of class nb.DataSource.
- another   : An object of class nb.DataSource.
- func      : One of the above listed functions.
- type      : Either:
              > 'keep'    : Keep the variable names of the object with most variables. If they have the same number
```

```

of variables, they are taken from the first
object.
> 'rename' : The new variable names represent the operation
that has been done to the separate series. So
if you divide an object with one series named
'Var1' with another object with one series
named 'Var2', the new name will be
'Var1./Var2'. (Default)

```

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb.DataSource method. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```

d1 = nb_ts(rand(10,1),'''2012Q1',{'Var1'});
d2 = nb_ts(rand(10,1),'''2011Q1',{'Var2'});
d3 = callop(d1,d2,@minus);

d1 = nb_ts(rand(10,1),'''2012Q1',{'Var1'});
d2 = nb_ts(rand(10,2),'''2011Q1',{'Var2','Var3'});
d3 = callop(d1,d2,@minus);

```

[nb_bd.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callstat** ↑

```

obj = callstat(obj,func)
obj = callstat(obj,func,varargin)

```

Description:

Call a in-built or user defined function on the data of the nb.DataSource object(s) that goes from the data of the object have more than one variable to only having one. E.g. when taking the mean over a set of variables.

Input:

- obj : An object of class nb.DataSource.
- func : A function handle (or one line char) that maps a nObs x nVar x nPage double to nObs x 1 x nPage double, or that maps a nObs x nVar x nPage double to nObs x nVar x 1 double.

Optional input:

- 'name' : Set the name of the new variable, as a one line char.
Default is to use the str2func on the provided function handle.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class.

Output:

- obj : An object of class nb_dataSource with only one variable.

Examples:

```
d = nb_ts.rand('2012Q1',10,3);
d1 = callstat(d,@(x)mean(x,2),'name','mean')
```

See also:

[nb_bd.mean](#), [nb_bd.std](#), [nb_bd.var](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **ceil ↑**

```
obj = ceil(obj)
```

Description:

`ceil(obj)` rounds the elements of `obj` to the nearest integers towards infinity.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = ceil(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **conj** ↑

```
obj = conj(obj)
```

Description:

`conj(obj)` is the complex conjugate of the elements of `obj`.
For a complex element `x` of `obj`, $\text{conj}(x) = \text{REAL}(x) - i\text{IMAG}(x)$.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = conj(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **corr** ↑

```
obj = corr(obj,varargin)
```

Description:

Calculate the correlation of the timeseries of the `nb_bd` object

Caution: Calculates the correlation matrix of the variables of the `nb_bd` object, if no optional inputs are given. If 'lags' is given this function calculates the correlation with the number of wanted lags for each variable with itself. (And only with itself)

If the `<ignorenan>` property of the `nb_bd` object is set to true, missing values are not accounted for. This is equal to setting the 'robust' argument to true in the `<corr>` method of `nb_ts`.

Input:

- `obj` : An object of class `nb_bd`

Optional input ('propertyName',PropertyValue):

- 'lags' : An integer with the number of lags you want

to calculate the correlation for. (Here for each variable)

- 'type' : 'pairwise' or 'default'. 'pairwise' calculate the correlation matrix for the selected lag or lead, while 'default' calculates the correlation with itself for lags from 1 to lags and the same for lead.

Output:

- obj : An nb_cs object with the wanted correlation

Examples:

```
corrMatrix = corr(obj);  
corrMatrix = corr(obj,'lags',2);
```

Written by Kenneth S. Paulsen

► **cos** ↑

```
obj = cos(obj)
```

Description:

Take cos of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = cos(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cosd** ↑

```
obj = cosd(obj)
```

Description:

`cosd(obj)` is the cosine of the elements of `obj`, expressed in degrees.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = cosd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **cosh** ↑

```
obj = csch(obj)
```

Description:

`cosh(obj)` is the hyperbolic cosine of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **cot** ↑

```
obj = cot(obj)
```

Description:

Take cotangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = cot(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cotd** ↑

```
obj = cotd(obj)
```

Description:

cotd(obj) is the cotangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cotd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **coth** ↑

```
obj = coth(obj)
```

Description:

`coth(obj)` is the hyperbolic cotangent of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = coth(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **cov ↑**

```
obj = cov(obj,varargin)
```

Description:

Calculate the covariances of the timeseries of the `nb_bd` object

Caution: Calculates the covariance matrix of the variables of the `nb_bd` object, if no optional inputs are given. If 'lags' is given this function calculates the covariance with the number of wanted lags for each variable with itself. (And only with itself)

If the `<ignorenan>` property of the `nb_bd` object is set to true, the dataset any row with a NaN will be removed and calculations will be done on that data for the whole vcv-matrix. If `<ignorenan>` is false, NaNs will be trimmed to make data vectors conform when calculating covariances, but for variances, max number of rows is kept.

Input:

- `obj` : An object of class `nb_bd`

Optional input ('propertyName',PropertyValue):

- 'lags' : An integer with the number of lags you want to calculate the covariance for. (Here for each variable)
- 'type' : 'pairwise' or 'default'. 'pairwise' calculate the covariance matrix fro the selected lag or lead, while 'default' calculates the covariance with itself for lags from 1 to lags and the same for lead.

Output:

- obj : An nb_cs object with the wanted covariances

Examples:

```
corrMatrix = cov(obj);  
corrMatrix = cov(obj,'lags',2);
```

Written by Kenneth S. Paulsen

► createVariable ↑

```
obj = createVariable(obj,nameOfNewVariable,expression)  
obj = createVariable(obj,nameOfNewVariable,expression,parameters,varargin)
```

Description:

Create variable(s) and add them to the nb_bd object dataset(s)

- This function only support methods of the class nb_math_ts for the expressions. Type the following in the command window;

```
methods(nb_math_ts)
```

Input:

- obj : An object of class nb_bd
- nameOfNewVariable : The created variable names as a cell array or a string.
Must have the same size as the 'expressions' input.
- expression : The expressions of how to create the data of all the created variables.
As a cell array or a string.
Must have the same size as the 'nameOfNewVariables' input.
- parameters : A struct with the parameters that can be used in the expressions. Caution: They will be added as series, so you need to use elementwise operators (.*, ./, .^)!

Optional input:

- 'overwrite' : true or false. Set to true to allow for overwriting of variables already in the data of the object. Default is false.

- 'warning' : true or false. Set to true to give warning if expressions fail (instead of error). Will result in series having all nan value, when warning is thrown.

Output:

- obj : An nb_bd object with the created variable(s) added.

Examples:

```
obj = obj.createVariable('var3','var1./var2');  
obj = obj.createVariable({'var3','var4',...},...  
{'var1./var2','var2./var1',...});
```

See also:

[nb_math_ts](#)

Written by Per Bjarne Bye

► **csc** ↑

obj = csc(obj)

Description:

Take csc of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = csc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cscd** ↑

```
obj = cscd(obj)
```

Description:

cscd(obj) is the cosecant of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cscd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **csch** ↑

```
obj = csch(obj)
```

Description:

csch(obj) is the hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cumnansum** ↑

```
obj = cumnansum(obj)
```

Description:

Cumulativ sum of the series of the object. Ignoring nan values.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumnansum(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumprod** ↑

```
obj = cumprod(obj,dim)
```

Description:

Cumulativ product of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ product should be calculated. Default is the first dimension.

Output:

- obj : A nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative product of the old objects 'data' property.

Examples:

```
obj = cumprod(obj);
obj = cumprod(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumsum** ↑

```
obj = cumsum(obj,dim)
```

Description:

Cumulativ sum of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ sum should be calculated. Default is the first dimension.

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumsum(obj);  
obj = cumsum(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **dates** ↑

```
allDates = dates(obj)  
allDates = dates(obj,format,type)
```

Description:

Get all the dates of the object. As a cellstr. Dates where all variables are nan are stripped.

Input:

- obj : An object of class nb_bd
- format : See the method toDates of the nb_year, nb_semiAnnual, nb_quarter, nb_month, nb_week or nb_day classes.
- type : Either 'stripped' or 'full' (default). If 'stripped' is given all dates where all observations of the data is nan is removed, otherwise all dates are returned.

Output:

- allDates : A cellstr array of the dates of the object

Examples:

```
allDates = obj.dates();  
allDates = obj.dates('xls');
```

Written by Kenneth S. Paulsen

► deleteMethodCalls ↑

```
obj = deleteMethodCalls(obj,c)
```

Description:

Delete some method calls of the object. The object needs to be updatable.

Caution: To set method calls use setMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- sourceNr : The source index to delete the methods from
- methodNrs : A index with the methods to delete.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

See also:

[setMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► deleteVariables ↑

```
obj = deleteVariables(obj,deletedVar)
```

Description:

```
Delete variables from the current nb_bd
```

If some of the variables you specify in deletedVar does not exist in the obj, this will not have anything to say for the obj. (The variables cannot be deleted, because the variables do not exist.)

This method overrides the implementation in nb_dataSource.

Input:

- obj : An object of class nb_bd
- deletedVar : Must be a char or a cellstr

Delete all the variable names, given in the char array or cellstr array deletedVar, of current the object.

NB! If deletedVar is just one string and include a * as the last letter, this function will delete all the variable names, from the object, that start with the letters which is in front of the * in the string.

i.e. obj = deleteVariables(obj,'DPQ*');

Deletes all the variables in the obj which has variable names starting with 'DPQ'.

If deletedVar is just one string and include a * as the first letter, this function will delete all the variable names, from the object, that include the letters which follows in the string.

i.e. obj = deleteVariables(obj, '*shift');

Deletes all the variables in the obj which has variable names which include 'shift'.

Output:

- obj : A nb_bd object with the variables specified in deletedVar deleted.

Examples:

```
obj = nb_bd([2,2],'test','2012',{'Var1','Var2'});  
obj = deleteVariables(obj, {'Var1','Var2'});  
obj = deleteVariables(obj, char('Var1','Var2'));  
obj = deleteVariables(obj, obj.variables);
```

Written by Per Bjarne Bye

► **demean** ↑

```
obj = demean(data,dim)
```

Description:

- Demeans data along the dimension you choose.

Input:

- obj : A nb_dataSource object.
- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- obj : A nb_dataSource object.

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATASOURCE

► **disp ↑**

disp(obj)

Description:

Display object (In the command window)

Input:

- obj : An object of class nb_bd

Output:

The dataset displayed in the command window.

Examples:

obj (Note without semicolon)

Written by Per Bjarne Bye

► **double ↑**

dataOfObject = double(obj,type)

Description:

```
Get the data of the nb_bd object as a double matrix
```

This method overrides the nb_dataSource method inherited by the other data objects, as we

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- type : Either 'full' (default), 'stripped' or 'sparse'. Can also be logical true ('full') or false ('sparse').

Output:

- dataOfObject : The data of the nb_bd object.

Examples:

```
dataOfObject = double(obj)
```

Written by Per Bjarne Bye

► **egrowth ↑**

```
obj = egrowth(obj)
obj = egrowth(obj,lag)
```

Description:

Calculate exact growth, using the formula: $(x(t) - x(t-1))/x(t-1)$ of all the timeseries of the nb_bd object.

Input:

- obj : An object of class nb_bd
- lag : The number of lags in the growth formula, default is 1.

Caution : The <ignorenan> property of nb_bd obj controls of NaNs will be stripped before calculation of growth or not.

Output:

- obj : An nb_bd object with the calculated timeseries stored.

Examples:

```
obj = egrowth(obj);
obj = egrowth(obj,4);
```

See also:

[growth](#), [aegrowth](#), [agrowth](#)

Written by Per Bjarne Bye

► **empty** ↑

`obj = empty(obj)`

Description:

Empty the nb_bd object

Input:

- obj : An object of class nb_bd

Output:

- obj : An empty nb_bd object

Examples:

`obj = empty(obj);`

Written by Per Bjarne Bye

► **eq** ↑

`a = eq(a,b)`

Description:

Test if the one object is equal (==) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.

- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a == b;  
obj = 2 == b;  
obj = a == 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **exp ↑**

```
obj = exp(obj)
```

Description:

Take exp of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = exp(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **expand ↑**

```
obj = expand(obj,newStartDate,newEndDate,warningOff)
```

Description:

Expand the current nb_bd object with more dates and data.

Input:

```
- obj : An object of class nb_bd  
- newStartDate : The wanted new start date of the data.  
- newEndDate : The wanted new end date of the data.  
- warningOff : Give 'off' to suppress warning if no expansion  
has taken place. Both 'newStartDate' and
```

Output:

```
- obj : An nb_bd object with expanded timespan
```

Examples:

```
obj = nb_bd.rand('1901Q1',10,2);  
obj = expand(obj,'1900Q1','1903Q4');
```

Written by Per Bjarne Bye

► **expml** ↑

```
obj = expml(obj)
```

Description:

`exp(obj)` is the exponential of the elements of `obj`, e to the `obj`.
`expml(obj)` computes `exp(obj)-1`, compensating for the roundoff in
`exp(obj)`.
(For small real `X`, `expml(X)` should be approximately `X`, whereas the
computed value of `EXP(X)-1` can be zero or have high relative error.)

Input:

```
- obj : An object of class nb_ts, nb_cs or nb_data
```

Output:

```
- obj : An object of class nb_ts, nb_cs or nb_data where the  
data are equal to  $e.^obj.data - 1$ 
```

Examples:

```
obj = expml(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **extMethod** ↑

```
obj = extMethod(obj,method,variables,postfix,varargin)
```

Description:

This method can call a nb_dataSource method on a selected variables, and merge the result with the old object by adding a postfix to the new variables.

This method is the same as calling:

```
obj1 = window(obj,'','','variables');
method = str2func(method);
obj = method(obj,varargin{:});
obj1 = addPostfix(obj1,method);
obj = merge(obj,obj1);
```

But without replicating the links property unnecessary many times!

Caution : If the object is not updateable this will result in the same as the code above!

Input:

- obj : An object of class nb_ts, nb_data or nb_cs
- method : A str with the method to call. Must be a method of the nb_ts, nb_data or nb_cs class that does not change other dimensions than the second dimension!
- variables : A cellstr with the variables of the object to call the method on. Must be included in the object.
- postfix : A string with the postfix. If empty, the old variables will be replaced by the new ones.

Optional inputs:

These will be the inputs casted to the method except the object itself.

Extra for nb_ts and nb_data:

- '<start>' : The start date/obs of the function evaluation. Given as the second input to the window method call.
- '<end>' : The end date/obs of the function evaluation. Given as the third input to the window method call.

Output:

- obj : A nb_ts, nb_data or nb_cs object

Examples:

```
obj = nb_ts.rand(1,10,3);
obj = extMethod(obj,'lag',{'Var1'},'lag1',1)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **floor** ↑

```
obj = floor(obj)
```

Description:

`floor(obj)` rounds the data elements of `obj` to the nearest integers towards minus infinity

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = floor(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **ge** ↑

```
a = ge(a,b)
```

Description:

Test if the one object is greater than or equal to (\geq) the other object elemetswise and return a `nb_dataSource` object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- `a` : An object of class `nb_dataSource` or a scalar number.
- `b` : An object of class `nb_dataSource`, but must be of same subclass as `a`, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a >= b;  
obj = 2 >= b;  
obj = a >= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **getClassOfData** ↑

```
cl = getClassOfData(obj)
```

Description:

Get the class of the data stored by the object.

Input:

- obj : An object of class nb_dataSource.

Output:

- cl : Name of the class that the data of the object is stored as.

See also:

[nb_bd.isDistribution](#), [nb_bd.isDouble](#)
[nb_bd.isBoolean](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getCreatedVariables** ↑

```
created = getCreatedVariables(obj)
```

Description:

Get a N x 2 table of the variables created using the createVariable method. The first column list the created variables, while the second column list the expressions.

Input:

- obj : An object that is a subclass of nb_dataSource.

Output:

- created : A N x 2 cell array. See description of this method for more.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getLocInd** ↑

[loc,ind,dataOut,numberOfDatasets] = getLocInd(dataIn)

Description:

Given a n x n double of data, return the locations of data as a sparse logical, the indicator with information if missing values is stored as a 1/0, and the data as a vector with no missing values.

Input:

- data : A n x n double with the data.

Output:

- loc : A n x n sparse logical with information of the positions.

- ind : A 1 x 1 logical. 1 if observations are stored as a 1 and missing values as a 0 in loc, and 0 otherwise.

- dataOut : A n x 1 double with only the data (no missing values).

- numberOfDatasets : A 1 x 1 double. This is equal to the third dimension of the data as a sparse logical can only be 2D. The third dimension is preserved by stacking locations horizontally.

Examples:

```
data = [1,2,3;1,NaN,4;5,NaN,7];
[loc,ind,dataOut,numberOfDatasets] = getLocInd(data)
```

Written by Per Bjarne Bye

► **getMethodCalls** ↑

[s,c] = getMethodCalls(obj)

Description:

Get all method calls as a cell matrix. The object needs to be updatable to get a list of methods called on the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.
- c : A cell matrix with a table of the method called on the object and its input. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► getRealEndDate ↑

```
realEndDate = getRealEndDate(obj)
realEndDate = getRealEndDate(obj,format,type)
realEndDate = getRealEndDate(obj,format,type,variables)
```

Description:

Get the real end date of the nb_ts object. I.e the last observation which is not nan or infinite.

Input:

- obj : An object of class nb_ts
- format : The date format returned.
 - Return a string:
> 'xls'
> 'pprnorsk' or 'mprnorwegian'
> 'pprengelsk' or 'mprenglish'
> 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
> 'nb_date'
- type : Either 'any' (default) or 'all'.
- variables : A cellstr of the variables to check.

Output:

- realEndData : The last observation of the object which is not nan or infinite. As a string

Examples:

```
realEndDate = obj.getRealEndDate();  
realEndDate = obj.getRealEndDate('pprnorsk');
```

Written by Kenneth S. Paulsen

► **getRealStartDate ↑**

```
realStartDate = getRealStartDate(obj)  
realStartDate = getRealStartDate(obj,format,type,variables)
```

Description:

Get the real start date of the nb_bd object. I.e the first observation which is not nan or infinite.

Input:

- obj : An object of class nb_bd
- format : The date format returned.
 - Return a string:
 - > 'xls'
 - > 'pprnorsk' or 'mprnorwegian'
 - > 'pprengelsk' or 'mprenglish'
 - > 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
 - > 'nb_date'
- type : Either 'any' (default) or 'all'.
- variables : A cellstr of the variables to check.

Output:

- realStartDate : The first observation of the object which is not nan or infinite. As a string

Examples:

```
realStartDate = obj.getRealStartDate();  
realStartDate = obj.getRealStartDate('pprnorsk');
```

Written by Kenneth S. Paulsen

► **getSource** ↑

```
sourceType = getSource(obj)
sourceType = getSource(obj,type)
```

Description:

Get source type.

Input:

- obj : An object of class nb_dataSource.
- type : Give 'program' to get the general source. Default is to give the specific type of source.

Output:

- sourceType : A one line char with the source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getSourceList** ↑

```
s = getSourceList(obj)
```

Description:

Get the source list of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getVariable** ↑

```

variableData = getVariable(obj,variableName)
variableData = getVariable(obj,variableName,startDate, ...
                           endDate, pages)
variableData = getVariable(obj,type,variableName)
variableData = getVariable(obj,type,variableName,startDate, ...
                           endDate, pages)

```

Description:

Get the data of a variable, as a double

Input:

- obj : An object of class nb_ts
- type : Either 'stripped' or 'full' (default). If 'stripped' is given all dates where all observations of the data is nan is removed, otherwise all dates are returned.
- variableName : The variable you want the data of. Must be given as a string (name of variable) or a cellstr.
- startDate : Start date of the return data of the given variable. As a string or an object which is of a subclass of nb_date
- endDate : End date of the return data of the given variable. As a string or an object which is of a subclass of nb_date
- pages : Pages of the return data of the given variable. As a double or logical array, e.e. [1:2] or [1,3,5].

Output:

- variableData : The data of the variable you have given. Return [] if not found.

Examples:

```

variableData = getVariable(obj,'Var1');
variableData = getVariable(obj,'Var1','2012Q1','2012Q4');
variableData = getVariable(obj,'full','Var1');
variableData = getVariable(obj,'full','Var1','2012Q1');
variableData = getVariable(obj,'full','Var1','2012Q1','2012Q4');
variableData = getVariable(obj,'full','Var1','2012Q1','2012Q4',[1:3]);

```

Written by Kenneth S. Paulsen

► **growth ↑**

```

obj = growth(obj)
obj = growth(obj,lag,stripNaN)

```

Description:

Calculate approx growth, using the formula: $\log(x(t)) - \log(x(t-1))$ of all the timeseries of the nb_ts object.

Input:

- obj : An object of class nb_bd
- lag : The number of lags in the approx. growth formula, default is 1.

Output:

- obj : An nb_bd object with the calculated timeseries stored.

Examples:

```
obj = growth(obj);
obj = growth(obj, 4);
```

See also:

[egrowth](#), [aegrowth](#), [agrowth](#)

Written by Per Bjarne Bye

► **gt** ↑

```
a = gt(a,b)
```

Description:

Test if the one object is greater then ($>$) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a > b;  
obj = 2 > b;  
obj = a > 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **hasVariable** ↑

```
[ret,location] = hasVariable(obj,variable)
```

Description:

Test if an nb_cs object has a given variable

Input:

- obj : An object of class nb_cs
- variable : The variable name as a string. Can also be a cellstr with more variables.

Output:

- ret : 1 if found otherwise 0
- location : The location of the variable if found. Otherwise [].

Examples:

```
ret = obj.hasVariable('Var1')  
[ret,location] = hasVariable(obj,'Var1')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **head** ↑

```
head(obj,nRows,page)
```

Description:

Display the first n rows of a nb_bd object.

Input:

- obj : An nb_bd object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_bd](#), [window](#), [tail](#)

Written by Per Bjarne Bye

► **histogram** ↑

```
data          = histogram(obj)
[data,plotter] = histogram(obj,M)
```

Description:

Create a histogram of a object containing only one variable and one page!

Input:

- obj : A nb_dataSource object with size N x 1 x 1.
- M : The number of bins of the histogram.

Output:

- data : A nb_cs object with size M x 1 x 1.
- plotter : A nb_graph_cs object with the histogram plotted.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **horzcat** ↑

```
obj = horzcat(a,b,varargin)
```

Description:

Horizontal concatenation of nb_bd objects. ([a,b]) This is only possible if the different objects contain different variables or have variables with the same values (start and/or end dates can differ). Uses the merge method.

Input:

- a : An object of class nb_bd
- varargin : Optional number of nb_bd objects

Output:

- obj : An nb_bd object with all the variables from the different nb_bd object merged into one dataset

Examples:

```
obj = [a,b];  
obj = [a,b,c];
```

See also:

[merge](#)

Written by Kenneth S. Paulsen

► **initialize ↑**

```
obj = nb_bd.initialize(data,nameOfDatasets,dates,variables,sorted)
```

Description:

Initialize a nb_db object with a stripped set of dates and its matching data points.

Input:

- data : A r x c x p double, logical or nb_distribution array.
- nameOfDatasets : Either a one line char or a 1 x p cellstr.
- dates : A 1 x r or r x 1 nb_date array.
- variables : A 1 x c cellstr.
- sorted : true or false. Default is true.

Output:

- obj : A nb_bd object.

See also:

[nb_bd](#)

► **interpolate** ↑

```
obj = interpolate(obj,method)
```

Description:

Interpolate the data of the nb_data object. Will discard leading and trailing nan values.

Input:

- data : An nb_ts, nb_cs or nb_data object.
- method :
 - 'nearest' : Nearest neighbor interpolation
 - 'linear' : Linear interpolation. Default
 - 'spline' : Piecewise cubic spline interpolation (SPLINE)
 - 'pchip' : Shape-preserving piecewise cubic interpolation
 - 'cubic' : Same as 'pchip'
 - 'v5cubic' : The cubic interpolation from MATLAB 5, which does not extrapolate and uses 'spline' if X is not equally spaced.

Output:

- data : An nb_ts, nb_cs or nb_data object with the interpolated data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isBoolean** ↑

```
ret = isBoolean(obj)
```

Description:

Check if the data of the nb_dataSource object is of class logical (boolean, i.e. true or false).

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isCrossSectional ↑**

ret = isCrossSectional(obj)

Description:

Test if this object is a cross sectional data object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_cs, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isDistribution ↑**

ret = isDistribution(obj)

Description:

Check if the data of the nb_dataSource object is of class nb_distribution

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isDouble ↑**

```
ret = isDouble(obj)
```

Description:

Check if the data of the nb_dataSource object is of class double (numeric)

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isTimeseries** ↑

```
ret = isTimeseries(obj)
```

Description:

Test if a nb_dataSource object is a time series object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_ts, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isUpdateable** ↑

```
ret = isUpdateable(obj)
```

Description:

Test if this object is updateable.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : 1 if updateable, otherwise 0.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isempty** ↑

ret = isempty(obj)

Description:

Test if a nb_ts, nb_cs or nb_data object is empty. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

ret = isempty(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isfinite** ↑

obj = isfinite(obj)

Description:

Test if each element of a nb_ts, nb_cs or nb_data object is finite.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is finite, otherwise 0.

Examples:

```
obj = isfinite(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isnan** ↑

```
obj = isnan(obj)
```

Description:

Test if each element of an nb_ts, nb_cs or nb_data object is nan.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is nan, otherwise 0.

Examples:

```
obj = isnan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isscalar** ↑

```
ret = isscalar(obj)
```

Description:

Test if a nb_ts, nb_cs or nb_data object is a scalar. Will always return 0, as an object of class nb_ts, nb_cs or nb_data is not a scalar.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : false

Examples:

```
0 = isscalar(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **keepPages** ↑

```
obj = keepPages(obj, pages)
```

Description:

Keep pages of the current nb_ts object

Input:

- obj : An object of class nb_ts
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty a empty nb_ts object is returned.

Can also be a cellstr with the names to keep, or a logical array with length equal to the number of pages (datasets).

Output:

- obj : An nb_ts object with the pages specified in the input are kept.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **kurtosis** ↑

```
obj = kurtosis(obj, flag, outputType, dimension)
```

Description:

Calculate the kurtosis of each timeseries. The result will be an object of class nb_bd where all the non-nan values of all the timeseries are being set to their kurtosis.

The output can also be set to be a double or a nb_cs object consisting of the kurtosis values of the data.

Input:

- obj : An object of class nb_bd
- flag : > 0 : normalises by N-1 (Default)
> 1 : normalises by N
 - Where N is the sample length.
- outputType :
 - > 'nb_bd' : The result will be an object of class nb_bd where all the non-nan values of all the timeseries are being set to their kurtosis.
 - > 'double' : Get the kurtosis values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the kurtosis values as nb_cs object. The kurtosis will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the kurtosis over.

Caution: the `<ignorenan>` property of obj controls the behavior of how to handle NaNs. This is equal to the 'notHandleNaN' optional input of the std method of the nb_ts class.

Output:

- obj : See the input outputType for available options.

Examples:

```
nb_bdObj = kurtosis(obj);
double    = kurtosis(obj,0,'double');
nb_csObj = kurtosis(obj,0,'nb_cs');
```

Written by Per Bjarne Bye

► le ↑

```
a = le(a,b)
```

Description:

Test if the one object is less than or equal to (\leq) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a <= b;  
obj = 2 <= b;  
obj = a <= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► log ↑

```
obj = log(obj)
```

Description:

Take log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on logs.

Examples:

```
obj = log(obj);  
  
Written by Kenneth S. Paulsen  
  
Inherited from superclass NB_DATASOURCE
```

► **log10** ↑

```
obj = log10(obj)
```

Description:

Take the common (base 10) log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on (base 10) logs.

Examples:

```
obj = log10(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **log1p** ↑

```
obj = log1p(obj)
```

Description:

log1p(obj) computes $\text{LOG}(1+xi)$, where xi are the elements of obj. Complex results are produced if $xi < -1$.

For small real xi, log1p(xi) should be approximately xi, whereas the computed value of $\text{LOG}(1+xi)$ can be zero or have high relative error.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = log1p(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **log2** ↑

```
obj = log2(obj)
```

Description:

log2(obj) is the base 2 logarithm of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = log2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **lt** ↑

```
a = lt(a,b)
```

Description:

Test if the one object is less than (<) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a < b;  
obj = 2 < b;  
obj = a < 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► map2Distribution ↑

```
obj = map2Distribution(obj,dist)  
obj = map2Distribution(obj,dist,varargin)
```

Description:

Map observation to the distributions given by dist.

The current distribution of the data is estimated using a kernel density estimator. The data must be strongly stationary. I.e. the unknown distribution from where the data has been drawn must not depend on time.

Input:

- obj : An object of class nb_dataSource.
- dist : An object of class nb_distribution with size 1 x size(obj,2).

Optional inputs:

- See the optional inputs of the nb_distribution.estimate function.

Output:

- obj : An object of class nb_dataSource.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **max** ↑

```
obj = max(obj,outputType,dimension)
```

Description:

Calculate the max of each timeseries. The result will be an object of class nb_bd where all the non-nan values of all the timeseries are being set to their max.

The output can also be set to be a double or a nb_cs object consisting of the max values of the data.

Input:

- obj : An object of class nb_bd
- outputType :
 - > 'nb_bd' : The result will be an object of class nb_bd where all the non-nan values of all the timeseries are being set to their max.
 - > 'double' : Get the max values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the max values as nb_cs object. The max will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the max over.

Output:

- obj : See the input outputType for more on the output from this method

Examples:

```
nb_bdObj = max(obj);
double   = max(obj,'double');
nb_csObj = max(obj,'nb_cs');
```

Written by Per Bjarne Bye

► **mean** ↑

```
obj = mean(obj,outputType,dimension,varargin)
```

Description:

Calculate the mean of each timeseries. The result will be an object of class nb_bd where all the non-nan values of all the timeseries are being set to their mean.

The output can also be set to be a double or a nb_cs object consisting of the mean values of the data.

Input:

- obj : An object of class nb_bd
- outputType :
 - > 'nb_bd' : The result will be an object of class nb_bd where all the non-nan values of all the timeseries are set to the mean.
 - > 'double' : Get the mean values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the mean values as nb_cs object. The mean will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calcualate the mean over.

Caution: the <ignorenan> property of obj controls the behavior of how to handle NaNs. This is equal to the 'notHandleNaN' optional input of the mean method of the nb_ts class.

Output:

- obj : See the input outputType for available options.

Examples:

```
nb_bdObj = mean(obj);  
double    = mean(obj,'double');  
nb_csObj = mean(obj,'nb_cs');
```

Written by Per Bjarne Bye

► **merge ↑**

```
obj = merge(obj,DB)
```

Description:

Merge another nb_bd object with the current one

Input:

- obj : An object of class nb_bd
- DB : An object of class nb_bd

Output:

- obj : An object of class nb_bd where the datasets from the DB object are merged with the data of the obj object.

Caution:

- > It is possible to merge datasets with the same variables as long as they are representing the same data or have different types.
- > If the datasets has different number of datasets and one of the merged objects only consists of one, this object will add as many datasets as needed (copies of the first dataset) so they can merge.
- > It is not possible to merge two bd objects of different frequencies. Use nb_ts instead.

Examples:

```
obj = nb_bd([2,2; 2,2],'test','2000Q1',{'Var1','Var2'});  
DB = nb_bd([2,1; 2,2],'test','2000Q2',{'Var1','Var3'});  
obj = obj.merge(DB)
```

Written by Per Bjarne Bye

► merge2Series ↑

```
obj = merge2Series(obj,var1,var2,new,method,varargin)
```

Description:

Merge 2 series. The var2 series is appended to the var1 series from where it is ending.

Input:

- obj : An object of class nb_dataSource.
- var1 : A one line char with the name of the base series.

- var2 : A one line char with the name of the appended series.
- new : Name of the new variable. If given as empty there will not be created a new series, but instead the var1 variable will be set to the new merged series. Default is empty.
- method : Either 'level', 'diff', 'growth', 'leveldiff' or 'levelgrowth'. Default is 'level'. For the cases 'level', 'diff' or 'growth' it is assumed the both series are in levels. 'leveldiff' assumes the first series is in level and the second in nLags-difference. 'levelgrowth' assumes the first series is in level and the second in growth rates over nLags periods, i.e. $(x(t) - x(t-nLags))/x(t-nLags)$.

Optional input:

- 'nLags' : The number of lages used for the methods 'diff' and 'growth'. Default is 1.
- 'date' : The date from where to use the second variable. Either a date as string or a nb_date object. If empty the merge will take place where the first variable end + 1 period.

Output:

- obj : An object of class nb_dataSource.

Examples:

```

obj           = nb_ts.rand('2012Q1',10,2,3);
obj(end-1:end,1,:) = nan;

obj1 = merge2Series(obj,'Var1','Var2','Var3')
obj2 = merge2Series(obj,'Var1','Var2')
obj3 = merge2Series(obj,'Var1','Var2','','diff','nLags',1)
obj4 = merge2Series(obj,'Var1','Var2','','diff','nLags',4)
obj5 = merge2Series(obj,'Var1','Var2','','level','date','2014Q1')

```

See also:

[nb_ts.merge](#), [nb_data.merge](#), [nb_cs.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► [nan ↑](#)

```

obj = nb_bd.nan()
obj = nb_bd.nan(start,obs,vars,pages,sorted)

```

Description:

Create an nb_bd object with all data set to nan. Notice, this might not make much sense as the raison d'être for this class is to strip NaNs from the data. The resulting object will be an empty nb_bd object, but with locations and indicator preserved in the object.

Input:

- start : The start date of the created nb_bd object.
- obs : The number of observations of the created nb_bd object.
- vars : Either a cellstr with the variables of the nb_bd object, or a scalar with the number of variables of the nb_bd object.
- pages : Number of pages of the nb_bd object.
- sorted : true or false. Default is true.

Output:

- obj : An nb_bd object.

Examples:

```
obj = nb_bd.nan();
obj = nb_bd.nan('2012Q1',10,['Var1','Var2','Var3']);
obj = nb_bd.nan('2012Q1',2,2,10);
```

See also:

[nb_bd](#), [nb_bd.zeros](#), [nb_bd.ones](#)

Written by Per Bjarne Bye

► [ne ↑](#)

a = ne(a,b)

Description:

Test if the one object is not equal to (~=) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a ~= b;  
obj = 2 ~= b;  
obj = a ~= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **not** ↑

```
a = not(a)
```

Description:

The not operator (~).

Input:

- a : An object of class nb_dataSource.

Output:

- a : An object of class nb_dataSource. Where the not operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

```
a = ~a;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **objSize** ↑

```
varargout = objSize(obj,dim)
```

Description:

Return the size(s) of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim :
 - 1 : Number of observations
 - 2 : Number of variables
 - 3 : Number of datasets (pages)

Output:

- varargout : See the examples below

Examples:

```
dim = objSize(obj)
```

Where dim is 1 x 2 double where the first element
is the number of observations/types and the second element is
the number of variables

```
[dim1, dim2] = objSize(obj)
```

```
[dim1, dim2, dim3] = objSize(obj)
```

```
dim1 = objSize(obj,1)
```

```
dim2 = objSize(obj,2)
```

```
dim3 = objSize(obj,3)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► ones ↑

```
obj = nb_bd.ones()  
obj = nb_bd.ones(start,obs,vars,pages,sorted)
```

Description:

Create an nb_bd object with all data set to ones.

Input:

- start : The start date of the created nb_bd object.
- obs : The number of observations of the created nb_bd object.
- vars : Either a cellstr with the variables of the nb_bd object, or a scalar with the number of variables of the

nb_bd object.

- pages : Number of pages of the nb_bd object.
- sorted : true or false. Default is true.

Output:

- obj : An nb_bd object.

Examples:

```
obj = nb_bd.ones();
obj = nb_bd.ones('2012Q1',10,['Var1','Var2','Var3']);
obj = nb_bd.ones('2012Q1',2,2,10);
```

See also:

[nb_bd](#), [nb_bd.nan](#), [nb_bd.zeros](#)

Written by Per Bjarne Bye

► [or](#) ↑

a = or(a,b)

Description:

The and operator (|).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nbDataSource.
- b : An object of class nbDataSource, but must be of same subclass as a!

Output:

- a : An object of class nbDataSource. Where the or operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

a = a | b;

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **packing** ↑

```
obj = packing(obj,packages,varargin)
```

Description:

Package variables by applying the wanted function. Default is summin (sum).

Input:

- obj : An object of class nb_ts.
- packages : A 2 x N cell matrix with groups of variables and the names of the groups. If you have not listed a variable it will be grouped in a group called 'Rest' (as long as 'includeRest' is not set to false).

Must be given in the following format:

```
{'group_name_1','...','group_name_N';  
 name_1 ,...,name_N}
```

Where name_x must be a string with a name of the variable or a cellstr array with the variable names. E.g 'Var1' or {'Var1','Var2'}.

Optional inputs:

- 'includeRest' : Give false to not include the 'Rest' variable, which will represent all the variable that has not been packed.
- 'func' : Either a function_handle or a one line char with the name of the function to use. The first input to this function is a nObs x nVar double, the second is the dimension (which is always 2). Examples; 'sum', 'prod', @sum or @prod.

Output:

- obj : A object of class nb_ts.

Examples:

```
data      = nb_ts.rand('2012Q1',10,4);  
packages = {'group1','group2';  
            {'Var1','Var2'},{'Var3'}};  
  
dataP1 = packing(data,packages)  
dataP2 = packing(data,packages,'includeRest',false)  
dataP3 = packing(data,packages,'func',@prod)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **permute** ↑

```
obj = permute(obj,variables)
```

Description:

Switch the second and third dimension of the nb_ts, nb_cs or nb_data object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- variables : A cellstr with size 1 x numberOfDatasets. Default is to use dataNames property. I.e. when not provided or if empty.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **plot** ↑

```
plot(obj,varargin)
plotter = plot(obj,varargin)
```

Description:

Plot the data of the nb_dataSource object.

Caution: If the data of the object is of class nb_distribution this method will redirect to plotDist.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- plotType : A string with either:
 - > 'graph' (Default)

```

> 'graphSubPlots'

> 'graphInfoStruct'

The name of the graphing method of the class
nb_graph_ts, nb_graph_cs or nb_graph_data.

Caution: This is an optional input. If not given it is
assumed that the optional input pairs are starting from the
second input to this function.

- varargin : Same as the input to the method set() of the
  nb_graph_ts, nb_graph_cs or nb_graph_data class.

I.e. ..., 'inputName', inputValue, ...

Caution: If the data of the object is of class
  nb_distribution, see nb_ts.plotDist for the
optional input pairs supported.

```

Output:

Plotted output

Examples:

```

plot(obj)

plot(obj,'graphSubPlots')

plot(obj,'','startGraph','2008Q1','endGraph','2011Q2')

same as

plot(obj,'graph','startGraph','2008Q1','endGraph','2011Q2')

```

See also:

[nb_graph_ts](#), [nb_ts.plotDist](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **pow2 ↑**

obj = pow2(obj)

Description:

pow2(obj) raises the number 2 to the power of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = pow2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **rand** ↑

```
obj = nb_bd.rand(start,obs,vars,pages,dist,sorted)
```

Description:

Create an nb_bd object with all data set to a random number.

Input:

- start : The start date of the created nb_bd object.
- obs : The number of observation of the created nb_bd object.
- vars : Either a cellstr with the variables of the nb_bd object, or a scalar with the number of variables of the nb_bd object.
- pages : Number of pages of the nb_bd object.
- dist : A nb_distribution object to draw from.
- sorted : true or false. Default is true.

Output:

- obj : An nb_bd object.

Examples:

```
obj = nb_ts.rand('1',10,['Var1','Var2']);  
obj = nb_ts.rand('2012Q1',2,2);  
obj = nb_ts.rand('2012Q1',2,2,10,nb_distribution('type','normal'));
```

See also:

[nb_bd](#)

► **real** ↑

```
obj = real(obj)
```

Description:

real(obj) returns the real part of the elements in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = real(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **reallog** ↑

```
obj = reallog(obj)
```

Description:

Take the real natural logarithm of the data stored in the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = reallog(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **realsqrt** ↑

```
obj = realsqrt(obj)
```

Description:

`realsqrt(obj)` is the square root of the elements of `obj`.
An error is produced if `obj` contains negative elements.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = realsqrt(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **rename** ↑

```
obj = rename(obj,type,oldName,newName)
```

Description:

Makes it possible to rename variables and datasets. For objects of class `nb_cs` types is also possible to rename.

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variable', but not when the input is 'dataset' or 'types'.

Input:

- `obj` : An object of class `nb_dataSource`

- `type` : Either:
- 'variable' : To rename a variable(s)
- 'dataset' : To rename a dataset(s) (The only input that is supported for `nb_cell`)
- 'types' : To rename a type(s) (only `nb_cs`)

- `oldName` : Case 1;

> The old variable/dataset/type name, as a string

Case 2:

> The string which should be replaced in all the variable names of the database. And reorder things afterwards. This input must end with a *.

- newName : Case 1;

> The new variable/dataset/type name, as a string

Case 2;

> The string which should replace the old string part given by the input 'oldName'.

Output:

- obj : An nb_dataSource object with the renamed variable(s), type(s) or dataset(s).

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = obj.rename('variable','Var1','Var3');  
obj = obj.rename('variable','Var*','N_Var');  
obj = rename(obj,'variable',{'Var1','Var2'},{'VAR1','VAR2'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **renameMore** ↑

obj = renameMore(obj,type,oldNames,newNames)

Description:

Makes it possible to rename more variables, datasets and types (only nb_cs).

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variables', but not when the input is 'datasets'.

Caution : This is the same as looping over nb_dataSource.rename, but more efficient.

Caution : * syntax is not supported as is the case for nb_dataSource.rename

Input:

- obj : An object of class nb_dataSource.
- type : Either:
 - 'variables' : To rename a variables
 - 'datasets' : To rename a datasets (The only input that is supported for nb_cell)
 - 'types' : To rename a type (Only nb_cs)
- oldNames : The old variable/dataset/type names, as a cellstr.
- newName : The new variable/dataset/type names, as a cellstr.

Output:

- obj : An nb_dataSource object where the variable(s)/dataname(s)/type(s) of the object given as input is/are renamed.

Examples:

```
obj = nb_cs([22,24;27,28],'Dataset1',{'Exp','Imp'},{'Nor','Swe'})
obj = renameMore(obj,'dataset',{'Dataset1'},{'tradeBal'});
obj = renameMore(obj,'variable',{'Nor','Swe'},{'Norway','Sweden'});
obj = renameMore(obj,'type',{'Exp','Imp'},{'Export','Import'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **reorder ↑**

```
obj = reorder(obj,newOrder,type)
```

Description:

Re-order the variables/types/datasets of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- newOrder : A cellstr with the new order of the variables/types/datasets.
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **round** ↑

```
obj = round(obj,value,startDate,endDate,variables)
```

Description:

Round to closest value. I.e. if value is 0.25 it will round to the closest 0.25. E.g. 0.67 will be rounded to 0.75.

Input:

- obj : A nb_bd object
- value : The rounding value. As a double. Default is 1.
- startDate : The start date of the rounding. As a date string or a nb_date object. Can be empty. Default is the start date of the data.
- endDate : The end date of the rounding. As a date string or a nb_date object. Can be empty. Default is the end date of the data.
- variables : The variables to round. Can be empty. Default is to round all variables.

Output:

- obj : A nb_bd object with the rounded data.

Examples:

```
obj = nb_bd([2.6923;4.1234;9.9987],'', '2012Q1','Var',[0;0;1;0],0);  
obj = round(obj,0.25)
```

```
obj =  
  
'Time'      'Var'  
'2012Q1'    [2.7500]  
'2012Q2'    [     4]  
'2012Q3'    [    NaN]  
'2012Q4'    [     10]  
'Time'      'Var'
```

Written by Per Bjarne Bye

► **saveDataBase** ↑

```
saveDataBase(obj,varargin)
```

Description:

Save data of the object to (a) file(s)

If no optional input is given, i.e. obj.saveDataBase(). The data of the object is save down to xlsx file(s). Each dataset of the object is saved down to a excel spreadsheet with the name of the dataset (Taken from the 'dataNames' property)

Input:

- obj : An object of class nb_bd

Optional input (..., 'propertyName', propertyName, ...):

- 'saveName' : A string with the wanted name of the saved file.

- 'ext' : > 'xlsx' : Saves the object down to a excel spreadsheet. Default

> 'matold' : Saves the data down to a mat file. The data is transformed into a structure, with the variables as the fieldnames, and the data as its fields. If the data consist of more pages, each field will consist of the same number of pages. See the toStructure method with input old set to 1.

Must be combined with the optional input 'saveName'.

> 'mat' : Saves the data down to a mat file. The data is transformed into a structure, with the variables stored in the field 'variables', while the data of the variables will be saved as its fields with generic names ('Var1', 'Var2' etc). If the data consist of more pages, each field will consist of the same number of pages. See the toStructure method.

Must be combined with the optional input 'saveName'.

> 'mats' : The object is saved down as a struct using the nb_ts.struct function.

> 'txt' : Saves the data down to a txt file.

> 'fame' ('db') : Writes a FAME database with the data stored in the nb_ts object. It is not possible to write to a database stored in the data warehouse.

- 'append' : > 1 : Saves all the datasets (pages of the data) to one excel spreadsheet, but in seperate worksheets. (Where the names of the worksheets are given by the dataNames

property of the object.)

Works only when 'ext' input is set to 'xlsx'. (The default)

> 0 : The default saving method.

- 'dateformat' : Sets the date format of the saved output Only if 'ext' are set to 'xlsx', which is default.
The supported date formats are:

> 'default'
 > 'fame'
 > 'xls'
 > 'NBNorsk' ('NBNorwegian')
 > 'NBEnglish' ('NBEngelsk')

See the toDates methods of the classes nb_day, nb_month, nb_quarter, nb_semiAnnual and nb_year for more information on the date formats

Output:

The nb_ts object saved to the wanted file format.

Examples:

Save the data to excel with the name 'test':
`saveDataBase(obj,'saveName','test');`

Save the data to excel with another date format:
`saveDataBase(obj,'saveName','test','dateformat','xls');`

Save the data to excel spreadsheet with the datasets as different worksheets:
`saveDataBase(obj,'saveName','test','append',1);`

Save the data to a .mat with the name 'test':
`obj.sav DataBase('ext','mat','saveName','test')`

See also:

Written by Kenneth S. Paulsen

► **sec ↑**

`obj = sec(obj)`

Description:

Secant of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = sec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **secd** ↑

```
obj = secd(obj)
```

Description:

Secant of argument in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = secd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sech** ↑

```
obj = sech(obj)
```

Description:

Hyperbolic secant.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **setInfinite2NaN** ↑

```
obj = setInfinite2NaN(obj)
```

Description:

Set all elements that are isfinite to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setMethodCalls** ↑

```
obj = setMethodCalls(obj,c)
```

Description:

Set all method calls of the object with a cell matrix. The object needs to be updatable.

Caution: To delete method calls use deleteMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.
- c : A cell matrix. See the output of getMethodCalls

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

See also:

[nb_bd.deleteMethodCalls](#), [nb_bd.getMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setValue ↑**

```
obj = setValue(obj,varname,value,startDateOfValues, ...
               endDateOfValues, pages)
```

Description:

Set some values of the dataset(s). (Only one variable at a time.)
You cannot use dates outside the objects dates (i.e. outside
obj.startDate:obj.endDate)

Input:

- obj : An object of class nb_bd
- varname : The variable name of the variable you want to set some values of. As a string
- value : The values you want to assign to the variable. Must be a numerical vector (with the same number of pages as given by pages or as the number of dataset the object consists of.) Cannot be outside the window of the data of the object.
- startDateOfValues : A date string with the start date of the data. If not given or given as a empty string it will assume that startDateOfValues to be the startDate of the object.

This input could also be an object which is of a subclass of the nb_date class.

- endDateOfValues : A date string with the end date of the data. If not given or given as a empty string it will assume that the endDateOfValues is the endDate of the object.

This input could also be an object which is

of a subclass of the nb_date class

- pages : At which pages you want to set the values of a variable. Must be a numerical index of the pages you want to set.
E.g. if you want to set the values of the 3 first datasets (pages of the data) of the object. And the number of datasets of the object is larger then 3. You can use; 1:3. If empty all pages must be set.

Output:

- obj : An nb_bd object where the data of the given variable has been set.

Examples:

```
obj = nb_bd(ones(2,1),'', '2012', {'Var1'}, [zeros(2,1);1;],0)
```

```
obj = obj.setValue('Var1',[1;2;3]);  
obj = obj.setValue('Var1',2,'2013','2013',1);  
obj = obj.setValue('Var1',[1;2;3],'2012','2014');
```

See also
addVariable

Written by Per Bjarne Bye

► **setZero2NaN** ↑

```
obj = setZero2NaN(obj)
```

Description:

Set all elements that are 0 to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth SÅ!terhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **sin** ↑

```
obj = sin(obj)
```

Description:

Sine of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = sin(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **sind** ↑

```
obj = sind(obj)
```

Description:

sind(obj) is the sine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sinh** ↑

```
obj = sinh(obj)
```

Description:

`sinh(obj)` is the hyperbolic sine of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = sinh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **skewness ↑**

```
obj = skewness(obj,flag,outputType,dimension)
```

Description:

Calculate the skewness of each timeseries. The result will be an object of class `nb_bd` where all the non-nan values of all the timeseries are being set to their skewness.

The output can also be set to be a double or a `nb_cs` object consisting of the skewness values of the data.

Input:

- `obj` : An object of class `nb_bd`
- `flag` : Same as for the function `skewness` created by MATLAB.
- `outputType` :
 - > '`nb_bd`' : The result will be an object of class `nb_bd` where all the non-nan values of all the timeseries are being set to their skewness.
 - > '`double`' : Get the skewness values as doubles, where each column of the double matches the variable location in the '`variables`' property. If the object consist of more pages the double will also consist of more pages.

```

> 'nb_cs' : Get the skewness values as nb_cs object.
    The skewness will when this option is used
    only be calculated over the number of
    observations. (I.e. dimension set to 1.)

- dimension : The dimension to calcualate the skewness over.

Caution: the <ignorenan> property of obj controls the behavior of
        how to handle NaNs. This is equal to the 'notHandleNaN'
        optional input of the std method of the nb_ts class.

```

Output:

- obj : See the input outputType for more one the output from this method
- dimension : The dimension to calcualate the skewness over.

Examples:

```

nb_tsObj = skewness(obj);
double    = skewness(obj,0,'double');
nb_csObj = skewness(obj,0,'nb_cs');

```

Written by Per Bjarne Bye

► **sort ↑**

```
obj = sort(obj,dim,mode,variable)
```

Description:

Sort the nb_bd object in the given dimension

Caution : Sorting does not reorder the dataNames, variables or dates!

Input:

- obj : An object of class nb_bd
- dim : The dimension to sort
- mode : 'descend' (default)
'ascend'
- variable : Give a string with the variable to sort. The rest of the variables will then be reordered accordingly.

If empty (default), all variables are sorted.

Caution: Only an option for dim == 1

Output:

- obj : An nb_bd object representing the sorted input

Examples:

```
obj = nb_bd([1,2;1 1],'test','2012',{'Var1','Var2'});  
obj = sort(obj,1,'ascend')
```

Written by Per Bjarne Bye

► **sortProperty** ↑

```
obj = sortProperty(obj,type)
```

Description:

Sort the variables/types/datasets of the object alphabetically.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **sqrt** ↑

```
obj = sqrt(obj)
```

Description:

sqrt(obj) is the square root of the elements of obj. Complex results are produced for non-positive elements.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sqrt(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **std ↑**

```
obj = std(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the std of each series. The result will be an object of class nb_bd where all the non-nan values of all the object are set to their std.

The output can also be set to be a double or a nb_cs object consisting of the skewness values of the data.

Input:

- obj : An object of class nb_cs

- flag : > 0 : normalises by N-1 (Default)
> 1 : normalises by N

Where N is the sample length.

- outputType :

> 'double' : Get the std values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.

> 'nb_cs' : Get the std values as nb_cs object.

- dimension : The dimension to calcualate the std over.

Caution: the <ignorenan> property of obj controls the behavior of how to handle NaNs. This is equal to the 'notHandleNaN' optional input of the std method of the nb_ts class.

Output:

- obj : See the input outputType for available options.

Examples:

```
double    = std(obj,0,'double');
nb_csObj = std(obj,0,'nb_cs');
```

Written by Per Bjarne Bye

► **stopSorting** ↑

```
obj = stopSorting(obj)
```

Description:

Stop sorting of variables.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where sorting is turned off.

Example:

```
obj = obj.addPrefix('NEMO.');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **struct** ↑

```
s = struct(obj)
```

Description:

Object to struct.

Input:

- obj : An nb_bd object.

Output:

- s : A structure representing an nb_bd object.

Written by Per Bjarne Bye

► **structure2Dataset** ↑

```
obj = structure2Dataset(obj,givenStruct,NameOfDataset)
```

Description:

When you give a struct to the constructor of this class all the fields of that struct will be added as a new dataset, but this method add all the fields of the input givenStruct as a variable in one dataset

If you only want to add a dataset from a structure in this way (no other datasets) initialize a empty object, and then use this method.

Caution : The structure must include a field 'startDate', which must be a string with the start date of the data to add

Inputs:

- obj : The object itself, could be empty.
- givenStruct : The structure which contains the data of the added variable. Where the fieldnames will be the variables name of the added dataset + plus one field 'startDate' with the start date of the dataset.
- nameOfDataset : Name of the added dataset. If not provided default name will be used, i.e Database<jj>
- startDate : The start date of the new dataset. Only needed if the structure <givenStruct> has no field 'startDate'.

Outputs:

- obj : An nb_bd object with the added dataset.

Examples:

```
s          = struct();
s.startDate = '2012';
s.Var1      = [2;2;2];
obj        = nb_bd();
obj        = obj.structure2Dataset(s)

data =
    'Time'    'var1'
    '2012'    [ 2]
    '2013'    [ 2]
    '2014'    [ 2]
```

Written by Per Bjarne Bye

► **sum** ↑

```
obj = sum(obj,dim)
```

Description:

Takes the sum of the object timeseries

Caution : All sums ignore nan values no matter what the <ignorenan> property is set to (if not all values are nan).

Input:

- obj : An object of class nb_bd
- dim : The dimension to sum over, returns:
 - > dim = 1: Either :
 - > An nb_bd object with all the elements of each variable set to their sum over the time horizon.
 - > An nb_cs with one type representing the sum over the time horizon). The type is named 'sum'.
 - > dim = 2: An nb_bd object with one variable representing the sum (Take the sum over the variables)
(Default)
 - > dim = 3: An nb_ts object with only on page, representing the sum over all pages.
- output : Either 'nb_bd' (default) or 'nb_cs'. This is only important when summing over the 1 dimension.

Output:

- obj : Either an nb_bd object or a nb_cs object representing the sum.

Examples:

```
D    = {[1,2;3,4],[5,6;7,8]};  
Z    = cat(3,D{:});  
obj = nb_bd(Z,'','2012',{'Var1','Var2'})  
obj =  
  
(:,:,1) =  
  
'Time'    'Var1'    'Var2'  
'2012'    [ 1]    [ 2]  
'2013'    [ 3]    [ 4]
```

```

(:,:,2) =
    'Time'      'Var1'      'Var2'
    '2012'      [ 5]       [ 6]
    '2013'      [ 7]       [ 8]

s1 = sum(obj,1,'nb_bd')

s1 =
(:,:,1) =
    'Time'      'Var1'      'Var2'
    '2012'      [ 4]       [ 6]
    '2013'      [ 4]       [ 6]

(:,:,2) =
    'Time'      'Var1'      'Var2'
    '2012'      [ 12]      [ 14]
    '2013'      [ 12]      [ 14]

s1_cs = sum(obj,1,'nb_cs')

s1_cs =
(:,:,1) =
    'Types'      'Var1'      'Var2'
    'sum'        [ 4]       [ 6]

(:,:,1) =
    'Types'      'Var1'      'Var2'
    'sum'        [ 12]      [ 14]

s2 = sum(obj,2)

s2 =
(:,:,1) =
    'Time'      'sum'
    '2012'      [ 3]
    '2013'      [ 7]

(:,:,2) =
    'Time'      'sum'
    '2012'      [ 11]
    '2013'      [ 15]

s2 = sum(obj,3)

s2 =
    'Time'      'Var1'      'var2'
    '2012'      [ 6]       [ 8]

```

'2013' [10] [12]

Written by Per Bjarne Bye

► **tail** ↑

`tail(obj,nRows,page)`

Description:

Display the last n rows of a nb_bd object.

Input:

- `obj` : An nb_bd object.
- `nRows` : An integer with the number of rows to display. Defaults to 6.
- `page` : An integer with what page to display. Defaults to 1.

See also:

[nb_bd](#), [window](#), [head](#)

Written by Per Bjarne Bye

► **tan** ↑

`obj = tan(obj)`

Description:

Take the tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- `obj` : An object of class nb_ts, nb_cs or nb_data

Output:

- `obj` : An object of class nb_ts, nb_cs or nb_data

Examples:

`obj = tan(obj);`

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **tand** ↑

```
obj = tand(obj)
```

Description:

tand(obj) is the tangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = tand(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **tanh** ↑

```
obj = tanh(obj)
```

Description:

tanh(obj) is the hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = tanh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **toStructure** ↑

```
S = toStructure(obj)
```

Description:

Transform the object to a structure. Data will be saved in its expanded form (i.e. filled with NaNs in place of missing values like nb_ts).

Input:

- obj : An object of class nb_bd

Output:

- S : A structure with fieldnames given by the object variables and variable data contained in the field.

Examples:

```
obj = nb_bd(ones(7,1),'',2012Q1,{'Var1'},[zeros(4,1);1;zeros(3,1)],0);
s = obj.toStructure()
s =
```

```
    Var1: [8x1 double]
    variables: {'Var1'}
    startDate: [1x1 nb_quarter]
    ignorenan: 1
    class: 'nb_bd'
    userData: ''
    localVariables: []
    sorted: 1
```

See also:

[nb_bd.struct](#)

Written by Per Bjarne Bye

► **tonb_ts** ↑

```
nb_ts_obj = tonb_ts(obj)
```

Description:

Transform from a nb_bd object to a nb_ts object

Input:

- obj : An object of class nb_bd

Output:

- nb_ts_obj : An object of class nb_ts

Examples:

nb_ts_obj = obj.tonb_ts();

Written by Per Bjarne Bye

► **uminus** ↑

obj = uminus(obj)

Description:

Unary minus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : A nb_ts, nb_cs or nb_data object where all the data are the unary minus of the input objects data

Examples:

obj = -obj;

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **unstruct** ↑

obj = nb_bd.unstruct(s)

Description:

Reverse of the struct method.

Input:

- s : See the s output of the struct method.

Output:

- obj : An nb_bd object.

Written by Per Bjarne Bye

► **update ↑**

obj = update(obj,warningOff,inGUI)

Description:

This method will try to update the data of the nb_ts object.

Caution : It is only possible to update an nb_dataSource object which has updateable links to a FAME database or a full directory (path) to an excel spreadsheet or .mat file or the SMART database.

Caution : If you want to create a link to a specific worksheet of a excel file you must provide the extension!

Caution : All method calls done on the object are preserved.
(There exist some exception; and, or etc.)

Input:

- obj : An object of class nb_dataSource which are updatable.
- warningOff : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'.

Output:

- obj : An object of class nb_dataSource with the data updated. If it is not possible a warning will be given.

Examples:

```
obj = nb_ts(['N:\Matlab\Utvikling\MATLAB_LIB\NEMO\'...
             'Documentation\Examples\example_ts_quarterly']);
obj = obj.update
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► uplus ↑

```
obj = uplus(obj)
```

Description:

Unary plus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where all the data are the unary plus of the input objects data

Examples:

```
obj = +obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► var ↑

```
obj = var(obj,outputType,dimension,varargin)
```

Description:

Calculate the var of object. The result will be an object of class nb_bd where all the non-nan values of all the object are being set to their variance.

The output can also be set to be a double or a nb_cs object consisting of the var values of the data.

Input:

- obj : An object of class nb_bd
- outputType :
 - > 'double' : Get the var values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.

```

> 'nb_cs' : Get the var values as nb_cs object.

- dimension : The dimension to calcualate the var over.

Caution: the <ignorenan> property of obj controls the behavior of
how to handle NaNs. This is equal to the 'notHandleNaN'
optional input of the std method of the nb_ts class.

```

Output:

- obj : See the input outputType for available options

Examples:

```

double    = var(obj,'double');
nb_csObj = var(obj,'nb_cs');

```

Written by Per Bjarne Bye

► **window ↑**

```
obj = window(obj,startDateWin,endDateWin,variablesWin,pages)
```

Description:

Narrow down window of the data of the nb_bd object

Input:

- obj : An object of class nb_bd
- startDateWin : The new wanted start date of the data of the object. Must be a string on the format; 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the start date of the data.
Can also be an object which is a subclass of the nb_date class.
- endDateWin : The new wanted end date of the data of the object. Must be a string on the format. 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the end date of the data.
Can also be an object which is a subclass of the nb_date class.
- variablesWin : A cellstr array of the variables you want to keep of the given object. If empty all the variables is kept.

- pages : A numerical index of the pages you want to keep.
E.g. if you want to keep the first 3 datasets
(pages of the data) of the object. And the
number of datasets of the object is larger than
3. You can use; 1:3. If empty all pages is kept.

I.e. `obj = obj.window('','',{},1:3)`

Output:

- obj : An nb_bd object where the datasets of the object is
narrowed down to the specified window.

Examples:

```
obj = nb_bd(ones(7,1),'','2012Q1',{'Var1'});  
obj = obj.window('2012Q2')
```

See also:

Written by Per Bjarne Bye

► **zeros** ↑

```
obj = nb_bd.zeros()  
obj = nb_bd.zeros(start,obs,vars,pages,sorted)
```

Description:

Create an nb_bd object with all data set to zeros.

Input:

- start : The start date of the created nb_bd object.
- obs : The number of observations of the created nb_bd object.
- vars : Either a cellstr with the variables of the nb_bd
object, or a scalar with the number of variables of the
nb_bd object.
- pages : Number of pages of the nb_bd object.
- sorted : true or false. Default is true.

Output:

- obj : An nb_bd object.

Examples:

```
obj = nb_bd.zeros()
obj = nb_bd.zeros('2012Q1',10,['Var1','Var2','Var3']);
obj = nb_bd.zeros('2012Q1',2,2,10);
```

See also:

[nb_bd](#), [nb_bd.nan](#), [nb_bd.ones](#)

Written by Per Bjarne Bye

■ **nb_cell**

Go to: [Properties](#) | [Methods](#)

A class for storing data from cell (May be linked to an excel spreadsheet).

Constructor:

```
obj = nb_cell(datasets,NameOfDatasets)
obj = nb_cell(datasets,NameOfDatasets)
```

Input:

- datasets:

Input can be one of the data types listed below:

- xls(x) : A name of the excel spreadsheet to import. (With or without extension.). As a string.

Caution : If you read a specific worksheet, and want the object to be updateable you must provide the extension.

- cell : As a cell matrix. Each page of the matrix will be added as separate datasets.

You can also give a cellstr array consisting of more excel file names. Each excel file will be added as a new dataset.

- NameOfDatasets :

Input will depend on the data type provided to the datasets input:

- xls(x) : A string with the wanted dataset name. Default is the excel file name. If the provided string is a sheet of the read spreadsheet that specific worksheet will be read.

- cell : A string with the wanted dataset name. Default is 'Dataset1'.

Caution: When you given cell matrices which has more pages then one. Each of the pages will be added as a dataset.

The name of this datasets will, if the input NameOfDatasets has the same size as the input datasets, get the name NameOfDatasets{jj}, where jj is the page number, or else get the name 'Database<jj>'.

- A cellstr array of excel spreadsheet:

If you give a cellstr array to the datasets input, this input must be a cell array of strings. If you give a cellstr array which doesn't have the same size as the cellstr array given to the datasets input, the datasets which is left gets the name 'Database<jj>', where <jj> stands for this added datasets number.

If you give an empty cell array, i.e. {} all the datasets get the names given by a cellstr with the excel file names.

Output:

- obj : An object of class nb_cell.

Examples:

- xls(x) :

One excel spreadsheet

```
obj = nb_cell('test1')
```

More excel spreadsheets

```
obj = nb_cell({'test1','test2',...})
```

same as

```
obj = nb_cell({'test1','test2',...},{'test1','test2',...})
```

- cell matrix:

One matrix

```
obj = nb_cell(cell1)
```

```
obj = nb_cell(cell1,'test1')
```

One matrix with more pages:

```
obj = nb_cell(cell1,{})
```

```
obj = nb_cell(cell1,{'name1','name2',...})
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- **cdata**
- **data**
- **dataNames**
- **localVariables**
- **numberOfDatasets**
- **numberOfVariables**
- **userData**
- **variables**

- **cdata** ↑

The data of the object as cell

- **data** ↑

The data of the object. As a double or logical.

Inherited from superclass NB_DATASOURCE

- **dataNames** ↑

The names of the different dataset. As a cellstr.

Inherited from superclass NB_DATASOURCE

- **localVariables** ↑

A nb_struct with the local variables of the nb_ts object.
I.e. a field with name 'test' can be reach with the string
input %#test. Only for dates and vintage inputs.

Inherited from superclass NB_DATASOURCE

- **numberOfDatasets** ↑

Number of datasets stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **numberOfVariables** ↑

Number of variables stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **userData** ↑

Add user data. Can be of any type.

Inherited from superclass NB_DATASOURCE

- **variables** ↑

Variables of the object. As a cellstr.

Inherited from superclass NB_DATASOURCE

► **abs ↑**

```
obj = abs(obj)
```

Description:

Take the absolute value of each data elements of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = abs(in);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acos** ↑

obj = acos(obj)

Description:

Take acos of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acos(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acosd** ↑

obj = acosd(obj)

Description:

acosd(obj) is the inverse cosine, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acosd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acosh** ↑

obj = acosh(obj)

Description:

acosh(obj) is the inverse hyperbolic cosine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acosh(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acot** ↑

obj = acot(obj)

Description:

Take acotangent of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = acot(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acotd** ↑

```
obj = acotd(obj)
```

Description:

acotd(obj) is the inverse cotangent, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acotd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acoth** ↑

```
obj = acoth(obj)
```

Description:

acoth(obj) is the inverse hyperbolic cotangent of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acoth(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acsc** ↑

obj = acsc(obj)

Description:

Take inverse csc of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acsc(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acscl** ↑

obj = acscl(obj)

Description:

acscl(obj) is the inverse cosecant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acscd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acsch** ↑

```
obj = acsch(obj)
```

Description:

acsch(obj) is the inverse hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acsch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **addColumn** ↑

```
obj = addColumn(obj,location,elements)
```

Description:

Add a coulmn at a given location.

Input:

- obj : A nb_cell object.

- location : The location to add a column. It will be added after this column. If empty a empty row will be added last in the nb_cell object.

- elements : A cell with size size(obj.cdata,1) x 1 x size(obj.cdata,3). If empty, a empty column will be added.

Output:

- obj : A nb_cell object with a added column.

See also:

[addRow](#)

Written by Kenneth Sæterhagen Paulsen

► **addDataset** ↑

```
obj = addDataset(obj,dataset,NameOfDataset)
```

Description:

Makes it possible to add one dataset to a existing nb_cell object

Caution : If more than one dataset is added to an object the link to the data source is broken!

Input:

- obj : An object of class nb_cell
- dataset : Either a string with the name of excel spreadsheet or a cell matrix.
- NameOfDataset : Must be a string with the dataset name. If not given (or given as '') the default name Database<jj> is given. Where jj is the number of added datasets of the object, including dataset you add with this method.

Output:

- obj : The object itself with the added dataset.

Examples:

```
obj = nb_cell;
obj = obj.addDataset([2,2],'test',{'First'},{'Var1','Var2'});
```

Written by Kenneth S. Paulsen

► **addDatasets** ↑

```
obj = addDatasets(datasets,NameOfDatasets)
```

Makes it possible to add more datasets to a existing nb_cell object

Input:

Same input as of the constructor but only cell arrays are supported for the inputs 'datasets' and 'NameOfDatasets'. 'NameOfDatasets' could be given as a empty cell; {};

Output:

- obj : An object of class nb_cell, now including the new datasets provided

Examples:

```
obj = addDatasets({'excel1','excel2'},{},{'First'})
```

Written by Kenneth S. Paulsen

► **addPageCopies** ↑

Description:

Add copies of the data of an object of class nb_cell and append it as new datasets of the object. Only possible if an object has only one page.

Input:

- obj : An object of class nb_cell
- num : Number of copies to be appended

Output:

- obj : An object of class nb_cell with the added copies of the first dataset in the object.

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = addPageCopies(obj,2);
```

Written by Kenneth S. Paulsen

► **addPages** ↑

```
obj = addPages(obj,DB)
```

Description:

Add all pages from a different nb_cell object with the current one

Caution : This method will break the link to the data source of updateable objects!

Input:

- obj : An object of class nb_cell
- DB : An object of class nb_cell
- varargin : Optional number of objects of class nb_cell

Output:

- obj : An object of class nb_cell with all the datasets from the objects obj and varargin.

Be aware: Objects will be expanded with nans to match sizes.

Examples:

```
obj = addPages(obj,DB);
```

Written by Kenneth S. Paulsen

► **addPostfix ↑**

```
obj = addPostfix(obj,postfix)
```

Description:

Add a postfix to all elements of the data of the nb_cell object.

Input:

- obj : An object of class nb_cell
- postfix : The prefix to add to all string elements of the objects cell data.

Output:

- obj : An object of class nb_cell with the postfix added.

Examples:

```
obj = obj.addPostfix('_NEW');
```

Written by Kenneth S. Paulsen

► **addPrefix** ↑

```
obj = addPrefix(obj,prefix)
```

Description:

Add a prefix to all elements of the data of the nb_cell object.

Input:

- obj : An object of class nb_cell
- prefix : The prefix to add to all string elements of the objects cell data.

Output:

- obj : An object of class nb_cell with the prefix added.

Examples:

```
obj = obj.addPrefix('_NEW');
```

Written by Kenneth S. Paulsen

► **addRow** ↑

```
obj = addRow(obj,location,elements)
```

Description:

Add a row at a given location.

Input:

- obj : A nb_cell object.
- location : The location to add a row. It will be added after this row.
If empty a empty row will be added last in the nb_cell object.
- elements : A cell with size 1 x size(obj.cdata,2) x size(obj.cdata,3).
If empty, a empty row will be added.

Output:

- obj : A nb_cell object with a added row.

See also:

[addColumn](#)

Written by Kenneth Sætherhagen Paulsen

► **and** ↑

a = and(a,b)

Description:

The and operator (&).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the and operator has evaluated all the data elements of the object.
The data will be a logical matrix

Examples:

a = a & b;

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **appendFromAnotherPage** ↑

obj = appendFromAnotherPage(obj,page)

Description:

Append data from another page where the rest has missing data.

Input:

- obj : A nObs1 x nVar x nPages nb_dataSource object.
- page : The page to append data from.

Output:

- obj : A nObs x nVar x nPages nb_dataSource object.

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_DATASOURCE

► asCell ↑

```
cellMatrix = asCell(obj,page)
```

Description:

Return the nb_cell objects data as a cell matrix.

Input:

- obj : An object of class nb_cell

- page : Which pages should be transformed to a cell. Must be a double (vector) with the indices.

Output:

- cellMatrix : The objects data transformed to a MATLAB cell.

Written by Kenneth S. Paulsen

► asCellForMPRReport ↑

```
cellMatrix = asCellForMPRReport(obj,roundoff)
```

Description:

Return the nb_cell objects data as a cell matrix, on the MPR publishing format

Input:

- obj : An object of class nb_cell

- roundoff : 1 if you want to round off to 2 decimals, 0 otherwise. 1 is default.

Output:

- `cellMatrix` : The objects data transformed to a cell. Only the first page is returned. Look very much like an excel spreadsheet.

Written by Kenneth S. Paulsen

► **asec** ↑

`obj = asec(obj)`

Description:

Take inverse sec of the data stored in the `nb_ts`, `nb_cs` or `nb_data` object

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`.

Examples:

`obj = asec(obj);`

Written by Kenneth S. Paulsen

Inherited from superclass `NB_DATASOURCE`

► **asecd** ↑

`obj = asecd(obj)`

Description:

`asecd(obj)` is the inverse secant, expressed in degrees, of the elements of `obj`

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = asecd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE
```

► **asech** ↑

```
obj = asech(obj)
```

Description:

asech(obj) is the inverse hyperbolic secant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asech(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE
```

► **asin** ↑

```
obj = asin(obj)
```

Description:

Take inverse sin of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = asin(obj);  
  
Written by Kenneth S. Paulsen  
  
Inherited from superclass NB_DATASOURCE
```

► **asind** ↑

```
obj = asind(obj)
```

Description:

asind(obj) is the inverse sine, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asinh** ↑

```
obj = asinh(obj)
```

Description:

asinh(obj) is the inverse hyperbolic sine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asinh(in);  
  
Written by Andreas Haga Raavand  
  
Inherited from superclass NB_DATASOURCE
```

► assignNan ↑

```
obj = expand(obj,variables,value)
```

Description:

Assign all the nan observation to the value input.

Input:

- obj : An object of class nb_dataSource.
- variables : A char or a cellstr with the variables to assign nan values.
- value : A scalar number.

Output:

- obj : An nb_ts object with expanded timespan

Examples:

```
obj = nb_ts.rand('2012Q1',10,2,3);  
obj(1:2,1,:) = nan;  
obj = assignNan(obj,'Var1',0)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► atan ↑

```
obj = atan(obj)
```

Description:

Take the inverse tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = atan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atand** ↑

```
obj = atand(obj)
```

Description:

atand(obj) is the inverse tangent, expressed in degrees, of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = atand(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **atanh** ↑

```
obj = atanh(obj)
```

Description:

atanh(obj) is the inverse hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = atanh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► breakLink ↑

```
obj = breakLink(obj)
```

Description:

Break link to source

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATASOURCE

► callfun ↑

```
obj      = callfun(obj,'func',func)
obj      = callfun(obj,another,'func',func)
obj      = callfun(obj,varargin,'func',func)
varargout = callfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the data of the nb.DataSource object(s). The data of the object is normally of class double, but may also be of class logical or nb_distribution. Use nb.DataSource.getClassOfData to find the class of the data of the object.

Input:

- obj : An object of class nb.DataSource.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function @(x)x will be used.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class. nb_dataSource objects are converted to a matrix with elements of class double, logical or nb_distribution.

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb_dataSource object. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```
d      = nb_ts.rand('2012Q1',10,3);
d1     = callfun(d,'func',@sin); % Same as d1 = sin(d) !
d2     = callfun(d,d,'func','plus') % Same as d2 = d + d !
[s1,s2] = callfun(d,'func',@size) % Same as [s1,s2] = size(d)
```

See also:

[nb_cell.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callop ↑**

```
obj = callop(obj,another,func)
obj = callop(obj,another,func,type)
```

Description:

Call mathematical operator on the data of the object. In contrast to calling the operator itself on the object, this method does not try to match the same variables from the two inputs, but instead operate in the same way as mathematical operators do on double matrices (bsxfun). The time domain is matched though!

Caution: The following operators are supported:

- > @plus or 'plus'
- > @minus or 'minus'
- > @times or 'times'
- > @rdivide or 'rdivide'
- > @power or 'power'

Input:

- obj : An object of class nb_dataSource.
- another : An object of class nb_dataSource.
- func : One of the above listed functions.
- type : Either:
 - > 'keep' : Keep the variable names of the object with most variables. If they have the same number of variables, they are taken from the first object.
 - > 'rename' : The new variable names represent the operation that has been done to the separate series. So if you divide an object with one series named 'Var1' with another object with one series named 'Var2', the new name will be 'Var1./Var2'. (Default)

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb_dataSource method. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```
d1 = nb_ts(rand(10,1),'''2012Q1',{'Var1'});  
d2 = nb_ts(rand(10,1),'''2011Q1',{'Var2'});  
d3 = callop(d1,d2,@minus);  
  
d1 = nb_ts(rand(10,1),'''2012Q1',{'Var1'});  
d2 = nb_ts(rand(10,2),'''2011Q1',{'Var2','Var3'});  
d3 = callop(d1,d2,@minus);
```

See also:

[nb_cell.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callstat ↑**

```
obj = callstat(obj,func)  
obj = callstat(obj,func,varargin)
```

Description:

Call a in-built or user defined function on the data of the nb_dataSource object(s) that goes from the data of the object have more than one variable to only having one. E.g. when taking the mean over a set of variables.

Input:

- obj : An object of class nbDataSource.
- func : A function handle (or one line char) that maps a nObs x nVar x nPage double to nObs x 1 x nPage double, or that maps a nObs x nVar x nPage double to nObs x nVar x 1 double.

Optional input:

- 'name' : Set the name of the new variable, as a one line char. Default is to use the str2func on the provided function handle.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class.

Output:

- obj : An object of class nbDataSource with only one variable.

Examples:

```
d = nb_ts.rand('2012Q1',10,3);
d1 = callstat(d,@(x)mean(x,2),'name','mean')
```

See also:

[nb_cell.mean](#), [nb_cell.std](#), [nb_cell.var](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **ceil ↑**

```
obj = ceil(obj)
```

Description:

ceil(obj) rounds the elements of obj to the nearest integers towards infinity.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = ceil(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **conj** ↑

obj = conj(obj)

Description:

conj(obj) is the complex conjugate of the elements of obj.
For a complex element x of obj, conj(x) = REAL(x) - i*IMAG(x).

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = conj(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cos** ↑

obj = cos(obj)

Description:

Take cos of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = cos(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cosd** ↑

```
obj = cosd(obj)
```

Description:

cosd(obj) is the cosine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cosd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cosh** ↑

```
obj = csch(obj)
```

Description:

cosh(obj) is the hyperbolic cosine of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = csch(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cot** ↑

obj = cot(obj)

Description:

Take cotangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = cot(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cotd** ↑

obj = cotd(obj)

Description:

cotd(obj) is the cotangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = cotd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **coth** ↑

obj = coth(obj)

Description:

coth(obj) is the hyperbolic cotangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = coth(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **csc** ↑

obj = csc(obj)

Description:

Take csc of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = csc(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cscd** ↑

obj = cscd(obj)

Description:

cscd(obj) is the cosecant of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = cscd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **csch** ↑

obj = csch(obj)

Description:

csch(obj) is the hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **ctranspose** ↑

```
obj = ctranspose(obj)
```

Description:

Take the transpose ('') of an nb_cell object

Caution : The former types will be sorted when transposing the object.

Input:

- obj : An object of class nb_cell

Output:

- obj : An nb_cell object which represents the transposed input object

Written by Kenneth S. Paulsen

► **cumnansum** ↑

```
obj = cumnansum(obj)
```

Description:

Cumulativ sum of the series of the object. Ignoring nan values.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumnansum(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumprod** ↑

```
obj = cumprod(obj,dim)
```

Description:

Cumulativ product of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ product should be calculated. Default is the first dimension.

Output:

- obj : A nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative product of the old objects 'data' property.

Examples:

```
obj = cumprod(obj);
obj = cumprod(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumsum** ↑

```
obj = cumsum(obj,dim)
```

Description:

Cumulativ sum of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ sum should be calculated. Default is the first dimension.

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumsum(obj);
obj = cumsum(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **deleteMethodCalls** ↑

```
obj = deleteMethodCalls(obj,c)
```

Description:

Delete some method calls of the object. The object needs to be updatable.

Caution: To set method calls use setMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- sourceNr : The source index to delete the methods from
- methodNrs : A index with the methods to delete.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

See also:

[setMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **deleteVariables** ↑

```
obj = deleteVariables(obj,deletedVar)
```

Description:

Delete variables from the current nb_ts, nb_data or nb_cs object (letter size has something to say)

If some of the variables you specify in deletedVar does not exist in the obj, this will not have anything to say for the obj. (The variables cannot be deleted, because the variables do not exist.)

Input:

- obj : An object of class nb_ts, nb_data or nb_cs
- deletedVar : Must be a char or a cellstr

Delete all the variable names, given in the char array or cellstr array deletedVar, of current the object.

NB! If deletedVar is just one string and include a * as the last letter, this function will delete all the variable names, from the object, that start with the letters which is in front of the * in the string.

i.e. `obj = deleteVariables(obj,'DPQ*');`

Deletes all the variables in the obj which has variable names starting with 'DPQ'.

If deletedVar is just one string and include a * as the first letter, this function will delete all the variable names, from the object, that include the letters which follows in the string.

i.e. `obj = deleteVariables(obj, '*shift');`

Deletes all the variables in the obj which has variable names which include 'shift'.

Output:

- obj : A nb_ts, nb_data or nb_cs object with the variables specified in deletedVar deleted.

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = deleteVariables(obj, {'Var1','Var2'});  
obj = deleteVariables(obj, char('Var1','Var2'));  
obj = deleteVariables(obj, obj.variables);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **demean** ↑

```
obj = demean(data,dim)
```

Description:

- Demeans data along the dimension you choose.

Input:

- obj : A nb_dataSource object.
- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- obj : A nb_dataSource object.

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATASOURCE

► **deptcat** ↑

```
obj = deptcat(obj,varargin)
```

Description:

Depth concatenation (add pages of different objects) (No short notation)

Be aware: The sizes of the cell matrices will be expanded automatically to match eachother.

Input:

- obj : An object of class nb_cell
- varargin : Optional number of nb_cell objects

Output:

- obj : An object of class nb_cell where all the objects datasets are added into.

See also:

[addPages](#)

► **disp ↑**

`disp(obj)`

Description:

Display the object on the command line (Without semicolon)

Input:

- `obj` : An object of class nb_cell

Output:

The nb_cell object displayed on the command line if you let out the semicolon at the end of the code line

Written by Kenneth S. Paulsen

► **double ↑**

`dataOfObject = double(obj)`

Description:

Get the data of the object as a double matrix

Caution : If the data of the object is represents as an object of class nb_distribution the mean is returned.

Input:

- `obj` : An object of class nb_ts, nb_cs or nb_data

Output:

- `dataOfObject` : The data of the nb_ts, nb_cs or nb_data object

Examples:

`dataOfObject = double(obj)`

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **empty** ↑

```
obj = empty(obj)
```

Description:

Empty the nb_cs object

Input:

- obj : An object of class nb_cs

Output:

- obj : An empty nb_cs object

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = empty(obj);
```

Written by Kenneth S. Paulsen

► **eq** ↑

```
a = eq(a,b)
```

Description:

Test if the one object is equal (==) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a == b;  
obj = 2 == b;  
obj = a == 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **exp ↑**

```
obj = exp(obj)
```

Description:

Take exp of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = exp(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **expm1 ↑**

```
obj = expm1(obj)
```

Description:

`exp(obj)` is the exponential of the elements of `obj`, e to the `obj`.
`expm1(obj)` computes `exp(obj)-1`, compensating for the roundoff in
`exp(obj)`.

(For small real X, `expm1(X)` should be approximately X, whereas the
computed value of EXP(X)-1 can be zero or have high relative error.)

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are equal to e.^obj.data-1

Examples:

```
obj = expm1(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► extMethod ↑

```
obj = extMethod(obj,method,variables,postfix,varargin)
```

Description:

This method can call a nb_dataSource method on a selected variables, and merge the result with the old object by adding a postfix to the new variables.

This method is the same as calling:

```
obj1 = window(obj,'','variables');
method = str2func(method);
obj = method(obj,varargin{:});
obj1 = addPostfix(obj1,method);
obj = merge(obj,obj1);
```

But without replicating the links property unnecessary many times!

Caution : If the object is not updateable this will result in the same as the code above!

Input:

- obj : An object of class nb_ts, nb_data or nb_cs
- method : A str with the method to call. Must be a method of the nb_ts, nb_data or nb_cs class that does not change other dimensions then the second dimension!
- variables : A cellstr with the variables of the object to call the method on. Must be included in the object.
- postfix : A string with the postfix. If empty, the old variables will be replaced by the new ones.

Optional inputs:

These will be the inputs casted to the method except the object itself.

Extra for nb_ts and nb_data:

- '<start>' : The start date/obs of the function evaluation. Given as the second input to the window method call.
- '<end>' : The end date/obs of the function evaluation. Given as the third input to the window method call.

Output:

- obj : A nb_ts, nb_data or nb_cs object

Examples:

```
obj = nb_ts.rand(1,10,3);
obj = extMethod(obj,'lag',{'Var1'},'lag1',1)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **floor** ↑

```
obj = floor(obj)
```

Description:

floor(obj) rounds the data elements of obj to the nearest integers towards minus infinity

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = floor(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **ge** ↑

```
a = ge(a,b)
```

Description:

Test if the one object is greater than or equal to (\geq) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a >= b;  
obj = 2 >= b;  
obj = a >= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► get ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get the properties of the object

Input:

- obj : An object of class nb_ts
- propertyName : Name of the property you want to get:
 - 'cdata' : The data of the object as a cell.
 - 'data' : The data of the object as a double
 - 'dataNames' : Name of the object datasets, as cellstr array
 - 'numberOfDatasets' : Number of datasets (pages) of the object. Size of the third dimension
 - 'links' : A structure of the data source links.
 - 'updateable' : 1 if updateable, 0 otherwise.

Output:

```
propertyValue : The property value of the object for the wanted  
                  property
```

Examples:

```
dataAsDouble = get(obj,'data');  
variables    = get(obj,'variables')
```

Written by Kenneth S. Paulsen

► getClassOfData ↑

```
cl = getClassOfData(obj)
```

Description:

Get the class of the data stored by the object.

Input:

- obj : An object of class nb_dataSource.

Output:

- cl : Name of the class that the data of the object is stored as.

See also:

[nb_cell.isDistribution](#), [nb_cell.isDouble](#)
[nb_cell.isBoolean](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► getCode ↑

```
code = getCode(obj,preamble)  
code = getCode(obj,preamble,'inputName',inputValue,...)
```

Description:

Get the LaTeX code of a table representing the data of the object

If the object consists of more pages (datasets) more tables will be created.

Input:

- obj : An object of class nb_cell
- preamble : Give 0 if you don't want to include the preamble in the returned output. Default is to include the preamble, i.e. 1.

Optional input:

- 'caption' : Adds a caption to the table. Must be a string.
- 'colors' : Set it to 0 if the colored rows of the table should be turned off. Default is 1.
- 'firstRowColor' : A string with the color, e.g. 'blue','white','black','blue!20!white'. Default is 'nbblue'.

- 'fontSize' : Sets the font size of the table. Either:
'Huge', 'huge', 'LARGE', 'Large', 'large',
'normalsize' (default), 'small',
'footnotesize', 'scriptsize','tiny'.

Caution : This option is case sensitive.

- 'justification' : Sets the justification of the caption of the table. Must be a string.
Either 'justified','centering' (default),
'raggedright', 'RaggedRight', 'raggedleft'.

Caution : This option is case sensitive.

- language : Either 'english' (default) or 'norwegian'
('norsk').

- lookUpMatrix :

Sets how the given mnemonics (variable names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';  
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
lookUpMatrix = {  
  
'mnemonics1','englishDescription1','norwegianDescription1';  
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Be aware : Each of the given description can be multi-lined char, which will result in multi-line text of the table.

Caution : This will act on both variables and types.

- 'precision' : Sets the precision of the numbers in the table. Must be a string. Default is '%3.2f'. I.e. two decimals.
- 'rotation' : The rotation of the table in LaTeX. Either:
 - > 'sidewaystable' : A sideways table
 - > 'landscape' : Rotate the whole page
 - > '' : No rotation
- 'rowColor1' : Color of every second row of the table starting from the second row. Same options as was the case for the 'firstRowColor' option.
- 'rowColor2' : Color of every second row of the table starting from the third row. Same options as was the case for the 'firstRowColor' option.

Output:

- code : A char with the tex code of the table

Examples:

```
obj = nb_cell({'Test', 2, 'Test2', 3});
code = obj.getCode(1)
```

See also:

[nb_cell](#)

Written by Kenneth Sæterhagen Paulsen

► **getCreatedVariables ↑**

```
created = getCreatedVariables(obj)
```

Description:

Get a N x 2 table of the variables created using the createVariable method. The first column list the created variables, while the second column list the expressions.

Input:

- obj : An object that is a subclass of nb_dataSource.

Output:

- created : A N x 2 cell array. See description of this method for more.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getMethodCalls** ↑

```
[s,c] = getMethodCalls(obj)
```

Description:

Get all method calls as a cell matrix. The object needs to be updatable to get a list of methods called on the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.

- c : A cell matrix with a table of the method called on the object and its input. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getSource** ↑

```
sourceType = getSource(obj)
sourceType = getSource(obj,type)
```

Description:

Get source type.

Input:

- obj : An object of class nb_dataSource.

- type : Give 'program' to get the general source. Default is to give the specific type of source.

Output:

- sourceType : A one line char with the source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getSourceList** ↑

s = getSourceList(obj)

Description:

Get the source list of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **gt** ↑

a = gt(a,b)

Description:

Test if the one object is greater then (>) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.

- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a > b;  
obj = 2 > b;  
obj = a > 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **hasVariable** ↑

```
[ret,location] = hasVariable(obj,variable)
```

Description:

Test if an nb_cs object has a given variable

Input:

- obj : An object of class nb_cs
- variable : The variable name as a string. Can also be a cellstr with more variables.

Output:

- ret : 1 if found otherwise 0
- location : The location of the variable if found. Otherwise [].

Examples:

```
ret = obj.hasVariable('Var1')  
[ret,location] = hasVariable(obj,'Var1')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **head** ↑

```
head(obj,nRows,page)
```

Description:

Display the first n rows of a nb_cell object.

Input:

- obj : An nb_cell object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_cell](#), [window](#), [tail](#)

Written by Per Bjarne Bye

► **histogram** ↑

```
data          = histogram(obj)
[data,plotter] = histogram(obj,M)
```

Description:

Create a histogram of a object containing only one variable and one page!

Input:

- obj : A nb_dataSource object with size N x 1 x 1.
- M : The number of bins of the histogram.

Output:

- data : A nb_cs object with size M x 1 x 1.
- plotter : A nb_graph_cs object with the histogram plotted.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **horzcat** ↑

```
obj = horzcat(a,b,varargin)
```

Description:

Horizontal concatenation of nb_cell objects. ([a,b])

Input:

- a : An object of class nb_cell
- varargin : Optional number of nb_cell objects

Output:

- obj : An nb_cell object with all the variables from the different nb_cell object merge into one dataset

Examples:

```
obj = [a,b];
obj = [a,b,c];
```

See also:

[merge](#)

Written by Kenneth S. Paulsen

► **interpolate** ↑

```
obj = interpolate(obj,method)
```

Description:

Interpolate the data of the nb_data object. Will discard leading and trailing nan values.

Input:

- data : An nb_ts, nb_cs or nb_data object.
- method :
 - 'nearest' : Nearest neighbor interpolation
 - 'linear' : Linear interpolation. Default
 - 'spline' : Piecewise cubic spline interpolation (SPLINE)
 - 'pchip' : Shape-preserving piecewise cubic interpolation
 - 'cubic' : Same as 'pchip'
 - 'v5cubic' : The cubic interpolation from MATLAB 5, which does not extrapolate and uses 'spline' if X is not equally spaced.

Output:

- data : An nb_ts, nb_cs or nb_data object with the interpolated data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **intertwine** ↑

```
obj = intertwine(varargin)
```

Description:

Intertwine objects of class nb_cell objects with equal sizes.

Caution: This method will break the link to the data source.

Optional input:

- 'header' : Intertwine header, i.e. first row. true or false.
Default is false.
- varargin : Supply nb_cell objects (obj, obj2, ...)

Output:

- obj : An object of class nb_cell

Written by Kenneth Sæterhagen Paulsen

► **isBoolean** ↑

```
ret = isBoolean(obj)
```

Description:

Check if the data of the nb_dataSource object is of class logical (boolean, i.e. true or false).

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isCrossSectional** ↑

```
ret = isCrossSectional(obj)
```

Description:

Test if this object is a cross sectional data object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_cs, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isDistribution** ↑

```
ret = isDistribution(obj)
```

Description:

Check if the data of the nb_dataSource object is of class nb_distribution

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isDouble** ↑

```
ret = isDouble(obj)
```

Description:

Check if the data of the nb_dataSource object is of class double (numeric)

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isTimeseries** ↑

```
ret = isTimeseries(obj)
```

Description:

Test if a nb_dataSource object is a time series object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_ts, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isUpdateable** ↑

```
ret = isUpdateable(obj)
```

Description:

Test if this object is updateable.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : 1 if updateable, otherwise 0.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if a nb_ts, nb_cs or nb_data object is empty. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isfinite** ↑

```
obj = isfinite(obj)
```

Description:

Test if each element of a nb_ts, nb_cs or nb_data object is finite.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is finite, otherwise 0.

Examples:

```
obj = isfinite(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE
```

► **isnan** ↑

```
obj = isnan(obj)
```

Description:

Test if each element of an nb_ts, nb_cs or nb_data object is nan.
Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is nan, otherwise 0.

Examples:

```
obj = isnan(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE
```

► **isscalar** ↑

```
ret = isscalar(obj)
```

Description:

Test if a nb_ts, nb_cs or nb_data object is a scalar. Will always return 0, as an object of class nb_ts, nb_cs or nb_data is not a scalar.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : false

Examples:

```
0 = isscalar(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **keepPages ↑**

```
obj = keepPages(obj, pages)
```

Description:

Keep pages of the current nb_ts object

Input:

- obj : An object of class nb_ts
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty a empty nb_ts object is returned.

Can also be a cellstr with the names to keep, or a logical array with length equal to the number of pages (datasets).

Output:

- obj : An nb_ts object with the pages specified in the input are kept.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **le ↑**

```
a = le(a,b)
```

Description:

Test if the one object is less than or equal to (\leq) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a <= b;  
obj = 2 <= b;  
obj = a <= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **log ↑**

```
obj = log(obj)
```

Description:

Take log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on logs.

Examples:

```
obj = log(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **log10 ↑**

```
obj = log10(obj)
```

Description:

Take the common (base 10) log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on (base 10) logs.

Examples:

```
obj = log10(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► log1p ↑

```
obj = log1p(obj)
```

Description:

log1p(obj) computes $\text{LOG}(1+xi)$, where xi are the elements of obj. Complex results are produced if $xi < -1$.

For small real xi, log1p(xi) should be approximately xi, whereas the computed value of $\text{LOG}(1+xi)$ can be zero or have high relative error.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = log1p(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► log2 ↑

```
obj = log2(obj)
```

Description:

`log2(obj)` is the base 2 logarithm of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
obj = log2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **lt** ↑

```
a = lt(a,b)
```

Description:

Test if the one object is less than (`<`) the other object elemetswise and return a `nb_dataSource` object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- `a` : An object of class `nb_dataSource` or a scalar number.

- `b` : An object of class `nb_dataSource`, but must be of same subclass as `a`, or a scalar number.

Output:

- `a` : An `nb_dataSource` object where the data element are logical.

Examples:

```
obj = a < b;
obj = 2 < b;
obj = a < 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **map2Distribution** ↑

```
obj = map2Distribution(obj,dist)
obj = map2Distribution(obj,dist,varargin)
```

Description:

Map observation to the distributions given by dist.

The current distribution of the data is estimated using a kernel density estimator. The data must be strongly stationary. I.e. the unknown distribution from where the data has been drawn must not depend on time.

Input:

- obj : An object of class nb_dataSource.
- dist : An object of class nb_distribution with size 1 x size(obj,2).

Optional inputs:

- See the optional inputs of the nb_distribution.estimate function.

Output:

- obj : An object of class nb_dataSource.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **merge** ↑

```
obj = merge(obj,DB,'horzcat')
obj = merge(obj,DB,'vertcat')
```

Description:

Merge another nb_cell object with the current one

Input:

- obj : An object of class nb_cell
- DB : An object of class nb_cell
- type : Either 'horzcat' or 'vertcat'. Dimensions must agree!

Output:

- obj : An object of class nb_cell.

Written by Kenneth S. Paulsen

► **merge2Series ↑**

```
obj = merge2Series(obj,var1,var2,new,method,varargin)
```

Description:

Merge 2 series. The var2 series is appended to the var1 series from where it is ending.

Input:

- obj : An object of class nb_dataSource.
- var1 : A one line char with the name of the base series.
- var2 : A one line char with the name of the appended series.
- new : Name of the new variable. If given as empty there will not be created a new series, but instead the var1 variable will be set to the new merged series. Default is empty.
- method : Either 'level', 'diff', 'growth', 'leveldiff' or 'levelgrowth'. Default is 'level'. For the cases 'level', 'diff' or 'growth' it is assumed the both series are in levels. 'leveldiff' assumes the first series is in level and the second in nLags-difference. 'levelgrowth' assumes the first series is in level and the second in growth rates over nLags periods, i.e. $(x(t) - x(t-nLags))/x(t-nLags)$.

Optional input:

- 'nLags' : The number of lages used for the methods 'diff' and 'growth'. Default is 1.
- 'date' : The date from where to use the second variable. Either a date as string or a nb_date object. If empty the merge will take place where the first variable end + 1 period.

Output:

- obj : An object of class nb_dataSource.

Examples:

```
obj           = nb_ts.rand('2012Q1',10,2,3);
obj(end-1:end,1,:) = nan;

obj1 = merge2Series(obj,'Var1','Var2','Var3')
obj2 = merge2Series(obj,'Var1','Var2')
obj3 = merge2Series(obj,'Var1','Var2','','diff','nLags',1)
obj4 = merge2Series(obj,'Var1','Var2','','diff','nLags',4)
obj5 = merge2Series(obj,'Var1','Var2','','level','date','2014Q1')
```

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► [nan](#) ↑

```
obj = nb_cell.nan(rows,columns)
obj = nb_cell.nan(rows,columns,pages)
```

Description:

Create an nb_cell object with all elements set to nan.

Input:

- rows : Number of rows of the nb_cell object.
- vars : Number of columns of the nb_cell object.
- pages : Number of pages of the nb_cell object.

Output:

- obj : An nb_cell object.

See also:

[nb_cell](#)

Written by Kenneth Sæterhagen Paulsen

► [ne](#) ↑

```
a = ne(a,b)
```

Description:

Test if the one object is not equal to ($\sim=$) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a ~= b;  
obj = 2 ~= b;  
obj = a ~= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **not ↑**

```
a = not(a)
```

Description:

The not operator (~) .

Input:

- a : An object of class nb_dataSource.

Output:

- a : An object of class nb_dataSource. Where the not operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

```
a = ~a;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **objSize ↑**

```
varargout = objSize(obj,dim)
```

Description:

Return the size(s) of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim :
 - 1 : Number of observations
 - 2 : Number of variables
 - 3 : Number of datasets (pages)

Output:

- varargout : See the examples below

Examples:

```
dim = objSize(obj)
```

Where dim is 1 x 2 double where the first element is the number of observations/types and the second element is the number of variables

```
[dim1, dim2] = objSize(obj)
```

```
[dim1, dim2, dim3] = objSize(obj)
```

```
dim1 = objSize(obj,1)  
dim2 = objSize(obj,2)  
dim3 = objSize(obj,3)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **ones ↑**

```
obj = nb_cell.ones(rows,columns)  
obj = nb_cell.ones(rows,columns,pages)
```

Description:

Create an nb_cell object with all elements set to 1.

Input:

- rows : Number of rows of the nb_cell object.
- vars : Number of columns of the nb_cell object.
- pages : Number of pages of the nb_cell object.

Output:

- obj : An nb_cell object.

See also:

[nb_cell](#)

Written by Kenneth Sæterhagen Paulsen

► [or](#) ↑

a = or(a,b)

Description:

The and operator (|).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the or operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

a = a | b;

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **packing** ↑

```
obj = packing(obj,packages,varargin)
```

Description:

Package variables by applying the wanted function. Default is summin (sum).

Input:

- obj : An object of class nb_ts.
- packages : A 2 x N cell matrix with groups of variables and the names of the groups. If you have not listed a variable it will be grouped in a group called 'Rest' (as long as 'includeRest' is not set to false).

Must be given in the following format:

```
{'group_name_1','group_name_N';  
 name_1 ,...,name_N}
```

Where name_x must be a string with a name of the variable or a cellstr array with the variable names. E.g 'Var1' or {'Var1','Var2'}.

Optional inputs:

- 'includeRest' : Give false to not include the 'Rest' variable, which will represent all the variable that has not been packed.
- 'func' : Either a function_handle or a one line char with the name of the function to use. The first input to this function is a nObs x nVar double, the second is the dimension (which is always 2). Examples; 'sum', 'prod', @sum or @prod.

Output:

- obj : A object of class nb_ts.

Examples:

```
data      = nb_ts.rand('2012Q1',10,4);  
packages = {'group1','group2';  
            {'Var1','Var2'},{'Var3'}};  
  
dataP1 = packing(data,packages)  
dataP2 = packing(data,packages,'includeRest',false)  
dataP3 = packing(data,packages,'func',@prod)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **permute** ↑

```
obj = permute(obj,variables)
```

Description:

Switch the second and third dimension of the nb_ts, nb_cs or nb_data object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- variables : A cellstr with size 1 x numberOfDatasets. Default is to use dataNames property. I.e. when not provided or if empty.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **plot** ↑

```
plot(obj,varargin)
plotter = plot(obj,varargin)
```

Description:

Plot the data of the nb_dataSource object.

Caution: If the data of the object is of class nb_distribution this method will redirect to plotDist.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- plotType : A string with either:
 - > 'graph' (Default)

```

> 'graphSubPlots'

> 'graphInfoStruct'

The name of the graphing method of the class
nb_graph_ts, nb_graph_cs or nb_graph_data.

Caution: This is an optional input. If not given it is
assumed that the optional input pairs are starting from the
second input to this function.

- varargin : Same as the input to the method set() of the
  nb_graph_ts, nb_graph_cs or nb_graph_data class.

I.e. ..., 'inputName', inputValue, ...

Caution: If the data of the object is of class
  nb_distribution, see nb_ts.plotDist for the
optional input pairs supported.

```

Output:

Plotted output

Examples:

```

plot(obj)

plot(obj,'graphSubPlots')

plot(obj,'','startGraph','2008Q1','endGraph','2011Q2')

same as

plot(obj,'graph','startGraph','2008Q1','endGraph','2011Q2')

```

See also:

[nb_graph_ts](#), [nb_ts.plotDist](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **pow2 ↑**

obj = pow2(obj)

Description:

pow2(obj) raises the number 2 to the power of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = pow2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **rand** ↑

```
obj = nb_cell.rand(rows,columns)
obj = nb_cell.rand(rows,columns,pages)
obj = nb_cell.rand(rows,columns,pages,dist)
```

Description:

Create a random nb_cell object

Input:

- rows : Number of rows of the nb_cell object.
- vars : Number of columns of the nb_cell object.
- pages : Number of pages of the random nb_cell object.
- dist : A nb_distribution object to draw from.

Output:

- obj : An nb_cell object.

Examples:

```
obj = nb_cell.rand(2,2);
obj = nb_cell.rand(2,2,10,nb_distribution('type','normal'));
```

See also:

nb_cell

Written by Kenneth Sæterhagen Paulsen

► **real** ↑

```
obj = real(obj)
```

Description:

real(obj) returns the real part of the elements in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = real(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **reallog** ↑

```
obj = reallog(obj)
```

Description:

Take the real natural logarithm of the data stored in the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = reallog(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **realsqrt** ↑

```
obj = realsqrt(obj)
```

Description:

realsqrt(obj) is the square root of the elements of obj.
An error is produced if obj contains negative elements.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = realsqrt(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **rename** ↑

```
obj = rename(obj,type,oldName,newName)
```

Description:

Makes it possible to rename variables and datasets. For objects of class nb_cs types is also possible to rename.

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variable', but not when the input is 'dataset' or 'types'.

Input:

- obj : An object of class nb_dataSource
- type : Either:
 - 'variable' : To rename a variable(s)
 - 'dataset' : To rename a dataset(s) (The only input that is supported for nb_cell)
 - 'types' : To rename a type(s) (only nb_cs)
- oldName : Case 1;

> The old variable/dataset/type name, as a string

Case 2:

> The string which should be replaced in all the variable names of the database. And reorder things

afterwards. This input must end with a *.

```
- newName : Case 1;  
    > The new variable/dataset/type name, as a string  
  
Case 2;  
    > The string which should replace the old string part  
      given by the input 'oldName'.
```

Output:

- obj : An nb_dataSource object with the renamed variable(s), type(s) or dataset(s).

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = obj.rename('variable','Var1','Var3');  
obj = obj.rename('variable','Var*','N_Var');  
obj = rename(obj,'variable',{'Var1','Var2'},{'VAR1','VAR2'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **renameMore** ↑

```
obj = renameMore(obj,type,oldNames,newNames)
```

Description:

Makes it possible to rename more variables, datasets and types (only nb_cs).

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variables', but not when the input is 'datasets'.

Caution : This is the same as looping over nb_dataSource.rename, but more efficient.

Caution : * syntax is not supported as is the case for nb_dataSource.rename

Input:

```
- obj      : An object of class nb_dataSource.  
- type    : Either:  
            - 'variables' : To rename a variables  
            - 'datasets'   : To rename a datasets (The only  
                            input that is supported for nb_cell)  
            - 'types'      : To rename a type (Only nb_cs)
```

- oldNames : The old variable/dataset/type names, as a cellstr.
- newName : The new variable/dataset/type names, as a cellstr.

Output:

- obj : An nb_dataSource object where the variable(s)/dataname(s)/type(s) of the object given as input is/are renamed.

Examples:

```
obj = nb_cs([22,24;27,28],'Dataset1',{'Exp','Imp'},{'Nor','Swe'})
obj = renameMore(obj,'dataset',{'Dataset1'},{'tradeBal'});
obj = renameMore(obj,'variable',{'Nor','Swe'},{'Norway','Sweden'});
obj = renameMore(obj,'type',{'Exp','Imp'},{'Export','Import'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **reorder** ↑

```
obj = reorder(obj,newOrder,type)
```

Description:

Re-order the variables/types/datasets of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- newOrder : A cellstr with the new order of the variables/types/datasets.
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **round** ↑

```
obj = round(obj,value)
```

Description:

Round to closes value. I.e. if value is 0.25 it will round to the closes 0.25. E.g. 0.67 will be rounded to 0.75.

Input:

- obj : A nb_cell object
- value : The rounding value. As a double. Default is 1.
- pages : A numerical index of the pages you want to keep.

Output:

- obj : A nb_cell object with the rounded numbers (only numerical values).

Written by Kenneth Sæterhagen Paulsen

► saveDataBase ↑

```
saveDataBase(obj,varargin)
```

Description:

Save data of the nb_cell object

If no optional input is given the data of the object is save down to xlsx file(s). Each dataset of the object is saved down to a excel spreadsheet with the name of the dataset (Taken from the dataNames property of the object)

Input:

- obj : An object of class nb_cell
- Optional input (...'propertyName',PropertyValue,...):
 - varargin :
 - > 'saveName' : The data is saved to a excel worksheet with the same name as the input after 'saveName'. If consisting of more dataset, each page of the data property is saved with the same name as the input after 'saveName' pluss the page number.
 - > 'ext' :
 - > 'xlsx' : Default. Save data to excel spreadsheet(s)
 - > 'matold' : Save the data down to a mat file. The data is saved down as a structure, with the variables

as the fieldnames, and the data as its fields.
If the data consist of more pages, each field
will consist of the same number of pages.

The types of the object is also added to the
field 'types' of the saved structure. Which
makes it possible to load the .mat field up
again to nb_cs object.

See the toStructure method with input old set to 1.

Must be combined with the optional input
'saveName'.

> 'mat' : Save the data down to a mat file. The data is
saved down as a structure, with the variables stored
in the field 'variables', while the data of the
variables will be saved as its fields with generic
names ('Var1','Var2' etc). If the data consist
of more pages, each field will consist of the same
number of pages.

The types of the object is also added to the
field 'types' of the saved structure. Which
makes it possible to load the .mat field up
again to nb_cs object.

See the toStructure method with input old set to 1.

Must be combined with the optional input
'saveName'.

> 'mats' : The object is saved down as a struct using
the nb_cell.struct function.

> 'txt' : Save the data to .txt file.

> 'append' :

> 1 : Saves all the datasets (pages of the data) to one
excel spreadsheet, but in seperate worksheets.
(With the names of the dataset, given by dataNames
property of the object.)

Works only when 'ext' input is set as 'xlsx'. (The
default)

Caution : If saved in this way, it is not possible
to load it up again to a nb_cs object

> 0 : The default saving method.

> 'sheets' : A cellstr with the sheet names to save the datasets/pages
of the object down to. Must match the dataNames property.
This option has precedence over 'append'.

Output:

Saved output in the wanted format.

See also:

[asCell](#), [toStructure](#), [nb_readMat](#), [nb_readExcel](#)

Written by Kenneth S. Paulsen

► **sec ↑**

`obj = sec(obj)`

Description:

Secant of argument in radians.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

`obj = sec(obj);`

Written by Kenneth S. Paulsen

Inherited from superclass `NB_DATASOURCE`

► **secd ↑**

`obj = secd(obj)`

Description:

Secant of argument in degrees.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = secd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sech** ↑

```
obj = sech(obj)
```

Description:

Hyperbolic secant.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **setInfinite2NaN** ↑

```
obj = setInfinite2NaN(obj)
```

Description:

Set all elements that are isfinite to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setMethodCalls** ↑

```
obj = setMethodCalls(obj,c)
```

Description:

Set all method calls of the object with a cell matrix. The object needs to be updatable.

Caution: To delete method calls use deleteMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.
- c : A cell matrix. See the output of getMethodCalls

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

See also:

[nb_cell.deleteMethodCalls](#), [nb_cell.getMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setValue** ↑

```
obj = setValue(obj,columns,Value,rows,pages)
```

Description:

Set some values of the dataset(s). (Only one column.)

Input:

- obj : An object of class nb_cs
- column : The index of the column you want to set some values of. As an integer.
- Value : The values you want to assign to the column. Must be a cell vector (with the same number of pages as given by pages or as the number of dataset the object consists of.) Must have the same length as the input

given by rows. (If this is not provided this input must the same number of rows as the cdata property)

- rows : A vector of row indexes to set.
- pages : At which pages you want to set the values of a column. Must be a numerical index of the pages you want to set.
E.g. if you want to set the values of the 3 first datasets (pages of the data) of the object. And the number of datasets of the object is larger then 3. You can use; 1:3. If empty all pages must be set.

Output:

- obj : An nb_cell object with the added variable

Written by Kenneth S. Paulsen

► **setZero2NaN** ↑

obj = setZero2NaN(obj)

Description:

Set all elements that are 0 to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **sin** ↑

obj = sin(obj)

Description:

Sine of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = sin(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **sind** ↑

```
obj = sind(obj)
```

Description:

sind(obj) is the sine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sinh** ↑

```
obj = sinh(obj)
```

Description:

sinh(obj) is the hyperbolic sine of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = sinh(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sortProperty** ↑

obj = sortProperty(obj,type)

Description:

Sort the variables/types/datasets of the object alphabetically.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **sqrt** ↑

obj = sqrt(obj)

Description:

sqrt(obj) is the square root of the elements of obj. Complex results are produced for non-positive elements.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sqrt(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **stopSorting** ↑

```
obj = stopSorting(obj)
```

Description:

Stop sorting of variables.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where sorting is turned off.

Example:

```
obj = obj.addPrefix('NEMO.');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **struct** ↑

```
s = struct(obj)
```

Description:

Object to struct.

Input:

- obj : An nb_cell object.

Output:

- s : A structure representing an nb_cell object.

Written by Kenneth SÃ¶therhagen Paulsen

► **subsasgn** ↑

```
varargout = subsasgn(obj,s,b)
```

Description:

Makes it possible to do subscripted assignment of the data of a nb_cell object

Input:

- obj : An object of class nb_cell

- s : The same input as when you do subscripted assignment one a cell matrix

- b : The assign data at the given index s.

Output:

- obj : An nb_cell object where the assign data property is set.

Examples:

```
obj(1:2) = {2;3};
```

same as

```
obj(1:2,1,1) = {2;3};
```

same as

```
obj.data(1:2,1,1) = {2;3};
```

```
obj(1:2,2,3) = {2;'Test'};
```

Written by Kenneth S. Paulsen

► **subsref** ↑

Description:

Makes it possible to do subscripted reference of the data of a nb_cell object. See the examples for more

Uses the method window, just using indexing instead

Input:

- obj : An object of class nb_cell
- s : A structure on have to index the object

Output:

- obj : An nb_cs object indexed as wanted.

Examples:

obj = obj(1,2:4,1)

same as

obj = obj(1,2:4)

Written by Kenneth S. Paulsen

► **tail ↑**

tail(obj,nRows,page)

Description:

Display the last n rows of a nb_cell object.

Input:

- obj : An nb_cell object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_cell](#), [window](#), [tail](#)

Written by Per Bjarne Bye

► **tan ↑**

```
obj = tan(obj)
```

Description:

Take the tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = tan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **tand** ↑

```
obj = tand(obj)
```

Description:

tand(obj) is the tangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = tand(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **tanh** ↑

```
obj = tanh(obj)
```

Description:

tanh(obj) is the hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = tanh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **toMfile** ↑

```
string = toMfile(obj)
toMfile(obj,filename)
string = toMfile(obj,filename,varName)
```

Description:

Write a .m file to generate the current object.

Input:

- obj : An nb_cell object.

- filename : The filename to write the code to. If empty no file will be written.

- varName : Name of decleared variable by this code. Default is data.

Output:

- string : A cellstr with the .m code to generate the current object.

Written by Kenneth Sæterhagen Paulsen

► **toStructure** ↑

```
retStruct = toStructure(obj)
```

Description:

Transform the obj to a structure.

Input:

- obj : An object of class nb_cell
- old : Indicate if old mat file format is wanted. Default is 0 (false).

Output:

- retStruct : A structure.

See also:

[nb_cs.struct](#)

Written by Kenneth S. Paulsen

► **transpose ↑**

```
obj = transpose(obj)
```

Description:

Take the transpose (.)' of an nb_cell object.

Input:

- obj : An object of class nb_cell

Output:

- obj : An nb_cell object which represents the transposed input object

Written by Kenneth S. Paulsen

► **uminus ↑**

```
obj = uminus(obj)
```

Description:

Unary minus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : A nb_ts, nb_cs or nb_data object where all the data are the unary minus of the input objects data

Examples:

```
obj = -obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **unstruct** ↑

```
obj = nb_cell.unstruct(s)
```

Description:

Reverse of the struct method.

Input:

- s : See the s output of the struct method.

Output:

- obj : An nb_cell object.

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj,warningOff,inGUI)
```

Description:

This method will try to update the data of the nb_ts object.

Caution : It is only possible to update an nb_dataSource object which has updateable links to a FAME database or a full directory (path) to an excel spreadsheet or .mat file or

the SMART database.

Caution : If you want to create a link to a specific worksheet of a excel file you must provide the extension!

Caution : All method calls done on the object are preserved.
(There exist some exception; and, or etc.)

Input:

- obj : An object of class nb_dataSource which are updatable.
- warningOff : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'.

Output:

- obj : An object of class nb_dataSource with the data updated. If it is not possible a warning will be given.

Examples:

```
obj = nb_ts(['N:\Matlab\Utvikling\MATLAB_LIB\NEMO\'...  
            'Documentation\Examples\example_ts_quarterly']);  
obj = obj.update
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **uplus ↑**

```
obj = uplus(obj)
```

Description:

Unary plus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where all the data are the unary plus of the input objects data

Examples:

```
obj = +obj;

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE
```

► **vertcat** ↑

```
obj = vertcat(a,b,varargin)
```

Description:

Vertical concatenation ([a;b])

Input:

- a : An object of class nb_cell
- b : An object of class nb_cell
- varargin : Optional numbers of objects of class nb_cell

Output:

- a : An nb_cell object where the data from the different objects are appended to each other.

Written by Kenneth S. Paulsen

► **window** ↑

```
obj = window(obj,rows,columns,pages)
```

Description:

Narrow down the dataset(s) of the nb_cell object

Input:

- obj : An object of class nb_cell
- rows : The row indexes. As a 1 x N integer.
- columns : The columns indexes. As a 1 x N integer.
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty all pages is kept.

```
I.e. obj = obj.window('','','',1:3)
```

Or it can be the name of the dataset you want to keep. Then the input must be a string.

```
I.e. obj = obj.window('','','','Database1')
```

Or it can be a cell array of the datasets names to keep.

```
I.e obj = obj.window('','','',{ 'Database1',...  
'DataBase2'})
```

Output:

- obj : An nb_cell object where the datasets of the input object are narrowed down to the given window.

Written by Kenneth S. Paulsen

► **writeTex ↑**

```
writeTex(obj,filename)  
writeTex(obj,filename,'inputName', inputValue,...)
```

Description:

Writes the object data to a LaTeX table saved to a .tex file.

If the object consists of more pages (datasets) more tables will be created.

Input:

- obj : An object of class nb_cell
- filename : The name of the saved .tex file. With or without the extension.

Optional input:

- 'caption' : Adds a caption to the table. Must be a string.
- 'colors' : Set it to 0 if the colored rows of the table should be turned off. Default is 1.
- 'firstRowColor' : A string with the color, e.g. 'blue','white','black','blue!20!white'. Default is 'nbblue'.
- 'fontSize' : Sets the font size of the table. Either:

```
'Huge', 'huge', 'LARGE', 'Large', 'large',
'normalsize' (default), 'small',
'footnotesize', 'scriptsize','tiny'.
```

Caution : This option is case sensitive.

- 'justification' : Sets the justification of the caption of the table. Must be a string.

```
Either 'justified','centering' (default),
'raggedright', 'RaggedRight', 'raggedleft'.
```

Caution : This option is case sensitive.

- language : Either 'english' (default) or 'norwegian' ('norsk').

- lookUpMatrix :

Sets how the given mnemonics (variable names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
lookUpMatrix = {

'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Be aware : Each of the given description can be multi-lined char, which will result in multi-line text of the table.

Caution : This will act on both variables and types.

- 'precision' : Sets the precision of the numbers in the table. Must be a string. Default is '%3.2f'. I.e. two decimals.

- 'rotation' : The rotation of the table in LaTeX. Either:

```
> 'sidewaystable' : A sideways table
> 'landscape'      : Rotate the whole page
> ''               : No rotation
```

- 'rowColor1' : Color of every second row of the table starting from the second row. Same options as was the case for the 'firstRowColor' option.

- 'rowColor2' : Color of every second row of the table starting from the third row. Same options as was the case for the 'firstRowColor' option.

Output:

A saved .tex file with the LaTeX table

Examples:

```
obj = nb_cell({'Test',2; 'Test2', 3});  
obj.writeTex('test')
```

[nb_cell](#)

Written by Kenneth Sæterhagen Paulsen

► **zeros** ↑

```
obj = nb_cell.zeros(rows,columns)  
obj = nb_cell.zeros(rows,columns,pages)
```

Description:

Create an nb_cell object with all elements set to 0.

Input:

- rows : Number of rows of the nb_cell object.
- vars : Number of columns of the nb_cell object.
- pages : Number of pages of the nb_cell object.

Output:

- obj : An nb_cell object.

See also:

[nb_cell](#)

Written by Kenneth Sæterhagen Paulsen

■ **nb_cs**

Go to: [Properties](#) | [Methods](#)

A class for storing cross-sectional data (Case data)

Constructor:

```
obj = nb_cs(datasets,NameOfDatasets,types,variables)
obj = nb_cs(datasets,NameOfDatasets,types,variables,sorted)
```

Input:

- datasets:

Input can be one of the data types listed below:

- xls(x) : A name of the excel spreadsheet to import. (With or without extension.). As a string.

Caution : If you read a specific worksheet, and want the object to be updateable you must provide the extension.

- mat : Name(s) of the .mat file(s) to import. (With or without extension.). As a string. This .mat file must store a struct where each field stores the data of a variable. The data stored at each field must be doubles with same size. The only exception is that you must include a field called 'types', storing a cellstr with the types of the data. (This cellstr must have the same size as the provided data (size of the first dimension)).

Caution : The data stored as seperate field could have more pages (size of the third dimension could be lager then 1). Again All the data of the variables must be of the same size.

- double : As a double matrix. Each page of the matrix will be added as separate datasets.

- struct : As a structure of double matrices. Each field is added as a separate datasets.

You can also give a cell array consisting of one or a combination of the data types mentioned above. Each cell will be added as a new dataset.

Extra: Use the method structure2nb_cs function to add all the fields of the structure as variables in an nb_cs object. (If each field has more page then 1, then each page will be a new datasets). See the method structure2nb_cs for more on the supported format of the structure you can provide as input.

- NameOfDatasets :

Input will depend on the data type provided to the datasets input:

- xls(x) : A string with the wanted dataset name. Default is the excel file name. If the provided string is a sheet of the read spreadsheet that specific worksheet will be read.

- mat : A string with the wanted dataset name. Default is the .mat file name.

- double : A string with the wanted dataset name. Default is 'Dataset1'.

Caution: When you given double matrices which has more pages then one, either directly or through a struct. Each of the pages will be added as a dataset. The name of this datasets will, if the input NameOfDatasets has the same size as the input datasets, get the name NameOfDatasets{jj}<jj>, where jj is the page number, or else get the name 'Database<jj>'.

- struct : This input has nothing to say. The dataset names will be given by the fieldnames.

- A cell array of the listed types above:

If you give a cell array to the datasets input, this input must be a cell array of strings. If you give a cell array which doesn't have the same size as the cell array given to the datasets input, the datasets which is left gets the name 'Database<jj>', where <jj> stands for this added datasets number.

If you give an empty cell array, i.e. {} all the datasets get the names; 'Database<jj>', where <jj> stands for the added datasets number. Except when the datasets input are given by a cellstr with the excel file names or .mat file names, then the default dataset names will be set to the same cellstr. Or if some elements of the cell is a struct, then the datasets provided through the struct will get their fieldnames as the dataset names.

- types :

A cell array of the type names of the data, as strings. Only needed when you give a double or a struct of doubles as the datasets input. The number of types must be the same as the size of the data (1- dimension).

- variables :

A cell array of the variable names of the data, as strings. Only needed when you give a double or a struct of doubles as the datasets input. The number of variables must be the same as the size of the data (2- dimension).

- sorted : true or false. Default is true.

Output:

- obj : An object of class nb_cs.

Examples:

```

- xls(x):
    One excel spreadsheet
    obj = nb_cs('test1')

    More excel spreadsheets
    obj = nb_cs({'test1','test2',...})
    same as
    obj = nb_cs({'test1','test2',...},{'test1','test2',...})

- mat:
    One .mat file:
    obj = nb_cs('test1')

    More .mat files:
    obj = nb_cs({'test1','test2',...})
    same as
    obj = nb_cs({'test1','test2',...},{'test1','test2',...})

-struct:
    One struct (Consisting of double matrices):
    obj = nb_cs(struct1,{},{'Type1','Type2',...},...
                {'Var1','Var2',...})

    More structs:
    obj = nb_cs({struct1,struct2,...},{},{'Type1','Type2',...},...
                {'Var1','Var2',...})

- double matrix:
    One matrix
    obj = nb_cs(double1,'',{'Type1','Type2',...},...
                {'Var1','Var2',...})

    obj = nb_cs(double1,'test1',{'Type1','Type2',...},...
                {'Var1','Var2',...})

    More matrices
    obj = nb_cs({double1,double2,...},{},...,
                {'Type1','Type2',...},{'Var1','Var2',...})

    obj = nb_cs({double1,double2,...},{'name1','name2',...},...
                {'Type1','Type2',...},{'Var1','Var2',...})

```

One matrix with more pages:

```
obj = nb_cs(double1, {}, {'Type1','Type2','...'},...
             {'Var1','Var2','...'})

obj = nb_cs(double1, {'name1','name2','...'},...
             {'Type1','Type2','...'}, {'Var1','Var2','...'})
```

Properties:

- **data**
- **dataNames**
- **localVariables**
- **numberOfDatasets**
- **numberOfTypes**
- **numberOfVariables**
- **types**
- **userData**
- **variables**

- **data** [↑](#)

The data of the object. As a double or logical.

Inherited from superclass NB_DATASOURCE

- **dataNames** [↑](#)

The names of the different dataset. As a cellstr.

Inherited from superclass NB_DATASOURCE

- **localVariables** [↑](#)

A nb_struct with the local variables of the nb_ts object.
I.e. a field with name 'test' can be reach with the string
input %#test. Only for dates and vintage inputs.

Inherited from superclass NB_DATASOURCE

- **numberOfDatasets** [↑](#)

Number of datasets stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **numberOfTypes** [↑](#)

Number of types of the object. As a double.

- **numberOfVariables** [↑](#)

Number of variables stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **types** [↑](#)

Description/names of the data types. As a cellstr.

- **userData** ↑

Add user data. Can be of any type.

Inherited from superclass NB_DATASOURCE

- **variables** ↑

Variables of the object. As a cellstr.

Inherited from superclass NB_DATASOURCE

► **abs** ↑

```
obj = abs(obj)
```

Description:

Take the absolute value of each data elements of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = abs(in);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acos** ↑

```
obj = acos(obj)
```

Description:

Take acos of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acos(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acosd** ↑

obj = acosd(obj)

Description:

acosd(obj) is the inverse cosine, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acosd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acosh** ↑

obj = acosh(obj)

Description:

acosh(obj) is the inverse hyperbolic cosine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acosh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acot** ↑

```
obj = acot(obj)
```

Description:

Take acotangent of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = acot(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acotd** ↑

```
obj = acotd(obj)
```

Description:

acotd(obj) is the inverse cotangent, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acotd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acoth** ↑

obj = acoth(obj)

Description:

acoth(obj) is the inverse hyperbolic cotangent of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acoth(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acsc** ↑

obj = acsc(obj)

Description:

Take inverse csc of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acsc(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acscd** ↑

obj = acscd(obj)

Description:

acscd(obj) is the inverse cosecant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acscd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acsch** ↑

obj = acsch(obj)

Description:

acsch(obj) is the inverse hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acsch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **addDataset ↑**

```
obj = addDataset(obj,dataset,NameOfDataset,types,variables)
```

Description:

Makes it possible to add one dataset to a existing nb_cs object

Caution : If more than one dataset is added to an object the link to the data source is broken!

Input:

- obj : An object of class nb_cs

- dataset : Either a string with the name of excel spreadsheet or a .mat file (no extension needed), or a numerical matrix.

- NameOfDataset : Must be a string with the dataset name. If not given (or given as '') the default name Database<jj> is given. Where jj is the number of added datasets of the object, including dataset you add with this method.

- types : A cell array of string with the names of the types you want to add. Only needed when numerical matrix of data is added to the object. Must have the same size as the data you add.

- variables : A cell array of string with the names of the variables you want to add. Only needed when numerical matrix of data is added to the object. Must have the same size as the data you add.

Output:

- obj : The object itself with the added dataset.

Examples:

```
obj = nb_cs;
obj = obj.addDataset([2,2],'test',{'First'},{'Var1','Var2'});
```

Written by Kenneth S. Paulsen

► **addDatasets** ↑

```
obj = addDatasets(datasets,NameOfDatasets,types,variables)
```

Makes it possible to add more datasets to a existing nb_cs object

Input:

Same input as of the constructor but only cell arrays are supported for the inputs 'datasets' and 'NameOfDatasets'. 'NameOfDatasets' could be given as a empty cell; {};

Output:

- obj : An object of class nb_cs, now including the new datasets provided

Examples:

```
obj = addDatasets({'excel1','excel2'},{},{'First'},...
{'Var1','Var2'})
```

Written by Kenneth S. Paulsen

► **addPageCopies** ↑

Description:

Add copies of the data of an object of class nb_cs and append it as new datasets of the object. Only possible if an object has only one page.

Input:

- obj : An object of class nb_cs
- num : Number of copies to be appended

Output:

- obj : An object of class nb_cs with the added copies of the first dataset in the object.

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = addPageCopies(obj,2);
```

Written by Kenneth S. Paulsen

► **addPages** ↑

```
obj = addPages(obj,DB)
```

Description:

Add all pages from a different nb_cs object with the current one

Caution : This method will break the link to the data source of updateable objects!

Input:

- obj : An object of class nb_cs
- DB : An object of class nb_cs
- varargin : Optional number of objects of class nb_cs

Output:

- obj : An object of class nb_cs with all the datasets from the objects obj and varargin.

Be aware: If the added datasets does not contain the same variables or types, the data of the nb_cs object with the tightest window will be expanded automatically to include all the same types and variables. (the added data will be set as nan)

Examples:

```
obj = addPages(obj,DB);
```

Written by Kenneth S. Paulsen

► **addPostfix** ↑

```
obj = addPostfix(obj,postfix)
obj = addPostfix(obj,postfix,vars)
```

Description:

Add a postfix to all the variables in the nb_ts, nb_cs or nb_data object, or a provided variable group.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- postfix : The postfix to add to all the variables of the object. Must be a string
- names : A cellstr of the variables/types to add the prefix to. Default is all variable of the object.
- type : Either:
 - 'variables' : To rename variables (default)
 - 'types' : To rename types

Output:

- obj : An object of class nb_ts, nb_cs, nb_bd or nb_data with the postfix added to the variables selected.

Examples:

```
obj = obj.addPostfix('_NEW');
```

Written by Kenneth S. Paulsen

► **addPrefix ↑**

```
obj = addPrefix(obj,prefix)
obj = addPrefix(obj,prefix,vars)
```

Description:

Add a prefix to all the variables in the nb_ts, nb_cs or nb_data object, or a provided variable group.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- prefix : The prefix to add to all the variables of the object. Must be a string
- vars : A cellstr of the variable to add the prefix to. Default is all variable of the object.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data with a prefix added to the selected variables

Example:

```
obj = obj.addPrefix('NEMO.');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► addType ↑

```
obj = addType(obj,type,addedData,vars)
```

Description:

Add a new type to the datasets (including all pages)

Input:

- obj : An object of class nb_cs
- type : The type to add. As a string. Cannot be the same as a existing type. Use setValue instead.
- addedData : The data of the added type. Must match the number of variables given. I.e. a double with size 1 x number of variables given in the cellstr variables.
- vars : A cellstr of the variables of the added type.

Output:

- obj : An nb_cs object with the added type

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = obj.addVariable('Second',[2,2],{'Var1','Var2'})
```

Written by Kenneth S. Paulsen

► addVariable ↑

```
obj = addVariable(obj,Types,Data,variable)
```

Description:

Add a new variable to the datasets (including all pages)

Input:

- obj : An object of class nb_cs
- Types : The types of the data of the added variable.
Must be a cellstr.
- Data : The data of the added variable. Must match the number of types given.
- Variable : A string with the added variable name. Cannot be the same as a existing variable. (Use setValue instead)

Output:

- obj : An nb_cs object with the added variable

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = obj.addVariable({'First'},2,'Var3')
```

Written by Kenneth S. Paulsen

► and ↑

```
a = and(a,b)
```

Description:

The and operator (&).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the and operator has evaluated all the data elements of the object.
The data will be a logical matrix

Examples:

```
a = a & b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **appendFromAnotherPage** ↑

```
obj = appendFromAnotherPage(obj,page)
```

Description:

Append data from another page where the rest has missing data.

Input:

- obj : A nObs1 x nVar x nPages nb_dataSource object.
- page : The page to append data from.

Output:

- obj : A nObs x nVar x nPages nb_dataSource object.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **asCell** ↑

```
cellMatrix = asCell(obj,page)
```

Description:

Return the nb_cs objects data as a cell matrix.

Input:

- obj : An object of class nb_cs
- page : Which pages should be transformed to a cell. Must be a double (vector) with the indicies.

Output:

- cellMatrix : The objects data transformed to a cell. (With types and variable names)

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});
cellMatrix = obj.asCell();
```

Written by Kenneth S. Paulsen

► **asCellForMPRReport** ↑

```
cellMatrix = asCellForMPRReport(obj,roundoff)
```

Description:

Return the nb_cs objects data as a cell matrix, on the MPR publishing format

Input:

- obj : An object of class nb_cs
- roundoff : 1 if you want to round off to 2 decimals, 0 otherwise. 1 is default.

Output:

- cellMatrix : The objects data transformed to a cell. (With types and variable names) Only the first page is returned. Look very much like an excel spreadsheet.

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});
cellMatrix = asCellForMPRReport(obj,1);
```

Written by Kenneth S. Paulsen

► **asec** ↑

```
obj = asec(obj)
```

Description:

Take inverse sec of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Examples:

```
obj = asec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **asecd** ↑

```
obj = asecd(obj)
```

Description:

asecd(obj) is the inverse secant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asecd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asech** ↑

```
obj = asech(obj)
```

Description:

asech(obj) is the inverse hyperbolic secant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asin** ↑

```
obj = asin(obj)
```

Description:

Take inverse sin of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = asin(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **asind** ↑

```
obj = asind(obj)
```

Description:

asind(obj) is the inverse sine, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► asinh ↑

```
obj = asinh(obj)
```

Description:

asinh(obj) is the inverse hyperbolic sine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asinh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► assignNan ↑

```
obj = expand(obj,variables,value)
```

Description:

Assign all the nan observation to the value input.

Input:

- obj : An object of class nb_dataSource.
- variables : A char or a cellstr with the variables to assign nan values.
- value : A scalar number.

Output:

- obj : An nb_ts object with expanded timespan

Examples:

```
obj      = nb_ts.rand('2012Q1',10,2,3);
obj(1:2,1,:) = nan;
obj      = assignNan(obj,'Var1',0)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atan** ↑

```
obj = atan(obj)
```

Description:

Take the inverse tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = atan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atand** ↑

```
obj = atand(obj)
```

Description:

atand(obj) is the inverse tangent, expressed in degrees, of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = atand(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **atanh** ↑

obj = atanh(obj)

Description:

atanh(obj) is the inverse hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = atanh(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **breakLink** ↑

obj = breakLink(obj)

Description:

Break link to source

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callfun ↑**

```
obj      = callfun(obj,'func',func)
obj      = callfun(obj,another,'func',func)
obj      = callfun(obj,varargin,'func',func)
varargout = callfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the data of the nb.DataSource object(s). The data of the object is normally of class double, but may also be of class logical or nb_distribution. Use nb.DataSource.getClassOfData to find the class of the data of the object.

Input:

- obj : An object of class nb.DataSource.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function @(x)x will be used.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class. nb.DataSource objects are converted to a matrix with elements of class double, logical or nb_distribution.

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb.DataSource object. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```

d      = nb_ts.rand('2012Q1',10,3);
d1     = callfun(d,'func',@sin); % Same as d1 = sin(d) !
d2     = callfun(d,d,'func','plus') % Same as d2 = d + d !
[s1,s2] = callfun(d,'func',@size) % Same as [s1,s2] = size(d)

```

See also:

[nb_cs.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callop** ↑

```

obj = callop(obj,another,func)
obj = callop(obj,another,func,type)

```

Description:

Call mathematical operator on the data of the object. In contrast to calling the operator itself on the object, this method does not try to match the same variables from the two inputs, but instead operate in the same way as mathematical operators do on double matrices (bsxfun). The time domain is matched though!

Caution: The following operators are supported:

- > @plus or 'plus'
- > @minus or 'minus'
- > @times or 'times'
- > @rdivide or 'rdivide'
- > @power or 'power'

Input:

- obj : An object of class nb_dataSource.
- another : An object of class nb_dataSource.
- func : One of the above listed functions.
- type : Either:
 - > 'keep' : Keep the variable names of the object with most variables. If they have the same number of variables, they are taken from the first object.
 - > 'rename' : The new variable names represent the operation that has been done to the separate series. So if you divide an object with one series named 'Var1' with another object with one series named 'Var2', the new name will be 'Var1./Var2'. (Default)

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb.DataSource method. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```
d1 = nb_ts(rand(10,1),'''2012Q1',{'Var1'});
d2 = nb_ts(rand(10,1),'''2011Q1',{'Var2'});
d3 = callop(d1,d2,@minus);

d1 = nb_ts(rand(10,1),'''2012Q1',{'Var1'});
d2 = nb_ts(rand(10,2),'''2011Q1',{'Var2','Var3'});
d3 = callop(d1,d2,@minus);
```

[nb_cs.getData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► callstat ↑

```
obj = callstat(obj,func)
obj = callstat(obj,func,varargin)
```

Description:

Call a in-built or user defined function on the data of the nb.DataSource object(s) that goes from the data of the object have more than one variable to only having one. E.g. when taking the mean over a set of variables.

Input:

- obj : An object of class nb.DataSource.

- func : A function handle (or one line char) that maps a nObs x nVar x nPage double to nObs x 1 x nPage double, or that maps a nObs x nVar x nPage double to nObs x nVar x 1 double.

Optional input:

- 'name' : Set the name of the new variable, as a one line char. Default is to use the str2func on the provided function handle.

- varargin : Optional inputs given as extra inputs to the function func. May be of any class.

Output:

- obj : An object of class nb_dataSource with only one variable.

Examples:

```
d = nb_ts.rand('2012Q1',10,3);
d1 = callstat(d,@(x)mean(x,2),'name','mean')
```

See also:

[nb_cs.mean](#), [nb_cs.std](#), [nb_cs.var](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► ceil ↑

```
obj = ceil(obj)
```

Description:

ceil(obj) rounds the elements of obj to the nearest integers towards infinity.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = ceil(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► conj ↑

```
obj = conj(obj)
```

Description:

conj(obj) is the complex conjugate of the elements of obj.
For a complex element x of obj, conj(x) = REAL(x) - i*IMAG(x).

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = conj(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **corr ↑**

```
obj = corr(obj,varargin)
```

Description:

Calculate the correlation of the series of the nb_cs object

Caution: Calculates the correlation matrix of the variables of the nb_cs object, if no optional inputs are given.

Input:

- obj : An object of class nb_cs

Output:

- obj : An nb_cs object with the wanted correlation

Examples:

```
corrMatrix = corr(obj);
```

Written by Kenneth S. Paulsen

► **cos ↑**

```
obj = cos(obj)
```

Description:

Take cos of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = cos(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cosd** ↑

obj = cosd(obj)

Description:

cosd(obj) is the cosine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = cosd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cosh** ↑

obj = csch(obj)

Description:

cosh(obj) is the hyperbolic cosine of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = csch(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cot** ↑

obj = cot(obj)

Description:

Take cotangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = cot(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cotd** ↑

obj = cotd(obj)

Description:

cotd(obj) is the cotangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cotd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **coth** ↑

```
obj = coth(obj)
```

Description:

coth(obj) is the hyperbolic cotangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = coth(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cov** ↑

```
obj = cov(obj,varargin)
```

Description:

Calculate the covariances of the timeseries of the nb_cs object

Caution: Calculates the covariance matrix of the variables of the nb_cs object, if no optional inputs are given. If 'lags' is given this function calculates the covariance with the number of wanted lags for each variable with itself. (And only with itself)

Input:

- obj : An object of class nb_cs
- Optional input ('propertyName',PropertyValue):
 - 'lags' : An integer with the number of lags you want to calculate the covariance for. (Here for each variable)

Output:

- obj : An nb_cs object with the wanted covariances

Examples:

```
covMatrix = cov(obj);
```

Written by Kenneth S. Paulsen

► createType ↑

```
obj = createType(obj, nameOfNewType, expression)
```

Description:

Create type(s) and add them to the nb_cs object dataset(s)

Caution :

- This function does not allow the type names to include mathematical operators (defined in matlab) as for example - + / . () !
- This function only support methods of the class double for the expressions. I.e. all the types of the nb_ts object are dumped as doubles, which you can use to create a new type

Input:

- obj : An object of class nb_cs
- nameOfNewType : The created types names as a cell array or a string.
 - Must have the same size as the 'expressions' input.
- expression : The expressions of how to create the data of all the created variables.
 - As a cell array or a string.
 - Must have the same size as the 'nameOfNewType' input.

Output:

- obj : An nb_cs object with the created types(s) added.

Examples:

```
obj = obj.createType('type1','type1./type2');
```

```
obj = obj.createType({'var3','var4',...},...  
{'type1./type2','type2./type1',...});
```

Written by Kenneth S. Paulsen

► **createVariable ↑**

```
obj = createVariable(obj,nameOfNewVariable,expression)  
obj = createVariable(obj,nameOfNewVariable,expression,parameters,varargin)
```

Description:

Create variable(s) and add them to the nb_cs object dataset(s)

Caution :

- This function only support methods of the class double for the expressions.

Input:

- obj : An object of class nb_cs
- nameOfNewVariable : The created variable names as a cell array or a string.
Must have the same size as the 'expressions' input.
- expression : The expressions of how to create the data of all the created variables.
As a cell array or a string.
Must have the same size as the 'nameOfNewVariable' input.
- parameters : A struct with the parameters that can be used in the expressions. Caution: They will be added as series, so you need to use elementwise operators (.*, ./, .^)!

Optional input:

- 'overwrite' : true or false. Set to true to allow for overwriting of variables already in the data of the object. Default is false.
- 'warning' : true or false. Set to true to give warning if expressions fail (instead of error). Will result in series having all nan value, when warning is thrown.

Output:

- obj : An nb_cs object with the created variable(s) added.

Examples:

```
obj = obj.createVariable('var3','var1./var2');  
  
obj = obj.createVariable({'var3','var4',...},...  
{'var1./var2','var2./var1',...});
```

Written by Kenneth S. Paulsen

► **csc** ↑

```
obj = csc(obj)
```

Description:

Take csc of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = csc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cscd** ↑

```
obj = cscd(obj)
```

Description:

cscd(obj) is the cosecant of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cscd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **csch** ↑

```
obj = csch(obj)
```

Description:

csch(obj) is the hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **ctranspose** ↑

```
obj = ctranspose(obj)
```

Description:

Take the transpose ('') of an nb_cs object

Caution : The former types will be sorted when transposing the object.

Input:

- obj : An object of class nb_cs

Output:

- obj : An nb_cs object which represents the transposed input object

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'})
```

```
obj =
```

```
'Types'      'Var1'      'Var2'  
'First'      [    2]      [    2]
```

```
t = obj'
```

```
t =
```

```
'Types'      'First'  
'Var1'       [    2]  
'Var2'       [    2]
```

Written by Kenneth S. Paulsen

► **cumnansum ↑**

```
obj = cumnansum(obj)
```

Description:

Cumulative sum of the series of the object. Ignoring nan values.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumnansum(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumprod** ↑

```
obj = cumprod(obj,dim)
```

Description:

Cumulativ product of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ product should be calculated. Default is the first dimension.

Output:

- obj : A nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative product of the old objects 'data' property.

Examples:

```
obj = cumprod(obj);
obj = cumprod(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumsum** ↑

```
obj = cumsum(obj,dim)
```

Description:

Cumulativ sum of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ sum should be calculated. Default is the first dimension.

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumsum(obj);  
obj = cumsum(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **deleteMethodCalls** ↑

```
obj = deleteMethodCalls(obj,c)
```

Description:

Delete some method calls of the object. The object needs to be updatable.

Caution: To set method calls use setMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- sourceNr : The source index to delete the methods from
- methodNrs : A index with the methods to delete.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

See also:

[setMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **deleteTypes** ↑

```
obj = deleteTypes(obj,deletedType)
```

Description:

Delete types from the current nb_cs object (letter size has something to say)

If some of the types you specify in deletedType does not exist in the obj, this will not have anything to say for the obj. (The types cannot be deleted, because the types do not exist.)

Input:

- obj : An object of class nb_cs
- deletedType : Must be a char or a cellstr

Delete all the type names, given in the char array or cellstr array deletedType, of current the nb_cs object.

NB! If deletedType is just one string and include a * as the last letter, this function will delete all the type names, from the object, that start with the letters which is in front of the * in the string.

i.e. obj = deleteTypes(obj,'DPQ*');

Deletes all the types in the obj which has type names starting with 'DPQ'.

If deletedType is just one string and include a * as the first letter, this function will delete all the type names, from the object, that include the letters which follows in the string.

i.e. obj = deleteTypes(obj, '*shift');

Deletes all the types in the obj which has type names which include 'shift'.

Output:

- obj : A nb_cs object with the types specified in deletedType deleted.

Examples:

```
obj = nb_cs([2;2],'test',{'First','Second'},{'Var1'});  
obj = deleteTypes(obj, {'First','Second'});  
obj = deleteTypes(obj, char('First','Second'));  
obj = deleteTypes(obj, obj.types);
```

Written by Kenneth S. Paulsen

► **deleteVariables ↑**

```
obj = deleteVariables(obj,deletedVar)
```

Description:

Delete variables from the current nb_ts, nb_data or nb_cs object (letter size has something to say)

If some of the variables you specify in deletedVar does not exist in the obj, this will not have anything to say for the obj. (The variables cannot be deleted, because the variables do not exist.)

Input:

- obj : An object of class nb_ts, nb_data or nb_cs
- deletedVar : Must be a char or a cellstr

Delete all the variable names, given in the char array or cellstr array deletedVar, of current the object.

NB! If deletedVar is just one string and include a * as the last letter, this function will delete all the variable names, from the object, that start with the letters which is in front of the * in the string.

i.e. obj = deleteVariables(obj,'DPQ*');

Deletes all the variables in the obj which has variable names starting with 'DPQ'.

If deletedVar is just one string and include a * as the first letter, this function will delete all the variable names, from the object, that include the letters which follows in the string.

i.e. obj = deleteVariables(obj, '*shift');

Deletes all the variables in the obj which has variable names which include 'shift'.

Output:

- obj : A nb_ts, nb_data or nb_cs object with the variables specified in deletedVar deleted.

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = deleteVariables(obj, {'Var1','Var2'});  
obj = deleteVariables(obj, char('Var1','Var2'));  
obj = deleteVariables(obj, obj.variables);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **demean** ↑

```
obj = demean(data,dim)
```

Description:

- Demeans data along the dimension you choose.

Input:

- obj : A nb_dataSource object.
- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- obj : A nb_dataSource object.

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATASOURCE

► **deptcat** ↑

```
obj = deptcat(obj,varargin)
```

Description:

Depth concatenation (add pages of different objects) (No short notation)

Be aware: If the added datasets does not contain the same variables or types, the data of the nb_cs object with the tightest window will be expanded automatically to include all the same types and variables. (the added data will be set as nan)

Input:

- obj : An object of class nb_cs
- varargin : Optional number of nb_cs objects

Output:

- obj : An object of class nb_cs where all the objects datasets are added into.

Examples:

```
obj = obj.deptcat(DB);  
obj = obj.deptcat(DB,DB2,DB3);
```

See also:

addPages

Written by Kenneth S. Paulsen

► **diag ↑**

```
obj = diag(obj)
```

Description:

Take the diagonal elements of the data and return it as a own type.

The data must be symmetric matrix!

Input:

- obj : An object of class nb_cs.
- typeName : Name of the created type. Default is 'diag'.

Output:

- obj : An object of class nb_cs with one type.

Written by Kenneth Sæterhagen Paulsen

► **disp ↑**

```
disp(obj)
```

Description:

Display the object on the command line (Without semicolon)

Input:

- obj : An object of class nb_cs

Output:

The nb_cs object displayed on the command line if you let out the semicolon at the end of the code line

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'})
```

Written by Kenneth S. Paulsen

► **double** ↑

```
dataOfObject = double(obj)
```

Description:

Get the data of the object as a double matrix

Caution : If the data of the object is represents as an object of class nb_distribution the mean is returned.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- dataOfObject : The data of the nb_ts, nb_cs or nb_data object

Examples:

```
dataOfObject = double(obj)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **empty** ↑

```
obj = empty(obj)
```

Description:

Empty the nb_cs object

Input:

- obj : An object of class nb_cs

Output:

- obj : An empty nb_cs object

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = empty(obj);
```

Written by Kenneth S. Paulsen

► eq ↑

```
a = eq(a,b)
```

Description:

Test if the one object is equal (==) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a == b;  
obj = 2 == b;  
obj = a == 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► estimateDist ↑

```
dist = estimateDist(obj,type)
```

Description:

Estimate distributions of the series in the nb_cs object.

Caution : This method strip all nan values.

Input:

- obj : An object of class nb_cs.
- type : The type of distribution to estimate. See the 'type' property of the nb_distribution class for the supported types. (Some may not be possible to estimate using 'mle' and/or 'mme'.) Default is 'normal';
 - Caution : If estimator is equal to 'kernel', this input is not used.
 - Caution : If type is set to 'hist', no estimator is used but the returned nb_distribution object instead represent a histogram.
- estimator : Either 'mle' (maximum likelihood), 'mme' (methods of moments) or 'kernel' (normal kernel density estimation). Default is 'mle'.
- dim : The dimension to estimate densities over. Either 1, 2 or 3. Default is 1.
- output : Either 'nb_distribution' (default) or 'nb_dataSource'. If 'nb_dataSource' is chosen the output will be a nb_cs object.

Optional input:

- varargin : Optional input given to the nb_ksdensity function. Please see help for that function.

Output:

- dist : An object of class nb_distribution or nb_cs.

See also:

[nb_distribution](#)

Written by Kenneth Sæterhagen Paulsen

► [exp ↑](#)

obj = exp(obj)

Description:

Take exp of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = exp(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **expand ↑**

```
obj = expand(obj,newTypes,type,warning)
```

Description:

Expand the current nb_cs object with more types and data

Input:

- obj : An object of class nb_cs
- newTypes : The wanted new start date of the data.
- type : Type of the appended data :
 - 'nan' : Expanded data is all nan (default)
 - 'zeros' : Expanded data is all zeros
 - 'ones' : Expanded data is all ones
 - 'rand' : Expanded data is all random numbers
- warningOff : Give 'off' to suppress warning if no expansion has taken place. All 'newTypes' are already stored in the object.

Output:

- obj : An nb_cs object with expanded types.

Written by Kenneth S. Paulsen

► **expml** ↑

```
obj = expml(obj)
```

Description:

`exp(obj)` is the exponential of the elements of `obj`, e to the `obj`.
`expml(obj)` computes `exp(obj)-1`, compensating for the roundoff in
`exp(obj)`.
(For small real `X`, `expml(X)` should be approximately `X`, whereas the
computed value of `EXP(X)-1` can be zero or have high relative error.)

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data` where the
data are equal to `e.^obj.data-1`

Examples:

```
obj = expml(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **extMethod** ↑

```
obj = extMethod(obj,method,variables,postfix,varargin)
```

Description:

This method can call a `nb_dataSource` method on a selected variables, and merge the result with the old object by adding a postfix to the new variables.

This method is the same as calling:

```
obj1 = window(obj,'','variables');
method = str2func(method);
obj = method(obj,varargin{:});
obj1 = addPostfix(obj1,method);
obj = merge(obj,obj1);
```

But without replicating the `links` property unnecessary many times!

Caution : If the object is not updateable this will result in the same as
the code above!

Input:

- obj : An object of class nb_ts, nb_data or nb_cs
- method : A str with the method to call. Must be a method of the nb_ts, nb_data or nb_cs class that does not change other dimensions than the second dimension!
- variables : A cellstr with the variables of the object to call the method on. Must be included in the object.
- postfix : A string with the postfix. If empty, the old variables will be replaced by the new ones.

Optional inputs:

These will be the inputs casted to the method except the object itself.

Extra for nb_ts and nb_data:

- '<start>' : The start date/obs of the function evaluation. Given as the second input to the window method call.
- '<end>' : The end date/obs of the function evaluation. Given as the third input to the window method call.

Output:

- obj : A nb_ts, nb_data or nb_cs object

Examples:

```
obj = nb_ts.rand(1,10,3);
obj = extMethod(obj,'lag',{'Var1'},'lag1',1)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► floor ↑

```
obj = floor(obj)
```

Description:

floor(obj) rounds the data elements of obj to the nearest integers towards minus infinity

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = floor(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **ge** ↑

```
a = ge(a,b)
```

Description:

Test if the one object is greater than or equal to (\geq) the other object elementwise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.

- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a >= b;  
obj = 2 >= b;  
obj = a >= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get the properties of the object

Input:

- obj : An object of class nb_ts
- propertyName : Name of the property you want to get:
 - 'data' : The data of the object as a double
 - 'dataNames' : Name of the object datasets, as cellstr array
 - 'numberOfDatasets' : Number of datasets (pages) of the object. Size of the third dimension
 - 'numberOfTypes' : Number of types of the object. Size of the first dimension
 - 'numberOfVariables' : Number of variables of the object. Size of the second dimension
 - 'types' : The types of the object as a cellstr array
 - 'variables' : The variables of the object, given as a cellstr array
 - 'links' : A structure of the data source links.
 - 'sorted' : true or false
 - 'updateable' : 1 if updateable, 0 otherwise.

Output:

propertyValue : The property value of the object for the wanted property

Examples:

```
dataAsDouble = get(obj,'data');
variables     = get(obj,'variables')
```

Written by Kenneth S. Paulsen

► getClassOfData ↑

```
cl = getClassOfData(obj)
```

Description:

Get the class of the data stored by the object.

Input:

- obj : An object of class nb_dataSource.

Output:

- cl : Name of the class that the data of the object is stored as.

See also:

[nb_cs.isDistribution](#), [nb_cs.isDouble](#)
[nb_cs.isBoolean](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► getCode ↑

```
code = getCode(obj,preamble)
code = getCode(obj,preamble,'inputName',inputValue,...)
```

Description:

Get the LaTeX code of a table representing the data of the object

If the object consists of more pages (datasets) more tables will be created.

Input:

- obj : An object of class nb_cs
- preamble : Give 0 if you don't want to include the preamble in the returned output. Default is to include the preamble, i.e. 1.

Optional input:

- 'caption' : Adds a caption to the table. Must be a string.
- 'combine' : If the nb_cs object consist of two or three pages (datasets) this option can be used to combine all the data in one table. Either 1 or 0. Default is 0.
- 'colors' : Set it to 0 if the colored rows of the table should be turned off. Default is 1.
- 'firstRowColor' : A string with the color, e.g. 'blue','white','black','blue!20!white'. Default is 'nbblue'.
- 'fontSize' : Sets the font size of the table. Either:
'Huge', 'huge', 'LARGE', 'Large', 'large',
'normalsize' (default), 'small',
'footnotesize', 'scriptsize','tiny'.

Caution : This option is case sensitive.

- 'justification' : Sets the justification of the caption of the table. Must be a string.

Either 'justified', 'centering' (default), 'raggedright', 'RaggedRight', 'raggedleft'.

Caution : This option is case sensitive.

- 'language' : Either 'english' (default) or 'norwegian' ('norsk').

- 'lookUpMatrix' :

Sets how the given mnemonics (variable names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
 'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
lookUpMatrix = {
```

```
'mnemonics1','englishDescription1','norwegianDescription1';
 'mnemonics2','englishDescription2','norwegianDescription2'};
```

Be aware : Each of the given description can be multi-lined char, which will result in multi-line text of the table.

Caution : This will act on both variables and types.

- 'orientation' : The orientation of the table. Either:

> 'horizontal' : The dates as columns
> 'vertical' : The types as columns

- 'precision' : Sets the precision of the numbers in the table. Must be a string. Default is '%3.2f'. I.e. two decimals.

- 'rotation' : The rotation of the table in LaTeX. Either:

> 'sidewaystable' : A sideways table
> 'landscape' : Rotate the whole page
> '' : No rotation

- 'rowColor1' : Color of every second row of the table starting from the second row. Same options as was the case for the 'firstRowColor' option.

- 'rowColor2' : Color of every second row of the table starting from the third row. Same options as was the case for the 'firstRowColor'

option.

- 'rowColor3' : Color of every third row of the table starting from the fourth row. Only an option in combination with the 'combine' input set to 1 and that the nb_cs object has 3 pages. Same options as was the case for the 'firstRowColor' option.
- 'NaNrepl' : Replaces NaN's in a table by chosen symbol. Give as string, can be empty. Default: 'NaN', i.e. no replacement.

Output:

- code : A char with the tex code of the table

Examples:

```
obj = nb_cs([2,2,2],'',{'type1'},{'Var1','Var2','Var3'});  
code = obj.getCode(1)
```

Copyright (c) 2019, Norges Bank

► **getCreatedVariables ↑**

```
created = getCreatedVariables(obj)
```

Description:

Get a N x 2 table of the variables created using the createVariable method. The first column list the created variables, while the second column list the expressions.

Input:

- obj : An object that is a subclass of nb_dataSource.

Output:

- created : A N x 2 cell array. See description of this method for more.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getMethodCalls** ↑

```
[s,c] = getMethodCalls(obj)
```

Description:

Get all method calls as a cell matrix. The object needs to be updatable to get a list of methods called on the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.
- c : A cell matrix with a table of the method called on the object and its input. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getSource** ↑

```
sourceType = getSource(obj)
sourceType = getSource(obj,type)
```

Description:

Get source type.

Input:

- obj : An object of class nb_dataSource.
- type : Give 'program' to get the general source. Default is to give the specific type of source.

Output:

- sourceType : A one line char with the source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getSourceList** ↑

```
s = getSourceList(obj)
```

Description:

Get the source list of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getVariable** ↑

```
variableData = getVariable(obj, variableName, ...
                           typesOfVariable, pages)
```

Description:

Get the data of a variable of an nb_cs object

Input:

- obj : An object of class nb_cs
- variableName : The variable you want the data of. Must be given as a string (name of variable) or a cellstr.
- typesOfVariable : The wanted types, given as a cellstr.
- pages : Pages of the return data of the given variable. As a double or logical array, e.g. [1:2] or [1,3,5].

Output:

- variableData : The data of the variable you have given as a double. Return [] if not found.

Examples:

```
obj = nb_cs([2,2; 2,2],'test',{'Type1','Type2'},{'Var1','Var2'});
variableData = getVariable(obj,'Var1');
variableData = getVariable(obj,'Var1',{'Type1'});
variableData = getVariable(obj,'Var1',{'Type1'},1);
```

Written by Kenneth S. Paulsen

► **gt ↑**

```
a = gt(a,b)
```

Description:

Test if the one object is greater then (>) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a > b;
obj = 2 > b;
obj = a > 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **hasVariable ↑**

```
[ret,location] = hasVariable(obj,variable)
```

Description:

Test if an nb_cs object has a given variable

Input:

- obj : An object of class nb_cs
- variable : The variable name as a string. Can also be a cellstr with more variables.

Output:

- ret : 1 if found otherwise 0
- location : The location of the variable if found. Otherwise [].

Examples:

```
ret           = obj.hasVariable('Var1')
[ret,location] = hasVariable(obj,'Var1')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **head** ↑

```
head(obj,nRows,page)
```

Description:

Display the first n rows of a nb_cs object.

Input:

- obj : An nb_cs object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_cs](#), [window](#), [head](#)

Written by Per Bjarne Bye

► **histogram** ↑

```
data           = histogram(obj)
[data,plotter] = histogram(obj,M)
```

Description:

Create a histogram of a object containing only one variable and one page!

Input:

- obj : A nb_dataSource object with size N x 1 x 1.
- M : The number of bins of the histogram.

Output:

- data : A nb_cs object with size M x 1 x 1.
- plotter : A nb_graph_cs object with the histogram plotted.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **horzcat** ↑

obj = horzcat(a,b,varargin)

Description:

Horizontal concatenation of nb_cs objects. ([a,b]) This is only possible if the different objects contain differen variables or have variables with the same values (types can differ). Uses the merge method.

If the types differ, nan values will be added.

Input:

- a : An object of class nb_cs
- varargin : Optional number of nb_cs objects

Output:

- obj : An nb_cs object with all the variables from the different nb_cs object merge into one dataset

Examples:

```
obj = [a,b];
obj = [a,b,c];
```

See also:

[merge](#)

► **interpolate** ↑

```
obj = interpolate(obj,method)
```

Description:

Interpolate the data of the nb_data object. Will discard leading and trailing nan values.

Input:

- data : An nb_ts, nb_cs or nb_data object.
- method :
 - 'nearest' : Nearest neighbor interpolation
 - 'linear' : Linear interpolation. Default
 - 'spline' : Piecewise cubic spline interpolation (SPLINE)
 - 'pchip' : Shape-preserving piecewise cubic interpolation
 - 'cubic' : Same as 'pchip'
 - 'v5cubic' : The cubic interpolation from MATLAB 5, which does not extrapolate and uses 'spline' if X is not equally spaced.

Output:

- data : An nb_ts, nb_cs or nb_data object with the interpolated data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **intertwine** ↑

```
obj = intertwine(obj, cs2, '_emp', cs3, '_sim')
```

Description:

See intertwine...

Written by Henrik Halvorsen Hortemo

► **interwine** ↑

```
obj = interwine(obj, cs2, '_emp', cs3, '_sim')
```

Description:

Intertwine the current object with nb_cs objects of equal types and variables, adding postfixes to the type names of the intertwined objects.

Caution: This method will break the link to the data source.

Input:

- obj : A nb_cs object
- obj2 : A nb_cs object
- postfix2 : The postfix to add to the type names of obj2
- varargin : Supply more objects and postfixes (obj3, postfix3, ...)

Output:

- obj : An object of class nb_cs

Written by Henrik Halvorsen Hortemo

► **isBoolean** ↑

```
ret = isBoolean(obj)
```

Description:

Check if the data of the nb_dataSource object is of class logical (boolean, i.e. true or false).

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isCrossSectional** ↑

```
ret = isCrossSectional(obj)
```

Description:

Test if this object is a cross sectional data object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_cs, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isDistribution** ↑

ret = isDistribution(obj)

Description:

Check if the data of the nb_dataSource object is of class nb_distribution

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isDouble** ↑

ret = isDouble(obj)

Description:

Check if the data of the nb_dataSource object is of class double (numeric)

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isTimeseries** ↑

```
ret = isTimeseries(obj)
```

Description:

Test if a nb_dataSource object is a time series object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_ts, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isUpdateable** ↑

```
ret = isUpdateable(obj)
```

Description:

Test if this object is updateable.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : 1 if updateable, otherwise 0.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if a nb_ts, nb_cs or nb_data object is empty. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isfinite** ↑

```
obj = isfinite(obj)
```

Description:

Test if each element of a nb_ts, nb_cs or nb_data object is finite.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is finite, otherwise 0.

Examples:

```
obj = isfinite(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isnan** ↑

```
obj = isnan(obj)
```

Description:

Test if each element of an nb_ts, nb_cs or nb_data object is nan.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is nan, otherwise 0.

Examples:

```
obj = isnan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isscalar** ↑

```
ret = isscalar(obj)
```

Description:

Test if a nb_ts, nb_cs or nb_data object is a scalar. Will always return 0, as an object of class nb_ts, nb_cs or nb_data is not a scalar.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : false

Examples:

```
0 = isscalar(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **keepPages** ↑

```
obj = keepPages(obj, pages)
```

Description:

Keep pages of the current nb_ts object

Input:

- obj : An object of class nb_ts
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty a empty nb_ts object is returned.

Can also be a cellstr with the names to keep, or a logical array with length equal to the number of pages (datasets).

Output:

- obj : An nb_ts object with the pages specified in the input are kept.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **keepTypes** ↑

```
obj = keepTypes(obj, keptType)
```

Description:

Keep types from the current nb_cs object (letter size has something to say)

If some of the types you specify in keptType does not exist in the object, this will not have anything to say for the object. (The types cannot be kept, because the types do not exist.)

Input:

- obj : An object of class nb_cs
- keptType : Must be a char or a cellstr

Keeps all the type names, given in the char array or cellstr array keptType, of current the nb_cs object.

NB! If keptType is just one string and include a * as the last letter, this function will keep all the type names, from the DB, that start with the letters which is in front of the * in the string.

i.e. obj = keepTypes(obj,'DPQ*');

Keep all the types in the obj which has type names starting with 'DPQ'.

If keptType is just one string and include a * as the first letter, this function will keep all the type names, from the DB, that include the letters which follows in the string.

i.e. obj = keepTypes(obj, '*shift');

Keeps all the types in the obj which has type names which include 'shift'.

Output:

- obj : A nb_cs object with the types specified in the input keptType kept, all the others are deleted.

Examples:

```
obj = nb_cs([2;2],'test',{'First','Second'},{'Var1'});  
obj = obj.keepTypes({'First','Second'});  
obj = obj.keepTypes(char('First','Second'));  
obj = obj.keepTypes(obj.types);
```

Written by Kenneth S. Paulsen

► **keepVariables ↑**

```
obj = keepVariables(obj,keptVar)
```

Description:

Keep variables from the current nb_cs object (letter size has something to say)

If some of the variables you specify in keptVar does not exist in the object, this will not have anything to say for the object. (The variables cannot be kept, because the variables do not exist.)

Input:

- obj : An object of class nb_cs
- keptVar : Must be a char or a cellstr

Keeps all the variable names, given in the char array or cellstr array keptVar, of current the nb_cs object.

NB! If keptVar is just one string and include a * as the last letter, this function will keep all the variable names, from the DB, that start with the letters which is in front of the * in the string.

i.e. obj = keepVariables(obj,'DPQ*');

Keep all the variables in the obj which has variable names starting with 'DPQ'.

If keptVar is just one string and include a * as the first letter, this function will keep all the variable names, from the DB, that include the letters which follows in the string.

i.e. obj = keepVariables(obj, '*shift');

Keeps all the variables in the obj which has variable names which include 'shift'.

Output:

- obj : A nb_cs object with the variables specified in the input keptVar kept, all the others are deleted.

Examples:

```
obj = nb_cs([2,2,2],'test',{'First'},{'Var1','Var2','Var3'});  
obj = obj.keepVariables({'Var1','Var2'});  
obj = obj.keepVariables(char('Var1','Var2'));  
obj = obj.keepVariables(obj.variables);
```

Written by Kenneth S. Paulsen

► **kurtosis ↑**

```
obj = kurtosis(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the kurtosis of object. The result will be an object of class nb_cs where all the non-nan values of all the object are being set to their kurtosis.

Input:

- obj : An object of class nb_cs
 - flag :
 - > 0 : normalises by N-1 (Default)
 - > 1 : normalises by N
- Where N is the sample length.
- outputType :
 - > 'double' : Get the kurtosis values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the kurtosis values as nb_cs object.
 - dimension : The dimension to calcualate the kurtosis over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
double = kurtosis(obj,0,'double');
nb_csObj = kurtosis(obj,0,'nb_cs');
```

Written by Kenneth S. Paulsen

► le ↑

```
a = le(a,b)
```

Description:

Test if the one object is less than or equal to (\leq) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a <= b;  
obj = 2 <= b;  
obj = a <= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **log ↑**

```
obj = log(obj)
```

Description:

Take log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on logs.

Examples:

```
obj = log(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **log10 ↑**

```
obj = log10(obj)
```

Description:

Take the common (base 10) log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on (base 10) logs.

Examples:

```
obj = log10(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **log1p** ↑

```
obj = log1p(obj)
```

Description:

log1p(obj) computes $\text{LOG}(1+xi)$, where xi are the elements of obj. Complex results are produced if $xi < -1$.

For small real xi, log1p(xi) should be approximately xi, whereas the computed value of $\text{LOG}(1+xi)$ can be zero or have high relative error.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = log1p(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **log2** ↑

```
obj = log2(obj)
```

Description:

`log2(obj)` is the base 2 logarithm of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
obj = log2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **lt** ↑

```
a = lt(a,b)
```

Description:

Test if the one object is less than (`<`) the other object elemetswise and return a `nb_dataSource` object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- `a` : An object of class `nb_dataSource` or a scalar number.

- `b` : An object of class `nb_dataSource`, but must be of same subclass as `a`, or a scalar number.

Output:

- `a` : An `nb_dataSource` object where the data element are logical.

Examples:

```
obj = a < b;
obj = 2 < b;
obj = a < 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► map2Distribution ↑

```
obj = map2Distribution(obj,dist)
obj = map2Distribution(obj,dist,varargin)
```

Description:

Map observation to the distributions given by dist.

The current distribution of the data is estimated using a kernel density estimator. The data must be strongly stationary. I.e. the unknown distribution from where the data has been drawn must not depend on time.

Input:

- obj : An object of class nb_dataSource.
- dist : An object of class nb_distribution with size 1 x size(obj,2).

Optional inputs:

- See the optional inputs of the nb_distribution.estimate function.

Output:

- obj : An object of class nb_dataSource.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► max ↑

```
obj = max(obj,outputType,dimension)
```

Description:

Calculate the max of object. The result will be an object of class nb_cs where all the non-nan values of all the object are being set to their max.

Input:

- obj : An object of class nb_cs
- outputType :
 - > 'double' : Get the max values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the max values as nb_cs object.
- dimension : The dimension to calcualate the max over.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
double = max(obj,'double');
nb_csObj = max(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **mean ↑**

```
obj = mean(obj,outputType,dimension,varargin)
```

Description:

Calculate the mean of each the object. The result will be an object of class nb_cs where all the non-nan values of all the object are beeing set to their mean.

Input:

- obj : An object of class nb_cs
- outputType :
 - > 'double' : Get the mean values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the mean values as nb_cs object. The output will keep the same size as the input object.
 - > 'nb_cs_scalar' : The result will be an object of class nb_cs where all the non-nan values of all the

series are being set to their mean, but where the dimension taking the mean over is reduced to size 1. The name of the type/variable/page will be 'mean'.

- dimension : The dimension to calculate the mean over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
double = mean(obj,'double');
nb_csObj = mean(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **median** ↑

```
obj = median(obj,outputType,dimension,varargin)
```

Description:

Calculate the median of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their median.

Input:

- obj : An object of class nb_ts

- outputType :

> 'double' : Get the median values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.

> 'nb_cs' : Get the median values as nb_cs object.

- dimension : The dimension to calculate the median over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
double    = median(obj,'double');
nb_csObj = median(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **merge ↑**

```
obj = merge(obj,DB)
```

Description:

Merge another nb_cs object with the current one

Input:

- obj : An object of class nb_cs
- DB : An object of class nb_cs

Output:

- obj : An object of class nb_cs where the datasets from the DB object are merged with the data of the obj object.

Caution:

- > It is possible to merge datasets with the same variables as long as they are representing the same data or have different types.

- > If the datasets has different number of datasets and one of the merged objects only consists of one, this object will add as many datasets as needed (copies of the first dataset) so they can merge.

Examples:

```
obj = nb_cs([2,2; 2,2],'test',{'Type1','Type2'},{'Var1','Var2'});
DB  = nb_cs([2,1; 2,2],'test',{'Type1','Type2'},{'Var1','Var3'});
obj = obj.merge(DB)
```

Written by Kenneth S. Paulsen

► **merge2Series** ↑

```
obj = merge2Series(obj,var1,var2,new,method,varargin)
```

Description:

Merge 2 series. The var2 series is appended to the var1 series from where it is ending.

Input:

- obj : An object of class nb_dataSource.
- var1 : A one line char with the name of the base series.
- var2 : A one line char with the name of the appended series.
- new : Name of the new variable. If given as empty there will not be created a new series, but instead the var1 variable will be set to the new merged series. Default is empty.
- method : Either 'level', 'diff', 'growth', 'leveldiff' or 'levelgrowth'. Default is 'level'. For the cases 'level', 'diff' or 'growth' it is assumed the both series are in levels. 'leveldiff' assumes the first series is in level and the second in nLags-difference. 'levelgrowth' assumes the first series is in level and the second in growth rates over nLags periods, i.e. $(x(t) - x(t-nLags))/x(t-nLags)$.

Optional input:

- 'nLags' : The number of lages used for the methods 'diff' and 'growth'. Default is 1.
- 'date' : The date from where to use the second variable. Either a date as string or a nb_date object. If empty the merge will take place where the first variable end + 1 period.

Output:

- obj : An object of class nb_dataSource.

Examples:

```
obj           = nb_ts.rand('2012Q1',10,2,3);
obj(end-1:end,1,:) = nan;

obj1 = merge2Series(obj,'Var1','Var2','Var3')
obj2 = merge2Series(obj,'Var1','Var2')
obj3 = merge2Series(obj,'Var1','Var2','','diff','nLags',1)
obj4 = merge2Series(obj,'Var1','Var2','','diff','nLags',4)
obj5 = merge2Series(obj,'Var1','Var2','','level','date','2014Q1')
```

See also:

[nb_ts.merge](#), [nb_data.merge](#), [nb_cs.merge](#)

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **min ↑**

obj = min(obj, outputType, dimension)

Description:

Calculate the min of object. The result will be an object of class nb_cs where all the non-nan values of all the object are being set to their min.

Input:

- obj : An object of class nb_cs
- outputType :
 - > 'double' : Get the min values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the min values as nb_cs object.
- dimension : The dimension to calculate the min over.

Output:

- obj : See the input outputType for more on the output from this method
- dimension : The dimension to calculate the min over.

Examples:

```
double = min(obj,'double');
nb_csObj = min(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **minus ↑**

```
obj = minus(obj,DBOrNum)
```

Description:

Binary subtraction (-).

Caution: Will subtract the data of the corresponding variables from the two objects. All the variables not in common will result in series with nan values.

When one of the inputs are a scalar this function will subtract each element of the data by this number or each element of the data will be subtracted from the scalar.

Input:

- a : An object of class nb_cs or a scalar
- b : An object of class nb_cs or a scalar

Output:

- obj : An nb_cs object where all the variables are from the first object are subtracted from the other.

Or

An nb_cs object where the scalar are substracted from all the elements of the input object

Or

An nb_cs object where all the elements of the input object are substracted from scalar.

Examples:

```
obj = obj - anotherObj;  
obj = obj - 2;  
obj = 2 - obj;
```

See also:

[nb_cs.plus](#), [nb_cs.callop](#), [nb_cs.callfun](#)

Written by Andreas Haga Raavand

► **mldivide** ↑

```
obj = mldivide(a,b)
```

Description:

Matrix left division (\). See examples.

Input:

- a : An object of class nb_cs.
- b : A scalar or a string representing a variable name or type name.

Output:

- obj : An nb_cs object.

Examples:

```
obj = nb_cs.rand(10,3)
obj = obj\1          % 1/obj
obj = obj\'Type1'   % 'Type1'/obj
obj = obj\'Var1'    % 'Var1'/obj
```

See also:

[nb_cs.ldivide](#), [nb_cs.mrdivide](#), [nb_cs.rdivide](#)

Written by Kenneth S. Paulsen

► **mode** ↑

```
obj = mode(obj,outputType,dimension,varargin)
```

Description:

Calculate the mode of object. The result will be an object of class nb_cs where all the non-nan values of all the object are being set to their mode.

Input:

- obj : An object of class nb_cs
- outputType :
 - > 'double' : Get the mode values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the mode values as nb_cs object.
- dimension : The dimension to calculate the mode over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
double    = mode(obj,'double');
nb_csObj = mode(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **mpower** ↑

```
obj = mpower(a,b)
```

Description:

Matrix power (^). Defined when raised by a scalar, a string which either represent a variable or type.

Input:

- a : An object of class nb_data
- b : A scalar or a string.

Output:

- obj : An nb_data object.

Examples:

```
obj  = nb_cs.rand(10,2)
obj1 = obj^'Type1'
obj2 = obj^'Var1'
obj3 = obj^1
```

See also:

nb_cs.power

Written by Kenneth S. Paulsen

► **mrddivide** ↑

```
obj = mrdivide(a,b)
```

Description:

Matrix right division (/). See examples.

Input:

- a : An object of class nb_cs, a scalar number or a string representing a variable name or type name.
- b : An object of class nb_cs, a scalar or a string representing a variable name or type name.

Output:

- obj : An nb_cs object.

Examples:

```
obj = nb_cs.rand(10,3)
obj1 = obj/1
obj2 = obj/'Var1'
obj3 = obj//Type1'
obj4 = 1/obj
obj5 = 'Var1'/obj
obj6 = 'Type1'/obj
```

See also:

[nb_cs.ldivide](#), [nb_cs.mldivide](#), [nb_cs.rdivide](#)

Written by Kenneth S. Paulsen

► **mtimes** ↑

```
obj = mtimes(obj,Num)
```

Description:

Matrix multiplication (*) Defined for multiplication with a constant, a string which either represent a variable or type.

Input:

- obj : An object of class nb_cs or scalar
- b : An object of class nb_cs or a scalar or a string.

Output:

- obj : An nb_cs object where the number (date or variable as a vector) is multiplied with all the elements of the input objects data

Examples:

```
obj = 2*obj;
obj = obj*2;
obj = obj*'Type1'
obj = obj*'Var1'
```

See also:

[nb_cs.times](#)

Written by Kenneth S. Paulsen

► **nan ↑**

```
obj = nb_cs.nan(types,vars)
obj = nb_cs.nan(types,vars,pages)
```

Description:

Create an nb_cs object with all set to nan.

Input:

- types : Either a cellstr with the types of the nb_cs object, or a scalar with the number of types of the nb_cs object.
- vars : Either a cellstr with the variables of the nb_cs object, or a scalar with the number of variables of the nb_cs object.
- pages : Number of pages of the nb_cs object.

Output:

- obj : An nb_cs object.

Examples:

```
obj = nb_cs.nan({'Type','Type2'},{'Var1','Var2'});
obj = nb_cs.nan(2,2);
obj = nb_cs.nan(2,2,10);
```

See also:

[nb_cs](#)

► **ne** ↑

```
a = ne(a,b)
```

Description:

Test if the one object is not equal to ($\sim=$) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a ~= b;  
obj = 2 ~= b;  
obj = a ~= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **not** ↑

```
a = not(a)
```

Description:

The not operator (~).

Input:

- a : An object of class nb_dataSource.

Output:

- a : An object of class nb_dataSource. Where the not operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

```
a = ~a;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► objSize ↑

```
varargout = objSize(obj,dim)
```

Description:

Return the size(s) of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim :
 - 1 : Number of observations
 - 2 : Number of variables
 - 3 : Number of datasets (pages)

Output:

- varargout : See the examples below

Examples:

```
dim = objSize(obj)
```

Where dim is 1 x 2 double where the first element is the number of observations/types and the second element is the number of variables

```
[dim1, dim2] = objSize(obj)
```

```
[dim1, dim2, dim3] = objSize(obj)
```

```
dim1 = objSize(obj,1)  
dim2 = objSize(obj,2)  
dim3 = objSize(obj,3)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **ones** ↑

```
obj = nb_cs.ones(types,vars)
obj = nb_cs.ones(types,vars,pages)
```

Description:

Create an nb_cs object with all set to 1.

Input:

- types : Either a cellstr with the types of the nb_cs object, or a scalar with the number of types of the nb_cs object.
- vars : Either a cellstr with the variables of the nb_cs object, or a scalar with the number of variables of the nb_cs object.
- pages : Number of pages of the nb_cs object.

Output:

- obj : An nb_cs object.

Examples:

```
obj = nb_cs.ones({'Type','Type2'},{'Var1','Var2'});
obj = nb_cs.ones(2,2);
obj = nb_cs.ones(2,2,10);
```

See also:

[nb_cs](#)

Written by Kenneth Sæterhagen Paulsen

► **or** ↑

```
a = or(a,b)
```

Description:

The and operator (|).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the or operator has evaluated all the data elements of the object. The data will be a logical matrix.

Examples:

```
a = a | b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **packing ↑**

```
obj = packing(obj,packages,varargin)
```

Description:

Package variables by applying the wanted function. Default is summin (sum).

Input:

- obj : An object of class nb_ts.
- packages : A 2 x N cell matrix with groups of variables and the names of the groups. If you have not listed a variable it will be grouped in a group called 'Rest' (as long as 'includeRest' is not set to false).

Must be given in the following format:

```
{'group_name_1','group_name_N';
 name_1 ,...,name_N}
```

Where name_x must be a string with a name of the variable or a cellstr array with the variable names. E.g 'Var1' or {'Var1','Var2'}.

Optional inputs:

- 'includeRest' : Give false to not include the 'Rest' variable, which will represent all the variable that has not been packed.
- 'func' : Either a function_handle or a one line char with the

name of the function to use. The first input to this function is a nObs x nVar double, the second is the dimension (which is always 2). Examples; 'sum', 'prod', @sum or @prod.

Output:

- obj : A object of class nb_ts.

Examples:

```
data      = nb_ts.rand('2012Q1',10,4);
packages = {'group1','group2';
            {'Var1','Var2'},{'Var3'}};

dataP1 = packing(data,packages)
dataP2 = packing(data,packages,'includeRest',false)
dataP3 = packing(data,packages,'func',@prod)
```

See also:

[nb_ts.createVariable](#), [nb_data.createVariable](#), [nb_cs.createVariable](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **percentiles** ↑

obj = percentiles(obj,perc)

Description:

Take the percentile over the third dimension of the data of the object.

Input:

- obj : An object of class nb_cs
- perc : A double with the wanted percentiles of the data. E.g. 0.5 (median), or [0.05,0.15,0.25,0.35,0.5,0.65,0.75,0.85,0.95].

Output:

- obj : A nb_cs object with the percentiles stored as different pages of the object. See the dataNames property for the ordering.

Written by Kenneth Sæterhagen Paulsen

► **permute** ↑

```
obj = permute(obj,variables)
```

Description:

Switch the second and third dimension of the nb_ts, nb_cs or nb_data object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- variables : A cellstr with size 1 x numberOfDatasets. Default is to use dataNames property. I.e. when not provided or if empty.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **plot ↑**

```
plot(obj,varargin)
plotter = plot(obj,varargin)
```

Description:

Plot the data of the nb_dataSource object.

Caution: If the data of the object is of class nb_distribution this method will redirect to plotDist.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

- plotType : A string with either:

```
> 'graph'    (Default)  
> 'graphSubPlots'  
> 'graphInfoStruct'
```

The name of the graphing method of the class nb_graph_ts, nb_graph_cs or nb_graph_data.

Caution: This is an optional input. If not given it is assumed that the optional input pairs are starting from the second input to this function.

```
- varargin : Same as the input to the method set() of the
            nb_graph_ts, nb_graph_cs or nb_graph_data class.

            I.e. ..., 'inputName', inputValue, ...

Caution: If the data of the object is of class
         nb_distribution, see nb_ts.plotDist for the
         optional input pairs supported.
```

Output:

Plotted output

Examples:

```
plot(obj)

plot(obj,'graphSubPlots')

plot(obj,'','startGraph','2008Q1','endGraph','2011Q2')

same as

plot(obj,'graph','startGraph','2008Q1','endGraph','2011Q2')
```

See also:

[nb_graph_ts](#), [nb_ts.plotDist](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **plus ↑**

```
obj = plus(obj,DBOrNum)
```

Description:

Binary addition (+).

Caution: Will add the data of the corresponding variables from
 the two objects. All the variables not in common will result
 in series with nan values.

When one of the inputs are a scalar this function will add
 each element of the data by this number.

Input:

- a : An object of class nb_cs or a scalar
- b : An object of class nb_cs or a scalar

Output:

- obj : An nb_cs object where all the variables from the two objects are added.

Or

An nb_cs object where the scalar are added to all elements of the given nb_cs object

Examples:

```
obj = obj + anotherObj;  
obj = obj + 2;  
obj = 2 + obj;
```

See also:

[nb_cs.minus](#), [nb_cs.callop](#), [nb_cs.callfun](#)

Written by Andreas Haga Raavand

► **pow2** ↑

```
obj = pow2(obj)
```

Description:

`pow2(obj)` raises the number 2 to the power of the elements of `obj`

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = pow2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **power** ↑

```
obj = power(a,b)
```

Description:

Element-wise power (.^).

If both inputs are nb_cs objects this method will raise the data of the first object with the data from the second object. This will only be done for the variables which are found to be in both nb_cs objects. The rest of the variables will get nan values.

Input:

- obj : An object of class nb_cs or a scalar
- DBOrNum : An object of class nb_cs or a scalar

Output:

- obj : An nb_cs object where the data from th one object are raised with the data from the other object

or

An nb_cs object where all the elements are raised by the scalar DBOrNum.

or

An nb_cs object where the scalar obj are raised by all the elements of the object DBOrNum.

Examples:

```
obj = a.^b;
obj = a.^2;
obj = 2.^a;
```

See also:

[nb_cs.mpower](#), [nb_cs.callop](#), [nb_cs.callfun](#)

Written by Andreas Haga Raavand

► rand ↑

```
obj = nb_cs.rand(types,vars)
obj = nb_cs.rand(types,vars,pages)
```

Description:

Create a random nb_cs object

Input:

- types : Either a cellstr with the types of the random nb_cs object, or a scalar with the number of types of the random nb_cs object.
- vars : Either a cellstr with the variables of the random nb_cs object, or a scalar with the number of variables of the random nb_cs object.
- pages : Number of pages of the random nb_cs object.
- dist : A nb_distribution object to draw from.

Output:

- obj : An nb_cs object.

Examples:

```
obj = nb_cs.rand({'Type','Type2'},{'Var1','Var2'});
obj = nb_cs.rand(2,2);
obj = nb_cs.rand(2,2,10,nb_distribution('type','normal'));
```

See also:

[nb_cs](#)

Written by Kenneth Sæterhagen Paulsen

► [rdivide](#) ↑

```
obj = rdivide(obj,DB)
```

Description:

Right element-wise division (./)

Do right element-wise division of the matching variables of the two nb_cs objects. If some variables are not found to be in both objects, the resulting object will have series with nan values only for these variables.

Input:

- a : An object of class nb_cs
- b : An object of class nb_cs

Output:

- obj : An object of class nb_cs, where the data are the result of the element-wise division.

Examples:

```
obj = obj./DB;
```

See also:

[nb_cs.mldivide](#), [nb_cs.mrdivide](#), [nb_cs.callop](#), [nb_cs.callfun](#)

Written by Kenneth S. Paulsen

► **real** ↑

```
obj = real(obj)
```

Description:

`real(obj)` returns the real part of the elements in the `nb_cs` object

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
obj = real(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **reallog** ↑

```
obj = reallog(obj)
```

Description:

Take the real natural logarithm of the data stored in the object

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = reallog(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **realpow** ↑

obj = realpow(obj,DBOrNum)

Description:

Same as nb_cs.power.

See also:

[nb_cs.power](#)

Written by Kenneth S. Paulsen

► **realsqrt** ↑

obj = realsqrt(obj)

Description:

realsqrt(obj) is the square root of the elements of obj.
An error is produced if obj contains negative elements.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = realsqrt(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► rename ↑

```
obj = rename(obj,type,oldName,newName)
```

Description:

Makes it possible to rename variables and datasets. For objects of class nb_cs types is also possible to rename.

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variable', but not when the input is 'dataset' or 'types'.

Input:

- obj : An object of class nb_dataSource
- type : Either:
 - 'variable' : To rename a variable(s)
 - 'dataset' : To rename a dataset(s) (The only input that is supported for nb_cell)
 - 'types' : To rename a type(s) (only nb_cs)
- oldName : Case 1;
 - > The old variable/dataset/type name, as a string
- Case 2:
 - > The string which should be replaced in all the variable names of the database. And reorder things afterwards. This input must end with a *.
- newName : Case 1;
 - > The new variable/dataset/type name, as a string
- Case 2;
 - > The string which should replace the old string part given by the input 'oldName'.

Output:

- obj : An nb_dataSource object with the renamed variable(s), type(s) or dataset(s).

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = obj.rename('variable','Var1','Var3');  
obj = obj.rename('variable','Var*','N_Var');  
obj = rename(obj,'variable',{'Var1','Var2'},{'VAR1','VAR2'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **renameMore** ↑

```
obj = renameMore(obj,type,oldNames,newNames)
```

Description:

Makes it possible to rename more variables, datasets and types (only nb_cs).

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variables', but not when the input is 'datasets'.

Caution : This is the same as looping over nb_dataSource.rename, but more efficient.

Caution : * syntax is not supported as is the case for nb_dataSource.rename

Input:

- obj : An object of class nb_dataSource.
- type : Either:
 - 'variables' : To rename a variables
 - 'datasets' : To rename a datasets (The only input that is supported for nb_cell)
 - 'types' : To rename a type (Only nb_cs)
- oldNames : The old variable/dataset/type names, as a cellstr.
- newName : The new variable/dataset/type names, as a cellstr.

Output:

- obj : An nb_dataSource object where the variable(s)/dataname(s)/type(s) of the object given as input is/are renamed.

Examples:

```
obj = nb_cs([22,24;27,28],'Dataset1',{'Exp','Imp'},{'Nor','Swe'})  
obj = renameMore(obj,'dataset',{'Dataset1'},{'tradeBal'});  
obj = renameMore(obj,'variable',{'Nor','Swe'},{'Norway','Sweden'});  
obj = renameMore(obj,'type',{'Exp','Imp'},{'Export','Import'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **reorder** ↑

```
obj = reorder(obj,newOrder,type)
```

Description:

Re-order the variables/types/datasets of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- newOrder : A cellstr with the new order of the variables/types/datasets.
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **round** ↑

```
obj = round(obj,value,types,variables)
```

Description:

Round to closes value. I.e. if value is 0.25 it will round to the closes 0.25. E.g. 0.67 will be rounded to 0.75.

Input:

- obj : A nb_cs object
- value : The rounding value. As a double. Default is 1.
- types : The types to round. Can be empty. Default is to round all types.
- variables : The variables to round. Can be empty. Default is to round all variables.
- pages : A numerical index of the pages you want to keep.

Output:

- obj : A nb_cs object with the rounded numbers.

Written by Kenneth Sæterhagen Paulsen

► **saveDataBase** ↑

```
saveDataBase(obj,varargin)
```

Description:

Save data of the nb_cs object

If no optional input is given the data of the object is save down to xlsx file(s). Each dataset of the object is saved down to a excel spreadsheet with the name of the dataset (Taken from the dataNames property of the object)

Input:

- obj : An object of class nb_cs

Optional input (...'propertyName',PropertyValue,...):

- varargin :

> 'saveName' : The data is saved to a excel worksheet with the same name as the input after 'saveName'. If consisting of more dataset, each page of the data property is saved with the same name as the input after 'saveName' pluss the page number.

> 'ext' :

> 'xlsx' : Default. Save data to excel spreadsheet(s)

> 'matold' : Save the data down to a mat file. The data is saved down as a structure, with the variables as the fieldnames, and the data as its fields. If the data consist of more pages, each field will consist of the same number of pages.

The types of the object is also added to the field 'types' of the saved structure. Which makes it possible to load the .mat field up again to nb_cs object.

See the toStructure method with input old set to 1.

Must be combined with the optional input 'saveName'.

> 'mat' : Save the data down to a mat file. The data is saved down as a structure, with the variables stored in the field 'variables', while the data of the variables will be saved as its fields with generic names ('Var1','Var2' etc). If the data consist of more pages, each field will consist of the same number of pages.

The types of the object is also added to the field 'types' of the saved structure. Which makes it possible to load the .mat field up again to nb_cs object.

See the `toStructure` method with input `old` set to 1.

Must be combined with the optional input
`'saveName'`.

> `'mats'` : The object is saved down as a struct using
the `nb_cs.struct` function.

> `'txt'` : Save the data to .txt file.

> `'append'` :

> 1 : Saves all the datasets (pages of the data) to one
excel spreadsheet, but in seperate worksheets.
(With the names of the dataset, given by `dataNames`
property of the object.)

Works only when `'ext'` input is set as `'xlsx'`. (The
default)

Caution : If saved in this way, it is not possible
to load it up again to a `nb_cs` object

> 0 : The default saving method.

> `'sheets'` : A cellstr with the sheet names to save the datasets/pages
of the object down to. Must match the `dataNames` property.
This option has precedence over `'append'`.

Output:

Saved output in the wanted format.

Examples:

Save data to excel:

```
obj = nb_cs(ones(1,2,2)*2,'test',{'First'},{'Var1','Var2'});
obj.saveDataBase();
obj.saveDataBase('saveName','test','append',1);
```

Save data to .mat file:

```
obj.savDataBase('ext','mat','saveName','test')
```

See also:

[asCell](#), [toStructure](#), [nb_readMat](#), [nb_readExcel](#)

Written by Kenneth S. Paulsen

► **sec ↑**

```
obj = sec(obj)
```

Description:

Secant of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = sec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **secd** ↑

```
obj = secd(obj)
```

Description:

Secant of argument in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = secd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sech** ↑

```
obj = sech(obj)
```

Description:

Hyperbolic secant.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **setInfinite2NaN** ↑

```
obj = setInfinite2NaN(obj)
```

Description:

Set all elements that are isfinite to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setMethodCalls** ↑

```
obj = setMethodCalls(obj,c)
```

Description:

Set all method calls of the object with a cell matrix. The object needs to be updatable.

Caution: To delete method calls use deleteMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.
- c : A cell matrix. See the output of getMethodCalls

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

See also:

[nb_cs.deleteMethodCalls](#), [nb_cs.getMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► setValue ↑

obj = setValue(obj,VarName,Value,Types,pages)

Description:

Set some values of the dataset(s). (Only one variable.)

Input:

- obj : An object of class nb_cs
- VarName : The variable name of the variable you want to set some values of. As a string
- Value : The values you want to assign to a variable. Must be a numerical vector (with the same number of pages as given by pages or as the number of dataset the object consists of.) Must have the same length as the input given by Types. (If this is not provided this input must of same length as the number of existing types of the object)
- Types : A cellstr of the type names to set.
- pages : At which pages you want to set the values of a variable. Must be a numerical index of the pages you want to set.
E.g. if you want to set the values of the 3 first datasets (pages of the data) of the object. And the number of datasets of the object is larger then 3. You can use; 1:3. If empty all pages must be set.

Output:

- obj : An nb_cs object with the added variable

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});
obj = obj.setValue('Var2',3);
obj = obj.setValue('Var2',4,['First'],1);
```

Written by Kenneth S. Paulsen

► **setZero2NaN** ↑

```
obj = setZero2NaN(obj)
```

Description:

Set all elements that are 0 to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **sin** ↑

```
obj = sin(obj)
```

Description:

Sine of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = sin(obj);  
  
Written by Kenneth S. Paulsen  
  
Inherited from superclass NB_DATASOURCE
```

► **sind** ↑

```
obj = sind(obj)
```

Description:

sind(obj) is the sine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sinh** ↑

```
obj = sinh(obj)
```

Description:

sinh(obj) is the hyperbolic sine of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sinh(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE
```

► **skewness** ↑

```
obj = skewness(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the skewness of object. The result will be an object of class nb_cs where all the non-nan values of all the object are being set to their skewness.

Input:

- obj : An object of class nb_cs
- flag : Same as for the function skewness created by MATLAB.
- outputType :
 - > 'double' : Get the skewness values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the skewness values as nb_cs object.
- dimension : The dimension to calculate the skewness over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method
- dimension : The dimension to calculate the skewness over.

Examples:

```
double    = skewness(obj,0,'double');
nb_csObj = skewness(obj,0,'nb_cs');
```

Written by Kenneth S. Paulsen

► **sort** ↑

```
obj = sort(obj,dim,mode,variable)
```

Description:

Sort the nb_cs object in the given dimension

Caution : Sorting does not reorder the dataNames, variables or types!

Input:

- obj : An object of class nb_cs
- dim : The dimension to sort
- mode : 'descend' (default)
 'ascend'
- variable : Give a string with the variable to sort. The rest of the variables will then be reordered accordingly.

 If empty (default), all variables are sorted.

Caution: Only an option for dim == 1

Output:

- obj : An nb_cs object representing the sorted input

Examples:

```
obj = nb_cs([1,2;1 1],'test',{'First','Second'},{'Var1','Var2'});  
obj = sort(obj,1,'ascend')
```

Written by Kenneth S. Paulsen

► **sortProperty** ↑

```
obj = sortProperty(obj,type)
```

Description:

Sort the variables/types/datasets of the object alphabetically.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► sortTypes ↑

```
obj = sortTypes(obj,typesOrder)
```

Description:

Sort the types alphabetically, or reorder them according to typesOrder.

Input:

- obj : An object of class nb_cs
- typesOrder : A cellstr with the wanted order of the types. If empty an alphabetical order is used.

Caution: Must contain all types of the object if not empty.

Output:

- obj : An object of class nb_cs.

Written by Kenneth Sæterhagen Paulsen

► sqrt ↑

```
obj = sqrt(obj)
```

Description:

`sqrt(obj)` is the square root of the elements of `obj`. Complex results are produced for non-positive elements.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sqrt(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **squeeze ↑**

```
obj = squeeze(obj)
```

Description:

Squeezes the different datasets (pages) of the given nb_cs object. It will append the variables in each dataset with the given data name

Input:

- obj : An nb_cs object. If the object has only one dataset (page) this method has nothing to do.

Output:

- obj : An nb_cs object, where all the pages are squeezed together. I.e. all data will be stored in one dataset, and all variable names will get the dataset name appended.

Example:

```
obj = nb_cs(ones(1,1,2),{'b','c'},{'Type'},{'Var1'})
```

```
obj =
```

```
(:,:,1) =
```

```
'Types'    'Var1'  
'Type'     [ 1]
```

```
(:,:,2) =
```

```
'Types'    'Var1'  
'Type'     [ 1]
```

```
sObj = squeeze(obj)
```

```
sObj =
```

```
'Time'    'Var1_b'    'Var1_c'  
'2012'   [ 1]      [ 1]
```

Written by Kenneth Sæterhagen Paulsen

► std ↑

```
obj = std(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the std of each series. The result will be an object of class nb_cs where all the non-nan values of all the object are being set to their std.

The output can also be set to be a double.

Input:

- obj : An object of class nb_cs
 - flag :
 - > 0 : normalises by N-1 (Default)
 - > 1 : normalises by N
- Where N is the sample length.
- outputType :
 - > 'double' : Get the std values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the std values as nb_cs object.
 - dimension : The dimension to calculate the std over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
double = std(obj,0,'double');
nb_csObj = std(obj,0,'nb_cs');
```

Written by Kenneth S. Paulsen

► stopSorting ↑

```
obj = stopSorting(obj)
```

Description:

Stop sorting of variables.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where sorting is turned off.

Example:

```
obj = obj.addPrefix('NEMO.');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **struct** ↑

```
s = struct(obj)
```

Description:

Object to struct.

Input:

- obj : An nb_cs object.

Output:

- s : A structure representing an nb_cs object.

Written by Kenneth Sæterhagen Paulsen

► **structure2Dataset** ↑

```
obj = structure2Dataset(obj,givenStruct,NameOfDataset)
```

Description:

When you give a struct to the constructor of this class all the fields af that struct will be added as a new dataset, but this method add all the fields of the input givenStruct as a variable in one dataset

If you only want to add a dataset from a structure in this way (no other datasets) initialize a empty object, and then use this method.

Caution : The structure must include a field 'types', which must be a cellstr with the added types of the nb_cs object. This cellstr must have the same number length as the length of the data of the other field

Inputs:

- obj : The object itself, could be empty.
- givenStruct : The structure which contains the data of the added variable. Where the fieldnames will be the variables name of the added dataset + plus one field 'types' with the data types of the dataset.
- NameOfDataset : Name of the added dataset. If not provided default name will be used, i.e Database<jj>

Outputs:

- obj : An nb_cs object with the added dataset.

Examples:

```
s      = struct();
s.types = {'First'};
s.var1  = 2;
obj    = nb_cs;
obj    = obj.structure2Dataset(s)

obj =
{'Types'   'var1'
 'First'   [ 2]
```

Written by Kenneth S. Paulsen

► **subsasgn** ↑

```
varargout = subsasgn(obj,s,b)
```

Description:

Makes it possible to do subscripted assignment of the data of an nb_cs object

Input:

- obj : AN object of class nb_cs
- s : The same input as when you do subscripted assignment
one a double matrix
- b : The assign data at the given index s.

Output:

- obj : An nb_cs object where the assign data property is setted.

Examples:

```
obj(1:2) = [2;3];
```

same as

```
obj(1:2,1,1) = [2;3];
```

same as

```
obj.data(1:2,1,1) = [2;3];
```

```
obj(1:2,2,3) = [2;3];
```

Written by Kenneth S. Paulsen

► subsref ↑**Description:**

Makes it possible to do subscripted reference of the data of an nb_cs object. See the examples for more

Uses the method window, just using indexing instead

Input:

- obj : An object of class nb_cs
- s : A structure on have to index the object

Output:

- obj : An nb_cs object indexed as wanted.

Examples:

```

obj = obj(1,2:4,1)

same as

obj = obj(1,2:4)

obj = obj({'Type1','Type2',...})

same as

obj.window({'Type1','Type2',...})

obj = obj({'Type1','Type2',...},{'Var1','Var2',...})

same as

obj.window({'Type1','Type2',...},{'Var1','Var2',...})

obj = obj({'Type1','Type2',...},{'Var1','Var2',...},1:2)

same as

obj.window({'Type1','Type2',...},{'Var1','Var2',...},1:2)

obj = obj('Var1','Var2',...)

same as

obj.window('',',{Var1','Var2',...},1:obj.numberOfDatasets)

```

Written by Kenneth S. Paulsen

► sum ↑

```
obj = sum(obj,dim)
```

Description:

Take the sum over a given dimension of an nb_cs object

Input:

- obj : An object of class nb_cs
- dim : The dimension to take the sum over

Output:

- obj : An nb_cs object representing the sum

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});
obj = sum(obj,2)
obj =
'Types'      'sum'
'First'       [ 4]
```

Written by Kenneth S. Paulsen

► **summary** ↑

```
obj = summary(obj)
```

Description:

Summary of the series of the nb_cs object

Input:

- obj : An object of class nb_cs

Output:

- obj : the summary statistics - min, max, std, var, skewness and kurtosis

Written by Kenneth S. Paulsen

► **tail** ↑

```
tail(obj,nRows,page)
```

Description:

Display the last n rows of a nb_cs object.

Input:

- obj : An nb_cs object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

`nb_cs, window, head`

Written by Per Bjarne Bye

► **tan ↑**

`obj = tan(obj)`

Description:

Take the tangent of the data stored in the `nb_ts`, `nb_cs` or `nb_data` object

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

`obj = tan(obj);`

Written by Kenneth S. Paulsen

Inherited from superclass `NB_DATASOURCE`

► **tand ↑**

`obj = tand(obj)`

Description:

`tand(obj)` is the tangent of the elements of `obj`, expressed in degrees.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = tand(in);  
  
Written by Andreas Haga Raavand  
  
Inherited from superclass NB_DATASOURCE
```

► **tanh** ↑

```
obj = tanh(obj)
```

Description:

`tanh(obj)` is the hyperbolic tangent of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = tanh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **times** ↑

```
obj = times(obj, DB)
```

Description:

Element-wise multiplication (`.*`)

Caution : Will only multiply the data of corresponding variables of the two objects. I.e. variable not found to be in both object will result in series with all values set to nan.

Input:

- `obj` : An object of class `nb_cs`
- `DB` : An object of class `nb_cs`

Output:

- obj : An nb_data object the data results from element-wise multiplication of the data of the input objects.

Examples:

```
obj = obj.*DB;
```

See also:

[nb_cs.mtimes](#), [nb_data.callop](#), [nb_data.callfun](#)

Written by Andreas Haga Raavand

► **toMFile** ↑

```
string = toMFile(obj)
toMFile(obj,filename)
string = toMFile(obj,filename,varName)
```

Description:

Write a .m file to generate the current object.

Input:

- obj : An nb_cs object.
- filename : The filename to write the code to. If empty no file will be written.
- varName : Name of decleared variable by this code. Default is data.

Output:

- string : A cellstr with the .m code to generate the current object.

Written by Kenneth Sæterhagen Paulsen

► **toStructure** ↑

```
retStruct = toStructure(obj)
retStruct = toStructure(obj,old)
```

Description:

Transform the obj to a structure

Input:

- obj : An object of class nb_cs
- old : Indicate if old mat file format is wanted. Default is 0 (false).

Output:

- retStruct : A structure with fieldsnames given by the object variables and field given as the variables data. (Can have more than one page).

Caution: A extra field is also added to save the objects types. (Saved under the field 'types')

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});
s   = obj.toStructure()
s =
    Var1: 2
    Var2: 2
    variables: {'Var1'  'Var2'}
    types: {'First'}
    class: 'nb_cs'
    userData: ''
    localVariables: []
    sorted: 1
```

See also:

[nb_cs.struct](#)

Written by Kenneth S. Paulsen

► **tonb_cell ↑**

nb_cell_DB = tonb_cell(obj)

Description:

Transform from a nb_cs object to a nb_cell object

Input:

- obj : An object of class nb_cs

Output:

- nb_cell_DB : An object of class nb_cell

Examples:

```
nb_cell_DB = obj.tonb_cell();
```

Written by Kenneth S. Paulsen

► **tonb_data ↑**

```
nb_data_DB = tonb_data(obj)
```

Description:

Transform from an nb_cs object to an nb_data object

Caution : This will only succeed if the types can be interpreted as observations.

Input:

- obj : An object of class nb_cs

Output:

- nb_data_DB : An object of class nb_data

Examples:

```
nb_data_DB = obj.tonb_data();
```

Written by Kenneth S. Paulsen

► **tonb_ts ↑**

```
nb_ts_DB = tonb_data(obj)
```

Description:

Transform from a nb_cs object to a nb_ts object

Caution : This will only succeed if the types can be interpreted as dates.

Input:

- obj : An object of class nb_cs

Output:

- nb_data_DB : An object of class nb_ts

Examples:

```
nb_ts_DB = obj.tonb_ts();
```

Written by Kenneth S. Paulsen

► **transpose ↑**

```
obj = transpose(obj)
```

Description:

Take the transpose (.)' of an nb_cs object.

Caution : The former types will be sorted when transposing the object.

Input:

- obj : An object of class nb_cs

Output:

- obj : An nb_cs object which represents the transposed input object

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'})
```

```
obj =
```

```
'Types'    'Var1'    'Var2'  
'First'     [ 2]     [ 2]
```

```
t = obj.'
```

```
t =
```

```
'Types'    'First'  
'Var1'      [ 2]  
'Var2'      [ 2]
```

Written by Kenneth S. Paulsen

► **uminus** ↑

```
obj = uminus(obj)
```

Description:

Unary minus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : A nb_ts, nb_cs or nb_data object where all the data are the unary minus of the input objects data

Examples:

```
obj = -obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **unstruct** ↑

```
obj = nb_cs.unstruct(s)
```

Description:

Reverse of the struct method.

Input:

- s : See the s output of the struct method.

Output:

- obj : An nb_cs object.

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj,warningOff,inGUI)
```

Description:

This method will try to update the data of the nb_ts object.

Caution : It is only possible to update an nb_dataSource object which has updateable links to a FAME database or a full directory (path) to an excel spreadsheet or .mat file or the SMART database.

Caution : If you want to create a link to a specific worksheet of a excel file you must provide the extension!

Caution : All method calls done on the object are preserved.
(There exist some exception; and, or etc.)

Input:

- obj : An object of class nb_dataSource which are updatable.
- warningOff : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'.

Output:

- obj : An object of class nb_dataSource with the data updated. If it is not possible a warning will be given.

Examples:

```
obj = nb_ts(['N:\Matlab\Utvikling\MATLAB_LIB\NEMO\'...
             'Documentation\Examples\example_ts_quarterly']);
obj = obj.update
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► uplus ↑

```
obj = uplus(obj)
```

Description:

Unary plus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where all the data are the unary plus of the input objects data

Examples:

```
obj = +obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► var ↑

```
obj = var(obj,outputType,dimension,varargin)
```

Description:

Calculate the var of object. The result will be an object of class nb_cs where all the non-nan values of all the object are being set to their var.

The output can also be set to be a double or a nb_cs object consisting of the var values of the data.

Input:

- obj : An object of class nb_cs
- outputType :
 - > 'double' : Get the var values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the var values as nb_cs object.
- dimension : The dimension to calculate the var over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more on the output from this method

Examples:

```
double    = var(obj,'double');
nb_csObj = var(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **vertcat** ↑

```
obj = vertcat(a,b,varargin)
```

Description:

Vertical concatenation ([a;b])

Input:

- a : An object of class nb_cs
- b : An object of class nb_cs
- varargin : Optional numbers of objects of class nb_cs

Output:

- a : An nb_cs object where the data from the different objects are appended to each other.

Examples:

Written by Kenneth S. Paulsen

► **window** ↑

```
obj = window(obj,typesWin,variablesWin,pages)
```

Description:

Narrow down the dataset(s) of the nb_cs object

Input:

- obj : An object of class nb_cs
- typesWin : A cellstr array of the types you want to keep of the given object. If empty all the types is kept.
- variablesWin : A cellstr array of the variables you want to keep of the given object. If empty all the

variables is kept.

- pages : A numerical index of the pages you want to keep.
E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger then 3. You can use; 1:3. If empty all pages is kept.

I.e. `obj = obj.window('','','',1:3)`

Or it can be the name of the dataset you want to keep. Then the input must be a string.

I.e. `obj = obj.window('','','','Database1')`

Or it can be a cell array of the datasets names to keep.

I.e `obj = obj.window('','','',{ 'Database1',...,'DataBase2' })`

Output:

- `obj` : An `nb_cs` object where the datasets of the input object are narrowed down to the given window.

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = obj.window({},{'Var1'},1);
```

Written by Kenneth S. Paulsen

► **writeTex** ↑

```
writeTex(obj,filename)  
writeTex(obj,filename,'inputName', inputValue,...)
```

Description:

Writes the object data to a LaTeX table saved to a `.tex` file.

If the object consists of more pages (datasets) more tables will be created.

Input:

- `obj` : An object of class `nb_cs`
- `filename` : The name of the saved `.tex` file. With or without the extension.

Optional input:

See optional inputs to nb_cs.getCode.

Output:

A saved .tex file with the LaTeX table

Examples:

```
obj = nb_cs([2,2,2],'',{'type1'},{'Var1','Var2','Var3'});
obj.writeTex('test')
```

See also:

[nb_cs](#), [nb_cs.getCode](#)

Written by Kenneth SÅ!terhagen Paulsen

► **zeros** ↑

```
obj = nb_cs.zeros()
obj = nb_cs.zeros(types,vars,pages)
```

Description:

Create an nb_cs object with all set to 0.

Input:

- types : Either a cellstr with the types of the nb_cs object, or a scalar with the number of types of the nb_cs object.
- vars : Either a cellstr with the variables of the nb_cs object, or a scalar with the number of variables of the nb_cs object.
- pages : Number of pages of the nb_cs object.

Output:

- obj : An nb_cs object.

Examples:

```
obj = nb_cs.zeros({'Type','Type2'},{'Var1','Var2'});
obj = nb_cs.zeros(2,2);
obj = nb_cs.zeros(2,2,10);
```

See also:

■ nb_data

Go to: [Properties](#) | [Methods](#)

A class representing data with links to the variable names.

Constructor:

```
obj = nb_data(datasets,NameOfDatasets,startObs,variables)
obj = nb_data(datasets,NameOfDatasets,startObs,variables,sorted)
```

Input:

- datasets :

Input can be one of the data types listed below:

- xls(x) : A name of the excel spreadsheet to import.
(With or without extension.)

Caution : If you read a specific worksheet, and
want the object to be updateable
you must provide the extension.

Caution : The first column of the worksheet must start
with 'obs' or 'observations', and the rest
of the column you must provide the
observation number to each row. E.g:

'obs'		'Var1'

1		2.5

2		2.0

- mat : Name(s) of the .mat files to import. (With or
without extension.).

Format of the .mat file:

The .mat file must be saved structure with the
fieldnames as the variable names and the fields
as the data of the variables, as doubles. Plus
it must have a field with name 'startObs' with
the start obs of the data, as an integer.

- double : As double matrix. Each page of the matrix will
be added as separate datasets.

- struct : As a structure of either double matrices. Each field is
added as separate datasets.

You can also give a cell array consisting of one or a
combination of the data types mentioned above. Each cell

will be added as a new dataset.

Extra: Use the method structure2nb_data function to add all the fields of the structure as variables in an nb_data object. (If each field has more page then 1, then each page will be a datasets)

- NameOfDatasets :

Input options will depend on data types listed below:

- xls(x) : A string with the wanted dataset name. Default is the excel file name. If the provided string is a sheet of the read spreadsheet that specific worksheet will be read.

- mat : A string with the wanted dataset name. Default is the .mat file name.

- double : A string with the wanted dataset name. Default is 'Dataset1'.

Caution: When you given double matrices which has more pages then one, either directly or through a struct. Each of the pages will be added as a dataset. The name of this datasets will, if the input NameOfDatasets has the same size as the input datasets, get the name NameOfDatasets{jj}<jj>, where jj is the page number, or else get the name 'Database<jj>'.

- struct : This input has nothing to say. The dataset names will be given by the fieldnames.

- A cell array of the listed types above:

If you give a cell array to the datasets input, this input must be a cell array of strings. If you give a cell array which doesn't have the same size as the cell array given to the datasets input, the datasets which is left gets the name 'Database<jj>', where <jj> stands for this added datasets number.

If you give an empty cell array, i.e. {} all the datasets get the names; 'Database<jj>', where <jj> stands for the added datasets number. Except when the datasets input are given by a cellstr with the excel file names, .mat file names or a FAME path names, then the default dataset names will be set to the same cellstr. Or if some elements of the cell is a struct, then the datasets provided through the struct will get their fieldnames as the dataset names.

- startDate :

The start date of the data. Only needed when you give numerical data as one element of the input datasets (also when numerical data is given through a struct). Default is 1.

```

- variables      :

A cellstr array of the names of the variables.

Needed when the dataset input is:

> Numerical matrix. The number of variables must be of the
same as the size of the data (2. dimension).

> A struct consisting of double matrices.

> When you give a cell array of one of the types mentioned
above.

- sorted        : true or false. Default is true.

Output:

- obj          : An object of class nb_data

Examples:

- xls(x) :

    One excel spreadsheet

    obj = nb_data('test1')

    More excel spreadsheets

    obj = nb_data({'test1','test2',...})

    same as

    obj = nb_data({'test1','test2',...},{'test1','test2',...})

- mat:

    One .mat file

    obj = nb_data('test1')

    More .mat files

    obj = nb_data({'test1','test2',...})

    same as

    obj = nb_data({'test1','test2',...},{'test1','test2',...})

-struct:

    One struct

    > Consisting of double matrices:

    obj = nb_data(struct1,{},1,['Var1','Var2',...])

```

More structs

> Consisting of double matrices:

```
obj = nb_data({struct1,struct2,...},[],1,...  
{'Var1','Var2',...})
```

- double matrix:

One matrix

```
obj = nb_data(double1,'',1,['Var1','Var2',...])
```

```
obj = nb_data(double1,'test1',1,['Var1','Var2',...])
```

More matrices

```
obj = nb_data({double1,double2,...},[],1,...  
{'Var1','Var2',...})
```

```
obj = nb_data({double1,double2,...},{'name1','name2',...},...  
1,['Var1','Var2',...])
```

One matrix with more pages:

```
obj = nb_data(double1,[],1,['Var1','Var2',...])
```

```
obj = nb_data(double1,{'name1','name2',...},1,...  
['Var1','Var2',...])
```

- **data** ↑

The data of the object. As a double or logical.

Inherited from superclass NB_DATASOURCE

- **dataNames** ↑

The names of the different dataset. As a cellstr.

Inherited from superclass NB_DATASOURCE

- **endObs** ↑

The end obs of the data. As an integer.

- **localVariables** ↑

A nb_struct with the local variables of the nb_ts object.
I.e. a field with name 'test' can be reach with the string
input %#test. Only for dates and vintage inputs.

Inherited from superclass NB_DATASOURCE

- **numberOfDatasets** ↑

Number of datasets stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **numberOfObservations** ↑

Number of observation of the data stored
in the object. As an integer.

- **numberOfVariables** ↑

Number of variables stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **startObs** ↑

The start obs of the data. As an integer.

- **userData** ↑

Add user data. Can be of any type.

Inherited from superclass NB_DATASOURCE

- **variables** ↑

Variables of the object. As a cellstr.

Inherited from superclass NB_DATASOURCE

► **abs** ↑

```
obj = abs(obj)
```

Description:

Take the absolute value of each data elements of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = abs(in);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acos** ↑

```
obj = acos(obj)
```

Description:

Take acos of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = acos(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acosd** ↑

```
obj = acosd(obj)
```

Description:

acosd(obj) is the inverse cosine, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acosd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acosh** ↑

```
obj = acosh(obj)
```

Description:

acosh(obj) is the inverse hyperbolic cosine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acosh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acot** ↑

```
obj = acot(obj)
```

Description:

Take acotangent of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = acot(obj);  
  
Written by Kenneth S. Paulsen  
  
Inherited from superclass NB_DATASOURCE
```

► **acotd** ↑

```
obj = acotd(obj)
```

Description:

acotd(obj) is the inverse cotangent, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acotd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acoth** ↑

```
obj = acoth(obj)
```

Description:

acoth(obj) is the inverse hyperbolic cotangent of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acoth(in);  
  
Written by Andreas Haga Raavand  
  
Inherited from superclass NB_DATASOURCE
```

► **acsc** ↑

```
obj = acsc(obj)
```

Description:

Take inverse csc of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = acsc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acscd** ↑

```
obj = acscd(obj)
```

Description:

acscd(obj) is the inverse cosecant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acscd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE
```

► **acsch** ↑

```
obj = acsch(obj)
```

Description:

acsch(obj) is the inverse hyperbolic cosecant of the elements of obj

Input:

```
- obj : An object of class nb_ts, nb_cs or nb_data
```

Output:

```
- obj : An object of class nb_ts, nb_cs or nb_data
```

Examples:

```
out = acsch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **addDataset** ↑

```
obj = addDataset(obj, dataset, NameOfDataset, startObs, variables)
```

Description:

Makes it possible to add one dataset to a existing nb_data object.

Caution : If more than one dataset is added to an object the link to the data source is broken!

Input:

```
- obj : An object of class nb_data
```

```
- dataset : One of the following:
```

```
> A string with the name of excel spreadsheet.  
(With or whitout extension)
```

```

> A string with the name of a .mat file
  (With or whitout extension)

> A numerical matrix.

- NameOfDataset : Must be a string with the dataset name. If not
  given (or given as '') the default name
  Database<jj> is given. Where jj is the number
  of added datasets of the object, including the
  dataset you add with this method.

When fetching from FAME this input could be a
vintage tag. I.e. you could specify the vintage
you want to fetch from FAME of the given
series. If the vintage tag does not exist it
will fetch the last vintage before the given
vintage tag.

- startObs      : Number indicatating the observation number. 1 is
  default

- variables     : A cell array of strings with the names of the
  variables you want to add. Only needed when a
  numerical matrix of data, an tseries object, an
  nb_math_ts object or when data from FAME is
  added to the object.

  Must have the same size as the data you add.
  (Second dimension)

When fetching data from FAME this input decides
which variables to fetch.

```

Output:

- obj : An nb_data object with the added dataset.

Examples:

```

obj = nb_data();
obj = obj.addDataset('excelFileName');
obj = obj.addDataset('excelFileName2','A dataset name');
obj = obj.addDataset('matFileName');

```

See also:

[nb_data](#), [addDatasets](#), [structure2Dataset](#)

Written by Kenneth S. Paulsen

► **addDatasets ↑**

```

obj = addDatasets(obj,datasets,NameOfDatasets,startObs, ...
  variables)

```

Description:

Makes it possible to add more datasets to a existing nb_data object.

Input:

Same input as of the constructor but only cell arrays are supported for the inputs 'datasets' and 'NameOfDatasets'. 'NameOfDatasets' could be given as a empty cell; {};

Output:

- obj : An nb_data object now with the added datasets.

Examples:

See also:

[nb_data](#), [addDataset](#), [structure2Dataset](#)

Written by Kenneth S. Paulsen

► **addPageCopies ↑**

obj = addPageCopies(obj,num)

Description:

Add copies of the data of an object and append it as new datasets of the object. Only possible if an object has only one page.

Input:

- obj : An object of class nb_data
- num : Number of copies to be appended

Output:

- obj : An object of class nb_data with the added copies of the first dataset in the object.

Examples:

```
data = nb_data([2,2;2,2],'',1,{'Var1','Var2'});
data = data.addPageCopies(10);
```

Written by Kenneth S. Paulsen

► **addPages** ↑

```
obj = addPages(obj,DB,varargin)
```

Description:

Add all pages from different nb_data objects.

Caution : This method will break the link to the data source of updateable objects!

Input:

- obj : An object of class nb_data
- DB : An object of class nb_data
- varargin : Optional number of objects of class nb_data

Output:

- obj : The object itself with added datasets from the objects given by varargin.

Be aware: If the added datasets does not contain the same variables or observations, the data of the nb_data object with the tightest window will be expanded automatically to include all the same observations and variables. (the added data will be set as nan)

Examples:

```
obj = obj.addPages(DB);  
obj = obj.addPages(DB1,DB2,DB3);
```

Written by Kenneth S. Paulsen

► **addPostfix** ↑

```
obj = addPostfix(obj,postfix)  
obj = addPostfix(obj,postfix,vars)
```

Description:

Add a postfix to all the variables in the nb_ts, nb_cs or nb_data object, or a a provided variable group.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- postfix : The postfix to add to all the variables of the object. Must be a string
- vars : A cellstr of the variable to add the prefix to. Default is all variable of the object.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data with the postfix added to the variables selected

Examples:

```
obj = obj.addPostfix('_NEW');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **addPrefix ↑**

```
obj = addPrefix(obj,prefix)
obj = addPrefix(obj,prefix,vars)
```

Description:

Add a prefix to all the variables in the nb_ts, nb_cs or nb_data object, or a provided variable group.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- prefix : The prefix to add to all the variables of the object. Must be a string
- vars : A cellstr of the variable to add the prefix to. Default is all variable of the object.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data with a prefix added to the selected variables

Example:

```
obj = obj.addPrefix('NEMO');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **addVariable** ↑

```
obj = addVariable(obj,startObsOfData,Data,Variable)
```

Description:

Add a new variable to a existing nb_data object (including all pages)

Input:

- obj : An object of class nb_data
- startObsOfData : The start observation of the data of the added variable. Must be an integer. Cannot be outside the window of the dates of the object. If empty, 1 is default.
- Data : The data of the added variable. Cannot be outside the window of the data of the object. Must be a double.
- Variable : A string with the added variable name. Cannot be the same as a existing variable. (Then use setValue instead)

Output:

- obj : An object of class nb_data with the added variable

Examples:

```
obj = addVariable(obj,'2012Q1',[2;2;2;2],'newVariable');
```

Written by Kenneth S. Paulsen

► **and** ↑

```
a = and(a,b)
```

Description:

The and operator (&).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the and operator has evaluated all the data elements of the object.
The data will be a logical matrix

Examples:

```
a = a & b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **append ↑**

```
obj = append(obj,DB,method)
```

Description:

Append a nb_data object to another nb_data object.

Caution:

- It is possible to merge datasets with the same variables as long as they represent the same data or have different observation ids.
- If the datasets has different number of datasets and one of the merged objects only consists of one, this object will add as many datasets as needed (copies of the first dataset) so they the one object can append the other.
- In contrast to the vertcat method, this method will keep the first inputs end obs and cut all the shared observations of the appended object.

Input:

- obj : An object of class nb_data
- DB : An object of class nb_data

Output:

- obj : An nb_data object where the datasets from the two nb_data objects are merged

Examples:

```
obj = append(obj,DB)
obj = obj.append(DB)
```

Written by Kenneth S. Paulsen

► **appendFromAnotherPage** ↑

```
obj = appendFromAnotherPage(obj,page)
```

Description:

Append data from another page where the rest has missing data.

Input:

- obj : A nObs1 x nVar x nPages nb_dataSource object.
- page : The page to append data from.

Output:

- obj : A nObs x nVar x nPages nb_dataSource object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **asCell** ↑

```
cellMatrix = asCell(obj,strip)
```

Description:

Return the data of the object as a cell matrix.
(In the dyn_ts format, i.e. looks like a excel spreadsheet.)

Input:

- obj : An object of class nb_data
- strip :
 - 'on' : Strip all observation where all the variables has no value.
 - 'off' : Does not strip all observation where all the variables has no value. Default.

Output:

- `cellMatrix` : The `nb_data` objects data transformed to a cell.

Examples:

```
cellMatrix = obj.asCell();
cellMatrix = obj.asCell('on');
```

Written by Kenneth S. Paulsen

► **asCellForMPRReport ↑**

```
cellMatrix = asCellForMPRReport(obj, roundoff)
```

Description:

Return the data of the object as a cell matrix, which is rounded off to two decimals and striped

Input:

- `obj` : An object of class `nb_data`
- `roundoff` : 1 if you want to round off to 2 decimals, 0 otherwise. 1 is default.

Output:

- `cellMatrix` : The objects data transformed to a cell.

Examples:

```
cellMatrix = obj.asCellForMPRReport();
cellMatrix = obj.asCellForMPRReport(0);
```

See also:

[asCell](#)

Written by Kenneth S. Paulsen

► **asec ↑**

```
obj = asec(obj)
```

Description:

Take inverse sec of the data stored in the `nb_ts`, `nb_cs` or `nb_data` object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Examples:

```
obj = asec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **asecd** ↑

```
obj = asecd(obj)
```

Description:

asecd(obj) is the inverse secant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asecd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asech** ↑

```
obj = asech(obj)
```

Description:

asech(obj) is the inverse hyperbolic secant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asin** ↑

```
obj = asin(obj)
```

Description:

Take inverse sin of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = asin(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **asind** ↑

```
obj = asind(obj)
```

Description:

asind(obj) is the inverse sine, expressed in degrees,
of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asinh** ↑

```
obj = asinh(obj)
```

Description:

asinh(obj) is the inverse hyperbolic sine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asinh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **assignNan** ↑

```
obj = expand(obj,variables,value)
```

Description:

Assign all the nan observation to the value input.

Input:

- obj : An object of class nb_dataSource.
- variables : A char or a cellstr with the variables to assign nan values.
- value : A scalar number.

Output:

- obj : An nb_ts object with expanded timespan

Examples:

```
obj = nb_ts.rand('2012Q1',10,2,3);
obj(1:2,1,:) = nan;
obj = assignNan(obj,'Var1',0)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atan** ↑

```
obj = atan(obj)
```

Description:

Take the inverse tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = atan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atand** ↑

```
obj = atand(obj)
```

Description:

atand(obj) is the inverse tangent, expressed in degrees, of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = atand(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **atanh** ↑

```
obj = atanh(obj)
```

Description:

atanh(obj) is the inverse hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = atanh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **autocorr** ↑

```
obj = autocorr(obj,numLags)
obj = autocorr(obj,numLags,errorBound,alpha)
```

Description:

Compute the sample autocorrelation function (ACF) of all the variables stored in the nb_data object, and return a nb_data object with the results.

Reference:

[1] Box, G. E. P., G. M. Jenkins, and G. C. Reinsel. Time Series Analysis: Forecasting and Control. 3rd edition. Upper Saddle River, NJ: Prentice-Hall, 1994.

Input:

- obj : An object of class nb_data.
Caution : This method does not handle nan or infinite for any of the stored data of the nb_data object!
- numLags : Positive integer indicating the number of lags of the ACF to compute. If empty or missing, the default is to compute the ACF at lags 1. Since ACF is symmetric about lag zero, negative lags are ignored. Must be a scalar.
- errorBound : A string. The data must be stationary. Either:
 - > 'asymptotic' : Using asymptotically derived formulas.
 - > 'bootstrap' : Calculated by estimating the data generating process. And use the fitted model to simulate artificial time-series. Then the error bands are constructed by the wanted percentile.
 - > 'blockbootstrap' : Calculated by blocking the observed series and using these blocks to simulate artificial time-series. Then the error bands are constructed by the wanted percentile.
- alpha : Significance value. As a scalar. Default is 0.05.

Optional inputs:

- 'maxAR' : As an integer. See the nb_arima function. Default is 3.
- 'maxMA' : As an integer. See the nb_arima function. Default is 3.
- 'criterion' : As a string. See the nb_arima function. Default

```
        is 'aicc'.
```

- 'method' : As a string. See the nb_arima function. Default is 'hr'.

Output:

- obj : An nb_data object with the autocorrelations stored in the dataset 'Autocorrelations'.
If the errorbounds are to be calculated they are stored in the datasets 'Error bound (lower)' and 'Error bound (upper)'

Examples:

```
obj = autocorr(obj)
obj = autocorr(obj,10)
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **bkfilter** ↑

```
obj = bkfilter(obj,low,high)
```

Description:

Do band pass filtering of all the dataseries of the object.
(Returns the gap). Will strip nan values when calculating the filter

Input:

- obj : An object of class nb_data
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_data with the band pass filtered data.

Examples:

```
obj = bkfilter(obj,8,32);
obj = obj.bkfilter(8,32);
```

See also:

[bkfilter1s](#)

Written by Kenneth S. Paulsen

► **bkfilter1s** ↑

```
obj = bkfilter1s(obj,low,high)
```

Description:

Do one sided band pass-filtering of all the dataseries of the object. (Returns the gap) Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_data
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_data with the one-sided band pass filtered data.

Examples:

```
obj = obj.bkfilter1s(12,24);
obj = bkfilter1s(obj,12,24);
```

See also:

[bkfilter](#)

Written by Kenneth S. Paulsen

► **breakLink** ↑

```
obj = breakLink(obj)
```

Description:

Break link to source

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth SÃ¶therhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callfun** ↑

```
obj      = callfun(obj,'func',func)
obj      = callfun(obj,another,'func',func)
obj      = callfun(obj,varargin,'func',func)
varargout = callfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the data of the nb.DataSource object(s). The data of the object is normally of class double, but may also be of class logical or nb_distribution. Use nb.DataSource.getClassOfData to find the class of the data of the object.

Input:

- obj : An object of class nb.DataSource.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function @(x)x will be used.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class. nb.DataSource objects are converted to a matrix with elements of class double, logical or nb_distribution.

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb.DataSource object. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```
d      = nb_ts.rand('2012Q1',10,3);
d1     = callfun(d,'func',@sin); % Same as d1 = sin(d) !
d2     = callfun(d,d,'func','plus') % Same as d2 = d + d !
[s1,s2] = callfun(d,'func',@size) % Same as [s1,s2] = size(d)
```

See also:

[nb_data.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callop** ↑

```
obj = callop(obj,another,func)
obj = callop(obj,another,func,type)
```

Description:

Call mathematical operator on the data of the object. In contrast to calling the operator itself on the object, this method does not try to match the same variables from the two inputs, but instead operate in the same way as mathematical operators do on double matrices (bsxfun). The time domain is matched though!

Caution: The following operators are supported:

```
> @plus or 'plus'
> @minus or 'minus'
> @times or 'times'
> @rdivide or 'rdivide'
> @power or 'power'
```

Input:

- obj : An object of class nbDataSource.
- another : An object of class nbDataSource.
- func : One of the above listed functions.
- type : Either:
 - > 'keep' : Keep the variable names of the object with most variables. If they have the same number of variables, they are taken from the first object.
 - > 'rename' : The new variable names represent the operation that has been done to the separate series. So if you divide an object with one series named 'Var1' with another object with one series named 'Var2', the new name will be 'Var1./Var2'. (Default)

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb.DataSource method. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```
d1 = nb_ts(rand(10,1),'''2012Q1',{'Var1'});
d2 = nb_ts(rand(10,1),'''2011Q1',{'Var2'});
d3 = callop(d1,d2,@minus);

d1 = nb_ts(rand(10,1),'''2012Q1',{'Var1'});
d2 = nb_ts(rand(10,2),'''2011Q1',{'Var2','Var3'});
d3 = callop(d1,d2,@minus);
```

See also:

[nb_data.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► callstat ↑

```
obj = callstat(obj,func)
obj = callstat(obj,func,varargin)
```

Description:

Call a in-built or user defined function on the data of the nb.DataSource object(s) that goes from the data of the object have more than one variable to only having one. E.g. when taking the mean over a set of variables.

Input:

- obj : An object of class nb.DataSource.

- func : A function handle (or one line char) that maps a nObs x nVar x nPage double to nObs x 1 x nPage double, or that maps a nObs x nVar x nPage double to nObs x nVar x 1 double.

Optional input:

- 'name' : Set the name of the new variable, as a one line char. Default is to use the str2func on the provided function handle.

- varargin : Optional inputs given as extra inputs to the function func. May be of any class.

Output:

- obj : An object of class nb_dataSource with only one variable.

Examples:

```
d = nb_ts.rand('2012Q1',10,3);
d1 = callstat(d,@(x)mean(x,2),'name','mean')
```

See also:

[nb_data.mean](#), [nb_data.std](#), [nb_data.var](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► ceil ↑

```
obj = ceil(obj)
```

Description:

ceil(obj) rounds the elements of obj to the nearest integers towards infinity.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = ceil(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► conj ↑

```
obj = conj(obj)
```

Description:

conj(obj) is the complex conjugate of the elements of obj.
For a complex element x of obj, conj(x) = REAL(x) - i*IMAG(x).

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = conj(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► corr ↑

```
obj = corr(obj,varargin)
```

Description:

Calculate the correlation of the series of the nb_data object

Caution: Calculates the correlation matrix of the variables of the nb_data object, if no optional inputs are given. If 'lags' is given this function calculates the correlation with the number of wanted lags for each variable with itself. (And only with itself)

Input:

- obj : An object of class nb_data

Optional input ('propertyName',propertyValue):

- 'lags' : An integer with the number of lags you want to calculate the correlation for. (Here for each variable)

Output:

- obj : An nb_cs object with the wanted correlation

Examples:

```
corrMatrix = corr(obj);
corrMatrix = corr(obj,'lags',2);
```

Written by Kenneth S. Paulsen

► **cos** ↑

```
obj = cos(obj)
```

Description:

Take cos of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = cos(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cosd** ↑

```
obj = cosd(obj)
```

Description:

cosd(obj) is the cosine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cosd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cosh** ↑

```
obj = csch(obj)
```

Description:

`cosh(obj)` is the hyperbolic cosine of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **cot** ↑

```
obj = cot(obj)
```

Description:

Take cotangent of the data stored in the `nb_ts`, `nb_cs` or `nb_data` object

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
obj = cot(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass `NB_DATASOURCE`

► **cotd** ↑

```
obj = cotd(obj)
```

Description:

`cotd(obj)` is the cotangent of the elements of `obj`, expressed in degrees.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = cotd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **coth** ↑

```
obj = coth(obj)
```

Description:

`coth(obj)` is the hyperbolic cotangent of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = coth(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **cov** ↑

```
obj = cov(obj,varargin)
```

Description:

Calculate the covariances of the timeseries of the nb_data object

Caution: Calculates the covariance matrix of the variables of the nb_data object, if no optional inputs are given. If 'lags' is given this function calculates the covariance with the number of wanted lags for each variable with itself. (And only with itself)

Input:

- obj : An object of class nb_data

Optional input ('propertyName',propertyValue):

- 'lags' : An integer with the number of lags you want to calculate the covariance for. (Here for each variable)

Output:

- obj : An nb_cs object with the wanted covariances

Examples:

```
covMatrix = cov(obj);
covMatrix = cov(obj,'lags',2);
```

Written by Kenneth S. Paulsen

► **createObsDummy** ↑

```
obj = createObsDummy(obj,nameOfDummy,obs,condition)
```

Description:

Creates and adds a dummy variable to the nb_data object. Will test the conditions given the date provided.

Input:

- obj : An object of class nb_data.

- nameOfDummy : Name of the added dummy variable.

- obs : The obs to test. As an integer.
- condition : The conditions to test.
 - '<' : True before.
 - '>' : True after.
 - '<=' : True before and including.
 - '>=' : False before and including.
 - '==' : True for the given period.
 - '~=': True for all but the given period.

Output:

- obj : An object of class nb_data. (With the added dummy variable)

Examples:

```
obj = nb_ts([1,2;-3,1;-1,3],'',1,['Var1','Var2']);
obj = createObsDummy(obj,'Dummy',2,'>');
```

See also:

[nb_ts](#)

Written by Kenneth Sæterhagen Paulsen

► **createVarDummy** ↑

```
obj = createVarDummy(obj,nameOfDummy,varargin)
```

Description:

Creates and adds a dummy variable to the nb_data object. Will test the conditions given for the variable provided by the testedVariable input.

Input:

- obj : An object of class nb_data.
- nameOfDummy : Name of the added dummy variable.
- varargin : The conditions to test.
 - '<' : Less than. Second input must be a double (scalar), an nb_data object

(if more variables it must be less than all the stored variables) or a string with the variable to test against. The third input must either be '!' or '&' indicating if you want to check that this condition and ('&') or or ('|') the next is satisfied. The and operator(s) will have presedens over the or operator.

- '>' : Greater than. (Or else same as '<')
- '<=' : Less than or equal to. (Or else same as '<')
- '>=' : Less than or equal to. (Or else same as '<')
- '==' : Equal to. (Or else same as '<')
- '~=': Not equal to. (Or else same as '<')

Output:

- obj : An object of class nb_data. (With the added dummy variable)

Examples:

```
obj = nb_data([1,2;-3,1;-1,3],'',1,['Var1','Var2']);  
obj = createVarDummy(obj,'Dummy','Var1','>',0,'&');  
obj = createVarDummy(obj,'Dummy','Var1','>','Var2','&');  
obj = createVarDummy(obj,'D2','Var1','>',0,'|','Var2','<',1,'&');  
obj = createVarDummy(obj,'D2','Var1','>',0,'&','Var2','<',1,'&');
```

[nb_ts](#)

Written by Kenneth Sæterhagen Paulsen

► **createVariable ↑**

```
obj = createVariable(obj,nameOfNewVariable,expression)  
obj = createVariable(obj,nameOfNewVariable,expression,parameters,varargin)
```

Description:

Create variable(s) and add them to the nb_data object dataset(s)

Caution :

- This function only support methods of the class nb_math_ts for the expressions.

Input:

- obj : An object of class nb_data
- nameOfNewVariable : The created variable names as a cell array or a string.
Must have the same size as the 'expressions' input.
- expression : The expressions of how to create the data of all the created variables.
As a cell array or a string.
Must have the same size as the 'nameOfNewVariables' input.
- parameters : A struct with the parameters that can be used in the expressions. Caution: They will be added as series, so you need to use elementwise operators (.*, ./, .^)!

Optional input:

- 'overwrite' : true or false. Set to true to allow for overwriting of variables already in the data of the object. Default is false.
- 'warning' : true or false. Set to true to give warning if expressions fail (instead of error). Will result in series having all nan value, when warning is thrown.

Output:

- obj : An nb_data object with the created variable(s) added.

Examples:

```
obj = obj.createVariable('var3','var1./var2');  
  
obj = obj.createVariable({'var3','var4',...},...  
{'var1./var2','var2./var1',...});
```

Written by Kenneth S. Paulsen

► csc ↑

```
obj = csc(obj)
```

Description:

Take csc of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = csc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cscd** ↑

```
obj = cscd(obj)
```

Description:

cscd(obj) is the cosecant of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cscd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **csch** ↑

```
obj = csch(obj)
```

Description:

`csch(obj)` is the hyperbolic cosecant of the elements of `obj`

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **cumnansum** ↑

`obj = cumnansum(obj)`

Description:

Cumulative sum of the series of the object. Ignoring nan values.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An `nb_ts`, `nb_cs` or `nb_data` object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumnansum(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass `NB_DATASOURCE`

► **cumprod** ↑

`obj = cumprod(obj, dim)`

Description:

Cumulativ product of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ product should be calculated. Default is the first dimension.

Output:

- obj : A nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative product of the old objects 'data' property.

Examples:

```
obj = cumprod(obj);  
obj = cumprod(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumsum** ↑

```
obj = cumsum(obj,dim)
```

Description:

Cumulativ sum of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ sum should be calculated. Default is the first dimension.

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumsum(obj);  
obj = cumsum(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cutAtObs** ↑

```
obj = cutAtObs(obj, endObs)
```

Description:

Cut the series of the variables of the object.

Input:

- obj : An object of class nb_data
- endDates : A nPages x nVars double array.

Output:

- obj : An object of class nb_data

Written by Kenneth S. Paulsen

► **deleteMethodCalls** ↑

```
obj = deleteMethodCalls(obj, c)
```

Description:

Delete some method calls of the object. The object needs to be updatable.

Caution: To set method calls use setMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- sourceNr : The source index to delete the methods from
- methodNrs : A index with the methods to delete.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

See also:

[setMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **deleteVariables** ↑

```
obj = deleteVariables(obj,deletedVar)
```

Description:

Delete variables from the current nb_ts, nb_data or nb_cs object (letter size has something to say)

If some of the variables you specify in deletedVar does not exist in the obj, this will not have anything to say for the obj. (The variables cannot be deleted, because the variables do not exist.)

Input:

- obj : An object of class nb_ts, nb_data or nb_cs
- deletedVar : Must be a char or a cellstr

Delete all the variable names, given in the char array or cellstr array deletedVar, of current the object.

NB! If deletedVar is just one string and include a * as the last letter, this function will delete all the variable names, from the object, that start with the letters which is in front of the * in the string.

i.e. obj = deleteVariables(obj,'DPQ*');

Deletes all the variables in the obj which has variable names starting with 'DPQ'.

If deletedVar is just one string and include a * as the first letter, this function will delete all the variable names, from the object, that include the letters which follows in the string.

i.e. obj = deleteVariables(obj, '*shift');

Deletes all the variables in the obj which has variable names which include 'shift'.

Output:

- obj : A nb_ts, nb_data or nb_cs object with the variables specified in deletedVar deleted.

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});
obj = deleteVariables(obj, {'Var1','Var2'});
obj = deleteVariables(obj, char('Var1','Var2'));
obj = deleteVariables(obj, obj.variables);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **demean** ↑

```
obj = demean(data,dim)
```

Description:

- Demeans data along the dimension you choose.

Input:

- obj : A nb_dataSource object.
- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- obj : A nb_dataSource object.

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATASOURCE

► **deptcat** ↑

```
obj = deptcat(obj,varargin)
```

Description:

Depth concatenation (add pages of different objects) (No short notation)

Be aware: If the added datasets does not contain the same variables or obs, the data of the nb_data object with the tightest window will be expanded automatically to include all the same dates and variables. (the added data will be set as nan)

Input:

- obj : An object of class nb_data
- varargin : Optional number of nb_data objects

Output:

- obj : An object of class nb_ts where all the objects datasets are added into.

Examples:

```
obj = obj.deptcat(DB);  
obj = obj.deptcat(DB,DB2,DB3);
```

See also:

[addPages](#)

Written by Kenneth S. Paulsen

► **detrend** ↑

```
[obj,trendObj] = detrend(obj,method)
```

Description:

Detrending nb_data object.

Input:

- obj : As an nb_data object.
- method : Either {'linear'} or 'mean'.

Output:

- obj : As an nb_data object with the detrended data.

Examples:

```
obj = detrend(obj,'linear');
```

See also:

Written by Kenneth Sæterhagen Paulsen

► **diff** ↑

```
obj = diff(obj)  
obj = diff(obj,lags)  
obj = diff(obj,lags,skipNaN)
```

Description:

Calculate diff, using the formula: $x(t)-x(t-lag)$ of all the series of the nb_data object.

Input:

- obj : An object of class nb_data
- lags : The number of lags in the diff formula, default is 1.
- skipNaN : - 1 : Skip nan while using the diff operator. (E.g. when dealing with working days.)
 - 0 : Do not skip nan values. Default.

Output:

- obj : An nb_data object with the calculated series stored.

Examples:

```
obj = diff(obj);  
obj = diff(obj,4);
```

See also:

[nb_data](#)

Written by Kenneth S. Paulsen

► disp ↑

`disp(obj)`

Description:

Display object (On the commandline)

Input:

- obj : An object of class nb_data

Output:

The dataset displayed on the command, as an excel spreadsheet

Examples:

```
obj (Note without semicolon)
```

Written by Kenneth S. Paulsen

► **double** ↑

```
dataOfObject = double(obj)
```

Description:

Get the data of the object as a double matrix

Caution : If the data of the object is represents as an object of class nb_distribution the mean is returned.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- dataOfObject : The data of the nb_ts, nb_cs or nb_data object

Examples:

```
dataOfObject = double(obj)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **ecdf** ↑

```
obj = ecdf(obj,varargin)
```

Description:

A method for creating an nb_data object with the Empirical (Kaplan-Meier) cumulative distribution function. It utilizes the inbuilt ecdf function to estimate the distribution. See ecdf for more information on the optional inputs for the function.

Input:

- obj : An nb_data object with the data.

Optional input:

- 'recursive' : True or false. If true, the CDF will be estimated recursively. Default is false.
- 'recStart' : Sets the start obs for the recursive estimation. Default is the start obs of the obj + 9 observations. As a scalar integer.
- 'recEnd' : Sets the end obs for the recursive estimation. Default is the end obs of the object. As a scalar integer.
- 'estStart' : Sets the start of the estimation sample. As a scalar integer.

Output:

- obj : A numIter x numVar nb_data object where each observation point contains a nb_distribution object with the estimated parameters of the distribution.

Examples:

```
f = nb_data(randn(100,1),'',1,['v1']);
obj = f.ecdf('recStart',80,'recEnd',100, 'recursive',1);
```

See also:

[nb_data.ksdensity](#)

Written by Kenneth Sæterhagen Paulsen

► **egrowth ↑**

```
obj = egrowth(obj,lag)
```

Description:

Calculate exact growth, using the formula: $(x(t) - x(t-1))/x(t-1)$ of all the timeseries of the nb_data object.

Input:

- obj : An object of class nb_data
- lag : The number of lags in the growth formula, default is 1.

Output:

- obj : An nb_data object with the calculated series stored.

Examples:

```
obj = egrowth(obj);
obj = egrowth(obj,4);
```

See also:

[growth](#)

Written by Kenneth S. Paulsen

► **empty** ↑

```
obj = empty(obj)
```

Description:

Empty the existing nb_data object.

Input:

- obj : An object of class nb_data

Output:

- obj : An empty nb_data object

Examples:

```
obj = empty(obj)
```

Written by Kenneth S. Paulsen

► **epcn** ↑

```
obj = epcn(obj,lag)
```

Description:

Calculate exact percentage growth, using the formula:
100*(x(t) - x(t-1))/x(t-1) of all the timeseries of the nb_data
object.

Input:

- obj : An object of class nb_data

- lag : The number of lags in the growth formula, default is 1.

Output:

- obj : An nb_ts object with the calculated timeseries stored.

Examples:

```
obj = epcn(obj); % period-on-period growth  
obj = epcn(obj,4); % 4-periods growth
```

Written by Kenneth S. Paulsen

► eq ↑

```
a = eq(a,b)
```

Description:

Test if the one object is equal (==) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a == b;  
obj = 2 == b;  
obj = a == 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► estimateDist ↑

```
dist = estimateDist(obj,type)
```

Description:

Estimate distributions of the series in the nb_data object.

Caution : This method strip all nan values.

Input:

- obj : An object of class nb_data.
- type : The type of distribution to estimate. See the 'type' property of the nb_distribution class for the supported types. (Some may not be possible to estimate using 'mle' and/or 'mme'.) Default is 'normal';
 - Caution : If estimator is equal to 'kernel', this input is not used.
 - Caution : If type is set to 'hist', no estimator is used but the returned nb_distribution object instead represent a histogram.
- estimator : Either 'mle' (maximum likelihood), 'mme' (methods of moments) or 'kernel' (normal kernel density estimation). Default is 'mle'.
- dim : The dimension to estimate densities over. Either 1, 2 or 3. Default is 1.
- output : Either 'nb_distribution' (default) or 'nbDataSource'. If 'nbDataSource' is chosen the output will be a nb_data object if dim equal 2 or 3, while it will be a nb_cs object if dim equal 1.

Optional input:

- varargin : Optional input given to the nb_ksdensity function. Please see help for that function.

Output:

- dist : An object of class nb_distribution, nb_data or nb_cs.

See also:

[nb_distribution](#)

Written by Kenneth Sæterhagen Paulsen

► [exp ↑](#)

`obj = exp(obj)`

Description:

Take exp of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = exp(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **expand ↑**

```
obj = expand(obj,newStartDate,newEndDate,type,warning)
```

Description:

Expand the current nb_ts object with more dates and data

Input:

- obj : An object of class nb_data
- newStartDate : The wanted new start obs of the data.
- newEndDate : The wanted new end obs of the data.
- type : Type of the appended data :
 - 'nan' : Expanded data is all nan (default)
 - 'zeros' : Expanded data is all zeros
 - 'ones' : Expanded data is all ones
 - 'rand' : Expanded data is all random numbers
 - 'obs' : Expand the data with first observation (before) or last observation after
- warningOff : Give 'off' to suppress warning if no expansion has taken place. Both 'newStartObs' and 'newEndObs' is inside the window.

Output:

- obj : An nb_data object with expanded span

Examples:

```
obj = expand(obj,1,100);
obj = expand(obj,1,100,'zeros');
```

Written by Kenneth S. Paulsen

► **expandPeriods** ↑

```
obj = expandPeriods(obj,periods,type)
```

Description:

Expand the data of the object by the number of wanted periods.

Input:

- obj : An object of class nb_data.
- periods : The number of periods to expand by. If negative the added periods will be added before the first observation.
- type : Type of the appended data :
 - 'nan' : Expanded data is all nan (default)
 - 'zeros' : Expanded data is all zeros
 - 'ones' : Expanded data is all ones
 - 'rand' : Expanded data is all random numbers
 - 'obs' : Expand the data with first observation (before) or last observation after

Output:

- obj : An object of class nb_data.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

► **expml** ↑

```
obj = expml(obj)
```

Description:

`exp(obj)` is the exponential of the elements of `obj`, `e` to the `obj`.
`expm1(obj)` computes `exp(obj)-1`, compensating for the roundoff in
`exp(obj)`.
(For small real `X`, `expm1(X)` should be approximately `X`, whereas the
computed value of `EXP(X)-1` can be zero or have high relative error.)

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data` where the
data are equal to `e.^obj.data-1`

Examples:

```
obj = expm1(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **extMethod** ↑

```
obj = extMethod(obj,method,variables,postfix,varargin)
```

Description:

This method can call a `nb.DataSource` method on a selected variables, and
merge the result with the old object by adding a postfix to the new
variables.

This method is the same as calling:

```
obj1 = window(obj,'','variables');
method = str2func(method);
obj = method(obj,varargin{:});
obj1 = addPostfix(obj1,method);
obj = merge(obj,obj1);
```

But without replicating the `links` property unnecessary many times!

Caution : If the object is not updateable this will result in the same as
the code above!

Input:

- `obj` : An object of class `nb_ts`, `nb_data` or `nb_cs`
- `method` : A str with the method to call. Must be a method of the
`nb_ts`, `nb_data` or `nb_cs` class that does not change other
dimensions then the second dimension!

- variables : A cellstr with the variables of the object to call the method on. Must be included in the object.
- postfix : A string with the postfix. If empty, the old variables will be replaced by the new ones.

Optional inputs:

These will be the inputs casted to the method except the object itself.

Extra for nb_ts and nb_data:

- '<start>' : The start date/obs of the function evaluation. Given as the second input to the window method call.
- '<end>' : The end date/obs of the function evaluation. Given as the third input to the window method call.

Output:

- obj : A nb_ts, nb_data or nb_cs object

Examples:

```
obj = nb_ts.rand(1,10,3);
obj = extMethod(obj,'lag',{'Var1'},'lag1',1)
```

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **floor** ↑

```
obj = floor(obj)
```

Description:

floor(obj) rounds the data elements of obj to the nearest integers towards minus infinity

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = floor(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE
```

► **fromRise_ts** ↑

```
data = nb_data.fromRise_ts(obj)
```

Description:

Transform from an RISE ts object or a struct of RISE ts objects to a nb_data object.

Input:

- obj : An object of class ts, or a structure of ts objects.

Output:

- data : An nb_data object. Be aware that the time dimension is stripped when using this transformation.

Examples:

```
data = nb_data.fromRise_ts();
```

Written by Kenneth S. Paulsen

► **ge** ↑

```
a = ge(a,b)
```

Description:

Test if the one object is greater than or equal to (\geq) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a >= b;
obj = 2 >= b;
obj = a >= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get the properties of the object

Input:

- obj : An object of class nb_data
- propertyName : Name of the property you want to get:
 - 'data' : The data of the object as a double
 - 'dataNames' : Name of the object datasets, as cellstr array
 - 'endObs' : The end obs of the object as double
 - 'numberOfDatasets' : Number of datasets (pages) of the object. Size of the third dimension
 - 'numberOfObservations' : Number of observations of the object. Size of the first dimension
 - 'numberOfVariables' : Number of variables of the object. Size of the second dimension
 - 'startObs' : The start obs of the object as double
 - 'variables' : The variables of the object, given as a cellstr array
 - 'links' : A structure of the data source links.
 - 'sorted' : true or false
 - 'updateable' : 1 if updateable, 0 otherwise.

Output:

```
propertyValue : The property value of the object for the wanted  
                  property
```

Examples:

```
dataAsDouble = get(obj,'data');  
variables    = get(obj,'variables')
```

Written by Kenneth S. Paulsen

► getClassOfData ↑

```
cl = getClassOfData(obj)
```

Description:

Get the class of the data stored by the object.

Input:

- obj : An object of class nb_dataSource.

Output:

- cl : Name of the class that the data of the object is stored as.

See also:

[nb_data.isDistribution](#), [nb_data.isDouble](#)
[nb_data.isBoolean](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► getCode ↑

```
code = getCode(obj,preamble)  
code = getCode(obj,preamble,'inputName',inputValue,...)
```

Description:

Get the LaTeX code of a table representing the data of the object

If the object consists of more pages (datasets) more tables will be created.

Input:

- obj : An object of class nb_data
- preamble : Give 0 if you don't want to include the preamble in the returned output. Default is to include the preamble, i.e. 1.

Optional input:

- 'caption' : Adds a caption to the table. Must be a string.
- 'combine' : If the nb_data object consist of two or three pages (datasets) this option can be used to combine all the data in one table. Either 1 or 0. Default is 0.
- 'colors' : Set it to 0 if the colored rows of the table should be turned off. Default is 1.
- 'firstRowColor' : A string with the color, e.g. 'blue','white','black','blue!20!white'. Default is 'nbblue'.
- 'fontSize' : Sets the font size of the table. Either:

'Huge', 'huge', 'LARGE', 'Large', 'large',
'normalsize' (default), 'small',
'footnotesize', 'scriptsize','tiny'.

Caution : This option is case sensitive.

- 'justification' : Sets the justification of the caption of the table. Must be a string.

Either 'justified','centering' (default),
'raggedright', 'RaggedRight', 'raggedleft'.

Caution : This option is case sensitive.

- language : Either 'english' (default) or 'norwegian' ('norsk').

- lookUpMatrix :

Sets how the given mnemonics (variable names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';  
 'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
lookUpMatrix = {  
  
 'mnemonics1','englishDescription1','norwegianDescription1';  
 'mnemonics2','englishDescription2','norwegianDescription2'};
```

Be aware : Each of the given description can be multi-lined
char, which will result in multi-line text of the
table.

- 'orientation' : The orientation of the table. Either:
 - > 'horizontal' : The dates as columns
 - > 'vertical' : The types as columns
- 'precision' : Sets the precision of the numbers in the
table. Must be a string. Default is '%3.2f'.
I.e. two decimals.
- 'rotation' : The rotation of the table in LaTeX. Either:
 - > 'sidewaystable' : A sideways table
 - > 'landscape' : Rotate the whole page
 - > '' : No rotation
- 'rowColor1' : Color of every second row of the table
starting from the second row. Same options
as was the case for the 'firstRowColor'
option.
- 'rowColor2' : Color of every second row of the table
starting from the third row. Same options
as was the case for the 'firstRowColor'
option.
- 'rowColor3' : Color of every third row of the table
starting from the fourth row. Only an option
in combination with the 'combine' input set
to 1 and that the nb_ts object has 3 pages.
Same options as was the case for the
'firstRowColor' option.

Output:

- code : A char with the tex code of the table

Examples:

```
obj = nb_data(rand(10,3),'',1,['Var1','Var2','Var3']);  
code = obj.getCode(1)
```

See also:

[nb_data](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **getCreatedVariables ↑**

```
created = getCreatedVariables(obj)
```

Description:

Get a N x 2 table of the variables created using the createVariable method. The first column list the created variables, while the second column list the expressions.

Input:

- obj : An object that is a subclass of nb_dataSource.

Output:

- created : A N x 2 cell array. See description of this method for more.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATASOURCE

► getMethodCalls ↑

```
[s,c] = getMethodCalls(obj)
```

Description:

Get all method calls as a cell matrix. The object needs to be updatable to get a list of methods called on the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.
- c : A cell matrix with a table of the method called on the object and its input. Will return {} if the object is not updatable.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATASOURCE

► getRealEndObs ↑

```
realEndObs = getRealEndObs(obj)
realEndObs = getRealEndObs(obj,type)
```

Description:

Get the real end obs of the nb_data object. I.e the last observation which is not nan or infinite.

Input:

- obj : An object of class nb_data
- type : Either 'any' (default) or 'all'.

Output:

- realEndData : The last observation of the object which is not nan or infinite. As a double

Examples:

```
realEndObs = obj.getRealEndObs();  
realEndObs = obj.getRealEndObs('all');
```

Written by Kenneth S. Paulsen

► **getRealStartObs ↑**

```
realStartObs = getRealStartObs(obj)  
realStartObs = getRealStartObs(obj,format,type)
```

Description:

Get the real start obs of the nb_data object. I.e the first observation which is not nan or infinite.

Input:

- obj : An object of class nb_data
- type : Either 'any' (default) or 'all'.

Output:

- realStartObs : The first observation of the object which is not nan or infinite. As a double

Examples:

```
realStartObs = obj.getRealStartObs();  
realStartObs = obj.getRealStartObs('all');
```

Written by Kenneth S. Paulsen

► **getSource** ↑

```
sourceType = getSource(obj)
sourceType = getSource(obj,type)
```

Description:

Get source type.

Input:

- obj : An object of class nb_dataSource.
- type : Give 'program' to get the general source. Default is to give the specific type of source.

Output:

- sourceType : A one line char with the source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getSourceList** ↑

```
s = getSourceList(obj)
```

Description:

Get the source list of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getVariable** ↑

```
variableData = getVariable(obj,variableName,startObs,endObs, pages)
```

Description:

Get the data of a variable, as a double

Input:

- obj : An object of class nb_data
- variableName : The variable you want the data of. Must be given as a string (name of variable) or a cellstr.
- startObs : Start obs of the return data of the given variable. As an integer
- endObs : End obs of the return data of the given variable. As an integer
- pages : Pages of the return data of the given variable. As a double or logical array, e.e. [1:2] or [1,3,5].

Output:

- variableData : The data of the variable you have given. Return [] if not found.

Examples:

```
variableData = getVariable(obj,'Var1');  
variableData = getVariable(obj,'Var1',1);  
variableData = getVariable(obj,'Var1',1,2);  
variableData = getVariable(obj,'Var1',1,2,[1:3]);
```

Written by Kenneth S. Paulsen

► **growth ↑**

```
obj = growth(obj,lag)
```

Description:

Calculate approx growth, using the formula: $\log(x(t)) - \log(x(t-1))$ of all the series of the nb_data object.

Input:

- obj : An object of class nb_data
- lag : The number of lags in the approx. growth formula, default is 1.

Output:

- obj : An nb_data object with the calculated series stored.

Examples:

```
obj = growth(obj);
obj = growth(obj,4);
```

See also:

[egrowth](#)

Written by Kenneth S. Paulsen

► [gt](#) ↑

```
a = gt(a,b)
```

Description:

Test if the one object is greater then (>) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nbDataSource or a scalar number.
- b : An object of class nbDataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nbDataSource object where the data element are logical.

Examples:

```
obj = a > b;
obj = 2 > b;
obj = a > 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **hasVariable** ↑

```
[ret,location] = hasVariable(obj,variable)
```

Description:

Test if an nb_CS object has a given variable

Input:

- obj : An object of class nb_CS
- variable : The variable name as a string. Can also be a cellstr with more variables.

Output:

- ret : 1 if found otherwise 0
- location : The location of the variable if found. Otherwise [].

Examples:

```
ret = obj.hasVariable('Var1')
[ret,location] = hasVariable(obj,'Var1')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **hdi** ↑

```
obj = hdi(obj,perc)
```

Description:

Calculate the highest density interval (hdi) over the third dimension of the data of the object.

Input:

- obj : An object of class nb_data
- limits : A double with the wanted mass of the hdi of the data. E.g. 0.9, or [0.10,0.20].

Output:

- obj : A nb_data object with the limits of the hdis stored as different pages of the object. See the dataNames property for the ordering.

Be aware that the hdis may not be overlapping!

Written by Kenneth Sætherhagen Paulsen

► **head** ↑

`head(obj,nRows,page)`

Description:

Display the first n rows of a nb_data object.

Input:

- obj : An nb_data object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_data](#), [window](#), [tail](#)

Written by Per Bjarne Bye

► **histcounts** ↑

`obj = histcounts(obj,interval,centered)`

Description:

Order the observation (dim1) into bins using the specified interval

Input:

- obj : An object of class nb_data
- interval : A 1 x nBins double
- centered : A 1 x nBins double with the centered bins value.

Output:

- obj : An object of class nb_data

Examples:

```
obj = nb_data.rand(1,100,4,2);
obj = histcounts(obj,0.1:0.1:1)
obj = histcounts(obj,0.1:0.1:1,0.05:0.1:1)
```

See also:

[nb_histcount](#)

Written by Kenneth Sæterhagen Paulsen

► **histogram** ↑

```
data          = histogram(obj)
[data,plotter] = histogram(obj,M)
```

Description:

Create a histogram of a object containing only one variable and one page!

Input:

- obj : A nb_dataSource object with size N x 1 x 1.
- M : The number of bins of the histogram.

Output:

- data : A nb_cs object with size M x 1 x 1.
- plotter : A nb_graph_cs object with the histogram plotted.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **horzcat** ↑

```
obj = horzcat(a,varargin)
```

Description:

Horizontal concatenation of nb_data objects. ([a,b]) This is only possible if the different objects contain differen variables or have variables with the same values (start and/or end obs can differ). Uses the merge method.

If the start and/or end obs differ, nan values will be appended.

Input:

- a : An object of class nb_data
- varargin : Optional number of nb_data objects

Output:

- obj : An nb_data object with all the variables from the different nb_data object merge into one dataset

Examples:

```
obj = [a,b];
obj = [a,b,c];
```

See also:

[merge](#)

Written by Kenneth S. Paulsen

► **hpfilter** ↑

```
obj = hpfilter(obj,lambda)
```

Description:

Do hp-filtering of all the dataseries of the nb_data object.
(Returns the gap). Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_data
- lambda : The lambda of the hp-filter

Output:

- obj : An nb_data object with the hp-filtered series.

Examples:

```
gap = hpfilter(data,3000);
trend = data-gap;
```

See also:

[hpfilter](#)

► **hpfilter1s** ↑

```
obj = hpfilter1s(obj,lambda)
```

Description:

Do one-sided hp-filtering of all the dataseries of the nb_data object. (Returns the gap). Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_data
- lambda : The lambda of the hp-filter

Output:

- obj : An nb_data object with the hp-filtered timeseries.

Examples:

```
gap = hpfilter1s(data,3000);
trend = data-gap;
```

See also:

[hpfilter](#)

Written by Kenneth S. Paulsen

► **iegrowth** ↑

```
obj = iegrowth(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of exact growth, i.e. the inverse method of the egrowth method of the nb_data class

Input:

- obj : An object of class nb_data
 - InitialValues : A nb_data object with a bigger window than obj, or a scalar or a double with the initial values of the indices. Must be of the same size as the number of variables of the nb_data object. If not provided 100 is default.
- Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.
- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_data object with the indices.

Examples:

```
obj = iegrowth(obj);
obj = iegrowth(obj,100);
obj = iegrowth(obj,[78,89]);
```

See also
`nb_data.egrowth`, `nb_data.igrowth`, `nb_data.growth`

Written by Kenneth S. Paulsen

► **iepcn ↑**

```
obj = iepcn(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of exact percentage growth, i.e. the inverse method of the epcn method of the nb_data class

Input:

- obj : An object of class nb_data
- InitialValues : A nb_data object with a bigger window than obj, or a scalar or a double with the initial values of the indices. Must be of the same size as the number of variables of the nb_data object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input

must be given, and has at least have periods number of rows.

- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_data object with the indicies.

Examples:

```
obj = iepcn(obj);
obj = iepcn(obj,100);
obj = iepcn(obj,[78,89]);
```

See also:

[nb_data.epcn](#)

Written by Kenneth S. Paulsen

► [igrowth ↑](#)

```
obj = igrowth(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of log approx. growth, i.e. the inverse method of the growth method of the nb_data class

Input:

- obj : An object of class nb_data
- InitialValues : A nb_data object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_data object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.

- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_data object with the indicies.

Examples:

```
obj = igrowth(obj);
obj = igrowth(obj,100);
obj = igrowth(obj,[78,89]);
```

See also
nb_data.growth, nb_data.egrowth, nb_data.iegrowth

Written by Kenneth S. Paulsen

► **interpolate** ↑

```
obj = interpolate(obj,method)
```

Description:

Interpolate the data of the nb_data object. Will discard leading and trailing nan values.

Input:

- data : An nb_ts, nb_cs or nb_data object.
- method :
 - 'nearest' : Nearest neighbor interpolation
 - 'linear' : Linear interpolation. Default
 - 'spline' : Piecewise cubic spline interpolation (SPLINE)
 - 'pchip' : Shape-preserving piecewise cubic interpolation
 - 'cubic' : Same as 'pchip'
 - 'v5cubic' : The cubic interpolation from MATLAB 5, which does not extrapolate and uses 'spline' if X is not equally spaced.

Output:

- data : An nb_ts, nb_cs or nb_data object with the interpolated data.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **ipcn** ↑

```
obj = ipcn(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of percentage log approx. growth, i.e. the inverse method of the pcn method of the nb_data class

Input:

- obj : An object of class nb_data
- InitialValues : A nb_data object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_data object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.
- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_data object with the indicies.

Examples:

```
obj = ipcн(obj);
obj = ipcн(obj,100);
obj = ipcн(obj,[78,89]);
```

See also:

[nb_data.pcn](#)

Written by Kenneth S. Paulsen

► **isBoolean ↑**

```
ret = isBoolean(obj)
```

Description:

Check if the data of the nb_dataSource object is of class logical (boolean, i.e. true or false).

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isCrossSectional** ↑

ret = isCrossSectional(obj)

Description:

Test if this object is a cross sectional data object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_cs, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isDistribution** ↑

ret = isDistribution(obj)

Description:

Check if the data of the nb_dataSource object is of class nb_distribution

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isDouble** ↑

```
ret = isDouble(obj)
```

Description:

Check if the data of the nb_dataSource object is of class double (numeric)

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isTimeseries** ↑

```
ret = isTimeseries(obj)
```

Description:

Test if a nb_dataSource object is a time series object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_ts, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isUpdateable** ↑

```
ret = isUpdateable(obj)
```

Description:

Test if this object is updateable.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : 1 if updateable, otherwise 0.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isempty** ↑

ret = isempty(obj)

Description:

Test if a nb_ts, nb_cs or nb_data object is empty. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

ret = isempty(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isfinite** ↑

obj = isfinite(obj)

Description:

Test if each element of a nb_ts, nb_cs or nb_data object is finite.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is finite, otherwise 0.

Examples:

```
obj = isfinite(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isnan** ↑

```
obj = isnan(obj)
```

Description:

Test if each element of an nb_ts, nb_cs or nb_data object is nan.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is nan, otherwise 0.

Examples:

```
obj = isnan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isscalar** ↑

```
ret = isscalar(obj)
```

Description:

Test if a nb_ts, nb_cs or nb_data object is a scalar. Will always return 0, as an object of class nb_ts, nb_cs or nb_data is not a scalar.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : false

Examples:

```
0 = isscalar(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **keepPages** ↑

```
obj = keepPages(obj, pages)
```

Description:

Keep pages of the current nb_ts object

Input:

- obj : An object of class nb_ts
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty a empty nb_ts object is returned.

Can also be a cellstr with the names to keep, or a logical array with length equal to the number of pages (datasets).

Output:

- obj : An nb_ts object with the pages specified in the input are kept.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **keepVariables** ↑

```
obj = keepVariables(obj, keptVar)
```

Description:

Keep variables from the current nb_data object (letter size has something to say)

If some of the variables you specify in keptVar does not exist in the object, this will not have anything to say for the object. (The variables cannot be kept, because the variables do not exist.)

Input:

- obj : An object of class nb_data
- keptVar : Must be a char or a cellstr

Keeps all the variable names, given in the char array or cellstr array keptVar, of current the nb_ts object.

NB! If keptVar is just one string and include a * as the last letter, this function will keep all the variable names, from the DB, that start with the letters which is in front of the * in the string.

i.e. obj = keepVariables(obj,'DPQ*');

Keep all the variables in the obj which has variable names starting with 'DPQ'.

If keptVar is just one string and include a * as the first letter, this function will keep all the variable names, from the DB, that include the letters which follows in the string.

i.e. obj = keepVariables(obj, '*shift');

Keeps all the variables in the obj which has variable names which include 'shift'.

Output:

- obj : An nb_data object with the variables specified in input 'keptVar' kept, all the others are deleted.

Examples:

```
obj = keepVariables(obj, {'Var1','Var2'});  
obj = keepVariables(obj, char('Var1','Var2'));  
obj = keepVariables(obj, DB.variables);
```

Written by Kenneth S. Paulsen

► **ksdensity ↑**

```
obj = ksdensity(obj,varargin)
```

Description:

A method for creating an nb_data object with the estimated kernel density of a sample. It can estimate a single probability density function, as well as recursive estimation.

Input:

- obj : An nb_data object with the data.

Optional input:

- 'recursive' : True or false. If true, the CDF will be estimated recursively. Default is false.
- 'recStart' : Sets the start obs for the recursive estimation. Default is the start obs of the obj + 9 observations. As a scalar integer.
- 'recEnd' : Sets the end obs for the recursive estimation. Default is the end obs of the object. As a scalar integer.
- 'estStart' : Sets the start of the estimation sample. As a scalar integer.
- Rest of the optional input id given to the nb_ksdensity function.

Output:

- obj : A numIter x numVar nb_data object where each observation point contains a nb_distribution object with the estimated parameters of the distribution.

Examples:

```
f = nb_data(randn(100,1),'',1,['v1']);
obj = f.ksdensity('recStart',80,'recEnd',100, 'recursive',1);
```

See also:

[nb_data.ecdf](#)

Written by Kenneth Sæterhagen Paulsen

► **kurtosis** ↑

```
obj = kurtosis(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the kurtosis of each timeseries. The result will be an object of class nb_data where all the non-nan values of all the series are being set to their kurtosis.

The output can also be set to be a double or a nb_cs object consisting of the kurtosis values of the data.

Input:

- obj : An object of class nb_data
- flag : > 0 : normalises by N-1 (Default)
> 1 : normalises by N
 - Where N is the sample length.
- outputType :
 - > 'nb_data' : The result will be an object of class nb_data where all the non-nan values of all the series are being set to their kurtosis.
 - > 'double' : Get the kurtosis values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the kurtosis values as nb_cs object. The kurtosis will be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the kurtosis over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more on the output from this method

Examples:

```
nb_dataObj = kurtosis(obj);
double      = kurtosis(obj,0,'double');
nb_csObj   = kurtosis(obj,0,'nb_cs');
```

Written by Kenneth S. Paulsen

► lag ↑

```
obj = lag(obj,periods,varargin)
```

Description:

Lag the data of the object. The input periods decides for how many periods.

Input:

- obj : An object of class nb_data
- periods : Lag the data with this number of periods. Default is 1 period.

Optional input:

- 'cut' : true (cut sample to fit old sample length) or false (append new observations). Default is true.

Output:

- obj : An nb_data object where the data lagged by number of periods given by the input periods.

Examples:

```
obj = lag(obj,1);
```

Written by Kenneth S. Paulsen

► **lastObservation ↑**

```
obj = lastObservation(obj,number)
```

Description:

Get the last (real) observation(s) of the object.

Input:

- obj : An object of class nb_data.
- number : Number of elements to return. Default is 1, i.e only the last. As a integer.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

► **le** ↑

```
a = le(a,b)
```

Description:

Test if the one object is less than or equal to (\leq) the other object elementwise and return a nbDataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nbDataSource or a scalar number.
- b : An object of class nbDataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nbDataSource object where the data element are logical.

Examples:

```
obj = a <= b;  
obj = 2 <= b;  
obj = a <= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **lead** ↑

```
obj = lead(obj,periods,varargin)
```

Description:

Lead the data of the object. The input periods decides for how many periods.

Input:

- obj : An object of class nb_data
- periods : Lead the data with this number of periods. Default is 1 period.

Optional input:

- 'cut' : true (cut sample to fit old sample length) or false (append new observations at the start). Default is true.

Output:

- obj : A nb_data object where the data leaded by number of periods given by the input periods.

Examples:

```
obj = lead(obj,1);
```

Written by Kenneth S. Paulsen

► **log ↑**

```
obj = log(obj)
```

Description:

Take log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on logs.

Examples:

```
obj = log(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **log10 ↑**

```
obj = log10(obj)
```

Description:

Take the common (base 10) log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on (base 10) logs.

Examples:

```
obj = log10(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► log1p ↑

```
obj = log1p(obj)
```

Description:

log1p(obj) computes $\text{LOG}(1+xi)$, where xi are the elements of obj. Complex results are produced if $xi < -1$.

For small real xi, log1p(xi) should be approximately xi, whereas the computed value of $\text{LOG}(1+xi)$ can be zero or have high relative error.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = log1p(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► log2 ↑

```
obj = log2(obj)
```

Description:

`log2(obj)` is the base 2 logarithm of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
obj = log2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► lt ↑

```
a = lt(a,b)
```

Description:

Test if the one object is less than (`<`) the other object elemetswise and return a `nb_dataSource` object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- `a` : An object of class `nb_dataSource` or a scalar number.
- `b` : An object of class `nb_dataSource`, but must be of same subclass as `a`, or a scalar number.

Output:

- `a` : An `nb_dataSource` object where the data element are logical.

Examples:

```
obj = a < b;
obj = 2 < b;
obj = a < 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass `NB_DATASOURCE`

► **map2Distribution** ↑

```
obj = map2Distribution(obj,dist)
obj = map2Distribution(obj,dist,varargin)
```

Description:

Map observation to the distributions given by dist.

The current distribution of the data is estimated using a kernel density estimator. The data must be strongly stationary. I.e. the unknown distribution from where the data has been drawn must not depend on time.

Input:

- obj : An object of class nb_ts.
- dist : An object of class nb_distribution with size 1 x
numberOfVariables.

Optional inputs:

- See the optional inputs of the nb_distribution.estimate function.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

► **mavg** ↑

```
obj = mavg(obj,backward,forward,flag)
```

Description:

Taking moving average of all the series of the nb_data object

Input:

- obj : An object of class nb_data
- backward : Number of periods backward in time to calculate the moving average
- forward : Number of periods forward in time to calculate the moving average
- flag : If set to true the periods that does not have enough observations forward or backward should be set to nan. Default is false.

Output:

- obj : An nb_data object storing the calculated moving average

Examples:

```
data = nb_data(rand(50,2)*3,'',1,['Var1','Var2']);  
  
mAvg10 = mavg(data,9,0); % (10 year moving average)
```

Written by Kenneth S. Paulsen

► max ↑

```
obj = max(obj,outputType,dimension)
```

Description:

Calculate the max of each timeseries. The result will be an object of class nb_data where all the non-nan values of all the timeseries are being set to their max.

The output can also be set to be a double or a nb_cs object consisting of the max values of the data.

Input:

- obj : An object of class nb_data
- outputType :
 - > 'nb_data' : The result will be an object of class nb_data where all the non-nan values of all the series are being set to their max.
 - > 'double' : Get the max values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the max values as nb_cs object. The max will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the max over.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
nb_dataObj = max(obj);
double    = max(obj,'double');
nb_csObj = max(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **mean ↑**

```
obj = mean(obj,outputType,dimension,varargin)
```

Description:

Calculate the mean of each series. The result will be an object of class nb_data where all the non-nan values of all the timeseries are being set to their mean.

The output can also be set to be a double or a nb_cs object consisting of the mean values of the data.

Input:

- obj : An object of class nb_data
- outputType :
 - > 'nb_data' : The result will be an object of class nb_data where all the non-nan values of all the series are being set to their mean.
 - > 'double' : Get the mean values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the mean values as nb_cs object. The mean will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the mean over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
nb_tsObj = mean(obj);
double    = mean(obj,'double');
nb_csObj = mean(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **meanDiff** ↑

```
obj = meanDiff(obj)
```

Description:

Construct level variables that has the mean change for each period.

Input:

- obj : An object of class nb_data

Output:

- obj : A nb_data object where the data has been updated.

Written by Kenneth S. Paulsen

► **meanGrowth** ↑

```
obj = meanGrowth(obj)
```

Description:

Construct level variables that has the mean growth for each period.

Input:

- obj : An object of class nb_data

Output:

- obj : A nb_data object where the data has been updated.

Written by Kenneth S. Paulsen

► **median** ↑

```
obj = median(obj,outputType,dimension,varargin)
```

Description:

Calculate the median of each series. The result will be an object of class nb_data where all the non-nan values of all the series are being set to their median.

The output can also be set to be a double or a nb_cs object consisting of the median values of the data.

Input:

- obj : An object of class nb_data
- outputType :
 - > 'nb_data' : The result will be an object of class nb_data where all the non-nan values of all the series are being set to their median.
 - > 'double' : Get the median values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the median values as nb_cs object. The median will be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the median over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more on the output from this method

Examples:

```
nb_dataObj = median(obj);
double      = median(obj,'double');
nb_csObj   = median(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **merge ↑**

```
obj = merge(obj,DB)
```

Description:

Merge two nb_data objects

Caution:

- It is possible to merge datasets with the same variables as long as they represent the same data or have different spans.
- If the datasets has different number of datasets and one of the merged objects only consists of one, this object will add as many datasets as needed (copies of the first dataset) so they can merge.

Input:

- obj : An object of class nb_data
- DB : An object of class nb_data

Output:

- obj : An nb_data object where the datasets from the two nb_data objects are merged

Examples:

```
obj = merge(obj,DB)
obj = obj.merge(DB)
```

See also:

[horzcat](#), [vertcat](#)

Written by Kenneth S. Paulsen

► **merge2Series** ↑

```
obj = merge2Series(obj,var1,var2,new,method,varargin)
```

Description:

Merge 2 series. The var2 series is appended to the var1 series from where it is ending.

Input:

- obj : An object of class nb_dataSource.
- var1 : A one line char with the name of the base series.
- var2 : A one line char with the name of the appended series.
- new : Name of the new variable. If given as empty there will not be created a new series, but instead the var1 variable will be set to the new merged series. Default is empty.
- method : Either 'level', 'diff', 'growth', 'leveldiff' or 'levelgrowth'. Default is 'level'. For the cases 'level', 'diff' or 'growth' it is assumed the both series are in levels. 'leveldiff' assumes the first series is in level and the second in nLags-difference. 'levelgrowth' assumes the first series is in level and the second in growth rates over nLags periods, i.e. $(x(t) - x(t-nLags))/x(t-nLags)$.

Optional input:

- 'nLags' : The number of lages used for the methods 'diff' and 'growth'. Default is 1.
- 'date' : The date from where to use the second variable. Either a date as string or a nb_date object. If empty the merge will take place where the first variable end + 1 period.

Output:

- obj : An object of class nb_dataSource.

Examples:

```

obj           = nb_ts.rand('2012Q1',10,2,3);
obj(end-1:end,1,:) = nan;

obj1 = merge2Series(obj,'Var1','Var2','Var3')
obj2 = merge2Series(obj,'Var1','Var2')
obj3 = merge2Series(obj,'Var1','Var2','','diff','nLags',1)
obj4 = merge2Series(obj,'Var1','Var2','','diff','nLags',4)
obj5 = merge2Series(obj,'Var1','Var2','','level','date','2014Q1')

```

See also:

[nb_ts.merge](#), [nb_data.merge](#), [nb_cs.merge](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► [min ↑](#)

obj = min(obj,outputType,dimension)

Description:

Calculate the min of each series. The result will be an object of class nb_data where all the non-nan values of all the timeseries are being set to their min.

The output can also be set to be a double or a nb_cs object consisting of the min values of the data.

Input:

- obj : An object of class nb_data
- outputType :
 - > 'nb_data' : The result will be an object of class nb_data where all the non-nan values of all the series are being set to their min.
 - > 'double' : Get the min values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the min values as nb_cs object. The min will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the min over.

Output:

- obj : See the input outputType for more on the output from this method

Examples:

```
nb_dataObj = min(obj);
double      = min(obj,'double');
nb_csObj   = min(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► minus ↑

```
obj = minus(obj,DBOrNum)
```

Description:

Binary subtraction (-).

Caution: Will subtract the data of the corresponding variables from the two objects. All the variables not in common will result in series with nan values.

When one of the inputs are a scalar this function will subtract each element of the data by this number or each element of the data will be subtracted from the scalar.

Input:

- a : An object of class nb_data or a scalar
- b : An object of class nb_data or a scalar

Output:

- obj : An nb_data object where all the variables are from the first object are subtracted from the other.

Or

An nb_data object where the scalar are subtracted from all the elements of the input object

Or

An nb_data object where all the elements of the input object are subtracted from scalar.

Examples:

```
obj = obj - anotherObj;  
obj = obj - 2;  
obj = 2 - obj;
```

See also:

[nb_data.plus](#), [nb_data.callop](#), [nb_data.callfun](#)

Written by Kenneth S. Paulsen

► **mldivide** ↑

```
obj = mldivide(a,b)
```

Description:

Matrix left division (\). See examples.

Input:

- a : An object of class nb_data.
- b : A scalar or a string.

Output:

- obj : An nb_data object.

Examples:

```
obj = nb_data.rand(1,10,3)
obj = obj\1      % 1/obj
obj = obj\'1'    % '1'/obj
obj = obj\'Var1' % 'Var1'/obj
```

See also:

[nb_data.mrdivide](#), [nb_data.rdivide](#)

Written by Kenneth S. Paulsen

► **mode ↑**

```
obj = mode(obj,outputType,dimension,varargin)
```

Description:

Calculate the mode of each series. The result will be an object of class nb_data where all the non-nan values of all the series are being set to their mode.

The output can also be set to be a double or a nb_cs object consisting of the mode values of the data.

Input:

- obj : An object of class nb_data
- outputType :
 - > 'nb_data' : The result will be an object of class nb_data where all the non-nan values of all the series are being set to their mode. Default
 - > 'double' : Get the mode values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the mode values as nb_cs object. The mode will when this option is used only be

calculated over the number of observations.
(I.e. dimension set to 1.)

- dimension : The dimension to calculate the mode over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from
this method

Examples:

```
nb_dataObj = mode(obj);
double      = mode(obj,'double');
nb_csObj   = mode(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **mpower** ↑

```
obj = mpower(a,b)
```

Description:

Matrix power (^). Defined when raised by a scalar, a string
which either represent a variable or observation.

Input:

- a : An object of class nb_data
- b : A scalar or a string.

Output:

- obj : An nb_data object.

Examples:

```
obj  = nb_data.rand(1,10,2)
obj1 = obj^'1'
obj2 = obj^'Var1'
obj3 = obj^1
```

See also:

`nb_data.power`

Written by Kenneth S. Paulsen

► **mrdivide** ↑

`obj = mrdivide(a,b)`

Description:

Matrix right division (/). See examples.

Input:

- `a` : An object of class `nb_data`, a scalar number or a string representing a variable name or the observation number.
- `b` : An object of class `nb_data`, a scalar number or a string representing a variable name or the observation number.

Output:

- `obj` : An `nb_data` object.

Examples:

```
obj  = nb_data.rand(1,10,3)
obj1 = obj/1
obj2 = obj/'1'
obj3 = obj/'Var1'
obj4 = 1/obj
obj5 = '1'/obj
obj6 = 'Var1'/obj
```

See also:

`nb_data.mldivide`, `nb_data.rdivide`

Written by Kenneth S. Paulsen

► **mstd** ↑

`obj = mstd(obj,backward,forward)`

Description:

Taking moving standard deviation of all the series of the `nb_data` class

Input:

- obj : An object of class nb_data
- backward : Number of periods backward in time to calculate the moving std
- forward : Number of periods forward in time to calculate the moving std

Output:

- obj : An nb_data object storing the calculated moving standard deviation

Examples:

```
data = nb_data(rand(50,2)*3,'',1,['Var1','Var2']);  
  
mstd10 = mstd(data,9,0); % (10 year moving std)
```

Written by Kenneth S. Paulsen

► mtimes ↑

```
obj = mtimes(obj,Num)
```

Description:

Matrix multiplication (*) Defined for multiplication with a constant, a string which either represent a variable or obs.

Input:

- obj : An object of class nb_data or scalar
- b : An object of class nb_data or a scalar or a string.

Output:

- obj : An nb_data object where the number (date or variable as a vector) is multiplied with all the elements of the input objects data

Examples:

```
obj = 2*obj;  
obj = obj*2;  
obj = obj*'1'  
obj = obj*'Var1'
```

See also:

[nb_data.times](#)

Written by Kenneth S. Paulsen

► **nan** ↑

```
obj = nb_data.nan()
obj = nb_data.nan(start,obs,vars,pages,sorted)
```

Description:

Create an nb_data object with all data set to nan.

Input:

- start : The start obs of the created nb_data object.
- obs : The number of observation of the created nb_data object.
- vars : Either a cellstr with the variables of the nb_data object, or a scalar with the number of variables of the nb_data object.
- pages : Number of pages of the nb_data object.
- sorted : true or false. Default is true.

Output:

- obj : An nb_data object.

Examples:

```
obj = nb_data.nan(1,10,{'Var1','Var2'});
obj = nb_data.nan(1,2,2);
obj = nb_data.nan(1,2,2,10);
```

See also:

[nb_data](#)

Written by Kenneth Sæterhagen Paulsen

► **nan2var** ↑

```
obj = nan2var(obj,testedVariables,assignVariable)
```

Input:

- obj : An object of class nb_data
- testedVariables : A cellstr with the variables you are setting equal to the assignVariable for the nan values found.
- assignVariable : A string with the name of the variable you are assigning the found nan values.

Output:

- obj : An nb_data object where all the nan values of the variables in the testedVariables input is set to the matching value of the variable given by the assignVariable input.

Examples:

```
obj = nb_data([1,2;nan,1;nan,3],'',1,{'Var1','Var2'});  
nan2var(obj,'Var1','Var2')
```

```
ans =
```

'Time'	'Var1'	'Var2'
'2012'	[1]	[2]
'2013'	[1]	[1]
'2014'	[3]	[3]

```
Written by Kenneth S. Paulsen
```

► ne ↑

```
a = ne(a,b)
```

Description:

Test if the one object is not equal to ($\sim=$) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a ~= b;  
obj = 2 ~= b;  
obj = a ~= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **not ↑**

```
a = not(a)
```

Description:

The not operator (~) .

Input:

- a : An object of class nb_dataSource.

Output:

- a : An object of class nb_dataSource. Where the not operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

```
a = ~a;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **objSize ↑**

```
varargout = objSize(obj,dim)
```

Description:

Return the size(s) of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : - 1 : Number of observations
- 2 : Number of variables
- 3 : Number of datasets (pages)

Output:

- varargout : See the examples below

Examples:

```
dim = objSize(obj)
```

Where dim is 1 x 2 double where the first element is the number of observations/types and the second element is the number of variables

```
[dim1, dim2] = objSize(obj)
```

```
[dim1, dim2, dim3] = objSize(obj)
```

```
dim1 = objSize(obj,1)
dim2 = objSize(obj,2)
dim3 = objSize(obj,3)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **observations** ↑

```
obs = observations(obj,type)
```

Description:

Get all the observations of the nb_data object

Input:

- obj : An object of class nb_data
- type : A string. Either 'double' (default) or 'cellstr'.

Output:

- obs : Either a double or cellstr.

See also:

[nb_data](#)

► **ones** ↑

```
obj = nb_data.ones()  
obj = nb_data.ones(start,obs,vars,sorted)
```

Description:

Create an nb_data object with all data set to 1.

Input:

- start : The start obs of the created nb_data object. As an integer.
- obs : The number of observation of the created nb_data object.
- vars : Either a cellstr with the variables of the nb_data object, or a scalar with the number of variables of the nb_data object.
- pages : Number of pages of the nb_data object.
- sorted : true or false. Default is true.

Output:

- obj : An nb_data object.

Examples:

```
obj = nb_data.ones(1,10,['Var1','Var2']);  
obj = nb_data.ones(1,2,2);  
obj = nb_data.ones(1,2,2,10);
```

See also:

[nb_data](#)

► **or** ↑

```
a = or(a,b)
```

Description:

The and operator (|).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the or operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

a = a | b;

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **packing ↑**

obj = packing(obj,packages,varargin)

Description:

Package variables by applying the wanted function. Default is summin (sum).

Input:

- obj : An object of class nb_ts.
- packages : A 2 x N cell matrix with groups of variables and the names of the groups. If you have not listed a variable it will be grouped in a group called 'Rest' (as long as 'includeRest' is not set to false).

Must be given in the following format:

```
{'group_name_1','...','group_name_N';
 name_1      ,...,name_N}
```

Where name_x must be a string with a name of the variable or a cellstr array with the variable names. E.g 'Var1' or {'Var1','Var2'}.

Optional inputs:

- 'includeRest' : Give false to not include the 'Rest' variable, which will represent all the variable that has not been packed.
- 'func' : Either a function_handle or a one line char with the name of the function to use. The first input to this function is a nObs x nVar double, the second is the dimension (which is always 2). Examples; 'sum', 'prod', @sum or @prod.

Output:

- obj : A object of class nb_ts.

Examples:

```
data      = nb_ts.rand('2012Q1',10,4);
packages = {'group1','group2';
            {'Var1','Var2'},{'Var3'}};

dataP1 = packing(data,packages)
dataP2 = packing(data,packages,'includeRest',false)
dataP3 = packing(data,packages,'func',@prod)
```

See also:

[nb_ts.createVariable](#), [nb_data.createVariable](#), [nb_cs.createVariable](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **parcorr ↑**

```
obj = parcorr(obj,numLags)
obj = parcorr(obj,numLags,errorBound,alpha)
```

Description:

Compute the sample partial autocorrelation function (PACF) of all the variables stored in the nb_data object, and return a nb_data object with the results.

Reference:

[1] Box, G. E. P., G. M. Jenkins, and G. C. Reinsel. Time Series Analysis: Forecasting and Control. 3rd edition. Upper Saddle River, NJ: Prentice-Hall, 1994.

Input:

- obj : An object of class nb_data.

```

Caution : This method does not handle nan or
           infinite for any of the stored data
           of the nb_data object!

- numLags      : Positive integer indicating the number of lags
                  of the PACF to compute. If empty or missing, the
                  default is to compute the PACF at lags 1.
                  Since PACF is symmetric about lag zero, negative
                  lags are ignored. Must be a scalar.

- errorBound   : A string. The data must be stationary. Either:

    > ''          : No errorbounds calculated.

    > 'asymtotic' : Using asymptotically derived
                     formulas.

    > 'bootstrap'  : Calculated by estimating the
                     data generating process. And
                     use the fitted model to
                     simulate artificial
                     time-series. Then the error
                     bands are constructed by
                     the wanted percentile.

    > 'blockbootstrap' : Calculated by blocking the
                        observed series and using
                        these blocks to simulate
                        artificial time-series. Then
                        the error bands are
                        constructed by the wanted
                        percentile.

- alpha        : Significance value. As a scalar. Default is 0.05.

```

Optional inputs:

- 'maxAR' : As an integer. See the nb_arima function. Default is 3.
- 'maxMA' : As an integer. See the nb_arima function. Default is 3.
- 'criterion' : As a string. See the nb_arima function. Default is 'aicc'.
- 'method' : As a string. See the nb_arima function. Default is 'hr'.

Output:

- obj : An nb_data object with the partial autocorrelations
 stored in the dataset 'Autocorrelations'.

 If the errorbounds are to be calculated they are stored
 in the datasets 'Error bound (lower)' and 'Error bound
 (upper)'

Examples:

```
obj = parcorr(obj)
obj = parcorr(obj,10)
```

See also:

[nb_data](#), [nb_cs](#), [corr](#), [nb_parcorr](#)

Written by Kenneth Sæterhagen Paulsen

► **pca** ↑

```
F = pca(obj)
[F,LAMBDA,R,varF,expl,c,sigma,e,Z] = pca(obj,r,method,varargin)
```

Description:

Principal Component Analysis of the data of the object.

Input:

- obj : An object of class nb_data.
- r : The number of principal component. If empty this number will be found by the Bai and Ng (2002) test, see the optional option crit below, i.e choose the CT part of the selection criterion; $\log(V(ii,F)) + CT$. Where;
 $V(ii,F) = \sum(\text{diag}(e_{ii}' * e_{ii}/T))/ii$
and e_{ii} is the residual when ii factors are used
- method : Either 'svd' or 'eig'. Default is 'svd'.
 - > 'svd' : Uses single value deomposition to construct the principal components. This is the numerically best way, as the 'eig' method could be very unprecise!
 - > 'eig' : Uses the eigenvalue decomposition approach instead

Optional inputs:

- 'crit' : You can choose between the follwing selection criterion
 - > 1: $\log(NT/NT1)*ii*NT1/NT;$
 - > 2: $(NT1/NT)*\log(\min([N;T]))*ii;$
 - > 3: $ii*\log(GCT)/GCT;$
 - > 4: $2*ii/T;$

```

> 5: log(T)*ii/T;
> 6: 2*ii*NT1/NT;
> 7: log(NT)*ii*NT1/NT; (default)

where NT1 = N + T, GCT = min(N,T), NT = N*T and ii = 1:rMax

- 'rMax' : The maximal number of factors to test for. Must be less than or equal to N. Default is N.

- 'trans' : Give 'demean' if you want to demean the data in the matrix X. Default. Give 'standardize' if you want to standardise the data in the matrix X. Give 'none' to drop any kind of transformation of the data in the matrix X.

Caution: To get back X when 'demean' is given you need to add the constant terms in c. I.e;

X = c(ones(T,1),1) + F*LAMBDA + e, e ~ N(0,R) (1*)

To get back X when 'standardise' you need to add the constant term and multiply with sigma. I.e.

X = c(ones(T,1),:) + F*LAMBDA.*sigma(ones(T,1),:) +
eps, eps ~ N(0,R*) (1*)

Be aware that the eps differ from e, as e is the residual from the standardised regression.

'output' : A string with the wanted output. Either 'F', 'LAMBDA', 'R', 'varF', 'expl', 'c', 'sigma', 'e'. See below for the matching output.

Caution: If provided it will be the only output from this function. I.e. return as F.

```

Output:

- F : The principal component, as a nb_data object.
- LAMBDA : The estimated loadings, as a nb_cs object
- R : The covariance matrix of the residual in (1), as a nb_cs object.
- varF : As a nb_cs object. Each column will be the variance of the corresponding column of F.
- expl : The percentage of the total variance explained by each principal component. As a 1 x r nb_cs object
- c : Constant in the factor equation. nb_cs object with size 1 x nvar.
- sigma : See 'trans'. nb_cs object with size 1 x nvar.
- e : Residual of the equation (1) above. As a nb_data object.

- Z : Normalized (and rebalanced) version of X.

See also:

[nb_pca](#)

Written by Kenneth Sæterhagen Paulsen

► **pcn** ↑

obj = pcn(obj,lag)

Description:

Calculate log approximated percentage growth. Using the formula
 $(\log(t+lag) - \log(t)) * 100$

Input:

- obj : An object of class nb_data
- lag : The number of lags. Default is 1.

Output:

- obj : An nb_data object with the log approximated percentage growth data stored.

Examples:

```
obj = pcn(obj); % period-on-period log approx. growth
obj = pcn(obj,4); % 4-periods log approx. growth
```

See also:

[growth](#), [egrowth](#), [ipcn](#)

Written by Kenneth S. Paulsen

► **percentiles** ↑

obj = percentiles(obj,perc)

Description:

Take the percentile over the third dimension of the data of the object.

Input:

- obj : An object of class nb_data
- perc : A double with the wanted percentiles of the data. E.g. 0.5 (median), or [0.05,0.15,0.25,0.35,0.5,0.65,0.75,0.85,0.95].

Output:

- obj : A nb_data object with the percentiles stored as different pages of the object. See the dataNames property for the ordering.

Written by Kenneth Sæterhagen Paulsen

► permute ↑

```
obj = permute(obj,variables)
```

Description:

Switch the second and third dimension of the nb_ts, nb_cs or nb_data object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- variables : A cellstr with size 1 x numberOfDatasets. Default is to use dataNames property. I.e. when not provided or if empty.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► plot ↑

```
plot(obj,varargin)
plotter = plot(obj,varargin)
```

Description:

Plot the data of the nb_dataSource object.

Caution: If the data of the object is of class nb_distribution this method will redirect to plotDist.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

- plotType : A string with either:

> 'graph' (Default)

> 'graphSubPlots'

> 'graphInfoStruct'

The name of the graphing method of the class nb_graph_ts, nb_graph_cs or nb_graph_data.

Caution: This is an optional input. If not given it is assumed that the optional input pairs are starting from the second input to this function.

- varargin : Same as the input to the method set() of the nb_graph_ts, nb_graph_cs or nb_graph_data class.

I.e. ..., 'inputName', inputValue, ...

Caution: If the data of the object is of class nb_distribution, see nb_ts.plotDist for the optional input pairs supported.

Output:

Plotted output

Examples:

plot(obj)

plot(obj, 'graphSubPlots')

plot(obj, 'startGraph', '2008Q1', 'endGraph', '2011Q2')

same as

plot(obj, 'graph', 'startGraph', '2008Q1', 'endGraph', '2011Q2')

See also:

[nb_graph_ts](#), [nb_ts.plotDist](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► [plus](#) ↑

obj = plus(obj, DBOrNum)

Description:

Binary addition (+).

Caution: Will add the data of the corresponding variables from the two objects. All the variables not in common will result in series with nan values.

When one of the inputs are a scalar this function will add each element of the data by this number.

Input:

- a : An object of class nb_data or a scalar
- b : An object of class nb_data or a scalar

Output:

- obj : An nb_ts object where all the variables from the two objects are added.

Or

An nb_data object where the scalar are added to all elements of the given nb_data object

Examples:

```
obj = obj + anotherObj;  
obj = obj + 2;  
obj = 2 + obj;
```

See also:

[nb_data.minus](#)

Written by Kenneth S. Paulsen

► pow2 ↑

obj = pow2(obj)

Description:

pow2(obj) raises the number 2 to the power of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = pow2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► power ↑

```
obj = power(a,b)
```

Description:

Element-wise power (.^).

If both inputs are nb_ts objects this method will raise the data of the first object with the data from the second object. This will only be done for the variables which are found to be in both nb_ts objects. The rest of the variables will get nan values.

Input:

- obj : An object of class nb_data or a scalar
- DBOrNum : An object of class nb_data or a scalar

Output:

- obj : An nb_data object where the data from th one object are raised with the data from the other object

or

An nb_data object where all the elements are raised by the scalar DBOrNum.

or

An nb_data object where the scalar obj are raised by all the elements of the object DBOrNum.

Examples:

```
obj = a.^b;
obj = a.^2;
obj = 2.^a;
```

See also:

[nb_data.mpower](#), [nb_data.callop](#), [nb_data.callfun](#)

Written by Kenneth S. Paulsen

► **rand** ↑

```
obj = nb_data.rand(start,obs,vars,pages,dist,sorted)
```

Description:

Create an nb_data object with all data set to random number.

Input:

- start : The start obs of the created nb_data object. As an integer
- obs : The number of observation of the created nb_data object.
- vars : Either a cellstr with the variables of the nb_data object, or a scalar with the number of variables of the nb_data object.
- pages : Number of pages of the nb_data object.
- dist : A nb_distribution object to draw from.
- sorted : true or false. Default is true.

Output:

- obj : An nb_data object.

Examples:

```
obj = nb_data.rand('1',10,['Var1','Var2']);  
obj = nb_data.rand('2012Q1',2,2);  
obj = nb_data.rand('2012Q1',2,2,10,nb_distribution('type', 'normal'));
```

See also:

[nb_data](#)

Written by Kenneth Sæterhagen Paulsen

► **rdivide** ↑

```
obj = rdivide(obj,DB)
```

Description:

Right element-wise division (./)

Do right element-wise division of the matching variables of the two nb_data objects. If some variables are not found to be in both objects, the resulting object will have series with nan values only for these variables.

Input:

- a : An object of class nb_data
- b : An object of class nb_data

Output:

- obj : An object of class nb_data, where the data are the result of the element-wise division.

Examples:

```
obj = obj./DB;
```

See also:

[nb_data.mldivide](#), [nb_data.mrdivide](#), [nb_data.callop](#), [nb_data.callfun](#)

Written by Kenneth S. Paulsen

► **reIndex** ↑

```
obj = reIndex(obj,date,baseValue)
```

Description:

Reindex the data of the object to a new obs.

Input:

- obj : An object of class nb_data
- obs : The obs at which the data should be reindexed to.
(Reindexed to baseValue, default is 100)
- baseValue : A number to re-index the series to. Default is 100.

Output:

- obj : An object of class nb_data where all the objects series are reindexed to 100 at the given obs

Examples:

```
obj = reIndex(obj,5)
```

Written by Kenneth S. Paulsen

► **real** ↑

```
obj = real(obj)
```

Description:

real(obj) returns the real part of the elements in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = real(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **reallog** ↑

```
obj = reallog(obj)
```

Description:

Take the real natural logarithm of the data stored in the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = reallog(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **realpow** ↑

```
obj = realpow(obj,DBOrNum)
```

Description:

Same as nb_data.power.

See also:

[nb_data.power](#)

Written by Kenneth S. Paulsen

► **realsqrt** ↑

```
obj = realsqrt(obj)
```

Description:

realsqrt(obj) is the square root of the elements of obj.
An error is produced if obj contains negative elements.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = realsqrt(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **rename** ↑

```
obj = rename(obj,type,oldName,newName)
```

Description:

Makes it possible to rename variables and datasets. For objects of class nb_cs types is also possible to rename.

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variable', but not when the input is 'dataset' or 'types'.

Input:

- obj : An object of class nb_dataSource
- type : Either:
 - 'variable' : To rename a variable(s)
 - 'dataset' : To rename a dataset(s) (The only input that is supported for nb_cell)
 - 'types' : To rename a type(s) (only nb_cs)
- oldName : Case 1;
 - > The old variable/dataset/type name, as a string
- Case 2:
 - > The string which should be replaced in all the variable names of the database. And reorder things afterwards. This input must end with a *.
- newName : Case 1;
 - > The new variable/dataset/type name, as a string
- Case 2;
 - > The string which should replace the old string part given by the input 'oldName'.

Output:

- obj : An nb_dataSource object with the renamed variable(s), type(s) or dataset(s).

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = obj.rename('variable','Var1','Var3');  
obj = obj.rename('variable','Var*','N_Var');  
obj = rename(obj,'variable',{'Var1','Var2'},{'VAR1','VAR2'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **renameMore** ↑

```
obj = renameMore(obj,type,oldNames,newNames)
```

Description:

Makes it possible to rename more variables, datasets and types (only nb_cs).

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variables', but not when the input is 'datasets'.

Caution : This is the same as looping over nb_dataSource.rename, but more efficient.

Caution : * syntax is not supported as is the case for nb_dataSource.rename

Input:

- obj : An object of class nb_dataSource.
- type : Either:
 - 'variables' : To rename a variables
 - 'datasets' : To rename a datasets (The only input that is supported for nb_cell)
 - 'types' : To rename a type (Only nb_cs)
- oldNames : The old variable/dataset/type names, as a cellstr.
- newName : The new variable/dataset/type names, as a cellstr.

Output:

- obj : An nb_dataSource object where the variable(s)/dataname(s)/type(s) of the object given as input is/are renamed.

Examples:

```
obj = nb_cs([22,24;27,28],'Dataset1',{'Exp','Imp'},{'Nor','Swe'})  
obj = renameMore(obj,'dataset',{'Dataset1'},{'tradeBal'});  
obj = renameMore(obj,'variable',{'Nor','Swe'},{'Norway','Sweden'});  
obj = renameMore(obj,'type',{'Exp','Imp'},{'Export','Import'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **reorder ↑**

```
obj = reorder(obj,newOrder,type)
```

Description:

Re-order the variables/types/datasets of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- newOrder : A cellstr with the new order of the variables/types/datasets.
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **ret ↑**

```
obj = ret(obj)
obj = ret(obj,nlag)
obj = ret(obj,nlag,skipNaN)
```

Description:

Calculate return, using the formula: $x(t)/x(t-lag)$ of all the series of the nb_data object.

Input:

- obj : An object of class nb_data
- nlag : The number of lags in the return formula, default is 1.
- skipNaN : -1 : Skip nan while using the ret operator. (E.g. when dealing with working days.)
 - 0 : Do not skip nan values. Default.

Output:

- obj : An nb_data object with the calculated series stored.

Examples:

```
obj = ret(obj);
obj = ret(obj,4);
```

See also:

[nb_data](#), [nb_ts](#)

► **rlag** ↑

```
obj = rlag(obj,t,endObs)
```

Description:

Append data with use of the rolling lag operator

Input:

- obj : An object of class nb_ts
- t : The number of lags to use for the rolling window
- endObs : The new end observation

Output:

- obj : An object of class ts

Examples:

```
obj = nb_data(rand(20,1),'',1,'Var1')
obj = rlag(obj,4,30)
```

► **round** ↑

```
obj = round(obj,value,startObs,endObs,variables,pages)
```

Description:

Round to closes value. I.e. if value is 0.25 it will round to the closes 0.25. E.g. 0.67 will be rounded to 0.75.

Input:

- obj : A nb_data object
- value : The rounding value. As a double. Default is 1.
- startObs : The start obs of the rounding. As an integer. Can be empty. Default is the start obs of the data.
- endObs : The end obs of the rounding. As an integer. Can be empty.

Default is the end obs of the data.

- variables : The variables to round. Can be empty. Default is to round all variables.
- pages : A numerical index of the pages you want to keep.

Output:

- obj : A nb_data object with the rounded numbers.

Written by Kenneth SÃ¶terhagen Paulsen

► **saveDataBase ↑**

saveDataBase(obj,varargin)

Description:

Save data of the object to (a) file(s)

If no optional input is given, i.e. obj.saveDataBase(). The data of the object is save down to xlsx file(s). Each dataset of the object is saved down to a excel spreadsheet with the name of the dataset (Taken from the 'dataNames' property)

Input:

- obj : An object of class nb_data
- Optional input (..., 'propertyName', PropertyValue, ...):
- 'saveName' : A string with the wanted name of the saved file.
 - 'ext' : > 'xlsx' : Saves the object down to a excel spreadsheet. Default
 - > 'matold' : Saves the data down to a mat file. The data is transformed into a structure, with the variables as the fieldnames, and the data as its fields. If the data consist of more pages, each field will consist of the same number of pages. See the toStructure method with input old set to 1.
Must be combined with the optional input 'saveName'.
 - > 'mat' : Saves the data down to a mat file. The data is transformed into a structure, with the variables stored in the field 'variables', while the data of the variables will be saved as its fields with generic

names ('Var1','Var2' etc). If the data consist of more pages, each field will consist of the same number of pages. See the toStructure method.

Must be combined with the optional input 'saveName'.

```

> 'mats'    : The object is saved down as a struct
               using the nb_data.struct function.

> 'txt'     : Saves the data down to a txt file.

- 'append'   : > 1 : Saves all the datasets (pages of the data)
               to one excel spreadsheet, but in separate
               worksheets. (Where the names of the
               worksheets are given by the dataNames
               property of the object.)
```

Works only when 'ext' input is set to
'xlsx'. (The default)

```

> 0 : The default saving method.

- 'strip'    : > 'on'  : Strip all observation dates where all
               the variables has no value. (is nan)

> 'off' : Default
```

Caution : Only an option when saved to excel.

Output:

The nb_data object saved to the wanted file format.

Examples:

Save the data to excel with the name 'test':
saveDataBase(obj,'saveName','test');

Save the data to excel with another date format:
saveDataBase(obj,'saveName','test','dateformat','xls');

Save the data to excel spreadsheet with the datasets as different worksheets:
saveDataBase(obj,'saveName','test','append',1);

Save the data to a .mat with the name 'test':
obj.savDataBase('ext','mat','saveName','test')

See also:

[asCell](#), [toStructure](#), [nb_readMat](#), [nb_readExcel](#)

Written by Kenneth S. Paulsen

► **sec ↑**

```
obj = sec(obj)
```

Description:

Secant of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = sec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **secd ↑**

```
obj = secd(obj)
```

Description:

Secant of argument in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = secd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sech** ↑

```
obj = sech(obj)
```

Description:

Hyperbolic secant.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **set2nan** ↑

```
obj = set2nan(obj,testedVariable,settledVariable)
```

Input:

- obj : An object of class nb_data
- testedVariable : A string with the name of the variable you are testing for nan values
- settledVariable : A string with the name of the variable you are setting equal to nan where the testedVariable are in fact nan.

Output:

- obj : An nb_data object where the settledVariable are set equal to nan at all the same dates as the testedVariable is nan.

Examples:

```
obj = nb_data([1,2;nan,1;2,3],'',1,{'Var1','Var2'});  
  
obj = set2nan(obj,'Var1','Var2');  
  
obj =  
  
'Time'    'Var1'    'Var2'  
'2012'    [ 1]    [ 2]  
'2013'    [ NaN]    [ NaN]  
'2014'    [ 2]    [ 3]
```

Written by Kenneth S. Paulsen

► **setInfinite2NaN** ↑

```
obj = setInfinite2NaN(obj)
```

Description:

Set all elements that are isfinite to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setMethodCalls** ↑

```
obj = setMethodCalls(obj,c)
```

Description:

Set all method calls of the object with a cell matrix. The object needs to be updatable.

Caution: To delete method calls use deleteMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.

- c : A cell matrix. See the output of getMethodCalls

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

See also:

[nb_data.deleteMethodCalls](#), [nb_data.getMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setValue ↑**

```
obj = setValue(obj,VarName,Value,startObsOfValues,...  
              endObsOfValues,pages)
```

Description:

Set some values of the dataset(s). (Only one variable at a time.) You cannot use obs outside the objects observations (i.e. outside obj.startObs:obj.endObs)

Input:

- obj : An object of class nb_data
- VarName : The variable name of the variable you want to set some values of. As a string
- Value : The values you want to assign to the variable. Must be a numerical vector (with the same number of pages as given by pages or as the number of dataset the object consists of.) Cannot be outside the window of the data of the object.
- startObsOfValues : A obs a an integer with the start obs of the data. If not given or given as a empty double it will assume that the setted data start at the startObs of the object.
- endObsOfValues : A obs a an integer with the end date of the data. If not given or given as a empty double it will assume that the setted data end at the endObs of the object.
- pages : At which pages you want to set the values of a variable. Must be a numerical index of the pages you want to set. E.g. if you want to set the values of the 3 first datasets (pages of the data) of the object. And the number of datasets of the object is larger then 3. You can use; 1:3. If empty all pages must be set.

Output:

- obj : An nb_data object where the data of the given variable has been set.

Examples:

```
obj = nb_data([2;3;4],'',1,{'Var1'});  
  
obj = obj.setValue('Var1',[1;2;3]);  
obj = obj.setValue('Var1',2,2,2,1);  
obj = obj.setValue('Var1',[1;2;3],2,3);
```

See also
addVariable

Written by Kenneth S. Paulsen

► **setZero2NaN** ↑

```
obj = setZero2NaN(obj)
```

Description:

Set all elements that are 0 to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **sin** ↑

```
obj = sin(obj)
```

Description:

Sine of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = sin(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **sind** ↑

obj = sind(obj)

Description:

sind(obj) is the sine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = sind(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sinh** ↑

obj = sinh(obj)

Description:

sinh(obj) is the hyperbolic sine of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sinh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **skewness ↑**

```
obj = skewness(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the skewness of each series. The result will be an object of class nb_data where all the non-nan values of all the series are being set to their skewness.

The output can also be set to be a double or a nb_cs object consisting of the skewness values of the data.

Input:

- obj : An object of class nb_data

- flag : Same as for the function skewness created by MATLAB.

- outputType :

> 'nb_data' : The result will be an object of class nb_data where all the non-nan values of all the series are being set to their skewness.

> 'double' : Get the skewness values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.

> 'nb_cs' : Get the skewness values as nb_cs object. The skewness will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)

- dimension : The dimension to calculate the skewness over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method
- dimension : The dimension to calcualate the skewness over.

Examples:

```
nb_dataObj = skewness(obj);
double      = skewness(obj,0,'double');
nb_csObj   = skewness(obj,0,'nb_cs');
```

Written by Kenneth S. Paulsen

► **sort ↑**

```
obj = sort(obj,mode,dim,variable)
```

Description:

Sort the wanted dimension (observations) of the data in the order given by the order input.

Caution : Sorting does not reorder the dataNames, variables or observations!

Input:

- obj : An object of class nb_data
- mode : 'descend' (default)
'ascend'
- dim : The dimension to sort. Either 1, 2 or 3. Default is 3.
- variable : Give a string with the variable to sort. The rest of the variables will then be reordered accordingly.

If empty (default), all variables are sorted.

Caution: Only an option for dim == 1

Output:

- obj : An object of class nb_ts

Examples:

```
in  = nb_ts(rand(10,2,10),'',1,['Var1','Var2']);
out = sort(in);
out = sort(in,'descend')
```

Written by Kenneth S. Paulsen

► **sortProperty** ↑

```
obj = sortProperty(obj,type)
```

Description:

Sort the variables/types/datasets of the object alphabetically.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **splitSeries** ↑

```
obj = splitSeries(obj,variable,obs,postfix,overlapping)
```

Description:

Split a series into two variables at a given observation.

Input:

- obj : An object of class nb_data
- variable : The variable(s) to split. Either a string or a cellstr.
- obs : The observation to split the series. As an integer.
- postfix : A string with the postfix of the new variable(s).
- overlapping : Indicate if you want the splitted series to be overlapping or not. As a logical. Default is true.

Output:

- obj : An object of class nb_data with the splitted series added.

See also:

[nb_ts](#), [nb_ts.splitSample](#)

Written by Kenneth Sæterhagen Paulsen

► **sqrt** ↑

`obj = sqrt(obj)`

Description:

`sqrt(obj)` is the square root of the elements of `obj`. Complex results are produced for non-positive elements.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

`out = sqrt(in);`

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **squeeze** ↑

`obj = squeeze(obj)`

Description:

Squeezes the different datasets (pages) of the given `nb_data` object. It will append the variables in each dataset with the given data name

Input:

- `obj` : An `nb_data` object. If the object has only one dataset (page) this method has nothing to do.

Output:

- obj : An nb_data object, where all the pages are squeezed together. I.e. all data will be stored in one dataset, and all variable names will get the dataset name appended.

Example:

```
obj = nb_data(ones(1,1,2),{'b','c'},2,{'Var1'})  
  
obj =  
  
(:,:,1) =  
  
    'Time'      'Var1'  
    '2012'      [ 1]  
  
(:,:,2) =  
  
    'Time'      'Var1'  
    '2012'      [ 1]  
  
sObj = squeeze(obj)  
  
sObj =  
  
    'Time'      'Var1_b'      'Var1_c'  
    '2012'      [ 1]          [ 1]
```

Written by Kenneth Sæterhagen Paulsen

► std ↑

```
obj = std(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the std of each series. The result will be an object of class nb_data where all the non-nan values of all the series are being set to their std.

The output can also be set to be a double or a nb_cs object consisting of the std values of the data.

Input:

- obj : An object of class nb_data
- flag : > 0 : normalises by N-1 (Default)
> 1 : normalises by N

Where N is the sample length.
- outputType :

```

> 'nb_data': The result will be an object of class nb_data
    where all the non-nan values of all the
    timeseries are being set to their std.

> 'double' : Get the std values as doubles, where
    each column of the double matches the
    variable location in the 'variables' property.
    If the object consists of more pages the double
    will also consist of more pages.

> 'nb_cs' : Get the std values as nb_cs object.
    The std will when this option is used only
    be calculated over the number of observations.
    (I.e. dimension set to 1.)

- dimension : The dimension to calculate the std over.

```

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from
 this method

Examples:

```

nb_dataObj = std(obj);
double      = std(obj,0,'double');
nb_csObj   = std(obj,0,'nb_cs');

```

Written by Kenneth S. Paulsen

► **stdise ↑**

```
obj = stdise(obj,flag)
```

Description:

Standardise data of the object by subtracting mean and dividing
by std deviation.

Input :

- obj : An object of class nb_data
- flag : - 0 : normalises by N-1 (Default)
 - 1 : normalises by N

Where N is the sample length.

Output:

- obj : An nb_data object with the standardised data

Examples:

```
obj = stdise(obj);
```

Written by Kenneth S. Paulsen

► **stopSorting** ↑

```
obj = stopSorting(obj)
```

Description:

Stop sorting of variables.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where sorting is turned off.

Example:

```
obj = obj.addPrefix('NEMO.');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **strip** ↑

```
obj = strip(obj,startObs,endObs,variables)
```

Description:

Sets all values of the given variables of a nb_data object, between two given observations, to nan.

Input:

- obj : A nb_data object

- startObs : The starting point of the strip, must be either an nb_date object or a valid input to the toDate method of the nb_date class

- endObs : The starting point of the strip, must be either an nb_date object or a valid input to the toDate method of the nb_date class
- variables : A cellstring with the variables to perform the method on. Can be empty, in which case the method will be performed on all variables in the object.

Output:

- obj : A nb_data object

Examples:

```
strippedObj = strip(obj,'2011Q1','2012Q3',{'Var1','Var2'})
strippedObj = strip(obj,'2011Q1','2012Q3')
```

Written by Kenneth S. Paulsen

► **stripButLast** ↑

```
obj = stripButLast(obj,numPeriods,variables)
```

Description:

Sets all values of the given variables of a nb_data object, except a given amount of observations at the end, to nan.

Input:

- obj : A nb_data object
- numPeriods : The amount of observations to be left as-is in the object. If the input is given to 2, the returned object will have all it's observations set to nan except the last two observations.
- variables : A cellstring with the variables to perform the method on. Can be empty, in which case the method will be performed on all variables in the object.

Output:

- obj : A nb_data object

Examples:

```
strippedObj = stripButLast(obj,5',{'Var1','Var2'})
strippedObj = stripButLast(obj,'5')
```

Written by Eyo Herstad

► **struct** ↑

```
s = struct(obj)
```

Description:

Object to struct.

Input:

- obj : An nb_data object.

Output:

- s : A structure representing an nb_data object.

Written by Kenneth Sætherhagen Paulsen

► **structure2Dataset** ↑

```
obj = structure2Dataset(obj,givenStruct,NameOfDataset,startObs)
```

Description:

When you give a struct to the constructor of this class all the fields af that struct will be added as a new dataset, but this method add all the fields of the input struct as a variable in one dataset

If you only want to add a dataset from a structure in this way (no other datasets) intitialize an empty object, and then use this method.

Caution : The structure must include a field 'startObs', which must be an integer with the start observation.

Inputs:

- obj : An nb_data object, could be empty.
- givenStruct : The structure which contains the data of the added variable. Where the fieldnames will be the variables name of the added dataset + plus one field 'startObs' with the start obs of the dataset.
- NameOfDataset : Name of the added dataset. If not provided a default name will be given
- startObs : The start obs of the added structure. Only needed if the provided structure has no field

```
'startObs'.
```

Outputs:

- obj : An nb_data object with the added structure as a dataset.

Examples:

```
s = struct();
s.startDate = 1;
s.var1 = [2;2;2];
data = nb_data();
data = data.structure2Dataset(s)
```

Written by Kenneth S. Paulsen

► **subsasgn** ↑

```
varargout = subsasgn(obj,s,b)
```

Description:

Makes it possible to do subscripted assignment of the data of an object

Input:

- obj : An object of class nb_data
- s : The same input as when you do subscripted assignment one a double matrix
- b : The assign data at the given index s.

Output:

- obj : The assign data property setted of the given object.

Examples:

```
obj = nb_data([2;3;4],'',1,['Var1']);
obj(1:3,1) = [1;2;3]
obj =
{'Time'      'Var1'
 '2012'      [    1]
 '2013'      [    2]
 '2014'      [    3]
```

Written by Kenneth S. Paulsen

► **subsref** ↑

```
varargout = subsref(obj,s)
```

Description:

Makes it possible to do subscripted reference of the data of an object. See the examples for more

Using the method window, just using indexing instead

Input:

- obj : An object of class nb_data
- s : A structure on have to index the object

Output:

- obj : The indexed object.

Examples:

```
obj = obj(1,2:4,1)
```

same as

```
obj = obj(1,2:4)
```

Be aware that that obj(1,:) and obj(1,2:end) will also work

```
obj = obj('2')
```

same as

```
obj.window('2','2')
```

```
obj = obj('2','4')
```

same as

```
obj.window('2','4')
```

```
obj = obj('2','4',{'Var1','Var2',...})
```

same as

```
obj.window('2','4',{'Var1','Var2',...})
```

```
obj = obj('2','4',{'Var1','Var2',...},1:2)
```

```

same as

obj.window('2','4',{'Var1','Var2',...},1:2)

obj = obj('Var1','Var2',...)

same as

obj.window('','','{'Var1','Var2',...},1:obj.numberOfDatasets)

```

Written by Kenneth S. Paulsen

► sum ↑

```
obj = sum(obj,dim)
```

Description:

Takes the sum of the object series

Caution : All sums ignore nan values. If not all values is nan.

Input:

- obj : An object of class nb_data
- dim : The dimension to sum over, returns:
 - > dim = 1: Either :
 - > An nb_data object with all the elements of each variable set to their sum over the time horizon.
 - > An nb_cs with one type representing the sum over the obs horizon). The type is named 'sum'.
 - > dim = 2: An nb_data object with one variable representing the sum (Take the sum over the varibales) (Default)
 - > dim = 3: An nb_data object with only on page, representing the sum over all pages.
- output : Either 'nb_data' (default) or 'nb_cs'. Only important when summing over the 1 dimension.

Output:

- obj : Either an nb_data object or an nb_cs object representing the sum.

Examples:

```
obj      = nb_data([2,1;3,2;4,3],'', '1', {'Var1','var2'})  
obj =  
  
'Time'    'Var1'    'var2'  
'1'       [ 2]       [ 1]  
'2'       [ 3]       [ 2]  
'3'       [ 4]       [ 3]  
  
s1 = sum(obj,1,'nb_data')  
  
s1 =  
  
'Time'    'Var1'    'var2'  
'1'       [ 9]       [ 6]  
'2'       [ 9]       [ 6]  
'3'       [ 9]       [ 6]  
  
s1_cs = sum(obj,1,'nb_cs')  
  
s1_cs =  
  
'Types'   'Var1'    'var2'  
'sum'     [ 9]       [ 6]  
  
s2 = sum(obj,2)  
  
s2 =  
  
'Time'    'sum'  
'1'       [ 3]  
'2'       [ 5]  
'3'       [ 7]  
  
s2 = sum(obj,3)  
  
s2 =  
  
'Time'    'Var1'    'var2'  
'1'       [ 2]       [ 1]  
'2'       [ 3]       [ 2]  
'3'       [ 4]       [ 3]
```

Written by Kenneth S. Paulsen

► **summary ↑**

```
obj = summary(obj)
```

Description:

Summary of the series of the nb_data object

Input:

- obj : An object of class nb_data

Output:

- obj : the summary statistics - min, max, std, var, skewness and kurtosis

Written by Kenneth S. Paulsen

► **tail** ↑

`tail(obj,nRows,page)`

Description:

Display the last n rows of a nb_data object.

Input:

- obj : An nb_data object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_data](#), [window](#), [tail](#)

Written by Per Bjarne Bye

► **tan** ↑

`obj = tan(obj)`

Description:

Take the tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = tan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **tand** ↑

```
obj = tand(obj)
```

Description:

tand(obj) is the tangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = tand(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **tanh** ↑

```
obj = tanh(obj)
```

Description:

tanh(obj) is the hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = tanh(in);  
  
Written by Andreas Haga Raavand  
  
Inherited from superclass NB_DATASOURCE
```

► **times** ↑

```
obj = times(obj,DB)
```

Description:

Element-wise multiplication (.*)

Caution : Will only multiply the data of corresponding variables of the two objects. I.e. variable not found to be in both object will result in series with all values set to nan.

Input:

- a : An object of class nb_data
- b : An object of class nb_data

Output:

- obj : An nb_data object the data results from element-wise multiplication of the data of the input objects.

Examples:

```
obj = obj.*DB;
```

See also:

[nb_data.mtimes](#), [nb_data.callop](#), [nb_data.callfun](#)

Written by Kenneth S. Paulsen

► **toMFile** ↑

```
string = toMFile(obj)  
toMFile(obj,filename)  
string = toMFile(obj,filename,varName)
```

Description:

Write a .m file to generate the current object.

Input:

- obj : An nb_data object.
- filename : The filename to write the code to. If empty no file will be written.
- varName : Name of decleared variable by this code. Default is data.

Output:

- string : A cellstr with the .m code to generate the current object.

Written by Kenneth Sæterhagen Paulsen

► toStructure ↑

```
retStruct = toStructure(obj)
retStruct = toStructure(obj,old)
```

Description:

Transform an nb_data obj to a structure

Input:

- obj : An object of class nb_data
- old : Indicate if old mat file format is wanted. Default is 0 (false).

Output:

- retStruct : A structure with fieldsnames given by the object variables and field given by the variables data. (Can have more than one page). And a own field with the start obs of the data. (As an integer.)

Examples:

```
obj = nb_data(ones(8,1),'',1,{'Var1'});
s = obj.toStructure()
s =
    Var1: [8x1 double]
    variables: {'Var1'}
    startObs: 1
    class: 'nb_data'
    userData: ''
    localVariables: []
    sorted: 1
```

See also:

[nb_data.struct](#)

Written by Kenneth S. Paulsen

► **tonb_cell** ↑

`nb_cell_DB = tonb_cell(obj)`

Description:

Transform from a nb_data object to a nb_cell object

Input:

- `obj` : An object of class nb_data
- `strip` : - 'on' : Strip all observations where all the variables has no value.
 - 'off' : Does not strip all observations where all the variables has no value. Default.

Output:

- `nb_cell_DB` : An object of class nb_cell

Examples:

`nb_cell_DB = obj.tonb_cell();`

Written by Kenneth S. Paulsen

► **tonb_cs** ↑

`nb_cs_DB = tonb_cs(obj)`

Description:

Transform from a nb_data object to a nb_cs object

Input:

```
- obj : An object of class nb_data

- strip : - 'on' : Strip all observations where all
           the variables has no value.

           - 'off' : Does not strip all observations
           where all the variables has no value.
           Default.
```

Output:

```
- nb_cs_DB : An object of class nb_cs
```

Examples:

```
nb_cs_DB = obj.tonb_cs();
```

Written by Kenneth S. Paulsen

► **tonb_ts ↑**

```
nb_ts_DB = tonb_ts(obj,startDate)
```

Description:

Transform from a nb_data object to a nb_ts object

Input:

```
- obj : An object of class nb_data

- startDate : Sets the start date of the nb_ts object. If empty or
               not given it is default to use startObs as the start date.
```

Output:

```
- nb_ts_DB : An object of class nb_ts
```

Examples:

```
nb_ts_DB = obj.tonb_ts();
```

Written by Kenneth S. Paulsen

► **uminus ↑**

```
obj = uminus(obj)
```

Description:

Unary minus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : A nb_ts, nb_cs or nb_data object where all the data are the unary minus of the input objects data

Examples:

```
obj = -obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **undiff ↑**

```
obj = undiff(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series diff. Inverse of the diff method.

Input:

- obj : An object of class nb_data

- initialValues : A nb_data object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_data object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.

- periods : The number of periods the initial series has been taken diff over.

Output:

- Output : An nb_data object with the indicies.

Examples:

```
obj = undiff(obj);
obj = undiff(obj,100);
obj = undiff(obj,[78,89]);
```

See also
nb_data.diff

Written by Kenneth S. Paulsen

► **unstruct** ↑

```
obj = nb_ts.unstruct(s)
```

Description:

Reverse of the struct method.

Input:

- s : See the s output of the struct method.

Output:

- obj : An nb_data object.

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj,warningOff,inGUI)
```

Description:

This method will try to update the data of the nb_ts object.

Caution : It is only possible to update an nb_dataSource object which has updateable links to a FAME database or a full directory (path) to an excel spreadsheet or .mat file or the SMART database.

Caution : If you want to create a link to a specific worksheet of a excel file you must provide the extension!

Caution : All method calls done on the object are preserved.
(There exist some exception; and, or etc.)

Input:

- obj : An object of class nb_dataSource which are updatable.
- warningOff : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'.
- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'.

Output:

- obj : An object of class nb_dataSource with the data updated. If it is not possible a warning will be given.

Examples:

```
obj = nb_ts(['N:\Matlab\Utvikling\MATLAB_LIB\NEMO\'...
             'Documentation\Examples\example_ts_quarterly']);
obj = obj.update
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **uplus ↑**

```
obj = uplus(obj)
```

Description:

Unary plus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where all the data are the unary plus of the input objects data

Examples:

```
obj = +obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **var ↑**

```
obj = var(obj,outputType,dimension,varargin)
```

Description:

Calculate the var of each series. The result will be an object of class nb_ts where all the non-nan values of all the series are being set to their var.

The output can also be set to be a double or a nb_cs object consisting of the var values of the data.

Input:

- obj : An object of class nb_data
- outputType :
 - > 'nb_data' : The result will be an object of class nb_data where all the non-nan values of all the series are being set to their var.
 - > 'double' : Get the var values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the var values as nb_cs object. The variance will be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the var over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more on the output from this method

Examples:

```
nb_tsObj = var(obj);
double   = var(obj,'double');
nb_csObj = var(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **vertcat** ↑

```
obj = vertcat(a,b,varargin)
```

Description:

Vertical concatenation ([a;b])

Input:

- a : An object of class nb_data
- b : An object of class nb_data
- varargin : Optional numbers of objects of class nb_data

Output:

- a : An nb_data object where the data from the different objects are appended to each other.

Examples:

```
obj = nb_data(ones(2,1),'',1,['Var1']);  
aObj = nb_data(ones(2,1),'',3,['Var1']);  
m = [obj;aObj]
```

```
m =
```

'Time'	'Var1'
'1'	[1]
'2'	[1]
'3'	[1]
'4'	[1]

Written by Kenneth S. Paulsen

► **window ↑**

```
obj = window(obj,startObsWin,endObsWin,variablesWin,pages)
```

Description:

Narrow down window of the data of the nb_data object

Input:

- obj : An object of class nb_data
- startObsWin : The new wanted start obs of the data of the object. Must be an integer.
- endObsWin : The new wanted end obs of the data of the object. Must be an integer.

- variablesWin : A cellstr array of the variables you want to keep of the given object. If empty all the variables is kept.
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty all pages is kept.
I.e. `obj = obj.window('','',{ },1:3)`

Output:

- obj : An nb_data object where the datasets of the object is narrowed down to the specified window.

Examples:

```
obj = nb_data(ones(10,2,2),'',1',{'Var1','Var2'});
obj = obj.window(2)
obj = obj.window('',5)
obj = obj.window('','','',{'Var1'})
obj = obj.window('','','',{ },1)
```

See also:

[subsref](#)

Written by Kenneth S. Paulsen

► **writeTex** ↑

```
writeTex(obj,filename)
writeTex(obj,filename,'inputName', inputValue,...)
```

Description:

Writes the object data to a LaTeX table saved to a .tex file.

If the object consists of more pages (datasets) more tables will be created.

Input:

- obj : An object of class nb_data
- filename : The name of the saved .tex file. With or without the extension.

Optional input:

- 'caption' : Adds a caption to the table. Must be a string.
- 'combine' : If the nb_data object consist of two or three pages (datasets) this option can be used to combine all the data in one table. Either 1 or 0. Default is 0.
- 'colors' : Set it to 0 if the colored rows of the table should be turned off. Default is 1.
- 'firstRowColor' : A string with the color, e.g. 'blue','white','black','blue!20!white'. Default is 'nbblue'.
- 'fontSize' : Sets the font size of the table. Either:
 - 'Huge', 'huge', 'LARGE', 'Large', 'large',
 'normalsize' (default), 'small',
 'footnotesize', 'scriptsize','tiny'.

Caution : This option is case sensitive.
- 'justification' : Sets the justification of the caption of the table. Must be a string.
 - Either 'justified','centering' (default),
 'raggedright', 'RaggedRight', 'raggedleft'.

Caution : This option is case sensitive.
- language : Either 'english' (default) or 'norwegian'
 ('norsk').
- lookUpMatrix :

Sets how the given mnemonics (variable names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
 'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
lookUpMatrix = {

 'mnemonics1','englishDescription1','norwegianDescription1';
 'mnemonics2','englishDescription2','norwegianDescription2'};
```

Be aware : Each of the given description can be multi-lined char, which will result in multi-line text of the table.
- 'orientation' : The orientation of the table. Either:
 - > 'horizontal' : The obs as columns
 - > 'vertical' : The types as columns
- 'precision' : Sets the precision of the numbers in the

table. Must be a string. Default is '%3.2f'. I.e. two decimals.

- 'rotation' : The rotation of the table in LaTeX. Either:
 - > 'sidewaystable' : A sideways table
 - > 'landscape' : Rotate the whole page
 - > '' : No rotation
- 'rowColor1' : Color of every second row of the table starting from the second row. Same options as was the case for the 'firstRowColor' option.
- 'rowColor2' : Color of every second row of the table starting from the third row. Same options as was the case for the 'firstRowColor' option.
- 'rowColor3' : Color of every third row of the table starting from the fourth row. Only an option in combination with the 'combine' input set to 1 and that the nb_ts object has 3 pages. Same options as was the case for the 'firstRowColor' option.

Output:

A saved .tex file with the LaTeX table

Examples:

```
obj = nb_ts(rand(10,3),'',1,{'Var1','Var2','Var3'});
obj.writeTex('test')
```

[nb_data](#)

Written by Kenneth Sæterhagen Paulsen

► **zeros ↑**

```
obj = nb_data.zeros()
obj = nb_data.zeros(start,obs,vars,pages,sorted)
```

Description:

Create an nb_data object with all data set to 0.

Input:

- start : The start obs of the created nb_data object. As an integer.
- obs : The number of observation of the created nb_data object.
- vars : Either a cellstr with the variables of the nb_data object, or a scalar with the number of variables of the nb_data object.
- pages : Number of pages of the nb_data object.
- sorted : true or false. Default is true.

Output:

- obj : An nb_data object.

Examples:

```
obj = nb_data.zeros(1,10,{'Var1','Var2'});
obj = nb_data.zeros(1,2,2);
obj = nb_data.zeros(1,2,2,10);
```

See also:

[nb_data](#)

Written by Kenneth Sæterhagen Paulsen

■ nb_math_ts

Go to: [Properties](#) | [Methods](#)

A class representing timeseries data.

The difference between this and the nb_ts class is that all reference to the variables are removed. This makes some operators work as normal matrices. (Matrix multiplication, matrix division and matrix power of two object of class nb_math_ts is for example undefined for this class.)

That the object of this class has no reference to the object makes it easier to do datatransformations. E.g.

```
var1 = nb_math_ts([2;2;2;2],'2012Q1');
var2 = nb_math_ts([2;2;2;2],'2012Q1');
var3 = var1./var2;
var3 =
    '2012Q1'      [1]
    '2012Q2'      [1]
    '2012Q3'      [1]
    '2012Q4'      [1]
```

Caution : nb_ts and this class has not the same methods.

Constructor:

```

obj = nb_math_ts(data,startDate)

Input:

- data      :
    > A double with the data.

    > An object of class nb_ts

    > An object of class tseries (Needs the IRIS package)

- startDate :
    The start date of the data. Only needed when you give
    numerical data as one element of the input datasets (also
    when numerical data is given through a struct).

    Must be a string on the date format given below or an
    object which is of a subclass of the nb_date class.

    Dating convention:
    > Yearly      : 'yyyy'.           E.g. '2011'
    > Semiannualy : 'yyyySs'          E.g. '2011S1'
    > Quarterly   : 'yyyyQq'.          E.g. '2011Q1'
    > Monthly     : 'yyyyMm(m)'.      E.g. '2011M1',
                                '2011M11'
    > Daily       : 'yyyyMm(m)Dd(d)' E.g. '2011M1D1',
                                '2011M11D11'

    Caution: Must not be provided when the data input is of
              class nb_ts or tseries.

Output:

- obj      : An object of class nb_math_ts.

Examples:

obj = nb_math_ts([2,2;2,2],'2012Q1');

See also:

nb\_ts

Written by Kenneth Sæterhagen Paulsen

Properties:

- data    • dim1    • dim2    • dim3    • endDate    • startDate

- data ↑

The data of the object. As a double or logical

- dim1 ↑

The size of the first dimension of the data property. As a double.

```

- **dim2** ↑

The size of the second dimension of the data property. As a double.

- **dim3** ↑

The size of the third dimension of the data property. As a double.

- **endDate** ↑

The end date of data. Given as an object which is of a subclass of the nb_date class. Either: nb_day, nb_month, nb_quarter, nb_semiAnnual or nb_year

- **startDate** ↑

The start date of the data. Given as an object which is of a subclass of the nb_date class. Either: nb_day, nb_month, nb_quarter, nb_semiAnnual or nb_year.

► **abs ↑**

```
obj = abs(obj)
```

Description:

Take the absolute value of each data elements of the nb_math_ts

object

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = abs(in);
```

Written by Kenneth S. Paulsen

► **acos** ↑

obj = acos(obj)

Description:

Inverse cosine, expressed in radians

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj = acos(obj);
```

Written by Kenneth S. Paulsen

► **acosd** ↑

obj = acosd(obj)

Description:

Inverse cosine, expressed in degrees

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = acosd(in);
```

Written by Andreas Haga Raavand

► **acosh** ↑

```
obj = acosh(obj)
```

Description:

Inverse hyperbolic cosine

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = acosh(in);
```

Written by Andreas Haga Raavand

► **acot** ↑

```
obj = acot(obj)
```

Description:

Cotangent

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj = acot(obj);
```

Written by Kenneth S. Paulsen

► **acotd** ↑

```
obj = acotd(obj)
```

Description:

Inverse cotangent, expressed in degrees

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = acotd(in);
```

Written by Andreas Haga Raavand

► **acoth** ↑

```
obj = acoth(obj)
```

Description:

Inverse hyperbolic cotangent

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = acoth(in);
```

Written by Andreas Haga Raavand

► **acsc** ↑

```
obj = acsc(obj)
```

Description:

Inverse cosecant, expressed in radians

Input:

- obj : An object of class nb_math_ts

Output:

```
- obj : An object of class nb_math_ts
```

Examples:

```
obj = acsc(obj);
```

Written by Kenneth S. Paulsen

► **acsqd** ↑

```
obj = acsqd(obj)
```

Description:

Inverse cosecant, expressed in degrees

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = acscd(in);
```

Written by Andreas Haga Raavand

► **acsch** ↑

```
obj = acsch(obj)
```

Description:

Inverse hyperbolic cosecant

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = acsch(in);
```

Written by Andreas Haga Raavand

► **and** ↑

```
a = and(a,b)
```

Description:

The and operator (&). Act element-wise on the data of the two nb_math_ts objects

Input:

- a : An object of class nb_math_ts

- b : An object of class nb_math_ts

Output:

- a : An object of class nb_math_ts. Where the and operator has evaluated all the data elements of the object. The data will be a logical matrix

Examples:

```
a = a & b;
```

Written by Kenneth S. Paulsen

► **append** ↑

```
obj = append(obj,aObj)
obj = append(obj,aObj,priority)
```

Description:

Append aObj to obj with a given priority.

Input:

- obj : A nObs1 x nVar x nPages nb_math_ts object.
- aObj : A nObs2 x nVar x nPages nb_math_ts object.
- priority : 'first' or 'second'. If 'first' all the observations from obj is used before the observations from aObj, otherwise it is reverse. 'first' is default.

Output:

- obj : A nObs x nVar x nPages nb_math_ts object.

Examples:

```
obj = nb_math_ts(zeros(10,2),'2018Q1');
aObj = nb_math_ts([nan(2,1),ones(2,1);ones(6,2)],'2020Q1');
new1 = append(obj,aObj);
new2 = append(obj,aObj,'second');
```

Written by Kenneth Sæterhagen Paulsen

► **appendFromAnotherPage** ↑

```
obj = appendFromAnotherPage(obj,page)
```

Description:

Append data from another page where the rest has missing data.

Input:

- obj : A nObs1 x nVar x nPages nb_math_ts object.
- page : The page to append data from.

Output:

- obj : A nObs x nVar x nPages nb_math_ts object.

Examples:

```
obj          = nb_math_ts(zeros(10,2,4),'2018Q1');
obj(1:4,:,3:4) = nan;
new1         = appendFromAnotherPage(obj,1);
new2         = appendFromAnotherPage(obj,2);
```

Written by Kenneth Sætherhagen Paulsen

► **asec** ↑

```
obj = asec(obj)
```

Description:

Inverse secant, expressed in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj = asec(obj);
```

Written by Kenneth S. Paulsen

► **asecd** ↑

```
obj = asecd(obj)
```

Description:

Inverse secant, expressed in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = asecd(in);
```

Written by Andreas Haga Raavand

► **asech** ↑

```
obj = asech(obj)
```

Description:

Inverse hyperbolic secant

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = asech(in);
```

Written by Andreas Haga Raavand

► **asin** ↑

```
obj = sin(obj)
```

Description:

Inverse sine, expressed in radians.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj = sin(obj);
```

Written by Kenneth S. Paulsen

► **asind** ↑

```
obj = asind(obj)
```

Description:

Inverse sine, expressed in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = asind(in);
```

Written by Andreas Haga Raavand

► **asinh** ↑

```
obj = asinh(obj)
```

Description:

Inverse hyperbolic sine

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = asinh(in);
```

Written by Andreas Haga Raavand

► **atan ↑**

```
obj = atan(obj)
```

Description:

Inverse tangent, expressed in radians.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj = atan(obj);
```

Written by Kenneth S. Paulsen

► **atand ↑**

```
obj = atand(obj)
```

Description:

Inverse tangent, expressed in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = atand(in);
```

Written by Andreas Haga Raavand

► **atanh** ↑

```
obj = atanh(obj)
```

Description:

Inverse hyperbolic tangent.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = atanh(in);
```

Written by Andreas Haga Raavand

► **avgOAF** ↑

```
obj = avgOAF(obj,sumFreq)
```

Description:

Take the average over a lower frequency. Ignoring nan values!

I.e. if frequency is quartely, this function can take the average over all the quarters of a year. And it will return the average over the year in all quarters of the that year

Input:

- obj : An object of class nb_math_ts
- sumFreq : The frequency to average over

Output:

- obj : An object of class nb_math_ts where the data is averaged over a lower frequency

Examples:

```
obj = nb_math_ts.rand('2012Q1',8);
obj = obj.avgOAF(1)
```

Written by Kenneth S. Paulsen

► **bkfilter** ↑

```
obj = bkfilter(obj,low,high)
```

Description:

Do band pass filtering of all the dataseries of the object.
(Returns the gap). Will strip nan values when calculating the filter

Input:

- obj : An object of class nb_math_ts
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_math_ts with the band pass filtered data.

Examples:

```
obj = bkfilter(obj,8,32);
obj = obj.bkfilter(8,32);
```

Written by Kenneth S. Paulsen

► **bkfilterls** ↑

```
obj = bkfilter1s(obj,low,high)
```

Description:

Do one sided band pass-filtering of all the dataseries of the object. (Returns the gap) Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_math_ts
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_math_ts with the one-sided band pass filtered data.

Examples:

```
obj = obj.bkfilter1s(12,24);  
obj = bkfilter1s(obj,12,24);
```

Written by Kenneth S. Paulsen

► **breakAdj ↑**

```
obj = breakAdj(obj,method,varargin)
```

Description:

The intent of this method is to set observations around break points to nan, and interpolate the observation at these break-points. I.e. if you have a level series that has a break, and want smooth growth rates. In this case you can calculate the growth rates of the level series, and then use this method to smooth out the growth rate at the break-points. Then you can use the inverse growth methods to transform back to a level series without breaks.

Input:

- obj : An object of class nb_math_ts
- method : The wanted interpolation method to use. See the nb_interpolate function.

Optional input:

- A set of nb_date objects or one line chars with the dates that should be set to nan and interpolated.

Output:

- obj : An object of class nb_math_ts.

See also:

[nb_interpolate](#), [growth](#), [egrowth](#), [pcn](#), [epcn](#), [igrowth](#), [iegrowth](#), [ipcn](#)
[iepcn](#)

Written by Kenneth S. Paulsen

► **callfun ↑**

```
obj      = callfun(obj,'func',func)
obj      = callfun(obj,another,'func',func)
obj      = callfun(obj,varargin,'func',func)
varargout = callfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the data of the nb_math_ts object(s). The data of the object is normally of class double, but may also be of class logical. Use nb_math_ts.getClassOfData to find the class of the data of the object.

Input:

- obj : An object of class nb_math_ts.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function @(x)x will be used.
- 'frequency' : If the operator should act on the data of the object, as it was on another frequency, you set this option to that frequency. Either 1 (yearly), 2 (semi-annually), 4 (quarterly), 12 (monthly), 52 (weekly) or 365 (daily).

Caution: It will be applied to the obj input as well as all optional inputs being a nb_math_ts object.

Caution: The method applied when converting to a higher frequency is 'none', and to a

lower frequency is 'discrete'. See the nb_math_ts.convert method for more on these methods.

- 'interpolateDate' : See the nb_math_ts.convert method for more on this option. Default is 'start'.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class. nb_math_ts objects are converted to a matrix with elements of class double or logical.

Output:

- varargout : All output from the provided function which results in either a double or logical with the same size as obj input will be converted to a nb_math_ts object. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```
d      = nb_math_ts.rand('2012Q1',10,3);
d1     = callfun(d,'func',@sin); % Same as d1 = sin(d) !
d2     = callfun(d,d,'func','plus') % Same as d2 = d + d !
[s1,s2] = callfun(d,'func',@size) % Same as [s1,s2] = size(d)
```

See also:

[nb_dataSource.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

► **ceil ↑**

obj = ceil(obj)

Description:

ceil(obj) rounds the elements of obj to the nearest integers towards infinity.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = ceil(in);
```

Written by Andreas Haga Raavand

► **conj** ↑

```
obj = conj(obj)
```

Description:

`conj(obj)` is the complex conjugate of the elements of `obj`.
For a complex element `x` of `obj`, `conj(x) = REAL(x) - i*IMAG(x)`.

Input:

- `obj` : An object of class `nb_math_ts`

Output:

- `obj` : An object of class `nb_math_ts`

Examples:

```
out = conj(in);
```

Written by Andreas Haga Raavand

► **convert** ↑

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the `nb_math_ts` object

Input:

- `obj` : An object of class `nb_math_ts`

- `freq` : The new frequency of the data. As an integer:

> 1	: yearly
> 2	: semi annually
> 4	: quarterly
> 12	: monthly
> 52	: weekly
> 365	: daily

- method : The method to use. Either:

From a high frequency to a low:

```
> 'average'      : Takes averages over the subperiods
> 'diffAverage' : Uses a weighted average, so that the
                  diff operators can be converted
                  correctly. E.g. when converting from monthly
                  to quarterly, and the level of the variable
                  of interest is aggregated to quarterly data
                  using averages, but you want to convert
                  monthly data on diff to quarterly. The
                  formula used is:
                    diff_Y(q) = 1/3*diff_Y(m) + 2/3*diff_Y(m-1)
                               + diff_Y(m-2) + 2/3*diff_Y(m-3)
                               + 1/3*diff_Y(m-4)
> 'diffSum'      : Same as 'diffAverage', but now the
                  aggregation in levels are done using a sum
                  instead.
> 'discrete'     : Takes last observation in each
                  subperiod (Default)
> 'first'        : Takes first observation in each
                  subperiod
> 'max'          : Takes maximal value over the subperiods
> 'min'          : Takes minimum value over the subperiods
> 'sum'          : Takes sums over the subperiods
```

From a low frequency to a high:

```
> 'linear'       : Linear interpolation
> 'cubic'        : Shape-preserving piecewise cubic
                  interpolation
> 'spline'       : Piecewise cubic spline interpolation
> 'none'         : No interpolation. All data in between
                  is given by nans (missing values)
                  (Default)
> 'fill'         : No interpolation. All periods of the
                  higher frequency get the same value as
                  that of the lower frequency.
> 'daverage'     : Uses the Denton 1971 method using that
                  the average of the intra low frequency
                  periods should preserve the average.
> 'dsum'         : Uses the Denton 1971 method using that
                  the sum of the intra low frequency
                  periods should preserve the sum.
```

Caution: This input must be given if you provide some
of the optional inputs.

Caution: All these option will by default use the
first period of the subperiods as base for
the conversion. Provide the optional input
'interpolateDate' if you want to set the base
to the end periods instead ('end').

Optional input:

- 'includeLast' : Give this string as input if you want to
include the last period, even if it is not

finished. Only when converting to lower frequencies

```
E.g: obj = obj.convert(1,'average',...
'includeLast');
```

- 'rename' : Changes the postfixes of the variables names.

E.g. If you covert from the frequency 12 to 4 the prefixes of the variable names changes from 'MUA' to 'QUA', if the prefix exist.

```
E.g: obj = obj.convert('yearly','average',...
'rename');
```

Optional input (...,'inputName', inputValue,...):

- 'interpolateDate' : The input after this input must either be 'start' or 'end'.

Date of interpolation. Where 'start' means to interpolate the start date of the periods of the old frequency, while 'end' uses the end date of the periods.

Default is 'start'.

Caution : Only when converting to higher frequency.

Caution : For weekly data, the 'dayOfWeek' options is added. See nb_ts.setDayOfWeek for more on this.

```
E.g: obj = obj.convert(365,'linear',...
'interpolateDate','end');
```

Output:

- obj : An nb_math_ts object converted to wanted frequency.

Examples:

```
obj = obj.convert(4,'average');
obj = obj.convert(365,'linear','interpolateDate','end');
obj = obj.convert(1,'average','includeLast');
obj = obj.convert(1,'average','rename');
```

Written by Kenneth S. Paulsen

► **corr ↑**

```
d = corr(obj)
```

Description:

Calculate the correlation of the timeseries stored in the nb_math_ts object

Input:

obj : An object of class nb_math_ts

Output:

d : A double with the wanted correlation

Examples:

```
corrMatrix = corr(obj)
```

Written by Kenneth S. Paulsen

► **cos** ↑

```
obj = cos(obj)
```

Description:

Cosine

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts.

Examples:

```
obj = cos(obj);
```

Written by Kenneth S. Paulsen

► **cosd** ↑

```
obj = cosd(obj)
```

Description:

`cosd(obj)` is the cosine of the elements of `obj`, expressed in degrees.

Input:

- `obj` : An object of class `nb_math_ts`

Output:

- `obj` : An object of class `nb_math_ts`

Examples:

```
out = cosd(in);
```

Written by Andreas Haga Raavand

► **cosh** ↑

```
obj = acsch(obj)
```

Description:

`cosh(obj)` is the hyperbolic cosine of the elements of `obj`.

Input:

- `obj` : An object of class `nb_math_ts`

Output:

- `obj` : An object of class `nb_math_ts`

Examples:

```
out = acsch(in);
```

Written by Andreas Haga Raavand

► **cot** ↑

```
obj = cot(obj)
```

Description:

Cotangent

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts.

Examples:

```
obj = cot(obj);
```

Written by Kenneth S. Paulsen

► **cotd** ↑

```
obj = cotd(obj)
```

Description:

Cotangent, expressed in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = cotd(in);
```

Written by Andreas Haga Raavand

► **coth** ↑

```
obj = coth(obj)
```

Description:

Hyperbolic cotangent.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = coth(in);
```

Written by Andreas Haga Raavand

► **cov** ↑

```
obj = cov(obj)
```

Description:

Calculate the covariance of the timeseries stored in a nb_math_ts object

Input:

```
obj : An object of class nb_math_ts
```

Output:

d : A double with the wanted covariances

Written by Kenneth S. Paulsen

► **createDependentDummy** ↑

```
obj = createVarDummy(obj, condition)
obj = createVarDummy(obj, condition, scalar)
```

Description:

Creates a nb_math_ts object with dummy variables basted on the tested criterions.

Input:

- obj : An object of class nb_math_ts with size nObs x nVars x nPages.

- condition : Name of the added dummy variable.

- '<' : Less than.
- '>' : Greater than.
- '<=' : Less than or equal to.
- '>=' : Less than or equal to.
- '==' : Equal to.
- '~=': Not equal to.

- scalar : A scalar double. Default is 0.

Output:

- obj : An object of class nb_math_ts with size nObs x nVars x nPages.

Examples:

```
obj = nb_math_ts([1,2;-3,1;-1,3],'2012');  
obj = createDependentDummy(obj,'>',0);
```

See also:

[createDependentDummy](#)

Written by Kenneth Sæterhagen Paulsen

► **csc** ↑

obj = csc(obj)

Description:

Cosecant of argument in radians.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj = csc(obj);
```

Written by Kenneth S. Paulsen

► **cscd** ↑

```
obj = cscd(obj)
```

Description:

Cosecant, expressed in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = cscd(in);
```

Written by Andreas Haga Raavand

► **csch** ↑

```
obj = csch(obj)
```

Description:

Hyperbolic cosecant

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

► **cumprod** ↑

```
obj = cumprod(obj,dim)
```

Description:

Cumulativ product

Input:

- obj : An object of class nb_math_ts
- dim : In which dimension the cumulativ product should be calculated. Default is the first dimension.

Output:

- obj : An object of class nb_math_ts where the data property of the object is now the cumulative product of the old objects data property.

Examples:

```
obj = cumprod(obj,1);
```

Written by Kenneth S. Paulsen

► **cumsum ↑**

```
obj = cumsum(obj,dim)
```

Description:

Cumulativ sum

Input:

- obj : An object of class nb_math_ts
- dim : In which dimension the cumulativ sum should be calculated. Default is the first dimension.

Output:

- obj : An object of class nb_math_ts where the data property of the object is now the cumulative sum of the old objects data property.

Examples:

```
obj = cumsum(obj,1);
```

Written by Kenneth S. Paulsen

► **dates** ↑

```
allDates = dates(obj)
```

Description:

Get all the dates of the nb_math_ts object

Input:

- obj : An object of class nb_math_ts

Output:

- allDates : A cellstr with the dates of the object

Examples:

```
allDates = obj.dates();
```

Written by Kenneth S. Paulsen

► **demean** ↑

```
obj = demean(data,dim)
```

Description:

- Demeans data along the dimension you choose.

Input:

- obj : A nb_math_ts object

- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- obj : A nb_math_ts object.

See also:

[sgrowth](#), [subAvg](#).

Written by Tobias Ingebrigtsen

► **demeanMoving** ↑

```
obj = demeanMoving(data,backward)
obj = demeanMoving(data,backward,forward)
```

Description:

- Demeans data with a moving average process.

Input:

- obj : A nb_math_ts object
- backward : Number of periods backward in time to calculate the moving average
- forward : Number of periods forward in time to calculate the moving average

Output:

- obj : A nb_math_ts object.

See also:

[nb_math_ts.demean](#)

Written by Kenneth Å!terhagen Paulsen

► **denton** ↑

```
obj = denton(obj,z,k,type,d)
```

Description:

The Denton method of transforming a series from low to high frequency.

See Denton (1971), Adjustment of Monthly or Quarterly Series to Annual Totals: An Approach Based on Quadratic Minimization.

Input:

- obj : A nobs x nvars x npage nb_math_ts object with the main variables to transform.
- z : A nobs*k x nvars x npage double with observations on the judgment.
- k : The number intra low frequency observations. If you have annual

data and want out quarterly data use 4.

- type : Either 'sum', 'average', 'first' or 'last'. 'average' is default.
- d : 1 : first differences, 2 : second differences.

Output:

- x : Output series as a nobs*k x nvars x npage nb_math_ts object.

See also:

[nb_math_ts.convert](#), [nb_denton](#)

Written by Kenneth Sæterhagen Paulsen

► **deptcat** ↑

obj = deptcat(a,b,varargin)

Description:

Depth concatenation (add pages of different nb_math_ts objects)
(No short hand notation)

Input:

- a : An object of class nb_math_ts
- b : An object of class nb_math_ts
- varargin : Optional number of nb_math_ts objects

Output:

obj : An object of class nb_math_ts, which will result from adding all the pages from the input objects.

Examples:

```
obj = deptcat(a,b);  
obj = deptcat(a,b,c);
```

Written by Kenneth S. Paulsen

► **detrend** ↑

```

obj          = detrend(obj,method)
obj          = detrend(obj,method,output,varargin)
[obj,trendObj] = detrend(obj,method,output,varargin)

```

Description:

Detrending nb_ts object.

Input:

- obj : As a nb_math_ts object.
- method : Either {'linear', 'linearls', 'mean', 'hpfilter', 'hpfilterls', 'bkfilter', 'bkfilterls', 'baiPerron' or 'exponentialsmoother'.
- output : If given as 'trend' the first output will be the trend output instead. 'Normal' is default.
- varargin : Additional inputs. When:
 - > 'exponentialsmoother' : One more input must be given. I.e. weight on previous value. See extrend function for more.
 - > 'hpfilter' or 'hpfilterls' : One more input must be given. I.e. lambda.
 - > 'bkfilter' or 'bkfilterls' : Two more inputs must be given. I.e. lowFreq and highFreq.
 - > 'baiPerron' : Two input may be given:
 - The first:
 - * 'bic' : Bayesian information criterion is used to select the breaks. Default.
 - * 'lwz' : The Liu, Wu and Zidek information criterion is used to select the breaks.
 - * integer : An integer with the number of breaks to identify.
 - The second:
 - * integer : The maximum number of breaks to allow when using a information criterion to choose the number of breaks. Default is 2.

Output:

- obj : As a nb_math_ts object with the detrended data.
- trendObj : As a nb_math_ts object with the trend.

Examples:

```

obj = nb_math_ts.rand('2012Q1',10,3);
obj = detrend(obj,'linear');
obj = detrend(obj,'hpfilter','','1600');
obj = detrend(obj,'bkfilter','','6,32');

```

See also:

[createShift](#)

Written by Kenneth Sæterhagen Paulsen

► **diff** ↑

```
obj = diff(obj)
obj = diff(obj, lags)
obj = diff(obj, lags, skipNaN)
```

Description:

Calculate diff, using the formula: $x(t) - x(t-lag)$ of all the timeseries of the nb_math_ts object.

Input:

- obj : An object of class nb_math_ts
- lags : The number of lags in the diff formula, default is 1.
- skipNaN : - 1 : Skip nan while using the diff operator. (E.g. when dealing with working days.)
 - 0 : Do not skip nan values. Default.

Output:

- obj : An nb_math_ts object with the calculated timeseries stored.

Examples:

```
obj = diff(obj);
obj = diff(obj, 4);
```

See also:

[nb_math_ts](#)

Written by Kenneth S. Paulsen

► **disp** ↑

```
disp(obj)
```

Description:

Display object (On the commandline)

Input:

obj : An object of class nb_math_ts

Output:

The object display on the command line. (When not ending the command with an semicolon)

Examples:

obj

Written by Kenneth S. Paulsen

► **double** ↑

dataOfObject = double(obj)

Description:

Get the data of the object as a double matrix

Input:

- obj : An object of class nb_math_ts

Output:

- dataOfObject : The data of the nb_math_ts object

Examples:

dataOfObject = double(obj)

Written by Kenneth S. Paulsen

► **egrowth** ↑

obj = egrowth(obj,lag,stripNaN)

Description:

Calculate exact growth, using the formula: $(x(t) - x(t-1))/x(t-1)$ of all the timeseries of the nb_math_ts object.

Input:

- obj : An object of class nb_math_ts
- lag : The number of lags in the growth formula, default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An nb_math_ts object with the calculated timeseries stored.

Examples:

```
obj = egrowth(obj);
obj = egrowth(obj, 4);
```

Written by Kenneth S. Paulsen

► **empty** ↑

```
obj = empty(obj)
```

Description:

Empty the existing nb_math_ts object.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An empty nb_math_ts object

Examples:

```
obj = empty(obj)
```

Written by Kenneth S. Paulsen

► **epcn** ↑

```
obj = epcn(obj,lag,stripNaN)
```

Description:

Calculate exact percentage growth, using the formula:
 $100 * (x(t) - x(t-1)) / x(t-1)$ of all the timeseries of the
nb_math_ts object.

Input:

- obj : An object of class nb_math_ts
- lag : The number of lags in the growth formula, default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An nb_math_ts object with the calculated timeseries stored.

Examples:

```
obj = epcn(obj); % period-on-period growth
obj = epcn(obj,4); % 4-periods growth
```

Written by Kenneth S. Paulsen

► **eq ↑**

```
a = eq(a,b)
```

Description:

Test if the two objects are equal elemetswise and return a
nb_math_ts object where each element are 1 if true, otherwise 0.

The objects must have the same dimension

It is also possible to test each element of a object to a scalar

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- a : An nb_math_ts object where each element are 1 if the different data elemets are equal, otherwise 0.

Examples:

```
obj = a == b;  
obj = 2 == b;  
obj = a == 2;
```

Written by Kenneth S. Paulsen

► **exp ↑**

```
obj = exp(obj)
```

Description:

Take exp of the data stored in the nb_math_ts object

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts where the data
are equal to e raised to the data.

Examples:

```
obj = exp(obj);
```

Written by Kenneth S. Paulsen

► **expand ↑**

```
obj = expand(obj,newStartDate,newEndDate,type,warningOff)
```

Description:

Expand the current nb_math_ts object with more dates and data

Input:

- obj : An object of class nb_math_ts
- newStartDate : The wanted new start date of the data.
- newEndDate : The wanted new end date of the data.
- type : Type of the appended data :

```

- 'nan'      : Expanded data is all nan (default)
- 'zeros'    : Expanded data is all zeros
- 'ones'     : Expanded data is all ones
- 'rand'     : Expanded data is all random numbers
- 'obs'      : Expand the data with first observation
                (before) or last observation after

- warningOff : Give 'off' to suppress warning if no expansion
               has taken place. Both 'newStartDate' and
               'newEndDate' is inside the window.

```

Output:

```
- obj          : An nb_math_ts object with expanded timespan
```

Examples:

```
obj = expand(obj,'1900Q1','2050Q1');
obj = expand(obj,'1900Q1','2050Q1','zeros');
```

Written by Kenneth S. Paulsen

► **expml ↑**

```
obj = expml(obj)
```

Description:

`exp(obj)` is the exponential of the elements of `obj`, e to the `obj`.
`expml(obj)` computes $\exp(\text{obj}) - 1$, compensating for the roundoff in
 $\exp(\text{obj})$.
(For small real X , $\text{expml}(X)$ should be approximately X , whereas the
computed value of $\text{EXP}(X) - 1$ can be zero or have high relative error.)

Input:

```
- obj          : An object of class nb_math_ts
```

Output:

```
- obj          : An object of class nb_math_ts where the data are
               equal to  $e.^{\text{obj}.data} - 1$ 
```

Examples:

```
obj = expml(obj);
```

Written by Andreas Haga Raavand

► **extrapolate** ↑

```
obj = extrapolate(obj,toDate)
obj = extrapolate(obj,toDate,varargin)
```

Description:

Extrapolate the time-series.

Input:

- obj : An object of class nb_math_ts
- toDate : Extrapolate to the given date. If the date is before the end date of the given variable no changes will be made, and with no warning. Can also be a integer with the number of periods to extrapolate.

Optional inputs:

- 'alpha' : Significance level of ADF test for 'flow' or 'stock'.
- 'constant' : Give true to include constant in the AR models used to extrapolate the individual series. Default is true.
- 'freq' : The low frequency to fulfill the period for. E.g. if the object end at '2000M2', then '2000M3' is extrapolated so that all months of the 1st quarter of 2000 have values. toDate must be set to 'low'. Default is 1.
- 'method' :
 - > 'end' : Extrapolate series by using the last observation of each series. I.e. a random walk forecast. Default.
 - > 'ar' : Extrapolate each series individually using a fitted AR model.
- 'takeLog' : Take log before stock variables are extrapolated in first difference. true or false.
- 'type' : 'stock', 'flow' or 'test'. Default is 'flow'. 'stock' will extrapolate in (log) first difference. 'test' will use a ADF test to check if the variables are stationary ('flow') or not ('stock').

Output:

- obj : An nb_math_ts object with extrapolate series.

Examples:

```
obj = nb_math_ts.rand('2000M1',50,2,1);
obj = extrapolate(obj,'2004M3');
obj = extrapolate(obj,'2004M3','method','ar');
obj = extrapolate(obj,'low','method','ar','freq',4);
```

Written by Kenneth S. Paulsen

► **fillNaN** ↑

```
obj = fillNaN(obj)
obj = fillNaN(obj,date)
```

Description:

Fill in for nan values with last valid observation.

Input:

- obj : An object of class nb_math_ts.
- date : The end date of the returned dataset. Either a nb_date object or string with the date, or a number indicating how many periods back in time from the date today, i.e. 0 is today, -1 is past period and 1 is next period. Default is to use the end date of the object.

Caution : If the given date is before the end date of the data of the object no extrapolation is done.

Output:

- obj : An object of class nb_math_ts.

Examples:

```
d      = nb_math_ts.rand('2012Q1',10,3);
d(3,3) = nan;
d(6,1) = nan;
d2     = fillNaN(d);
```

Written by Kenneth SÃ¶terhagen Paulsen

► **floor** ↑

```
obj = floor(obj)
```

Description:

`floor(obj)` rounds the data elements of `obj` to the nearest integers towards minus infinity

Input:

- `obj` : An object of class `nb_data`

Output:

- `obj` : An object of class `nb_data`

Examples:

```
out = floor(in);
```

Written by Andreas Haga Raavand

► **ge ↑**

```
a = ge(a,b)
```

Description:

Test if the one object is greater or equal to the other object elemetswise and return a `nb_math_ts` object where each element are 1 if true, otherwise 0.

The objects must have the same dimension and variables

It is also possible to test each element of a object to a scalar

Input:

- `a` : An object of class `nb_math_ts` or a scalar
- `b` : An object of class `nb_math_ts` or a scalar

Output:

- `a` : An `nb_math_ts` object where each element are 1 if the data elemets of object `a` are greater or equal to the data elements of object `b`, otherwise 0.

Examples:

```
obj = a >= b;  
obj = 2 >= b;  
obj = a >= 2;
```

Written by Kenneth S. Paulsen

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get the properties of the object

Input:

- obj : An object
- propertyName :
 - > 'data' : The datz of the object as a double
 - > 'dim1' : Size of the first dimension
 - > 'dim2' : Size of the second dimension
 - > 'dim3' : Size of the third dimension
 - > 'endDate' : The end date of the object as string
 - > 'startDate' : The start date of the object as string

Output:

The property value of the object for the given property name

Examples:

```
dataAsDouble = get(obj,'data');
```

Written by Kenneth S. Paulsen

► **getClassOfData** ↑

```
cl = getClassOfData(obj)
```

Description:

Get the class of the data stored by the object.

Input:

- obj : An object of class nb_math_ts.

Output:

- cl : Name of the class that the data of the object is stored as.

Written by Kenneth Sæterhagen Paulsen

► **getRealEndDate** ↑

```
realEndDate = getRealEndDate(obj,format)
```

Description:

Get the real end date of the nb_math_ts object. I.e the last observation which is not nan or infinite.

Input:

- obj : An object of class nb_math_ts

- format : The date format returned.

Return a string:

> 'xls'
> 'pprnorsk' or 'mprnorwegian'
> 'pprengelsk' or 'mprenglish'
> 'default' (otherwise)

Return a date object which is of a subclass of the nb_date class:

> 'nb_date'

Output:

- realEndDate : The last observation of the object which is not nan or infinite. As a string

Examples:

```
realEndDate = obj.getRealEndDate();
```

Written by Kenneth S. Paulsen

► **getRealStartDate** ↑

```
realStartDate = getRealStartDate(obj,format)
```

Description:

Get the real start date of the nb_math_ts object. I.e the first observation which is not nan or infinite.

Input:

- obj : An object of class nb_math_ts
- format : The date format returned.
 - Return a string:
 - > 'xls'
 - > 'pprnorsk' or 'mprnorwegian'
 - > 'pprengelsk' or 'mprenglish'
 - > 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
 - > 'nb_date'

Output:

- realStartDate : The first observation of the object which is not nan or infinite. As a string

Examples:

```
realEndDate = obj.getRealStartDate();
```

Written by Kenneth S. Paulsen

► growth ↑

```
obj = growth(obj)
obj = growth(obj,lag,stripNaN)
```

Description:

Calculate approx growth, using the formula: $\log(x(t)) - \log(x(t-1))$ of all the timeseries of the nb_math_ts object.

Input:

- obj : An object of class nb_math_ts
- lag : The number of lags in the approx. growth formula, default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An nb_math_ts object with the calculated timeseries stored.

Examples:

```
obj = growth(obj);
obj = growth(obj,4);
```

Written by Kenneth S. Paulsen

► **gt** ↑

```
a = gt(a,b)
```

Description:

Test if the one object is greater then the other object elemetswise and return a nb_math_ts object where each element are 1 if true, otherwise 0.

The objects must have the same dimension and variables

It is also possible to test each element of a object to a scalar

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- a : An nb_math_ts object where each element are 1 if the data elemets of object a are greater then the data elements of object b, otherwise 0.

Examples:

```
obj = a > b;
obj = 2 > b;
obj = a > 2;
```

Written by Kenneth S. Paulsen

► **h21** ↑

```
obj = h21(obj,freq,type)
```

Description:

Will for each observation calculate the weighted cumulative sum over the last N periods (Including the present). The weights will depend on the frequency and the selected type. Examples will be given in the case of monthly data and freq = 4;

```

- 'levelSummed' : Y(q)      = Y(m) + Y(m-1) + Y(m-2)
- 'diffSummed' : Y(q)      = Y(m) + 2*Y(m-1) + 3*Y(m-2) +
                           2*Y(m-3) + Y(m-4)
- 'levelAverage' : Y(q)    = 1/3*(Y(m) + Y(m-1) + Y(m-2))
- 'diffAverage' : Y(q)    = 1/3*Y(m) + 2/3*Y(m-1) + Y(m-2) +
                           2/3*Y(m-3) + 1/3*Y(m-4)

```

Input:

- obj : An object of class nb_math_ts.
- freq : The low frequency to convert high frequency observations to.
- type : See description of method. Default is 'levelAverage'

Output:

- obj : An object of class nb_math_ts. Caution: The frequency of the nb_math_ts will not be converted. See nb_math_ts.convert in this case.

See also:

[nb_math_ts.convert](#)

Written by Kenneth S. Paulsen

► **head** ↑

`head(obj, nRows, page)`

Description:

Display the first n rows of a nb_math_ts object.

Input:

- obj : An nb_math_ts object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_math_ts](#), [window](#), [tail](#)

Written by Per Bjarne Bye

► **horzcat** ↑

```
obj = horzcat(a,b,varargin)
```

Description:

Horizontal concatenation ([a,b])

If the start or end dates differ, nan values will be appended

Input:

- a : An object of class nb_math_ts
- b : An object of class nb_math_ts
- varargin : Optional number of nb_math_ts objects

Output:

- obj : An object of class nb_math_ts with the input objects data are horizontally concatenated

Examples:

```
obj = [a,b];  
obj = [a,b,c];
```

Written by Kenneth S. Paulsen

► **horzcatfast** ↑

```
obj = horzcatfast(varargin)
```

Description:

Horizontal concatenation

The start or end dates cannot differ.

Input:

- varargin : Optional number of nb_math_ts objects

Output:

- obj : An object of class nb_math_ts with the input objects data are horizontally concatenated

See also
nb_math_ts.horzcat

Written by Kenneth S. Paulsen

► **hpfilter** ↑

```
obj = hpfilter(obj,lambda)
obj = hpfilter(obj,lambda,perc,fcstLen)
```

Description:

Do hp-filtering of all the dataseries of the nb_math_ts object.
(Returns the gap). Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_math_ts
- lambda : The lambda of the hp-filter
- perc : Set to true to calculate the gap as (gap/trend)*100.
- fcstLen : The forecast length. Extrapolates the original series using the average of the last 4 periods. Default is 0.

Output:

- obj : An nb_math_ts object with the hp-filtered timeseries.

Examples:

```
gap = hpfilter(data,3000);
trend = data-gap;
```

Written by Kenneth S. Paulsen

► **hpfilterls** ↑

```
obj = hpfilterls(obj,lambda)
obj = hpfilterls(obj,lambda,perc,fcstLen)
```

Description:

Do one-sided hp-filtering of all the dataseries of the nb_math_ts object. (Returns the gap). Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_math_ts
- lambda : The lambda of the hp-filter

- perc : Set to true to calculate the gap as (gap/trend)*100.
- fcstLen : The forecast length. Extrapolates the original series using the average of the last 4 periods. Default is 0.

Output:

- obj : An nb_math_ts object with the hp-filtered timeseries.

Examples:

```
gap = hpfilterls(data,3000);
trend = data-gap;
```

Written by Kenneth S. Paulsen

► **iegrowth** ↑

```
obj = iegrowth(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of exact growth, i.e. the inverse method of the egrowth method of the nb_math_ts class

Input:

- obj : An object of class nb_math_ts
- InitialValues : A nb_math_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_math_ts object. If not provided 100 is default.
- Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.
- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_math_ts object with the indicies.

Examples:

```
obj = iegrowth(obj);
obj = iegrowth(obj,100);
obj = iegrowth(obj,[78,89]);
```

Written by Kenneth S. Paulsen

► **iepcn** ↑

```
obj = iepcn(obj,initialValues,periods)
```

Description:

Construct indicies based on inital values and timeseries wich represent the series growth. Inverse of exact percentage growth, i.e. the inverse method of the epcn method of the nb_math_ts class

Input:

- obj : An object of class nb_math_ts
 - InitialValues : A nb_math_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_math_ts object. If not provided 100 is default.
- Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.
- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_math_ts object with the indicies.

Examples:

```
obj = iepcn(obj);
obj = iepcn(obj,100);
obj = iepcn(obj,[78,89]);
```

Written by Kenneth S. Paulsen

► **igrowth** ↑

```
obj = igrowth(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of log approx. growth, i.e. the inverse method of the growth method of the nb_math_ts class

Input:

- obj : An object of class nb_math_ts
- InitialValues : A nb_math_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_math_ts object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.
- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_math_ts object with the indicies.

Examples:

```
obj = igrowth(obj);  
obj = igrowth(obj,100);  
obj = igrowth(obj,[78,89]);
```

Written by Kenneth S. Paulsen

► **interpolate ↑**

```
obj = interpolate(obj,method)
```

Description:

Interpolate the data of the nb_math_ts object. Will discard leading and trailing nan values.

Input:

```
- data    : A nb_math_ts object.  
  
- method :  
  
- 'nearest'   : Nearest neighbor interpolation  
- 'linear'    : Linear interpolation. Default  
- 'spline'    : Piecewise cubic spline interpolation (SPLINE)  
- 'pchip'     : Shape-preserving piecewise cubic interpolation  
- 'cubic'     : Same as 'pchip'  
- 'v5cubic'   : The cubic interpolation from MATLAB 5, which  
                does not extrapolate and uses 'spline' if X is  
                not equally spaced.
```

Output:

```
- data : A nb_math_ts object with the interpolated data.
```

Written by Kenneth Sæterhagen Paulsen

► **ipcn ↑**

```
obj = ipcn(obj)  
obj = ipcn(obj,initialValues,periods,startAtNaN)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of percentage log approx. growth, i.e. the inverse method of the pcn method of the nb_math_ts class

Input:

```
- obj           : An object of class nb_math_ts  
  
- InitialValues : A nb_math_ts object with a bigger window than obj,  
                  or a scalar or a double with the initial  
                  values of the indicies. Must be of the same  
                  size as the number of variables of the  
                  nb_math_ts object. If not provided 100 is  
                  default.  
  
                  Caution : If periods > 1 the initialValues input  
                             must be given, and has at least have  
                             periods number of rows.  
  
- periods      : The number of periods the initial series  
                  has been taken growth over.
```

Output:

```
- Output        : An nb_math_ts object with the indicies.
```

Examples:

```
obj = ipcn(obj);
obj = ipcn(obj,100);
obj = ipcn(obj,[78,89]);
```

Written by Kenneth S. Paulsen

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_math_ts object is empty. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_math_ts

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **isfinite** ↑

```
obj = isfinite(obj)
```

Description:

Test if each element of an nb_math_ts object is finite.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : The object with data as logical. 1 if an element is finite, otherwise 0.

Examples:

```
obj = isfinite(obj);
```

Written by Kenneth S. Paulsen

► **isnan** ↑

```
obj = isnan(obj)
```

Description:

Test if each element of an nb_math_ts object is nan.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : The object with data as logical. 1 if an element is nan, otherwise 0.

Examples:

```
obj = isnan(obj);
```

Written by Kenneth S. Paulsen

► **kurtosis** ↑

```
obj = kurtosis(obj,flag,dim,outputType)
```

Description:

Calculate the kurtosis of each timeseries. The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are being set to their kurtosis.

The output can also be set to be a double only consisting of the kurtosis values of the data.

Input:

- obj : An object of class nb_math_ts
- flag : > 0 : normalises by N-1 (Default)
 > 1 : normalises by N

Where N is the sample length.

- dim : The dimension to take the kurtosis over
- outputType : - 'nb_math_ts': The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are being set to their kurtosis.
 - 'double': Get the kurtosis values as doubles, where each column of the double matches the same column of the data property of the nb_math_ts object. If the object consists of more pages the double will also consist of more pages.

Output:

- obj : The object itself where all the non-nan values of all the timeseries are being set to their kurtosis. Or a double with the kurtosis values.

Examples:

```
obj = kurtosis(obj)  
same as  
obj = kurtosis(obj,0,0,'nb_math_ts')
```

Output as a double (matrix)

```
double = kurtosis(obj,0,0,'double')
```

Written by Kenneth S. Paulsen

► **lag ↑**

```
obj = lag(obj,periods)
```

Description:

Lag the data of the object. The input periods decides for how many periods.

Input:

- obj : An object of class nb_math_ts
- periods : Lag the data with this number of periods. Default is 1 period.

Output:

- obj : An nb_math_ts object where the data lagged by number of periods given by the input periods.

Examples:

```
obj = lag(obj,1);
```

Written by Kenneth S. Paulsen

► **ldivide** ↑

```
obj = ldivide(a,b)
```

Description:

Left element-wise division (.\ \backslash). Same as right element-wise (./) division. See rdivide for more.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = a.\b;
obj = 2.\b;
obj = a.\2;
```

See also:

[rdivide](#), [mldivide](#), [mrdivide](#)

Written by Kenneth S. Paulsen

► **le** ↑

```
a = le(a,b)
```

Description:

Test if the one object is less or equal to the other object elemetswise and return a nb_math_ts object where each element are 1 if true, otherwise 0.

The objects must have the same dimension

It is also possible to test each element of a object to a scalar

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- a : An nb_math_ts object where each element are 1 if the data elemets of object a are less or equal to the data elements of object b, otherwise 0.

Examples:

```
obj = a <= b;  
obj = 2 <= b;  
obj = a <= 2;
```

Written by Kenneth S. Paulsen

► **lead** ↑

```
obj = lead(obj,periods)
```

Description:

Lead the data of the object. The input periods decides for how many periods.

Input:

- obj : An object of class nb_math_ts
- periods : Lead the data with this number of periods. Default is 1 period.

Output:

- obj : An nb_math_ts object where the data leaded by number of periods given by the input periods.

Examples:

```
obj = lead(obj,1);
```

Written by Kenneth S. Paulsen

► **log** ↑

```
obj = log(obj)
```

Description:

Take log of the data stored in the nb_math_ts object

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts where the data are on logs.

Examples:

```
obj = log(obj);
```

Written by Kenneth S. Paulsen

► **log10** ↑

```
obj = log10(obj)
```

Description:

Take the common (base 10) log of the data stored in the nb_math_ts object

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj = log10(obj);
```

Written by Andreas Haga Raavand

► **log1p** ↑

```
obj = log1p(obj)
```

Description:

`log1p(obj)` computes $\text{LOG}(1+xi)$, where xi are the elements of `obj`. Complex results are produced if $xi < -1$.

For small real xi , `log1p(xi)` should be approximately xi , whereas the computed value of $\text{LOG}(1+xi)$ can be zero or have high relative error.

Input:

- `obj` : An object of class `nb_math_ts`

Output:

- `obj` : An object of class `nb_math_ts`

Examples:

```
out = log1p(in);
```

Written by Andreas Haga Raavand

► **log2** ↑

```
obj = log2(obj)
```

Description:

`log2(obj)` is the base 2 logarithm of the elements of `obj`.

Input:

- `obj` : An object of class `nb_math_ts`

Output:

- `obj` : An object of class `nb_math_ts` where the data is the base 2 logs of `obj`.

Examples:

```
obj = log2(obj);
```

Written by Andreas Haga Raavand

► **lt** ↑

```
a = lt(a,b)
```

Description:

Test if the one object is less then the other object elemetswise and return a nb_math_ts object where each element are 1 if true, otherwise 0.

The objects must have the same dimension

It is also possible to test each element of a object to a scalar

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- a : An nb_math_ts object where each element are 1 if the data elemets of object a are less then the data elements of object b, otherwise 0.

Examples:

```
obj = a < b;  
obj = 2 < b;  
obj = a < 2;
```

Written by Kenneth S. Paulsen

► **mavg** ↑

```
obj = mavg(obj,backward,forward,flag)
```

Description:

Taking moving avarage of all the timeseries of the nb_math_ts object

Input:

- obj : An object of class nb_math_ts
- backward : Number of periods backward in time to calculate the moving average
- forward : Number of periods forward in time to calculate the moving average
- flag : If set to true the periods that does not have enough observations forward or backward should be set to nan. Default is false.

Output:

- obj : An nb_math_ts object storing the calculated moving average

Examples:

```
data = nb_math_ts(rand(50,2)*3,'2011Q1');
mAvg10 = mavg(data,9,0); % (10 year moving average)
```

Written by Kenneth S. Paulsen

► max ↑

```
obj = max(obj,dim,outputType)
```

Description:

Calculate the max values of each timeseries. The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are being set to their max.

The output can also be set to be a double only consisting of the max values of the data.

Input:

- obj : An object of class nb_math_ts
- dim : The dimension to find the max over
- outputType :
 - 'nb_math_ts': The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are being set to their max.
 - 'double': Get the max values as doubles, where each column of the double matches the

same column of the data property of the nb_math_ts object. If the object consist of more pages the double will also consist of more pages.

Output:

- obj : The object itself where all the non-nan values of all the timeseries are beeing set to their max. Or a double with the max values.

Examples:

```
obj = max(obj)
```

same as

```
obj = max(obj,1,'nb_math_ts')
```

Output as a double (matrix)

```
double = max(obj,1,'double')
```

Written by Kenneth S. Paulsen

► **mean ↑**

```
obj = mean(obj,dim,outputType)
```

Description:

Calculate the mean of each timeseries. The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are beeing set to their mean.

The output can also be set to be a double only consisting of the mean values of the data.

Input:

- obj : An object of class nb_math_ts
- dim : The dimension to take the mean over
- outputType : - 'nb_math_ts': The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are beeing set to their mean.
- 'double': Get the mean values as doubles, where each column of the double matches the same column of the data property of the

nb_math_ts object. If the object consist of more pages the double will also consist of more pages.

Output:

- obj : The object itself where all the non-nan values of all the timeseries are beeing set to their mean. Or a double with the mean values.

Examples:

```
obj = mean(obj)  
same as  
obj = mean(obj,1,'nb_math_ts')
```

Output as a double (matrix)

```
double = mean(obj,1,'double')
```

Written by Kenneth S. Paulsen

► **median** ↑

```
obj = median(obj,dim,outputType)
```

Description:

Calculate the median of each timeseries. The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are beeing set to their median.

The output can also be set to be a double only consisting of the median values of the data.

Input:

- obj : An object of class nb_math_ts
- dim : The dimension to take the median over
- outputType : - 'nb_math_ts': The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are beeing set to their median.
- 'double': Get the median values as doubles, where each column of the double matches the same column of the data property of the

nb_math_ts object. If the object consist of more pages the double will also consist of more pages.

Output:

- obj : The object itself where all the non-nan values of all the timeseries are being set to their median. Or a double with the median values.

Examples:

```
obj = median(obj)
```

same as

```
obj = median(obj,1,'nb_math_ts')
```

Output as a double (matrix)

```
double = median(obj,1,'double')
```

Written by Kenneth S. Paulsen

► **merge2Series ↑**

```
obj = merge2Series(obj,other,method,varargin)
```

Description:

Merge 2 series. The var2 series is appended to the var1 series from where it is ending.

Input:

- obj : An object of class nb_math_ts.
- other : An object of class nb_math_ts.
- method : Either 'level', 'diff', 'growth', 'leveldiff' or 'levelgrowth'. Default is 'level'. For the cases 'level', 'diff' or 'growth' it is assumed the both series are in levels. 'leveldiff' assumes the first series is in level and the second in nLags-difference. 'levelgrowth' assumes the first series is in level and the second in growth rates over nLags periods, i.e. $(x(t) - x(t-nLags))/x(t-nLags)$.

Optional input:

- 'nLags' : The number of lages used for the methods 'diff' and 'growth'. Default is 1.
- 'date' : The date from where to use the second variable. Either a date as string or a nb_date object. If empty the merge will take place where the first variable end + 1 period.

Output:

- obj : An object of class nb_math_ts.

Examples:

```
obj = nb_math_ts.rand('2012Q1',8,1,3);
other = nb_math_ts.rand('2012Q1',10,1,3);

obj1 = merge2Series(obj,other)
obj3 = merge2Series(obj,other,'diff','nLags',1)
obj4 = merge2Series(obj,other,'diff','nLags',4)
obj5 = merge2Series(obj,other,'level','date','2014Q1')
```

Written by Kenneth Sæterhagen Paulsen

► **min ↑**

```
obj = min(obj,dim,outputType)
```

Description:

Calculate the min values of each timeseries. The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are being set to their min.

The output can also be set to be a double only consisting of the min values of the data.

Input:

- obj : An object of class nb_math_ts
- dim : The dimension to find the min over
- outputType : - 'nb_math_ts': The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are being set to their min.
- 'double': Get the min values as doubles, where each column of the double matches the same column of the data property of the nb_math_ts object. If the object consist of more pages the double will also consist of more pages.

Output:

- obj : The object itself where all the non-nan values of all the timeseries are being set to their min. Or a double with the min values.

Examples:

```
obj = min(obj)
```

same as

```
obj = min(obj,1,'nb_math_ts')
```

Output as a double (matrix)

```
double = min(obj,1,'double')
```

Written by Kenneth S. Paulsen

► minus ↑

```
obj = minus(a,b)
```

Description:

Binary subtraction (-).

Subtract all elements of the first input objects data by the second input objects data pair-wise. The objects must be of the same sizes.

It is also possible to subtract data of the object by a scalar, or subtract a scalar by the objects data.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = a-b;  
obj = 2-b;  
obj = a-2;
```

See also:

[plus](#)

Written by Kenneth S. Paulsen

► **mldivide** ↑

`obj = mldivide(a,b)`

Description:

Matrix left division (\). Only defined when dividing by a scalar or when a scalar are divide by the object(s data)

Input:

- `a` : An object of class nb_math_ts or a scalar
- `b` : An object of class nb_math_ts or a scalar

Output:

- `obj` : An object of class nb_math_ts with the calculated data stored

Examples:

`obj = 2\obj;`
`obj = obj\2;`

See also:

[rdivide](#), [ldivide](#), [mrdivide](#)

Written by Kenneth S. Paulsen

► **mpower** ↑

`obj = power(a,b)`

Description:

Element-wise power (.^)

Makes it possible to raise the data of the obejct by a scalar, or raise a scalar by the objects data.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = 2^b;  
obj = a^2;
```

See also:

[power](#)

Written by Kenneth S. Paulsen

► **mrddivide** ↑

```
obj = mrddivide(a,b)
```

Description:

Matrix left division (/). Only defined when dividing by a scalar or when a scalar are divide by the object(s) data

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = 2/obj;  
obj = obj/2;
```

See also:

[rdivide](#), [ldivide](#), [mlddivide](#)

► **mstd** ↑

```
obj = mstd(obj,backward,forward)
```

Description:

Taking moving standard deviation of all the timeseries of the nb_math_ts object

Input:

- obj : An object of class nb_math_ts
- backward : Number of periods backward in time to calculate the moving std
- forward : Number of periods forward in time to calculate the moving std

Output:

- obj : An nb_math_ts object storing the calculated moving std

Examples:

```
data = nb_math_ts(rand(50,2)*3,'2011Q1');  
mstd10 = mstd(data,9,0); % (10 year moving std)
```

Written by Kenneth S. Paulsen

► **mtimes** ↑

```
obj = power(a,b)
```

Description:

Matrix multiplication (*) Only defined for multiplication with a scalar.

Makes it possible to multiply the data of the obejct by a scalar, or multiply a scalar by the objects data.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = 2*b;  
obj = a*2;
```

See also:

[times](#)

Written by Kenneth S. Paulsen

► **nan** ↑

```
obj = nb_math_ts.nan(start,obs,vars,pages)
```

Description:

Create an nb_math_ts object with all data set to nan.

Input:

- start : The start date of the created nb_math_ts object.
- obs : The number of observation of the created nb_math_ts object.
- vars : A scalar with the number of variables of the nb_math_ts object.
- pages : Number of pages of the nb_math_ts object.

Output:

- obj : An nb_math_ts object.

Examples:

```
obj = nb_math_ts.nan('2012Q1',2,2);  
obj = nb_math_ts.nan('2012Q1',2,2,10);
```

See also:

nb_math_ts

Written by Kenneth Sæterhagen Paulsen

► **ne ↑**

```
a = ne(a,b)
```

Description:

Test if the two objects are not equal elemetswise and return a nb_math_ts object where each element are 1 if true, otherwise 0.

The objects must have the same dimension

It is also possible to test each element of a object to a scalar

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- a : An nb_math_ts object where each element are 1 if the different data elemets are not equal, otherwise 0.

Examples:

```
obj = a ~= b;  
obj = 2 ~= b;  
obj = a ~= 2;
```

Written by Kenneth S. Paulsen

► **not ↑**

```
obj = not(obj)
```

Description:

The not operator (~)

Input:

- a : An object of class nb_math_ts

Output:

- a : An object of class nb_math_ts where each element of the input object are equal to 1 if it was 0, otherwise 0. The data will be a logical matrix

Examples:

```
obj = ~obj;
```

Written by Kenneth S. Paulsen

► objSize ↑

```
varargout = objSize(obj,dim)
```

Description:

Return the size(s) of the object

Input:

- obj : An object of class nb_math_ts
- dim : > 1 : Size of the first dimension
> 2 : Size of the second dimension
> 3 : Size of the third dimension

Output:

- varargout : > dim1 : Size of the first dimension
> dim2 : Size of the second dimension
> dim3 : Size of the third dimension

See the examples below.

Examples:

```
dim = objSize(obj)
```

Where dim is 1 x 2 double where the first element is the size of the first dimension and the second element is the size of the second dimension

```
[dim1, dim2] = objSize(obj)
```

```
[dim1, dim2, dim3] = objSize(obj)
```

```
dim1 = objSize(obj,1)
```

```
dim2 = objSize(obj,2)
```

```
dim3 = objSize(obj,3)
```

Written by Kenneth S. Paulsen

► **or** ↑

```
a = or(a,b)
```

Description:

The or operator (|)

Will test elemetwise the data property of the two input objects and return 1 if both elemets are above 1, otherwise will return 0.

Input:

- a : An object of class nb_math_ts
- b : An object of class nb_math_ts

Output:

- a : An nb_math_ts object where the || operator have been used for the corresponding elements of the input objects data and the result are given by the output objects data property. The data will be a logical matrix

Examples:

```
a = a | b;
```

Written by Kenneth S. Paulsen

► **pca** ↑

```
F = pca(obj)
[F,LAMBDA,R,varF,expl,c,sigma,e,Z] = pca(obj,r,method,varargin)
```

Description:

Principal Component Analysis of the data of the object.

Input:

- obj : An object of class nb_math_ts.
- r : The number of principal component. If empty this number will be found by the Bai and Ng (2002) test, see the optional option crit below, i.e choose the CT part of the selection criterion; log(V(ii,F)) + CT. Where;

```

V(ii,F) = sum(diag(e_ii'*e_ii/T))/ii

and e_ii is the residual when ii factors are used

- method : Either 'svd' or 'eig'. Default is 'svd'.

    > 'svd' : Uses single value deomposition to construct the
               principal components. This is the numerically best
               way, as the 'eig' method could be very unprecise!

    > 'eig' : Uses the eigenvalue decomposition approach instead

```

Optional inputs:

```

- 'crit' : You can choose between the follwing selection criterion

    > 1: log(NT/NT1)*ii*NT1/NT;

    > 2: (NT1/NT)*log(min([N;T]))*ii;

    > 3: ii*log(GCT)/GCT;

    > 4: 2*ii/T;

    > 5: log(T)*ii/T;

    > 6: 2*ii*NT1/NT;

    > 7: log(NT)*ii*NT1/NT; (default)

where NT1 = N + T, GCT = min(N,T), NT = N*T and ii = 1:rMax

- 'rMax' : The maximal number of factors to test for. Must be less than
            or equal to N. Default is N.

- 'trans' : Give 'demean' if you want to demean the data in the matrix
            X. Default. Give 'standardize' if you want to standardise the
            data in the matrix X. Gice 'none' to drop any kind of
            transformation of the data in the matrix X.

Caution: To get back X when 'demean' is given you need to add
          the constant terms in c. I.e;

X = c(ones(T,1),1) + F*LAMBDA + e, e ~ N(0,R) (1')

To get back X when 'standardise' you need to add
the constant term and multiply with sigma. I.e.

X = c(ones(T,1),:) + F*LAMBDA.*sigma(ones(T,1),:) +
    eps, eps ~ N(0,R*) (1*)

Be aware that the eps differ from e, as e is the
residual from the standardised regression.

- 'unbalanced' : true or false. Set to true to allow for unbalanced
                  dataset. Default is false. If false all rows of the
                  dataset containing nan value are removed from
                  calculations.

```

Output:

- F : The principal component, as a nb_math_ts object.
- LAMBDA : The estimated loadings, as a double
- R : The covariance matrix of the residual in (1), as a double.
- varF : As a double. Each column will be the variance of the corresponding column of F.
- expl : The percentage of the total variance explained by each principal component. As a 1 x r double
- c : Constant in the factor equation. double with size 1 x nvar.
- sigma : See 'trans'. double with size 1 x nvar.
- e : Residual of the equation (1) above. As a nb_math_ts object.
- Z : Normalized (and rebalanced) version of X.

See also:[nb_pca](#)

Written by Kenneth Sæterhagen Paulsen

► pca_func ↑

```
factors = pca_func(varargin)
```

Description:

Principal Component of selected number of series represented by a set of nb_math_ts.

Optional input:

- varargin : Optional number of nb_math_ts objects.
- 'numFactors' : Determine number of Factors to report. Standard is first factor only.
- 'unbalanced' : true or false.
- 'whichFactor' : Select the factor to return.

Output:

- factors : The principal component(s) as a nb_math_ts object.

See also:

[nb_math_ts.pca](#)

Written by Kenneth Sætherhagen Paulsen

► **pcn ↑**

obj = pcn(obj,lag,stripNaN)

Description:

Calculate log approximated percentage growth. Using the formula
 $(\log(t+lag) - \log(t)) * 100$

Input:

- obj : An object of class nb_math_ts
- lag : The number of lags. Default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An nb_math_ts object with the log approximated percentage growth data stored.

Examples:

```
obj = pcn(obj); % period-on-period log approx. growth
obj = pcn(obj,4); % 4-periods log approx. growth
```

See also:

[epcn](#)

Written by Kenneth S. Paulsen

► **plus ↑**

obj = plus(a,b)

Description:

Binary addition (+).

Added all elements of the two input objects data pair-wise.
The objects must be of the same sizes.

It is also possible to add a scalar to the data of the object.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = a+b;  
obj = 2+b;  
obj = a+2;
```

See also:

[minus](#)

Written by Kenneth S. Paulsen

► **pow2** ↑

```
obj = pow2(obj)
```

Description:

pow2(obj) raises the number 2 to the power of the elements of obj

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts where the data are the number 2 raised to the power of the elements of the original object.

Examples:

```
obj = pow2(obj);
```

Written by Andreas Haga Raavand

► **power** ↑

```
obj = power(a,b)
```

Description:

Element-wise power (.^)

All elements of the first input objects data is raised by the second input objects data pair-wise. The objects must be of the same sizes.

It is also possible to raise the data of the object by a scalar, or raise a scalar by the objects data, but it is recommended to use mpower (^) instead.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = a.^b;
obj = 2.^b;
obj = a.^2;
```

See also:

[mpower](#)

Written by Kenneth S. Paulsen

► **q2y ↑**

```
obj = q2y(obj)
```

Description:

Will for each quarter calculate the cumulative sum over the last 4 quarter (Including the present). The frequency of the return object will be quarterly.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An nb_math_ts object where the data are the sum over the last 4 quarters.

Written by Kenneth S. Paulsen

► **rand** ↑

```
obj = nb_math_ts.rand(start,obs,vars,pages,dist)
```

Description:

Create an nb_math_ts object with all data set to random number.

Input:

- start : The start date of the created nb_math_ts object.
- obs : The number of observation of the created nb_math_ts object.
- vars : A scalar with the number of variables of the nb_math_ts object.
- pages : Number of pages of the nb_math_ts object.
- dist : A nb_distribution object to draw from.

Output:

- obj : An nb_math_ts object.

Examples:

```
obj = nb_math_ts.rand('2012Q1',2,2);
obj = nb_math_ts.rand('2012Q1',2,2,10,nb_distribution('type','normal'));
```

See also:

[nb_math_ts](#)

Written by Kenneth Sæterhagen Paulsen

► **rdivide** ↑

```
obj = rdivide(a,b)
```

Description:

Right element-wise division (./)

Divide all elements of the first input objects data by the second input objects data pair-wise. The objects must be of the same sizes.

It is also possible to divide data of the obejct by a scalar, or divide a scalar by the objects data, but it is recommended to use mrdivide instead.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = a./b;
obj = 2./b;
obj = a./2;
```

See also:

[mrdivide](#), [mldivide](#), [ldivide](#)

Written by Kenneth S. Paulsen

► **reIndex** ↑

```
obj = reIndex(obj,date)
obj = reIndex(obj,date,value)
```

Description:

Reindex the data of the object to a new date. It is also possible to reindex the timeseries to a date with lower frequency. E.g. reindex quarterly data to be on average 100 in a given year.

Input:

- obj : An object of class nb_math_ts
- date : The date at which the data should be reindexed to.
- value : The value to re-index the data to. Default is 100

Output:

- obj : An object of class nb_math_ts where all the timeseries are reindexed to value at the given date.

Examples:

```
obj = reIndex(obj,'2012Q2')
```

Written by Kenneth S. Paulsen

► **real** ↑

```
obj = real(obj)
```

Description:

real(obj) returns the real part of the elements in the nb_math_ts object

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts where the data are the real part of the elements of the original object.

Examples:

```
obj = real(obj);
```

Written by Andreas Haga Raavand

► **reallog** ↑

```
obj = reallog(obj)
```

Description:

Take the natural logarithm of the data stored in the object

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts where the data are the natural logarithms of the elements of the original object.

Examples:

```
obj = reallog(obj);
```

Written by Kenneth S. Paulsen

► **realpow** ↑

```
obj = power(a,b)
```

Description:

Real power.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts

See also:

[mpower](#), [power](#)

Written by Kenneth S. Paulsen

► **realsqrt** ↑

```
obj = realsqrt(obj)
```

Description:

`realsqrt(obj)` is the square root of the elements of `obj`.
An error is produced if `obj` contains negative elements.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = realsqrt(in);
```

Written by Andreas Haga Raavand

► **ret ↑**

```
obj = ret(obj)
obj = ret(obj,nlag)
obj = ret(obj,nlag,skipNaN)
```

Description:

Calculate return, using the formula: $x(t)/x(t-lag)$ of all the timeseries of the nb_math_ts object.

Input:

- obj : An object of class nb_math_ts
- nlag : The number of lags in the return formula,
default is 1.
- skipNaN : - 1 : Skip nan while using the ret operator. (E.g.
when dealing with working days.)
- 0 : Do not skip nan values. Default.

Output:

- obj : An nb_math_ts object with the calculated timeseries stored.

Examples:

```
obj = ret(obj);
obj = ret(obj,4);
```

See also:

[nb_math_ts](#)

Written by Kenneth S. Paulsen

► **rlag ↑**

```
obj = rlag(obj, lags)
obj = rlag(obj, lags, periods)
```

Description:

Roll a pattern in the data forward with a given lag.

Input:

- obj : An object of class nb_math_ts
- lags : The number of lags
- periods : The extrapolated periods. The end date of the object will be the current end date plus these number of periods. Be aware that trailing nan values in the data will be filled in for even if periods == 0, which is the default.

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj1 = nb_math_ts([1,1;2,2;3,3;4,4;1,nan],'2012Q1');
obj2 = rlag(obj1,4,0);
obj2 = rlag(obj1,4,3);
```

See also:

[nb_rlag](#)

Written by Kenneth Sæterhagen Paulsen

► **round** ↑

```
obj = round(obj,value,startDate,endDate,pages)
```

Description:

Round to closes value. I.e. if value is 0.25 it will round to the closes 0.25. E.g. 0.67 will be rounded to 0.75.

Input:

- obj : A nb_math_ts object
- value : The rounding value. As a double. Default is 1.
- startDate : The start date of the rounding. As a date string or a nb_date object. Can be empty. Default is the start date

of the data.

- endDate : The end date of the rounding. As a date string or a nb_date object. Can be empty. Default is the end date of the data.
- variables : The variables to round. Can be empty. Default is to round all variables.

Output:

- obj : A nb_math_ts object with the rounded numbers.

Written by Kenneth Sæterhagen Paulsen

► **sec ↑**

obj = sec(obj)

Description:

Secant of argument in radians.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

obj = sec(obj);

Written by Kenneth S. Paulsen

► **secd ↑**

obj = secd(obj)

Description:

Secant of argument in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = secd(in);
```

Written by Andreas Haga Raavand

► **sech** ↑

```
obj = sech(obj)
```

Description:

Hyperbolic secant.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = sech(in);
```

Written by Andreas Haga Raavand

► **set2Value** ↑

```
obj = set2Value(obj,func,value)
```

Description:

Set all values applying to the restriction given by the input func to the provided value.

Input:

- obj : An object of class nb_math_ts.
- func : A function handle that takes in a double with size M x N x P and return a logical with same size.
- value : A scalar double.

Output:

- obj : An object of class nb_math_ts.

Examples:

```
obj = nb_math_ts.rand('2000',10,1) - 0.5;
obj = set2Value(obj,@(x)x<0,0)
```

Written by Kenneth SÃ¶terhagen Paulsen

► **setNan2Zero** ↑

```
obj = setNan2Zero(obj)
```

Description:

Set all nan values of the data of the object to 0.

Input:

- obj : An object of class nb_math_ts.

Output:

- obj : An object of class nb_math_ts.

Written by Kenneth SÃ¶terhagen Paulsen

► **sgrowth** ↑

```
obj = sgrowth(obj,horizon)
```

Description:

Calculates smoothed 12 or 6 months growth.

```
x(*) = ((x13+x14+x15)/(x1+x2+x3)-1)*100
```

```
x(*) = ((x7+x8+x9)/(x1+x2+x3)-1)*100
```

Note: Works only for monthly data.

Based on Anne Sofie Jores data transformation code.

Input:

- obj : A nb_math_ts object
- horizon : Either 1 or 2, depending on the frequency you want your growth to be calculated over. 1 is annual and 2 is semi-annual.

Output:

- out : A nb_math_ts object.

Examples:

See also:

nb_sgrowth

Written by Tobias Ingebrigtsen

► **sin ↑**

obj = sin(obj)

Description:

Sine of argument in radians.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts.

Examples:

obj = sin(obj);

Written by Kenneth S. Paulsen

► **sind ↑**

obj = sind(obj)

Description:

Sine, expressed in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = sind(in);
```

Written by Andreas Haga Raavand

► **sinh** ↑

```
obj = sinh(obj)
```

Description:

Hyperbolic sine.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = sinh(in);
```

Written by Andreas Haga Raavand

► **skewness** ↑

```
obj = skewness(obj,flag,dim,outputType)
```

Description:

Calculate the skewness of each timeseries. The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are being set to their skewness.

The output can also be set to be a double only consisting of the skewness values of the data.

Input:

- obj : An object of class nb_math_ts
- flag : > 0 : normalises by N-1 (Default)
> 1 : normalises by N
 - Where N is the sample length.
- dim : The dimension to take the skewness over
- outputType : - 'nb_math_ts': The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are being set to their skewness.
 - 'double': Get the skewness values as doubles, where each column of the double matches the same column of the data property of the nb_math_ts object. If the object consists of more pages the double will also consist of more pages.

Output:

- obj : The object itself where all the non-nan values of all the timeseries are being set to their skewness. Or a double with the skewness values.

Examples:

```
obj = skewness(obj)
```

same as

```
obj = skewness(obj,0,0,'nb_math_ts')
```

Output as a double (matrix)

```
double = skewness(obj,0,0,'double')
```

Written by Kenneth S. Paulsen

► **sqrt ↑**

```
obj = sqrt(obj)
```

Description:

`sqrt(obj)` is the square root of the elements of `obj`. Complex results are produced for non-positive elements.

Input:

- `obj` : An object of class `nb_math_ts`

Output:

- `obj` : An object of class `nb_math_ts`

Examples:

```
out = sqrt(in);
```

Written by Andreas Haga Raavand

► **std ↑**

```
obj = std(obj,flag,dim,outputType)
```

Description:

Calculate the std of each timeseries. The result will be an object of class `nb_math_ts` where all the non-nan values of all the timeseries are being set to their std.

The output can also be set to be a double only consisting of the std values of the data.

Input:

- `obj` : An object of class `nb_math_ts`

- `flag` : > 0 : normalises by N-1 (Default)
 > 1 : normalises by N

Where N is the sample length.

- `dim` : The dimension to take the std over

- `outputType` : - 'nb_math_ts': The result will be an object of class `nb_math_ts` where all the non-nan values of all the timeseries are being set to their std.

- 'double': Get the std values as doubles, where each column of the double matches the

same column of the data property of the nb_math_ts object. If the object consist of more pages the double will also consist of more pages.

Output:

- obj : The object itself where all the non-nan values of all the timeseries are beeing set to their std. Or a double with the std values.

Examples:

```
obj = std(obj)
```

same as

```
obj = std(obj,0,0,'nb_math_ts')
```

Output as a double (matrix)

```
double = std(obj,0,0,'double')
```

Written by Kenneth S. Paulsen

► **stdise** ↑

```
obj = stdise(obj,flag)
```

Description:

Standardise data of the object by subtracting mean and dividing by std deviation.

Input :

- obj : An object of class nb_math_ts
- flag : - 0 : normalises by N-1 (Default)
- 1 : normalises by N

Where N is the sample length.

Output:

- obj : An nb_math_ts object with the standardised data

Examples:

```
obj = stdise(obj);
```

Written by Kenneth S. Paulsen

► **subAvg ↑**

```
obj = subAvg(obj,k)
obj = subAvg(obj,k,w)
```

Description:

Will for the last k periods (including the present) calculate the cumulative sum and then divide by the amount of periods, which gives you the average over those periods.

Input:

- obj : An object of class nb_math_ts.
- k : Lets you choose what frequency you want to calculate the average over. As a double. E.g. 4 if you have quarterly data and want to calculate the average over the last 4 quarters.

Output:

- obj : An nb_math_ts object where the data are the average over the last k periods.

Examples:

```
obj = subAvg(obj,k)
```

[growth](#), [q2y](#), [pcn](#), [subSum](#)

Written by Tobias Ingebrigtsen

► **subSum ↑**

```
obj = subSum(obj,k)
obj = subSum(obj,k,w)
```

Description:

Calculates the cumulative sum over the last k periods (including the present period).

Input:

- obj : An object of class nb_math_ts.
- k : Lets you choose what frequency you want to calculate the cumulative sum over. As a double. E.g. 4 if you have quarterly data and want to calculate the average over the last 4 quarters.
- w : Weights applies to the k periods to sum over. Default is equal weights! As a double vector with length k.

Output:

- obj : An object of class nb_math_ts.

Examples:

```
obj = subSum(obj,k)
```

See also:

pcn, growth, subAvg

Written by Tobias Ingebrigtsen

► subsasgn ↑

```
varargout = subsasgn(obj,s,b)
```

Description:

Makes it possible to do subscripted assignment of the data of an object

Input:

- obj : An object of class nb_math_ts
- s : The same input as when you do subscripted assignment one a double matrix
- b : The assign data at the given index s, as a double or nb_math_ts object (disregard time dimension in this case!).

Output:

- obj : The assign data property setted of the given object.

Examples:

```
obj      = nb_math_ts.rand('2012',10,3);
obj(1:3,1) = [1;2;3]
obj =
    'Time'      'Var1'
    '2012'      [ 1]
    '2013'      [ 2]
    '2014'      [ 3]
```

Written by Kenneth S. Paulsen

► **subsref ↑**

```
varargout = subsref(obj,s)
```

Description:

Makes it possible to do subscripted reference of the data of an nb_math_ts object. See the examples for more

Using the method window, just using indexing instead

Input:

- obj : An object of class nb_math_ts
- s : A structure on have to index the object

Output:

- obj : The indexed object.

Examples:

```
obj = obj(1,2:4,1)
```

same as

```
obj = obj(1,2:4)
```

Be aware that that obj(1,:) will work but not obj(1,2:end)

```
obj = obj('1994Q1')
```

same as

```
obj.window('1994Q1','1994Q1')
```

```
obj = obj('1994Q1','1994Q4')
```

same as

```
obj.window('1994Q1','1994Q4')

obj = obj('1994Q1','1994Q4',1:2)

same as

obj.window('1994Q1','1994Q4',1:2)
```

Written by Kenneth S. Paulsen

► **sum ↑**

```
obj = sum(obj,dim)
```

Description:

Takes the sum of the object data in the wanted dimension

Input:

- obj : An object of class nb_math_ts
- dim : The dimension to sum over, returns:
 - dim = 1 : An nb_math_ts object with all the variables set to their cross observation sum
 - dim = 2: An nb_math_ts object with all variables set to their cross variable sum (Take the sum over the variables)
 - dim = 3: An nb_math_ts with only one page, representing the sum over all pages.

Caution : All sums ignore nan values. (If all values is not nan.)

Output:

- obj : An nb_math_ts object representing the sum.
(Keeps the dimension)

Examples:

```
obj = sum(obj,1)
obj = sum(obj,2)
obj = sum(obj,3)
```

Written by Kenneth S. Paulsen

► **sumOAF** ↑

```
obj = sumOAF(obj,sumFreq)
```

Description:

Take the sum over a lower frequency.

I.e. if frequency is quartely, this function can sum over all the quarters of a year. And it will return the sum over the year in all quarters of the that year

Input:

- obj : An object of class nb_math_ts
- sumFreq : The frequency to sum over

Output:

- obj : An object of class nb_math_ts where the data is summed over a lower frequency

Examples:

```
obj = nb_math_ts.rand('2012Q1',8);
obj = obj.sumOAF(1)
```

Written by Kenneth S. Paulsen

► **tail** ↑

```
tail(obj,nRows,page)
```

Description:

Display the last n rows of a nb_math_ts object.

Input:

- obj : An nb_math_ts object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_math_ts](#), [window](#), [head](#)

► **tan** ↑

```
obj = tan(obj)
```

Description:

Tangent

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
obj = tan(obj);
```

Written by Kenneth S. Paulsen

► **tand** ↑

```
obj = tand(obj)
```

Description:

Tangent, expressed in degrees.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = tand(in);
```

Written by Andreas Haga Raavand

► **tanh** ↑

```
obj = tanh(obj)
```

Description:

Hyperbolic tangent.

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An object of class nb_math_ts

Examples:

```
out = tanh(in);
```

Written by Andreas Haga Raavand

► **times** ↑

```
obj = times(a,b)
```

Description:

Element-wise multiplication (.*)

All elements of the first input objects data is multiplied by the second input objects data pair-wise. The objects must be of the same sizes.

It is also possible to multiply the data of the obejct by a scalar, or multiply a scalar by the objects data, but it is recommended to use mtimes (*) instead.

Input:

- a : An object of class nb_math_ts or a scalar
- b : An object of class nb_math_ts or a scalar

Output:

- obj : An object of class nb_math_ts with the calculated data stored

Examples:

```
obj = a.*b;
obj = 2.*b;
obj = a.*2;
```

See also:

[mtimes](#)

Written by Kenneth S. Paulsen

► **toTseries** ↑

```
tseries_DB = toTseries(obj)
```

Description:

Transform from an nb_math_ts object to an tseries object (IRIS)

To use this function you need to add the IRIS package to the MATLAB path.

Input:

- obj : An object of class nb_math_ts

Output:

- tseries_DB : An object of class tseries

Examples:

```
tseries_DB = obj.toTseries();
```

Written by Kenneth S. Paulsen

► **tonb_ts** ↑

```
obj = tonb_ts(obj,variables,dataName)
```

Description:

Convert the nb_math_ts object to an nb_ts object

Input:

- obj : An object of class nb_math_ts
- variables : The variable names of the created nb_ts object.
- dataName : The name of the dataset(s) of the created nb_ts object. Either a string or an cellstr. When given as cellstr it must match the number of pages of the provided nb_math_ts object. If not given default name(s) will be used.

Output:

- obj : An object of class nb_ts

Examples:

```
obj = nb_math_ts([2,2;2,2],'2012Q1');
obj1 = tonb_ts(obj,{'Var1','Var2'},'test')
obj2 = tonb_ts(obj,{'Var1','Var2'})
```

See also:

[nb_ts](#)

Written by Kenneth S. Paulsen

► **uminus** ↑

obj = uminus(obj)

Description

Unary minus

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An nb_math_ts object where all the data are the unary minus of the input objects data

Examples:

obj = -obj;

Written by Kenneth S. Paulsen

► **undiff** ↑

```
obj = undiff(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series diff. Inverse of the diff method.

Input:

- obj : An object of class nb_math_ts
- InitialValues : A nb_math_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_math_ts object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.
- periods : The number of periods the initial series has been taken diff over.

Output:

- Output : A nb_math_ts object with the indicies.

Examples:

```
obj = undiff(obj);  
obj = undiff(obj,100);  
obj = undiff(obj,[78,89]);
```

See also
diff

Written by Kenneth S. Paulsen

► uplus ↑

```
obj = uplus(obj)
```

Description:

Unary plus

Input:

- obj : An object of class nb_math_ts

Output:

- obj : An nb_math_ts object where all the data are the unary plus of the input objects data

Examples:

```
obj = +obj;
```

Written by Kenneth S. Paulsen

► var ↑

```
obj = var(obj,dim,outputType)
```

Description:

Calculate the variance of each timeseries. The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are beeing set to their var.

The output can also be set to be a double only consisting of the var values of the data.

Input:

- obj : An object of class nb_math_ts
- dim : The dimension to take the var over
- outputType :
 - 'nb_math_ts' : The result will be an object of class nb_math_ts where all the non-nan values of all the timeseries are beeing set to their var.
 - 'double' : Get the var values as doubles, where each column of the double matches the same column of the data property of the nb_math_ts object. If the object consist of more pages the double will also consist of more pages.

Output:

- obj : The object itself where all the non-nan values of all the timeseries are beeing set to their var. Or a double with the var values.

Examples:

```
obj = var(obj)  
      same as  
  
obj = var(obj,0,0,'nb_math_ts')  
  
Output as a double (matrix)  
  
double = var(obj,0,0,'double')  
  
Written by Kenneth S. Paulsen
```

► **vertcat** ↑

```
obj = vertcat(a,b,varargin)
```

Description:

Vertical concatenation ([a;b])

Input:

- a : An object of class nb_math_ts
- b : An object of class nb_math_ts
- varargin : Optional numbers of objects of class nb_math_ts

Output:

- a : An nb_math_ts object where the data from the different objects are appended to each other.

Examples:

```
obj = nb_math_ts(ones(2,1),'2012Q1');  
aObj = nb_math_ts(ones(2,1),'2012Q3');  
m = [obj;aObj]  
  
m =  
  
'2012Q1' [ 1]  
'2012Q2' [ 1]  
'2012Q3' [ 1]  
'2012Q4' [ 1]
```

Written by Kenneth S. Paulsen

► **window** ↑

```
obj = window(obj,startDateWin,endDateWin, pages)
```

Description:

Narrow down window of the data of the nb_math_ts object

Input:

- obj : An object of class nb_math_ts
- startDateWin : The new wanted start date of the data of the object. Must be a string on the format; 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the start date of the data.
Can also be an object which is a subclass of the nb_date class.
- endDateWin : The new wanted end date of the data of the object. Must be a string on the format. 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the end date of the data.
Can also be an object which is a subclass of the nb_date class.
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty all pages is kept.
I.e. obj = obj.window('', '', {}, 1:3)

Output:

- obj : An nb_math_ts object where the datasets of the object is narrowed down to the specified window.

Examples:

```
obj = nb_math_ts(ones(10,2,2),'2012Q1');
obj = obj.window('2012Q2')
obj = obj.window('', '2013Q4')
obj = obj.window('', '', 1)
```

See also:

Written by Kenneth S. Paulsen

► x12 ↑

```
varargout = x12(obj,range,varargin)
```

Description:

Seasonally adjust data of an nb_math_ts object, with the use of the x12 method of the tseries class provided by the IRIS package.

To use this function you need to add the IRIS package to the MATLAB path.

Input:

- obj : Input data that will seasonally adjusted or filtered by the Census X12 Arima. Must be an nb_math_ts object.

- range : Date range on which the X12 will be run; if not specified or Inf the entire available range will be used. Must be numeric.

Optional input (..., 'propertyName', PropertyValue, ...):

- 'backcast' : Run a backcast based on the fitted ARIMA model for this number of periods back to improve on the seasonal adjustment; see help on the 'x11' specs in the X12-ARIMA manual. The backcast is included in the output argument obj. Must be a scalar.

- 'cleanup' : Delete temporary X12 files when done; the temporary files are named iris_x12a.*. {'true'} | 'false'

- 'log' : Logarithmise the input data before, and de-logarithmise the output data back after, running x12. {'true'} | 'false'

- 'forecast' : Run a forecast based on the fitted ARIMA model for this number of periods ahead to improve on the seasonal adjustment; see help on the x11 specs in the X12-ARIMA manual. The forecast is included in the output argument obj. Must be a scalar.

- 'display' : Display X12 output messages in command window; if false the messages will be saved in a TXT file. {'true'} | 'false'

- 'dummy' : Dummy variable or variables (in case of a multivariate tseries object) used in X12-ARIMA regression; the dummy variables can also include values for forecasts and backcasts if you request them. Either an tseries or empty.

- 'dummyType' : Type of dummy; see the X12-ARIMA IRIS documentation. Either 'ao' | {'holiday'} | 'td'

- 'mode' : Seasonal adjustment mode (see help on the x11 specs in the IRIS X12-ARIMA manual); 'auto' means that series with only positive or only negative

```

numbers will be adjusted in the 'mult'
(multiplicative) mode, while series with combined
positive and negative numbers in the 'add'
(additive) mode. {'auto'} | 'add' | 'logadd' |
'mult' | 'pseudoadd' | 'sign'

- 'maxIter' : Maximum number of iterations for the X12
estimation procedure. See help on the estimation
specs in the IRIS X12-ARIMA manual. Must be
numeric. Default is 1500.

- 'maxOrder' : A 1-by-2 vector with maximum order for the
regular ARMA model (can be 1, 2, 3, or 4) and
maximum order for the seasonal ARMA model (can be
1 or 2). See help on the automdl specs in the
IRIS X12-ARIMA manual. Must be numeric. Default
is [1,2]. 

- 'missing' : Allow for in-sample missing observations, and
fill in values predicted by an estimated ARIMA
process; if false, the seasonal adjustment will
not run and a warning will be thrown. 'true' |
{'false'}

- 'output' : List of requested output data; the cellstr or
comma-separated list can combine 'IR' for the
irregular component, 'seasadj' for the final
seasonally adjusted series, 'SF' for seasonal
factors, 'trendcycle' for the trend-cycle, and
'MV' for the original series with missing
observations replaced with ARIMA estimates. See
also help on the x11 specs in the IRIS X12-ARIMA
manual. char | cellstr | {'seasadj'} ]

- 'specFile' : Name of the X12-ARIMA spec file; if 'default' the
IRIS default spec file will be used, see
description. Must be a char. Default is 'default'

- 'tdays' : Correct for the number of trading days. See help
on the x11regression specs in the IRIS X12-ARIMA
manual. 'true' | {'false'}

- 'tolerance' : Convergence tolerance for the X12 estimation
procedure. See help on the estimation specs in
the IRIS X12-ARIMA manual. Must be numeric.
Default is 1e-5.

```

Output:

See the IRIS X12-ARIMA manual. Same outputs as the x12 method of the tseries class. The only difference is that the tseries outputs are instead nb_math_ts objects.

Examples:

```
[obj,~,err] = x12(obj,inf,'output','seasadj');
```

► **x12Census** ↑

```
obj = x12Census(obj)
[obj,x,outputfile,errorfile,model] = x12Census(obj)
[obj,x,outputfile,errorfile,model] = x12Census(obj,varargin)
```

Description:

Do x12 Census adjustement to an nb_math_ts object using x12awin.exe.

This is a file copied from the IRIS Toolbox an adapted to the NB Toolbox. (I.e. using nb_math_ts instead of tseries)

x12awin.exe is a program developed by:

U. S. Department of Commerce, U. S. Census Bureau

X-12-ARIMA quarterly seasonal adjustment Method,
Release Version 0.3 Build 192

This method modifies the X-11 variant of Census Method II
by J. Shiskin A.H. Young and J.C. Musgrave of February, 1967.
and the X-11-ARIMA program based on the methodological research
developed by Estela Bee Dagum, Chief of the Seasonal Adjustment
and Time Series Staff of Statistics Canada, September, 1979.

This version of X-12-ARIMA includes an automatic ARIMA model
selection procedure based largely on the procedure of Gomez and
Maravall (1998) as implemented in TRAMO (1996).

Caution : The object must be of quarterly or monthly frequency!!

Input:

- obj : Input data that will seasonally adjusted or filtered
by the Census X12 Arima. Must be an nb_math_ts object.

Optional input (..., 'propertyName', PropertyValue, ...):

- 'backcast' : Run a backcast based on the fitted ARIMA model
for this number of periods back to improve on the
seasonal adjustment. The backcast is included
in the output argument x. Must be a scalar.

- 'log' : Logarithmise the input data before, and
de-logarithmise the output data back after,
running x12. {1} | 0

- 'forecast' : Run a forecast based on the fitted ARIMA model
for this number of periods ahead to improve on
the seasonal adjustment. The forecast is included
in the output argument x. Must be a scalar.

- 'display' : Display X12 output messages in command window.
{0} | 1. Default is not.
- 'dummy' : Dummy variable or variables (in case of a multivariate nb_ts object) used in X12-ARIMA regression; the dummy variables can also include values for forecasts and backcasts if you request them. Either an nb_math_ts object or empty.
- 'dummyType' : Type of dummy. Either 'ao' | {'holiday'} | 'td'
- 'mode' : Seasonal adjustment mode. 'auto' means that series with only positive or only negative numbers will be adjusted in the 'mult' (multiplicative) mode, while series with combined positive and negative numbers in the 'add' (additive) mode. {'auto'} | 'add' | 'logadd' | 'mult' | 'pseudoadd' | 'sign'
- 'maxIter' : Maximum number of iterations for the X12 estimation procedure. Must be numeric. Default is 1500.
- 'maxOrder' : A 1-by-2 vector with maximum order for the regular ARMA model (can be 1, 2, 3, or 4) and maximum order for the seasonal ARMA model (can be 1 or 2). Must be numeric. Default is [1,2].
- 'missing' : Allow for in-sample missing observations, and fill in values predicted by an estimated ARIMA process; if false, the seasonal adjustment will not run and a warning will be thrown. 1 | {0}.
- 'output' : Requested output data, as a string. Either:
 - 'irregular' : For the irregular component,
 - 'seasadj' : For the final seasonally adjusted series. Default.
 - 'seasonal' : For seasonal factors.
 - 'trendcycle' : For the trend-cycle.
 - 'missingvaladj' : For the original series with missing observations replaced with ARIMA estimates.
- 'specFile' : Name of the X12-ARIMA spec file Must be a char. Default is 'default'.
- 'tdays' : Correct for the number of trading days. 1 | {0}
- 'tolerance' : Convergence tolerance for the X12 estimation procedure. Must be numeric. Default is 1e-5.
- 'startDate' : Start date of seasonally adjustment.

```
- 'endDate' : End date of seasonally adjustment.
```

Output:

- obj : An nb_math_ts object with the seasonally/trend adjusted/component of all the stored series of the object.
- x : The original object with the backcast and forecast appended.

Caution : If the object is link to a data source this object will still not be updateable.
- outputfile : A cellstr array with the output files from the seasonal/trend adjustment.
- errorfile : A cellstr array with error files from the seasonal/trend adjustment.
- mdl : A struct with ARIMA model estimates.

Written by Kenneth Sætherhagen Paulsen

■ nb_ts

Go to: [Properties](#) | [Methods](#)

A class representing timeseries data.

Constructor:

```
obj = nb_ts(datasets,NameOfDatasets,startDate,variables)
obj = nb_ts(datasets,NameOfDatasets,startDate,variables,sorted)
```

Input:

- datasets :

Input can be one of the data types listed below:

- xls(x) : A name of the excel spreadsheet to import.
(With or without extension.)

Caution : If you read a specific worksheet, and want the object to be updateable you must provide the extension.

- mat : Name(s) of the .mat files to import. (With or without extension.).

Format of the .mat file:

The .mat file must be saved structure with the fieldnames as the variable names and the fields as the data of the variables, as doubles. Plus

it must have a field with name 'startDate' with the start date of the data, as a string.

- tseries : As an IRIS tseries object.
- dyn_ts : As dyn_ts object(s), each page of the dyn_ts object is added as separate datasets.
- double : As double matrix. Each page of the matrix will be added as separate datasets.
- struct : As a structure of either dyn_ts object or double matrices. Each field is added as separate datasets.
- FAME : A string with the FAME path for where the FAME database you want read is. Must include the extension .db. Not supported by public version.
- SMART : Give 'smart'. Not supported by public version.

You can also give a cell array consisting of one or a combination of the data types mentioned above. Each cell will be added as a new dataset.

Extra: Use the method structure2nb_ts function to add all the fields of the structure as variables in an nb_ts object. (If each field has more page then 1, then each page will be a datasets)

- NameOfDatasets :

Input options will depend on data types listed below:

- xls(x) : A string with the wanted dataset name. Default is the excel file name. If the provided string is a sheet of the read spreadsheet that specific worksheet will be read.
- mat : A string with the wanted dataset name. Default is the .mat file name.
- tseries : A string with the wanted dataset name. Default is 'Dataset1'.
- dyn_ts : A string with the wanted dataset name. Default is 'Dataset1'.
- double : A string with the wanted dataset name. Default is 'Dataset1'.

Caution: When you given double matrices which has more pages then one, either directly or through a struct. Each of the pages will be added as a dataset. The name of this datasets will, if the input NameOfDatasets has the same size as the input datasets, get the name NameOfDatasets{jj}<jj>, where jj is

the page number, or else get the name 'Database<jj>'.

- struct : This input has nothing to say. The dataset names will be given by the fieldnames.
- FAME : A string with the vintage date to fetch. Default is the FAME path name.
- SMART : A string with the context date to fetch. Default is to fetch last context.
- A cell array of the listed types above:

If you give a cell array to the datasets input, this input must be a cell array of strings. If you give a cell array which doesn't have the same size as the cell array given to the datasets input, the datasets which is left gets the name 'Database<jj>', where <jj> stands for this added datasets number.

If you give an empty cell array, i.e. {} all the datasets get the names; 'Database<jj>', where <jj> stands for the added datasets number. Except when the datasets input are given by a cellstr with the excel file names, .mat file names or a FAME path names, then the default dataset names will be set to the same cellstr. Or if some elements of the cell is a struct, then the datasets provided through the struct will get their fieldnames as the dataset names.

- startDate :

The start date of the data. Only needed when you give numerical data as one element of the input datasets (also when numerical data is given through a struct) or when you fetch data from a FAME database (the start date of the fetched data).

Must be a string on the date format given below or an object which is of a subclass of the nb_date class.

Dating convention:

> Yearly	:	'yyyy'.	E.g. '2011'
> Semiannualy	:	'yyyySs'	E.g. '2011S1'
> Quarterly	:	'yyyyQq'.	E.g. '2011Q1'
> Monthly	:	'yyyyMm(m)'.	E.g. '2011M1', '2011M11'
> Weekly	:	'yyyyWw(w)'	E.g. '2011W1'
> Daily	:	'yyyyMm(m)Dd(d)'	E.g. '2011M1D1', '2011M11D11'

- variables :

A cellstr array of the names of the variables.

Needed when the dataset input is:

> Numerical matrix. The number of variables must be of the same as the size of the data (2. dimension).

```

> A struct consisting of double matrices.

> An tseries or an nb_math_ts object. The number of
variables must be of the same as the size of the data
(2. dimension).

> When you want to fetch data from a FAME database. I.e.
the variables fetched.

> When you give a cell array of one of the types mentioned
above.

- sorted : true or false. Default is true.

Output:

- obj : An object of class nb_ts

Examples:

- xls(x):

    One excel spreadsheet

    obj = nb_ts('test1')

    More excel spreadsheets

    obj = nb_ts({'test1','test2',...})

    same as

    obj = nb_ts({'test1','test2',...},{'test1','test2',...})

- mat:

    One .mat file

    obj = nb_ts('test1')

    More .mat files

    obj = nb_ts({'test1','test2',...})

    same as

    obj = nb_ts({'test1','test2',...},{'test1','test2',...})

- nb_math_ts:

    One nb_math_ts object

    obj = nb_ts(test1,'test1','','varName1','varName2',...)

    obj = nb_ts(test1,'','','varName1','varName2',...)

    same as

```

```

obj = nb_ts(test1,'Database1','','...
             {'varName1','varName2',...})

More nb_math_ts objects

obj = nb_ts({test1,test2,...},{'test1','test2',...},...
             '',{'varName1','varName2',...})

obj = nb_ts({test1,test2,...},{},'',...
             {'varName1','varName2',...})

same as

obj = nb_ts({test1,test2,...},...
             {'Database1','Database2',...},'',...
             {'varName1','varName2',...})

- tseries (IRIS:

One tseries object

obj = nb_ts(test1,'test1','','',{'varName1','varName2',...})

obj = nb_ts(test1,'','','',{'varName1','varName2',...})

same as

obj = nb_ts(test1,'Database1','','...
             {'varName1','varName2',...})

More tseries objects

obj = nb_ts({test1,test2,...},{'test1','test2',...},...
             {'varName1','varName2',...})

obj = nb_ts({test1,test2,...},{},'',...
             {'varName1','varName2',...})

same as

obj = nb_ts({test1,test2},{'Database1','Database2',...},...
             '',{'varName1','varName2',...})

- dyn_ts:

One dyn_ts object

obj = nb_ts(test1,'test1')

obj = nb_ts(test1)

same as

obj = nb_ts(test1,'Database1')

More dyn_ts objects

obj = nb_ts({test1,test2,...},{'test1','test2',...})

```

```

obj = nb_ts({test1,test2,...})

same as

obj = nb_ts({test1,test2,...},{'Database1','Database2',...})

-struct:

One struct

> Consisting of dyn_ts object(s):

obj = nb_ts(struct1)

> Consisting of double matrices:

obj = nb_ts(struct1,{},'1994Q1',{'Var1','Var2',...})

More structs

> Consisting of dyn_ts object(s):

obj = nb_ts({struct1,stuct2,...})

> Consisting of double matrices:

obj = nb_ts({struct1,stuct2,...},{},'1994Q1',...
            {'Var1','Var2',...})

- double matrix:

One matrix

obj = nb_ts(double1,'','1994Q1',{'Var1','Var2',...})

obj = nb_ts(double1,'test1','1994Q1',{'Var1','Var2',...})

More matrices

obj = nb_ts({double1,double2,...},{},'1994Q1',...
            {'Var1','Var2',...})

obj = nb_ts({double1,double2,...},{'name1','name2',...},...
            '1994Q1',{'Var1','Var2',...})

One matrix with more pages:

obj = nb_ts(double1,{},'1994Q1',{'Var1','Var2',...})

obj = nb_ts(double1,{'name1','name2',...},'1994Q1',...
            {'Var1','Var2',...})

```

Properties:

- **data**
- **frequency**
- **numberOfObservations**
- **userData**
- **dataNames**
- **localVariables**
- **numberOfVariables**
- **variables**
- **endDate**
- **numberOfDatasets**
- **startDate**

- **data** [↑](#)

The data of the object. As a double or logical.

Inherited from superclass NB_DATASOURCE

- **dataNames** [↑](#)

The names of the different dataset. As a cellstr.

Inherited from superclass NB_DATASOURCE

- **endDate** [↑](#)

The end date of the data. Given as an object which is of a subclass of the nb_date class. Either: nb_day, nb_week, nb_month, nb_quarter, nb_semiAnnual or nb_year.

- **frequency** [↑](#)

Frequency of data:

```
1   : yearly (also used for integers)
2   : semiannually
4   : quarterly
12  : monthly
52  : weekly
365 : daily (Also when dealing with business days,
           which gets nan values for all the skipped days)
```

- **localVariables** [↑](#)

A nb_struct with the local variables of the nb_ts object.
I.e. a field with name 'test' can be reach with the string input %#test. Only for dates and vintage inputs.

Inherited from superclass NB_DATASOURCE

- **numberOfDatasets** [↑](#)

Number of datasets stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **numberOfObservations** [↑](#)

Number of observation of the data stored in the object. As a double.

- **numberOfVariables** [↑](#)

Number of variables stored in the object. As a double.

Inherited from superclass NB_DATASOURCE

- **startDate** ↑

The start date of the data. Given as an object which is of a subclass of the nb_date class. Either: nb_day, nb_week, nb_month, nb_quarter, nb_semiAnnual or nb_year.

- **userData** ↑

Add user data. Can be of any type.

Inherited from superclass NB_DATASOURCE

- **variables** ↑

Variables of the object. As a cellstr.

Inherited from superclass NB_DATASOURCE

► **abs** ↑

```
obj = abs(obj)
```

Description:

Take the absolute value of each data elements of the object

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = abs(in);
```

Written by Kenneth S. Paulsen

Inherited from superclass `NB_DATASOURCE`

► **acos** ↑

```
obj = acos(obj)
```

Description:

Take acos of the data stored in the `nb_cs` object

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acos(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acosd** ↑

obj = acosd(obj)

Description:

acosd(obj) is the inverse cosine, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acosd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acosh** ↑

obj = acosh(obj)

Description:

acosh(obj) is the inverse hyperbolic cosine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acosh(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acot** ↑

obj = acot(obj)

Description:

Take acotangent of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acot(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acotd** ↑

obj = acotd(obj)

Description:

acotd(obj) is the inverse cotangent, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acotd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acoth** ↑

obj = acoth(obj)

Description:

acoth(obj) is the inverse hyperbolic cotangent of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acoth(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acsc** ↑

obj = acsc(obj)

Description:

Take inverse csc of the data stored in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = acsc(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **acscd** ↑

obj = acscd(obj)

Description:

acscd(obj) is the inverse cosecant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = acscd(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **acsch** ↑

obj = acsch(obj)

Description:

acsch(obj) is the inverse hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = acsch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **addDataset ↑**

```
obj = addDataset(obj,dataset,NameOfDataset,startDate,variables)
```

Description:

Makes it possible to add one dataset to a existing nb_ts object

Caution : If more than one dataset is added to an object the link to the data source is broken!

Input:

- obj : An object of class nb_ts

- dataset : One of the following:

> A string with the name of excel spreadsheet.
(With or whitout extension)

> A string with the name of a .mat file
(With or whitout extension)

> A string with the filepath to a FAME database

> A dyn_ts object

> A tseries object

> A nb_math_ts object

> A numerical matrix.

> A JAVA TS object.

- NameOfDataset : Must be a string with the dataset name. If not given (or given as '') the default name Database<jj> is given. Where jj is the number of added datasets of the object, including the dataset you add with this method.

When fetching from FAME this input could be a vintage tag. I.e. you could specify the vintage you want to fetch from FAME of the given

series. If the vintage tag does not exist it will fetch the last vintage before the given vintage tag.

- startDate : Must be a string or an object which is of a subclass of nb_date with the start date of the data. Have only effect (and then it must be given) when you try to add data from a numerical matrix and fetch data from FAME.
- variables : A cell array of strings with the names of the variables you want to add. Only needed when a numerical matrix of data, a tseries object, a nb_math_ts object or when data from FAME is added to the object.

Must have the same size as the data you add.
(Second dimension)

When fetching data from FAME this input decides which variables to fetch.

Output:

- obj : An nb_ts object with the added dataset.

Examples:

```
obj = nb_ts();
obj = obj.addDataset('excelFileName');
obj = obj.addDataset('excelFileName2','sheetName');
obj = obj.addDataset('matFileName');
obj = obj.addDataset('famePath','','2012Q1',{'QUA_PCPI'});
obj = obj.addDataset(tseriesObject,'','','{'Var1','Var2'});
obj = obj.addDataset(nb_math_tsObject,'','','{'Var1','Var2'});
obj = obj.addDataset([2,2;2,2],'','2011Q1',{'var1','var2'});
```

See also:

[nb_ts](#), [addDatasets](#), [structure2Dataset](#)

Written by Kenneth S. Paulsen

► **addDatasets** ↑

```
obj = addDatasets(obj,datasets,NameOfDatasets,startDate, ...
                   variables)
```

Description:

Makes it possible to add more datasets to a existing nb_ts object.

Input:

Same input as of the constructor but only cell arrays are supported for the inputs 'datasets' and 'NameOfDatasets'. 'NameOfDatasets' could be given as a empty cell; {};

Output:

- obj : An nb_ts object now with the added datasets.

Examples:

See also:

[nb_ts](#), [addDataset](#), [structure2Dataset](#)

Written by Kenneth S. Paulsen

► **addLags ↑**

obj = addLags(obj,nLags)

Description:

Add the wanted number of lags to the object

Input:

- obj : An object of class nb_ts
- nLags : The number of added lags
- type : Either 'lagFast' (default) or 'varFast'

Output:

- obj : An object of class nb_ts

Examples:

obj = addLags(obj,2)

Written by Kenneth S. Paulsen

► **addPageCopies ↑**

obj = addPageCopies(obj,num)

Description:

Add copies of the data of an object and append it as new datasets of the object. Only possible if an object has only one page.

Input:

- obj : An object of class nb_ts
- num : Number of copies to be appended, or a vector of nb_date objects with the end date of each new page.

Output:

- obj : An object of class nb_ts with the added copies of the first dataset in the object.

Examples:

```
data    = nb_ts(rand(20,2),'', '2011Q1', {'Var1','Var2'});  
dataP  = data.addPageCopies(10);  
dates   = vec(nb_quarter('2015Q1'),nb_quarter('2015Q3'));  
dataP2 = data.addPageCopies(dates);
```

Written by Kenneth S. Paulsen

► addPages ↑

```
obj = addPages(obj,DB,varargin)
```

Description:

Add all pages from different nb_ts objects.

Caution : This method will break the link to the data source of updateable objects!

Input:

- obj : An object of class nb_ts
- DB : An object of class nb_ts
- varargin : Optional number of objects of class nb_ts

Output:

- obj : The object itself with added datasets from the objects given by varargin.

Be aware: If the added datasets does not contain the same variables or dates, the data of the nb_ts object with the tightest window will be expanded automatically to include all the same dates and variables. (the added data will be set as nan)

Examples:

```
obj = obj.addPages(DB);
obj = obj.addPages(DB1,DB2,DB3);
```

Written by Kenneth S. Paulsen

► **addPostfix** ↑

```
obj = addPostfix(obj,postfix)
obj = addPostfix(obj,postfix,vars)
```

Description:

Add a postfix to all the variables in the nb_ts, nb_cs or nb_data object, or a provided variable group.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- postfix : The postfix to add to all the variables of the object. Must be a string
- vars : A cellstr of the variable to add the prefix to. Default is all variable of the object.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data with the postfix added to the variables selected

Examples:

```
obj = obj.addPostfix('_NEW');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **addPrefix** ↑

```
obj = addPrefix(obj,prefix)
obj = addPrefix(obj,prefix,vars)
```

Description:

Add a prefix to all the variables in the nb_ts, nb_cs or nb_data object, or a provided variable group.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- prefix : The prefix to add to all the variables of the object.
Must be a string
- vars : A cellstr of the variable to add the prefix to.
Default is all variable of the object.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data with a prefix added to the selected variables

Example:

```
obj = obj.addPrefix('NEMO.');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► addTimeTrend ↑

```
obj = addTimeTrend(obj)
obj = addTimeTrend(obj,start,finish, name)
```

Description:

Add a time trend variable to the nb_ts object

Input:

- obj : A nb_ts object
- start : The start date of the time trend. Default is the start date of the dataset
- finish : The end date of time trend. Default is the end date of the dataset
- name : The name of the added variable. Default is 'timeTrend'

Output:

- obj : A nb_ts object with the added time trend variable

See also:

Written by Kenneth Sætherhagen Paulsen

► **addVariable** ↑

```
obj = addVariable(obj,startDateOfData,Data,Variable)
```

Description:

Add a new variable to a existing nb_ts object (including all pages)

Input:

- obj : An object of class nb_ts
- startDateOfData : The start date of the data of the added variable. Must be a string or a date object. Cannot be outside the window of the dates of the object.
- Data : The data of the added variable. Cannot be outside the window of the data of the object. Must be a double.
- Variable : A string with the added variable name. Cannot be the same as a existing variable. (Then use setValue instead)

Output:

- obj : An object of class nb_ts with the added variable

Examples:

```
obj = addVariable(obj,'2012Q1',[2;2;2;2],'newVariable');
```

Written by Kenneth S. Paulsen

► **aegrowth** ↑

```
obj = aegrowth(obj,percent)
```

Description:

Calculate exact annual growth, using the formula:
 $(x(t) - x(t-lag))/x(t-lag)$ of all the timeseries of the nb_ts object.

Input:

- obj : An object of class nb_ts
- percent : Either 1 (in percent) or 0 (not in percent). 0 is default.

Output:

- obj : An nb_ts object with the calculated timeseries stored.

Examples:

```
obj = aegrowth(obj);  
obj = aegrowth(obj,1);
```

See also:

[agrowth](#), [egrowth](#), [growth](#)

Written by Kenneth S. Paulsen

► **agrowth ↑**

```
obj = agrowth(obj,percent)
```

Description:

Calculate approx annual growth, using the formula:
 $\log(x(t)) - \log(x(t-lag))$ of all the timeseries of the nb_ts object.

Input:

- obj : An object of class nb_ts
- percent : Either 1 (in percent) or 0 (not in percent). 0 is default.

Output:

- obj : An nb_ts object with the calculated timeseries stored.

Examples:

```
obj = agrowth(obj);  
obj = agrowth(obj,1);
```

See also:

[aegrowth](#), [egrowth](#), [growth](#)

Written by Kenneth S. Paulsen

► **and** ↑

```
a = and(a,b)
```

Description:

The and operator (&).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the and operator has evaluated all the data elements of the object.
The data will be a logical matrix

Examples:

```
a = a & b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **append** ↑

```
obj = append(obj,DB,interpolateDate,method,rename,type)
```

Description:

Append a nb_ts object to another nb_ts object.

Caution:

- It is possible to merge datasets with the same variables as long as they represent the same data or have different timespans.
- If the datasets has different number of datasets and one of the merged objects only consists of one, this object will add as many datasets as needed (copies of the first dataset) so they the one object can append the other.
- In contrast to the vertcat method, this method will keep the

first inputs end date and cut all the shared dates of the appended object.

- If the frequencies of the objects is not the same the object with the lowest frequency will be converted.

Input:

- obj : An object of class nb_ts
- DB : An object of class nb_ts
- interpolateDate :
 - How to transform the database with the lowest frequency.
 - 'start' : The interpolated data are taken as given at the start of the periods. I.e. use 01.01.2012 and 01.01.2013 when interpolating data with yearly frequency. (Default)
 - 'end' : The interpolated data are taken as given at the end of the periods. I.e. use 31.12.2012 and 31.12.2013 when interpolating data with yearly frequency.
 - method : The method to use when converting:
 - 'linear' : Linear interpolation
 - 'cubic' : Shape-preserving piecewise cubic interpolation
 - 'spline' : Piecewise cubic spline interpolation
 - 'none' : No interpolation. All data in between is given by nans (missing values) (Default)
 - 'fill' : No interpolation. All periods of the higher frequency get the same value as that of the lower frequency.
 - rename :> 'on' : Renames the prefixes (default)
> 'off' : Do not rename the prefixes
 - For more see the 'rename' option of the convert method.
 - type : The type of series to merge.
 - > 'levelGrowth' : Append level data with growth rates. Must be one period growth. The merged series will be in level.
 - > 'growthLevel' : Append growth rates with level data. Must be one period growth. The merged series will be in growth rates.

```
> 'levelLevel' : Append level series, where the
      merging is done in growth rates,
      but the end result is still in
      levels.

> ''          : Standard merging
```

Output:

- obj : An nb_ts object where the datasets from the two nb_ts objects are merged

Examples:

```
obj = append(obj,DB)
obj = obj.append(DB)
```

Written by Kenneth S. Paulsen

► **appendFromAnotherPage** ↑

```
obj = appendFromAnotherPage(obj,page)
```

Description:

Append data from another page where the rest has missing data.

Input:

- obj : A nObs1 x nVar x nPages nb_dataSource object.
- page : The page to append data from.

Output:

- obj : A nObs x nVar x nPages nb_dataSource object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **appendRecursive** ↑

```
obj = appendRecursive(obj,app,dat)
```

Description:

Append data from app by adding new pages to obj.

Caution link to the data source will be broken.

Input:

- obj : A single paged nb_ts object.
- app : An object of class nb_data, nb_cs or double.
- dat : The dates where the data from app should start. Must match the number of pages of app. As a cellstr.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

► asCell ↑

```
cellMatrix = asCell(obj,dateFormat,strip)
```

Description:

Return the data of the object as a cell matrix.
(In the dyn_ts format, i.e. looks like a excel spreadsheet.)

Input:

- obj : An object of class nb_ts
- dateFormat : The date format of the dates of the cell.
 - > 'default' :
 - yearly : 'yyyy'
 - semiannually : 'yyyySs'
 - quarterly : 'yyyyQq'
 - monthly : 'yyyyMm(m)'
 - daily : 'yyyyMm(m)Dd(d)'
 - > 'xls' : 'dd.mm.yyyy' for all frequencies
- strip : - 'on' : Strip all observation dates where all the variables has no value.
 - 'off' : Does not strip all observation dates where all the variables has no value. Default.

Output:

- cellMatrix : The nb_ts objects data transformed to a cell.

Examples:

```
cellMatrix = obj.asCell();
cellMatrix = obj.asCell('xls');
cellMatrix = obj.asCell('xls','on');
```

Written by Kenneth S. Paulsen

► **asCellForMPRReport ↑**

```
cellMatrix = asCellForMPRReport(obj,roundoff)
```

Description:

Return the data of the object as a cell matrix, which is rounded off to two decimals and striped

Input:

- obj : An object of class nb_ts
- roundoff : Give the number of wanted decimals. If empty no round-off will be done. Default is 2, i.e. 2.02. 0 decimals is also possible. Must be an integer larger than or equal to 0, or empty (no round-off).

Output:

- cellMatrix : The objects data transformed to a cell.

Examples:

```
cellMatrix = obj.asCellForMPRReport();
cellMatrix = obj.asCellForMPRReport(0);
```

See also:

[asCell](#)

Written by Kenneth S. Paulsen

► **asec ↑**

```
obj = asec(obj)
```

Description:

Take inverse sec of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Examples:

```
obj = asec(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **asecd** ↑

```
obj = asecd(obj)
```

Description:

asecd(obj) is the inverse secant, expressed in degrees, of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asecd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asech** ↑

```
obj = asech(obj)
```

Description:

asech(obj) is the inverse hyperbolic secant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asin** ↑

```
obj = asin(obj)
```

Description:

Take inverse sin of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = asin(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **asind** ↑

```
obj = asind(obj)
```

Description:

asind(obj) is the inverse sine, expressed in degrees,
of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **asinh** ↑

```
obj = asinh(obj)
```

Description:

asinh(obj) is the inverse hyperbolic sine of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = asinh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **assignNan** ↑

```
obj = expand(obj,variables,value)
```

Description:

Assign all the nan observation to the value input.

Input:

- obj : An object of class nb_dataSource.
- variables : A char or a cellstr with the variables to assign nan values.
- value : A scalar number.

Output:

- obj : An nb_ts object with expanded timespan

Examples:

```
obj = nb_ts.rand('2012Q1',10,2,3);
obj(1:2,1,:) = nan;
obj = assignNan(obj,'Var1',0)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atan** ↑

```
obj = atan(obj)
```

Description:

Take the inverse tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = atan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **atand** ↑

```
obj = atand(obj)
```

Description:

atand(obj) is the inverse tangent, expressed in degrees, of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = atand(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **atanh** ↑

```
obj = atanh(obj)
```

Description:

atanh(obj) is the inverse hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = atanh(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **autocorr** ↑

```
obj = autocorr(obj,numLags)
obj = autocorr(obj,numLags,errorBound,alpha)
```

Description:

Compute the sample autocorrelation function (ACF) of all the variables stored in the nb_ts object, and return an nb_data object with the results.

Reference:

[1] Box, G. E. P., G. M. Jenkins, and G. C. Reinsel. Time Series Analysis: Forecasting and Control. 3rd edition. Upper Saddle River, NJ: Prentice-Hall, 1994.

Input:

- obj : An object of class nb_ts.

Caution : This method does not handle nan or infinite for any of the stored data of the nb_ts object!
- numLags : Positive integer indicating the number of lags of the ACF to compute. If empty or missing, the default is to compute the ACF at lags 1. Since ACF is symmetric about lag zero, negative lags are ignored. Must be a scalar.
- errorBound : A string. The data must be stationary. Either:
 - > '' : No errorbounds calculated.
 - > 'asymptotic' : Using asymptotically derived formulas.
 - > 'paramBootstrap' : Calculated by estimating the data generating process. And use the fitted model to simulate artificial time-series. Then the error bands are constructed by the wanted percentile.
 - > 'blockbootstrap' : Calculated by blocking the observed series and using these blocks to simulate artificial time-series. Then the error bands are constructed by the wanted percentile.
 - > 'copulaBootstrap' : The observed series is bootstrapped based on a copula approach. See Paulsen (2017).
- alpha : Significance value. As a scalar. Default is 0.05.

Optional inputs:

- 'maxAR' : As an integer. See the nb_arima function. Default is 3.
- 'maxMA' : As an integer. See the nb_arima function. Default is 3.
- 'criterion' : As a string. See the nb_arima function. Default is 'aicc'.
- 'method' : As a string. See the nb_arima function. Default is 'hr'.

Output:

- obj : An nb_data object with the autocorrelations stored in the dataset 'Autocorrelations'.
If the errorbounds are to be calculated they are stored in the datasets 'Error bound (lower)' and 'Error bound (upper)'

Examples:

```
obj = autocorr(obj)
obj = autocorr(obj,10)
```

See also:

[nb_ts](#), [nb_data](#), [corr](#), [nb_autocorr](#)

Written by Kenneth Sæterhagen Paulsen

► **avgOAF** ↑

```
obj = avgOAF(obj,sumFreq)
```

Description:

Take the average over a lower frequency. Ignoring nan values!

I.e. if frequency is quartely, this function can take the average over all the quarters of a year. And it will return the average over the year in all quarters of the that year

Input:

- obj : An object of class nb_ts
- sumFreq : The frequency to average over

Output:

- obj : An object of class nb_math_ts where the data is averaged over a lower frequency

Examples:

```
obj = nb_ts.ones('2012Q1',8,1);
obj = obj.avgOAF(1)
```

Written by Kenneth S. Paulsen

► **bkfilter** ↑

```
obj = bkfilter(obj,low,high)
```

Description:

Do band pass filtering of all the dataseries of the object.
(Returns the gap). Will strip nan values when calculating the filter

Input:

- obj : An object of class nb_ts
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_ts with the band pass filtered data.

Examples:

```
obj = bkfilter(obj,8,32);
obj = obj.bkfilter(8,32);
```

See also:

[bkfilter1s](#)

Written by Kenneth S. Paulsen

► **bkfilter1s** ↑

```
obj = bkfilter1s(obj,low,high)
```

Description:

Do one sided band pass-filtering of all the dataseries of the object. (Returns the gap) Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_ts
- low : Lowest frequency. > 2
- high : Highest frequency. > low

Output:

- obj : An object of class nb_ts with the one-sided band pass filtered data.

Examples:

```
obj = obj.bkfilterls(12,24);
obj = bkfilterls(obj,12,24);
```

See also:

[bkfilter](#)

Written by Kenneth S. Paulsen

► **breakAdj** ↑

```
obj = breakAdj(obj,method,varargin)
```

Description:

The intent of this method is to set observations around break points to nan, and interpolate the observation at these break-points. I.e. if you have a level series that has a break, and want smooth growth rates. In this case you can calculate the growth rates of the level series, and then use this method to smooth out the growth rate at the break-points. Then you can use the inverse growth methods to transform back to a level series without breaks.

Input:

- obj : An object of class nb_ts
- method : The wanted interpolation method to use. See the nb_interpolate function.

Optional input:

- A set of nb_date objects or one line chars with the dates that should be set to nan and interpolated.

Output:

- obj : An object of class nb_ts.

See also:

[nb_interpolate](#), [growth](#), [egrowth](#), [pcn](#), [epcn](#), [igrowth](#), [iegrowth](#), [ipcn](#)
[iepcn](#)

Written by Kenneth S. Paulsen

► **breakLink** ↑

obj = breakLink(obj)

Description:

Break link to source

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **callfun** ↑

```
obj      = callfun(obj,'func',func)
obj      = callfun(obj,another,'func',func)
obj      = callfun(obj,varargin,'func',func)
varargout = callfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the data of the nb_dataSource object(s). The data of the object is normally of class double, but may also be of class logical or nb_distribution. Use nb_dataSource.getClassOfData to find the class of the data of the object.

Input:

- obj : An object of class nbDataSource.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function @(x)x will be used.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class. nbDataSource objects are converted to a matrix with elements of class double, logical or nb_distribution.

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nbDataSource object. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```
d      = nb_ts.rand('2012Q1',10,3);
d1     = callfun(d,'func',@sin); % Same as d1 = sin(d) !
d2     = callfun(d,d,'func','plus') % Same as d2 = d + d !
[s1,s2] = callfun(d,'func',@size) % Same as [s1,s2] = size(d)
```

See also:

[nb_ts.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► callop ↑

```
obj = callop(obj,another,func)
obj = callop(obj,another,func,type)
```

Description:

Call mathematical operator on the data of the object. In contrast to calling the operator itself on the object, this method does not try to match the same variables from the two inputs, but instead operate in the same way as mathematical operators do on double matrices (bsxfun). The time domain is matched though!

Caution: The following operators are supported:
> @plus or 'plus'

```
> @minus or 'minus'  
> @times or 'times'  
> @rdivide or 'rdivide'  
> @power or 'power'
```

Input:

- obj : An object of class nb_dataSource.
- another : An object of class nb_dataSource.
- func : One of the above listed functions.
- type : Either:
 - > 'keep' : Keep the variable names of the object with most variables. If they have the same number of variables, they are taken from the first object.
 - > 'rename' : The new variable names represent the operation that has been done to the separate series. So if you divide an object with one series named 'Var1' with another object with one series named 'Var2', the new name will be 'Var1./Var2'. (Default)

Output:

- varargout : All output from the provided function which results in either a double, logical or nb_distribution with the same size as obj input will be converted to a nb_dataSource method. The rest will be given as return by the func function when applied to the data of the object.

Examples:

```
d1 = nb_ts(rand(10,1),'', '2012Q1', {'Var1'});  
d2 = nb_ts(rand(10,1),'', '2011Q1', {'Var2'});  
d3 = callop(d1,d2,@minus);  
  
d1 = nb_ts(rand(10,1),'', '2012Q1', {'Var1'});  
d2 = nb_ts(rand(10,2),'', '2011Q1', {'Var2','Var3'});  
d3 = callop(d1,d2,@minus);
```

See also:

[nb_ts.getClassOfData](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► [callrtfun ↑](#)

```
out = callrtfun(obj,another,'func',func)
out = callrtfun(obj,varargin,'func',func)
```

Description:

Call a in-built or user defined function on the data of the nb_ts object(s) representing real-time data. The data of the object is normally of class double, but may also be of class logical or nb_distribution. Use nb_dataSource.getClassOfData to find the class of the data of the object.

Caution: For the nb_ts object ot be taken as a real-time datasets it must have the context dates stored in the dataNames property on the format 'yyyymmdd' and only represent one variable.

Input:

- obj : An object of class nb_ts.

Optional input:

- 'func' : Either a function handle or a one line char with the name of a function (may be user defined in both cases). If not provided the function @(x)x will be used.
- 'name' : Name of the new variable. Default is 'new'.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class. nb_ts objects are converted to a matrix with elements of class double, logical or nb_distribution.

Output:

- out : An object of class nb_ts.

See also:

[nb_dataSource.getClassOfData](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **callstat** ↑

```
obj = callstat(obj,func)
obj = callstat(obj,func,varargin)
```

Description:

Call a in-built or user defined function on the data of the nb_dataSource object(s) that goes from the data of the object have more than one variable to only having one. E.g. when taking the mean over a set of variables.

Input:

- obj : An object of class nb_dataSource.
- func : A function handle (or one line char) that maps a nObs x nVar x nPage double to nObs x 1 x nPage double, or that maps a nObs x nVar x nPage double to nObs x nVar x 1 double.

Optional input:

- 'name' : Set the name of the new variable, as a one line char. Default is to use the str2func on the provided function handle.
- varargin : Optional inputs given as extra inputs to the function func. May be of any class.

Output:

- obj : An object of class nb_dataSource with only one variable.

Examples:

```
d = nb_ts.rand('2012Q1',10,3);
d1 = callstat(d,@(x)mean(x,2),'name','mean')
```

See also:

[nb_ts.mean](#), [nb_ts.std](#), [nb_ts.var](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► ceil ↑

```
obj = ceil(obj)
```

Description:

ceil(obj) rounds the elements of obj to the nearest integers towards infinity.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = ceil(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **checkExpressions** ↑

```
obj = checkExpressions(obj,expression)
obj = checkExpressions(obj,expression,shift)
```

Description:

Check expressions, and add to dataset

Input:

- obj : An object of class nb_ts

- expression : A cell on the format:

```
{Name1, expression1, description1;...
  Name2, expression2, description2};
```

The first column sets the name of the created variable.

The second column sets the expression to apply to the existing variables in the object. All methods of the nb_math_ts class that pserve the time span are supported in expression. You can also call user defined functions, as long as they take and return a nb_math_ts object. A nb_math_ts object is just a double with a time dimension! To get a list of all the methods of the nb_math_ts class use; methods('nb_math_ts').

Caution: expression2 can depend on the Name1 variable.

Caution: If Name1 is a name of an existing variable in the object, it will be replaced.

- shift : An object of class nb_ts storing the shift/trend variables. These are added to the matching variable before the transformations are applied. If empty, this input is ignored. Default is [].

Output:

- obj : An object of class nb_ts

Written by Kenneth SÃ¶terhagen Paulsen

► **cleanRealTime** ↑

```
obj = cleanRealTime(obj)
```

Description:

Secure that the real time data has new observations for each period. You have to options 'delete' or 'fill'.

Input:

- obj : An nb_ts object returned by the nb_fetchRealTimeFromFame function.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

► **conj** ↑

```
obj = conj(obj)
```

Description:

conj(obj) is the complex conjugate of the elements of obj.
For a complex element x of obj, conj(x) = REAL(x) - i*IMAG(x).

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = conj(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **convert** ↑

```
obj = convert(obj,freq,method,varargin)
```

Description:

Convert the frequency of the data of the nb_ts object

Input:

- obj : An object of class nb_ts
- freq : The new frequency of the data. As an integer:
 - > 1 : yearly
 - > 2 : semi annually
 - > 4 : quarterly
 - > 12 : monthly
 - > 52 : weekly
 - > 365 : daily
- method : The method to use. Either:
 - From a high frequency to a low:
 - > 'average' : Takes averages over the subperiods
 - > 'diffAverage' : Uses a weighted average, so that the diff operators can be converted correctly. E.g. when converting from monthly to quarterly, and the level of the variable of interest is aggregated to quarterly data using averages, but you want to convert monthly data on diff to quarterly. The formula used is:
$$\text{diff_Y}(q) = \frac{1}{3}\text{diff_Y}(m) + \frac{2}{3}\text{diff_Y}(m-1) + \text{diff_Y}(m-2) + \frac{2}{3}\text{diff_Y}(m-3) + \frac{1}{3}\text{diff_Y}(m-4)$$
 - > 'diffSum' : Same as 'diffAverage', but now the aggregation in levels are done using a sum instead.
 - > 'discrete' : Takes last observation in each subperiod (Default)
 - > 'first' : Takes first observation in each subperiod
 - > 'max' : Takes maximal value over the subperiods
 - > 'min' : Takes minimum value over the subperiods
 - > 'sum' : Takes sums over the subperiods
 - From a low frequency to a high:
 - > 'linear' : Linear interpolation
 - > 'cubic' : Shape-preserving piecewise cubic interpolation
 - > 'spline' : Piecewise cubic spline interpolation
 - > 'none' : No interpolation. All data in between is given by nans (missing values) (Default)
 - > 'fill' : No interpolation. All periods of the higher frequency get the same value as that of the lower frequency.
 - > 'daverage' : Uses the Denton 1971 method using that the average of the intra low frequency periods should preserve the average.
 - > 'dsum' : Uses the Denton 1971 method using that the sum of the intra low frequency

periods should preserve the sum.

Caution: This input must be given if you provide some of the optional inputs.

Caution: All these option will by default use the first period of the subperiods as base for the conversion. Provide the optional input 'interpolateDate' if you want to set the base to the end periods instead ('end').

Optional input:

- 'includeLast' : Give this string as input if you want to include the last period, even if it is not finished. Only when converting to lower frequencies

E.g: obj = obj.convert(1,'average',...
'includeLast');

- 'rename' : Changes the postfixes of the variables names.

E.g. If you covert from the frequency 12 to 4 the prefixes of the variable names changes from 'MUA' to 'QUA', if the prefix exist.

E.g: obj = obj.convert('yearly','average',...
'rename');

Optional input (...,'inputName', inputValue,...):

- 'fill' : Either 'nan' (default) or 'zeros'. This set how to fill the values that are not set when method is set to 'none'.

- 'interpolateDate' : The input after this input must either be 'start', 'end' or a scalar integer.

Date of interpolation. Where 'start' means to interpolate the start date of the periods of the old frequency, while 'end' uses the end date of the periods. If a scalar integer is added it is taken as 'end' minus the given number of periods.

Default is 'start'.

Caution : Only when converting to higher frequency.

Caution : For weekly data, the 'dayOfWeek' options is added. See nb_ts.setDayOfWeek for more on this.

E.g: obj = obj.convert(365,'linear',...
'interpolateDate','end');

Output:

- obj : An nb_ts object converted to wanted frequency.

Examples:

```
obj = obj.convert(4,'average');
obj = obj.convert(365,'linear','interpolateDate','end');
obj = obj.convert(1,'average','includeLast');
obj = obj.convert(1,'average','rename');
```

See also:

[nb_ts.convertEach](#)

Written by Kenneth S. Paulsen

► convertEach ↑

```
obj = convertEach(obj,freq,method,varargin)
```

Description:

Convert the frequency of each series of the nb_ts object.

Caution: If you want to apply same conversion method to all series use nb_ts.convert instead.

Input:

- obj : An object of class nb_ts.
- freq : The new frequency of the data. As an integer:
 - > 1 : yearly
 - > 2 : semi annually
 - > 4 : quarterly
 - > 12 : monthly
 - > 52 : weekly
 - > 365 : daily
- methods : The methods to use to convert each series. As a 1 x numberOfVariables cell array. Set to '' to use default.
See the method input to the nb_ts.convert to get information on the supported method you can use to convert the series.

Optional input:

- Same as for the nb_ts.convert method. Will be applied to all series.

Output:

- obj : An nb_ts object converted to wanted frequency.

See also:

[nb_ts.convert](#)

Written by Kenneth S. Paulsen

► **corr ↑**

obj = corr(obj,varargin)

Description:

Calculate the correlation of the timeseries of the nb_ts object

Caution: Calculates the correlation matrix of the variables of the nb_ts object, if no optional inputs are given. If 'lags' is given this function calculates the correlation with the number of wanted lags for each variable with itself. (And only with itself)

Input:

- obj : An object of class nb_ts

Optional input ('propertyName',PropertyValue):

- 'lags' : An integer with the number of lags you want to calculate the correlation for. (Here for each variable)
- 'robust' : true or false. Give true if you want to remove missing observations during calculations. (Also inf)
- 'type' : 'pairwise' or 'default'. 'pairwise' calculate the correlation matrix for the selected lag or lead, while 'default' calculates the correlation with itself for lags from 1 to lags and the same for lead.

Output:

- obj : An nb_cs object with the wanted correlation

Examples:

```
corrMatrix = corr(obj);
corrMatrix = corr(obj,'lags',2);
```

Written by Kenneth S. Paulsen

► **cos** ↑

```
obj = cos(obj)
```

Description:

Take cos of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = cos(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cosd** ↑

```
obj = cosd(obj)
```

Description:

cosd(obj) is the cosine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cosd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cosh** ↑

```
obj = csch(obj)
```

Description:

`cosh(obj)` is the hyperbolic cosine of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **cot** ↑

```
obj = cot(obj)
```

Description:

Take cotangent of the data stored in the `nb_ts`, `nb_cs` or `nb_data` object

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
obj = cot(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass `NB_DATASOURCE`

► **cotd** ↑

```
obj = cotd(obj)
```

Description:

`cotd(obj)` is the cotangent of the elements of `obj`, expressed in degrees.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = cotd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **coth** ↑

```
obj = coth(obj)
```

Description:

`coth(obj)` is the hyperbolic cotangent of the elements of `obj`.

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = coth(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **cov** ↑

```
obj = cov(obj,varargin)
```

Description:

Calculate the covariances of the timeseries of the nb_ts object

Caution: Calculates the covariance matrix of the variables of the nb_ts object, if no optional inputs are given. If 'lags' is given this function calculates the covariance with the number of wanted lags for each variable with itself. (And only with itself)

Input:

- obj : An object of class nb_ts

Optional input ('propertyName',PropertyValue):

- 'lags' : An integer with the number of lags you want to calculate the covariance for. (Here for each variable)
- 'robust' : true or false. Give true if you want to remove missing observations during calculations. (Also inf)
- 'type' : 'pairwise' or 'default'. 'pairwise' calculate the covariance matrix fro the selected lag or lead, while 'default' calculates the covariance with itself for lags from 1 to lags and the same for lead.

Output:

- obj : An nb_cs object with the wanted covariances

Examples:

```
corrMatrix = cov(obj);  
corrMatrix = cov(obj,'lags',2);
```

Written by Kenneth S. Paulsen

► **covidDummy** ↑

```
obj = covidDummy(obj)  
obj = covidDummy(obj,covidDummyDates)
```

Description:

A dummy for the covid-19 episode.

Input:

- obj : An object of class nb_ts.
- covidDummyDates : A cellstr with the dates of the covid-19 crisis.
Default is the period 16.03.2020 – 31.12.2021.
Hint: Use nb_month(3,2020):nb_month(12,2021).

Output:

- obj : An object of class nb_ts.

Examples:

```
Generate random data:  
data = nb_ts.rand('2018Q1',12,3)  
data = covidDummy(data)  
dataM = nb_ts.rand('2018M1',36,3)  
dataM = covidDummy(dataM)  
dataW = nb_ts.rand('2020W1',40,3)  
dataW = covidDummy(dataW)
```

See also:

[nb_covidDummyNames](#), [nb_covidDates](#)

Written by Kenneth Sæterhagen Paulsen

► **createSeasonalDummy** ↑

obj = createSeasonalDummy(obj,type)

Description:

Creates and adds seasonal dummy variables to the nb_ts object.

Input:

- obj : An object of class nb_ts.
- type : Centered/ uncentered

Output:

- obj : An object of class nb_ts. (With the added dummy variable)

Examples:

See also:

[nb_ts](#)

Written by Kenneth Sæterhagen Paulsen

► **createShift ↑**

```
[obj,shift]      = createShift(obj,variables,expression,output)
[obj,shift,plotter] = createShift(obj,variables,expression,output)
```

Description:

Remove trend/shift from variables and add them in a new database shift.

Each element of the expression input specify one of the following:

- How to demean the data or detrend data.
- How to get the trend given a calculate the gap. See the FGTS option below.

Functionalities:

- {'constant',value} or {'constant',value} :

With this option you can make the series stationary by subtracting a constant over the whole timespan. This will also be the projection going forward. (Could also be a mathematical expression)

Optional inputs: 'cmavg'. These inputs work the same as is the case for the 'hpfilter'.

- {'avg'} or {'avg',...} :

Subtract the mean from the dataseries. Including short term forecast. This will also be the projection going forward.

Optional inputs: 'wfcst', 'whist' and 'cmavg'. These inputs work the same as is the case for the 'hpfilter'.

- {'exponentialSmoothen',weight} or {'exponentialSmoothen',weight,...}:

Exponential smoother. See the exptrend function for more.

Optional inputs:

- Same as for the 'hpfilter' case.
- {'hpfilter',lambda} or {'hpfilter',lambda,...}:

HP filter with lambda given by lambda (a number). Switch 'hpfilter' to 'hpfilterls' to do one-sided HP-filter.

Optional inputs:

- 'wfcst'

When 'wfcst' is given, this function includes all the data after the date given in the cell after this one to compute the hpfilter. See last option for more on de-trending sub-periods.

- 'whist'

When 'whist' is given, this function includes all the data before the date given in the cell before this one to compute the hpfilter. See last option for more on de-trending sub-periods.

Both 'wfcst' and 'whist' does nothing if the hpfilter is not combined with other functions in a cell!

- 'randomWalk' : Use a 20 periods projection of the level in the series by a random walk before filtering the series.
- 'randomwalkgrowth' : Use a 20 periods projection of the growth in the series by a random walk before filtering the series.
- 'cmavg' : Apply the central moving average to the gap, i.e. nb_mavg(gap,1,1).
- function_handle : A function_handle that takes the time-series of gap as it's only input.
E.g: @(x)nb_mavg(x,1,1)

- {'bkfilter',low,high} or {'bkfilter',low,high,...} :

Band pass filter removing all the freq. outside the frequencies given by low and high. Switch 'bkfilter' to 'bkfilterls' to do one-sided band pass filter.

Optional inputs:

- Same as for the 'hpfilter' case.
- {'linear'} or {'linear',...} :
Apply the linear filter to the data.

Optional inputs:

- Same as for the 'hpfilter' case.
- {'M2T','ar',trend,arCoeff} or
{'M2T','ar',trend,arCoeff,trendStart,lambda}
(M2T = Merge To Trend)

If you don't want a constant trend in the future you can use this option. (Instead of {'end'}). This function will close

the gap between the given growth rate in the trend, at the date given before this sub-period, and the growth rate given by trend, with a AR process. Where the AR coefficient is given by arCoeff. And it will return the level trend implied by this growth "path".

- trend : Must be a number with the long term growth rate in the trend.
- arCoeff : Must be a scalar number with the ar coefficient
- trendStart : Must be a number with the starting value of the growth rate in the trend. Can also be set to 'hpfilter'. In this case it starts out with the growth rate of a hp-filter trend with lambda set by the lambda input. Optional.
- lambda : A scalar double with the lambda used for the hp-filter if trendStart is set to 'hpfilter'. Default is 3000. Optional.
- {'M2T','int',trend}

This function does the same as the one above, but it uses a linear growth "path" instead of the one implied by the AR process to close the "growth gap".

- {'FGTS',expression} (FGTS = From Gap To Shift)

If you have the gap but need the shift variable you can use this function. Where expression must be a string with the expression to evalute. I.e. the expression of data input which the gap was cumputed of. E.g. 'log(Var1)'.

- A cell where you give different ways to detrend data for different sub-periods. The cell must be given in the following way:

```
{{'constant',2}, '2011Q2', {'int',2,3}, '2012Q2', {'end'}}
```

Where each odd cell element is representing the period up and including the date given as the even cell elements which follows. The cell given above will therefore subtract 2 up and including 2011Q2, and will subtract the line starting at 2 in 2011Q3 and ending at 3 in 2012Q2. From then on it will subtract the last value given at 2012Q2 for all periods ahead.

Options for each cell (up and including the date given as the next cell):

- {'constant',value} : as above
- {'avg'} : as above
- {'hpfilter',lambda,...} : as above
- {'bkfilter',low,high,...} : as above
- {'M2T','ar',trend,arCoeff} : as above

- {'FGTS','expression'} : as above

Options for the last sub-period (last cell element):

- {'end'} : Project the trend using a random walk.
- {'endgrowth'} : Project the trend using a random walk in the growth rate.
- {'M2T','ar',trend,arCoeff} : as above

Input:

- obj : An object of class nb_ts
- nSteps : Number of steps to extrapolate the shift variable
- variables : The variables to be removed a trend/shift. As a cell array or a string.
Must have the same size as the 'expressions' input.
- expression : The expressions of how to create the trend/shift of all the variables.
As a cell array with the same size as the 'variables' input.
See the description of this method for the supported de-trending methods.
- output : If given as 'shift' the first output will be the shift output instead.

Output:

- obj : A nb_ts object where the listed variables has been detrended.
- shift : A nb_ts object storing the trend/shift variables. All the variables not included in the variables input will be given a shift variable of zero.
- plotter : A nb_graph_ts object that plots the de-trending of the data. Use the graphInfoStruct method or the nb_graphInfoStructGUI class to produce the graphs.

Caution: If dealing with real-time data, only the last vintage is displayed.

Examples:

```
obj = obj.createShift({'var1','var2',...},...
    {{'avg'},'2012Q1',{'end'}},{{'constant',2}},...);
```

Written by Kenneth S. Paulsen

► **createTimeDummy** ↑

```
obj = createTimeDummy(obj, nameOfDummy, date, condition)
```

Description:

Creates and adds a dummy variable to the nb_ts object. Will test the conditions given the date provided.

Input:

- obj : An object of class nb_ts.
- nameOfDummy : Name of the added dummy variable.
- date : The date to test. Either a string, a nb_date object or a 1 x 2 cell array, where each element is either a string, a nb_date object.
- condition : The conditions to test.
 - '<' : True before. Not supposed if date is a cell array.
 - '>' : True after. Not supposed if date is a cell array.
 - '<=' : True before and including. Not supposed if date is a cell array.
 - '>=' : False before and including. Not supposed if date is a cell array.
 - '==' : True for the given period (default).
 - '~=': True for all but the given period.

Output:

- obj : An object of class nb_ts. (With the added dummy variable)

Examples:

```
obj = nb_ts(ones(5,2),'', '2012', {'Var1','Var2'});  
obj = createTimeDummy(obj,'Dummy','2013','>');  
obj = createTimeDummy(obj,'Dummy2',{ '2013','2015'},'==');  
obj = createTimeDummy(obj,'Dummy3',{ '2013','2015'},'~=');
```

See also:

[nb_ts](#)

Written by Kenneth Sæterhagen Paulsen

► **createVarDummy** ↑

```
obj = createVarDummy(obj, nameOfDummy, varargin)
```

Description:

Creates and adds a dummy variable to the nb_ts object. Will test the conditions given for the variable provided by the testedVariable input.

Input:

- obj : An object of class nb_ts.
- nameOfDummy : Name of the added dummy variable.
- varargin : The conditions to test.
 - '<' : Less than. Second input must be a double (scalar), an nb_ts object (if more variables it must be less than all the stored variables) or a string with the variable to test against. The third input must either be '|' or '&' indicating if you want to check that this condition and ('&') or or ('|') the next is satisfied. The and operator(s) will have presedens over the or operator.
 - '>' : Greater than. (Or else same as '<')
 - '<=' : Less than or equal to. (Or else same as '<')
 - '>=' : Less than or equal to. (Or else same as '<')
 - '==' : Equal to. (Or else same as '<')
 - '~=': Not equal to. (Or else same as '<')

Output:

- obj : An object of class nb_ts. (With the added dummy variable)

Examples:

```
obj = nb_ts([1,2;-3,1;-1,3],'', '2012', {'Var1','Var2'});  
obj = createVarDummy(obj,'Dummy','Var1','>',0,'&');  
obj = createVarDummy(obj,'Dummy','Var1','>','Var2','&');  
obj = createVarDummy(obj,'D2','Var1','>',0,'|','Var2','<',1,'&');  
obj = createVarDummy(obj,'D2','Var1','>',0,'&','Var2','<',1,'&');
```

See also:

[nb_ts](#)

Written by Kenneth Sæterhagen Paulsen

► **createVariable** ↑

```
obj = createVariable(obj, nameOfNewVariable, expression)
obj = createVariable(obj, nameOfNewVariable, expression, parameters, varargin)
```

Description:

Create variable(s) and add them to the nb_ts object dataset(s)

- This function only support methods of the class nb_math_ts for the expressions. Type the following in the command window;

```
methods(nb_math_ts)
```

Input:

- obj : An object of class nb_ts
- nameOfNewVariable : The created variable names as a cell array or a string.
Must have the same size as the 'expressions' input.
- expression : The expressions of how to create the data of all the created variables.
As a cell array or a string.
Must have the same size as the 'nameOfNewVariables' input.
- parameters : A struct with the parameters that can be used in the expressions. Caution: They will be added as series, so you need to use elementwise operators (.*, ./, .^)!

Optional input:

- 'overwrite' : true or false. Set to true to allow for overwriting of variables already in the data of the object. Default is false.
- 'warning' : true or false. Set to true to give warning if expressions fail (instead of error). Will result in series having all nan value, when warning is thrown.

Output:

- obj : An nb_ts object with the created variable(s) added.

Examples:

```
obj = obj.createVariable('var3','var1./var2');  
  
obj = obj.createVariable({'var3','var4',...},...  
{'var1./var2','var2./var1',...});
```

See also:

[nb_math_ts](#)

Written by Kenneth S. Paulsen

► **csc** ↑

```
obj = csc(obj)
```

Description:

Take csc of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = csc(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cscd** ↑

```
obj = cscd(obj)
```

Description:

cscd(obj) is the cosecant of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = cscd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **csch** ↑

```
obj = csch(obj)
```

Description:

csch(obj) is the hyperbolic cosecant of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = csch(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **cumnansum** ↑

```
obj = cumnansum(obj)
```

Description:

Cumulative sum of the series of the object. Ignoring nan values.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumnansum(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumprod** ↑

```
obj = cumprod(obj, dim)
```

Description:

Cumulativ product of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ product should be calculated. Default is the first dimension.

Output:

- obj : A nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative product of the old objects 'data' property.

Examples:

```
obj = cumprod(obj);
obj = cumprod(obj, 2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cumsum** ↑

```
obj = cumsum(obj,dim)
```

Description:

Cumulativ sum of the series of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : In which dimension the cumulativ sum should be calculated. Default is the first dimension.

Output:

- obj : An nb_ts, nb_cs or nb_data object where the 'data' property of the object is now the cumulative sum of the old objects 'data' property.

Examples:

```
obj = cumsum(obj);  
obj = cumsum(obj,2);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **cutAtDates** ↑

```
obj = cutAtDates(obj,endDates)
```

Description:

Cut the time-series of the variables of the object.

Input:

- obj : An object of class nb_ts
- endDates : A nPages x nVars nb_date array.

Output:

- obj : An object of class nb_ts

Written by Kenneth S. Paulsen

► **cutAtVintage** ↑

```
obj = cutAtVintage(obj, lags)
```

Description:

Cut each vintage that include forecast at the period of the vintage tag minus the number of wanted lags.

Input:

- obj : An object of class nb_ts
- lags : The number of lags to do to find the end date at each vintage.
Default is 1.

Output:

- obj : An object of class nb_ts

Examples:

```
obj = cutAtVintage(obj);
```

Written by Kenneth S. Paulsen

► **cutSample ↑**

```
obj = cutSample(obj)
```

Description:

Remove leading and trailing nan values, will give an error if the sample still includes nan values.

Input:

- obj : An object of class nb_ts
- tolerate : Tolerate number of trailing nan. An integer greater than or equal to 0.

Output:

- obj : An object of class nb_ts

Examples:

```
out = cutSample(in);
```

See also
nb_ts.shrinkSample

Written by Kenneth S. Paulsen

► **dates** ↑

```
allDates = dates(obj)
allDates = dates(obj,format)
```

Description:

Get all the dates of the object. As a cellstr.

Input:

- obj : An object of class nb_ts
- format : See the method toDates in the nb_date class for supported formats

Output:

- allDates : A cellstr array of the dates of the object

Examples:

```
allDates = obj.dates();
allDates = obj.dates('xls');
```

Written by Kenneth S. Paulsen

► **deleteMethodCalls** ↑

```
obj = deleteMethodCalls(obj,c)
```

Description:

Delete some method calls of the object. The object needs to be updatable.

Caution: To set method calls use setMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- sourceNr : The source index to delete the methods from
- methodNrs : A index with the methods to delete.

Output:

- obj : An object of class nb_ts, nb_data or nb_cs

See also:

[setMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **deleteVariables ↑**

obj = deleteVariables(obj,deletedVar)

Description:

Delete variables from the current nb_ts, nb_data or nb_cs object (letter size has something to say)

If some of the variables you specify in deletedVar does not exist in the obj, this will not have anything to say for the obj. (The variables cannot be deleted, because the variables do not exist.)

Input:

- obj : An object of class nb_ts, nb_data or nb_cs

- deletedVar : Must be a char or a cellstr

Delete all the variable names, given in the char array or cellstr array deletedVar, of current the object.

NB! If deletedVar is just one string and include a * as the last letter, this function will delete all the variable names, from the object, that start with the letters which is in front of the * in the string.

i.e. obj = deleteVariables(obj,'DPQ*');

Deletes all the variables in the obj which has variable names starting with 'DPQ'.

If deletedVar is just one string and include a * as the first letter, this function will delete all the variable names, from the object, that include the letters which follows in the string.

i.e. obj = deleteVariables(obj, '*shift');

Deletes all the variables in the obj which has variable names which include 'shift'.

Output:

- obj : A nb_ts, nb_data or nb_cs object with the variables specified in deletedVar deleted.

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = deleteVariables(obj, {'Var1','Var2'});  
obj = deleteVariables(obj, char('Var1','Var2'));  
obj = deleteVariables(obj, obj.variables);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **demean** ↑

```
obj = demean(data,dim)
```

Description:

- Demeans data along the dimension you choose.

Input:

- obj : A nb_dataSource object.
- dim : A double corresponding to the dimension you want to take the average over. Default is 1.

Output:

- obj : A nb_dataSource object.

Written by Tobias Ingebrigtsen

Inherited from superclass NB_DATASOURCE

► **denton** ↑

```
obj = denton(obj,z,k,type,d)
```

Description:

The Denton method of transforming a series from low to high frequency.

See Denton (1971), Adjustment of Monthly or Quarterly Series to Annual Totals: An Approach Based on Quadratic Minimization.

Input:

- obj : A nobs x nvars x npage nb_ts object with the main variables to transform.
- z : A nobs*k x nvars x npage double with observations on the judgment.
- k : The number intra low frequency observations. If you have annual data and want out quarterly data use 4.
- type : Either 'sum', 'average', 'first' or 'last'. 'average' is default.
- d : 1 : first differences, 2 : second differences.

Output:

- x : Output series as a nobs*k x nvars x npage nb_ts object.

See also:

[nb_ts.convert](#), [nb_denton](#)

Written by Kenneth Sæterhagen Paulsen

► **deptcat ↑**

obj = deptcat(obj,varargin)

Description:

Depth concatenation (add pages of different objects) (No short notation)

Be aware: If the added datasets does not contain the same variables or dates, the data of the nb_ts object with the tightest window will be expanded automatically to include all the same dates and variables. (the added data will be set as nan)

Input:

- obj : An object of class nb_ts
- varargin : Optional number of nb_ts objects

Output:

- obj : An object of class nb_ts where all the objects datasets are added into.

Examples:

```
obj = obj.deptcat(DB);
obj = obj.deptcat(DB,DB2,DB3);
```

See also:

[addPages](#)

Written by Kenneth S. Paulsen

► **detrend** ↑

```
obj          = detrend(obj,method)
obj          = detrend(obj,method,output,varargin)
[obj,trendObj,plotter] = detrend(obj,method,output,varargin)
```

Description:

Detrending nb_ts object.

Input:

- obj : As a nb_ts object.
- method : Either {'linear'}, 'linearls', 'mean', 'hpfilter', 'hpfilterls', 'bkfilter', 'bkfilterls', 'baiPerron' or 'exponentialsmoother'.
- output : If given as 'trend' the first output will be the trend output instead. 'Normal' is default.
- varargin : Additional inputs. When:
 - > 'exponentialsmoother' : One more input must be given. I.e. weight on previous value. See exptrend function for more.
 - > 'hpfilter' or 'hpfilterls' : One more input must be given. I.e. lambda.
 - > 'bkfilter' or 'bkfilterls' : Two more inputs must be given. I.e. lowFreq and highFreq.
 - > 'baiPerron' : Two input may be given:
 - The first:
 - * 'bic' : Bayesian information criterion is used to select the breaks. Default.
 - * 'lwz' : The Liu, Wu and Zidek information criterion is used to select the breaks.
 - * integer : An integer with the number of breaks to identify.
 - The second:
 - * integer : The maximum number of breaks to allow when using a information criterion to choose the number of breaks. Default is 2.

Output:

- obj : As a nb_ts object with the detrended data.
- trendObj : As a nb_ts object with the trend.
- plotter : A nb_graph_ts object. Use the graphInfoStruct method or the nb_graphInfoStructGUI class on the returned object.

Examples:

```
obj = nb_ts.rand('2012Q1',10,3);
obj = detrend(obj,'linear');
obj = detrend(obj,'hpfilter','','1600');
obj = detrend(obj,'bkfilter','','6,32');
```

See also:

[createShift](#)

Written by Kenneth Sæterhagen Paulsen

► diff ↑

```
obj = diff(obj)
obj = diff(obj,lags)
obj = diff(obj,lags,skipNaN)
```

Description:

Calculate diff, using the formula: $x(t) - x(t-lag)$ of all the timeseries of the nb_ts object.

Input:

- obj : An object of class nb_ts
- lags : The number of lags in the diff formula, default is 1.
- skipNaN : -1 : Skip nan while using the diff operator. (E.g. when dealing with working days.)
 - 0 : Do not skip nan values. Default.

Output:

- obj : An nb_ts object with the calculated timeseries stored.

Examples:

```
obj = diff(obj);  
obj = diff(obj,4);
```

See also:

[nb_ts](#)

Written by Kenneth S. Paulsen

► **disp ↑**

```
disp(obj)
```

Description:

Display object (In the command window)

Input:

- obj : An object of class nb_ts

Output:

The dataset displayed in the command window.

Examples:

```
obj (Note without semicolon)
```

Written by Kenneth S. Paulsen

► **doTransformations ↑**

```
[obj,shift,plotter] = doTransformations(obj,expressions,fcstHorizon,varargin)
```

Description:

Do transformations on the variables of the object.

Input:

- obj : A nb_ts object

- expressions : A N x 4 cell matrix of how to transform input data to model variables. First column is the model variable name, while the second column is the expression to convert the input data to model variable. The third column is the expression on how to calculate the shift variable. While

the fourth column is for comments.

More on:

> second column : Any expression that can be interpreted by the nb_ts.createVariable method.

> third column : Any expression that can be interpreted by the nb_ts.createShift method.

> fourth column : Comments

- fcstHorizon : The forecast horizon. As an integer. Default is 0.

Optional input:

- 'warning' : true or false. Set to true to give warning if expressions fail (instead of error). Will result in series having all nan value, when warning is thrown.

Output:

- obj : A nb_ts object storing the de-trended created variables.
- shift : A nb_ts object storing the shifts/trend of the created variables.
- plotter : A nb_graph_ts object with a graph with the de-trending. Use the graphInfoStruct method or the nb_graphInfoStruct class to produce the graph.

Examples:

```
expressions = {%
    Name,      input,     shift,      description
    'VAR1_G',   'pcn(VAR1)', 'avg',    'VAR1 growth'
    'VAR2_G',   'pcn(VAR2)', 'avg',    'VAR2 growth'
    'VAR3_G',   'pcn(VAR3)', 'avg',    'VAR3 growth'};

obj = obj.doTransformations(expressions)
```

See also:

[nb_ts.createVariable](#), [nb_ts.createShift](#)

Written by Kenneth Sæterhagen Paulsen

► **double ↑**

```
dataOfObject = double(obj)
```

Description:

Get the data of the object as a double matrix

Caution : If the data of the object is represents as an object of class nb_distribution the mean is returned.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- dataOfObject : The data of the nb_ts, nb_cs or nb_data object

Examples:

```
dataOfObject = double(obj)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **easterDummy** ↑

```
obj = easterDummy(obj,greedy)
```

Description:

A seasonal dummy for easter. It utilizes the eastermethod to estimate when easter occurs every year.

Input:

- obj : An object of class nb_ts.
- greedy : Logical. If true this method will only return a dummy for the month when Easter Sunday occurs, otherwise it will return a dummy for the months where the easter week occurs (i.e. may overlap different months). Default is true.

Output:

- obj : An object of class nb_ts.

Examples:

```
Generate random data:  
data = nb_ts.rand('2012M1',10,3)  
data1 = easterDummy(data,1)  
data2 = easterDummy(data,0)
```

See also:

► **ecdf** ↑

```
obj = ecdf(obj,varargin)
```

Description:

A method for creating an nb_ts object with the Empirical (Kaplan-Meier) cumulative distribution function. It utilizes the inbuilt ecdf function to estimate the distribution. See ecdf for more information on the optional inputs for the function.

Input:

- obj : An nb_ts object with the data.

Optional input:

- 'recursive' : True or false. If true, the CDF will be estimated recursively. Default is false.
- 'recStart' : Sets the start date for the recursive estimation. Default is the start date of the obj + 9 observations. As a string or as an object of class nb_date.
- 'recEnd' : Sets the end date for the recursive estimation. Default is the end date of the object. As a string or as an object of class nb_date.
- 'estStart' : Sets the start of the estimation sample. As a string or as an object of class nb_date.

Output:

- obj : A numIter x numVar nb_ts object where each observation point contains an nb_distribution object with the estimated parameters of the distribution.

Examples:

```
f = nb_ts(randn(1000,1),'', '2010M1',{'v1'});  
obj = f.ecdf('recStart','2012M1','recEnd','2012M12', 'recursive',1);
```

See also:

[nb_ts.ksdensity](#)

► **egrowth** ↑

```
obj = egrowth(obj)
obj = egrowth(obj,lag,stripNaN)
```

Description:

Calculate exact growth, using the formula: $(x(t) - x(t-1))/x(t-1)$ of all the timeseries of the nb_ts object.

Input:

- obj : An object of class nb_ts
- lag : The number of lags in the growth formula, default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An nb_ts object with the calculated timeseries stored.

Examples:

```
obj = egrowth(obj);
obj = egrowth(obj,4);
```

See also:

[growth](#), [aegrowth](#), [agrowth](#)

Written by Kenneth S. Paulsen

► **empty** ↑

```
obj = empty(obj)
```

Description:

Empty the existing nb_ts object.

Input:

- obj : An object of class nb_ts

Output:

- obj : An empty nb_ts object

Examples:

```
obj = empty(obj)
```

Written by Kenneth S. Paulsen

► **epcn ↑**

```
obj = epcn(obj);
obj = epcn(obj,lag,stripNaN)
```

Description:

Calculate exact percentage growth, using the formula:
100*(x(t) - x(t-1))/x(t-1) of all the timeseries of the nb_ts
object.

Input:

- obj : An object of class nb_ts
- lag : The number of lags in the growth formula, default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An nb_ts object with the calculated timeseries stored.

Examples:

```
obj = epcn(obj); % period-on-period growth
obj = epcn(obj,4); % 4-periods growth
```

Written by Kenneth S. Paulsen

► **eq ↑**

```
a = eq(a,b)
```

Description:

Test if the one object is equal (==) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a == b;  
obj = 2 == b;  
obj = a == 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **estimateDist ↑**

```
dist = estimateDist(obj,type)
```

Description:

Estimate distributions of the series in the nb_ts object.

Caution : This method strip all nan values.

Input:

- obj : An object of class nb_ts.
- type : The type of distribution to estimate. See the 'type' property of the nb_distribution class for the supported types. (Some may not be possible to estimate using 'mle' and/or 'mme'.) Default is 'normal';

Caution : If estimator is equal to 'kernel', this input is not used.

```

Caution : If type is set to 'hist', no estimator is
          used but the returned nb_distribution
          object instead represent a histogram.

- estimator : Either 'mle' (maximum likelihood), 'mme' (methods
               of moments) or 'kernel' (normal kernel density
               estimation). Default is 'mle'.

- dim       : The dimension to estimate densities over. Either
               1, 2 or 3. Default is 1.

- output    : Either 'nb_distribution' (default) or 'nb_dataSource'.
               If 'nb_dataSource' is chosen the output will be a nb_ts
               object if dim equal 2 or 3, while it will be a nb_cs object
               if dim equal 1.

```

Optional input:

- varargin : Optional input given to the nb_ksdensity function. Please see help for that function.

Output:

- dist : An object of class nb_distribution, nb_ts or nb_cs.

See also:

[nb_distribution](#)

Written by Kenneth Sæterhagen Paulsen

► **exp ↑**

`obj = exp(obj)`

Description:

Take exp of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = exp(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE
```

► **expand** ↑

```
obj = expand(obj,newStartDate,newEndDate,type,warningOff)
```

Description:

Expand the current nb_ts object with more dates and data

Input:

- obj : An object of class nb_ts
- newStartDate : The wanted new start date of the data.
- newEndDate : The wanted new end date of the data.
- type : Type of the appended data :
 - 'nan' : Expanded data is all nan (default)
 - 'zeros' : Expanded data is all zeros
 - 'ones' : Expanded data is all ones
 - 'rand' : Expanded data is all random numbers
 - 'obs' : Expand the data with first observation (before) or last observation after
- warningOff : Give 'off' to suppress warning if no expansion has taken place. Both 'newStartDate' and 'newEndDate' is inside the window.

Output:

- obj : An nb_ts object with expanded timespan

Examples:

```
obj = expand(obj,'1900Q1','2050Q1');
obj = expand(obj,'1900Q1','2050Q1','zeros');
```

Written by Kenneth S. Paulsen

► **expandPeriods** ↑

```
obj = expandPeriods(obj,periods,type)
```

Description:

Expand the data of the object by the number of wanted periods.

Input:

- obj : An object of class nb_ts.
- periods : The number of periods to expand by. If negative the added periods will be added before the start date of the object.
- type : Type of the appended data :
 - 'nan' : Expanded data is all nan (default)
 - 'zeros' : Expanded data is all zeros
 - 'ones' : Expanded data is all ones
 - 'rand' : Expanded data is all random numbers
 - 'obs' : Expand the data with first observation (before) or last observation after

Output:

- obj : An object of class nb_ts.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

► expml ↑

```
obj = expml(obj)
```

Description:

`exp(obj)` is the exponential of the elements of `obj`, `e` to the `obj`.
`expml(obj)` computes `exp(obj)-1`, compensating for the roundoff in
`exp(obj)`.
(For small real `X`, `expml(X)` should be approximately `X`, whereas the
computed value of `EXP(X)-1` can be zero or have high relative error.)

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the
data are equal to $e.^obj.data-1$

Examples:

```
obj = expm1(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **extMethod ↑**

```
obj = extMethod(obj,method,variables,postfix,varargin)
```

Description:

This method can call a nb_dataSource method on a selected variables, and merge the result with the old object by adding a postfix to the new variables.

This method is the same as calling:

```
obj1 = window(obj,'','','variables);
method = str2func(method);
obj     = method(obj,varargin{:});
obj1   = addPostfix(obj1,method);
obj     = merge(obj,obj1);
```

But without replicating the links property unnecessary many times!

Caution : If the object is not updateable this will result in the same as the code above!

Input:

- obj : An object of class nb_ts, nb_data or nb_cs
- method : A str with the method to call. Must be a method of the nb_ts, nb_data or nb_cs class that does not change other dimensions then the second dimension!
- variables : A cellstr with the variables of the object to call the method on. Must be included in the object.
- postfix : A string with the postfix. If empty, the old variables will be replaced by the new ones.

Optional inputs:

These will be the inputs casted to the method except the object itself.

Extra for nb_ts and nb_data:

- '<start>' : The start date/obs of the function evaluation. Given as the second input to the window method call.
- '<end>' : The end date/obs of the function evaluation. Given as the third input to the window method call.

Output:

- obj : A nb_ts, nb_data or nb_cs object

Examples:

```
obj = nb_ts.rand(1,10,3);
obj = extMethod(obj,'lag',{'Var1'},'lag1',1)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **extrapolate** ↑

```
obj = extrapolate(obj,variables,toDate)
obj = extrapolate(obj,variables,toDate,varargin)
```

Description:

Extrapolate last of observation of one variable to the wanted date.

Caution: This method only works on a single paged nb_ts object.

Input:

- obj : An object of class nb_ts
- variables : A string with the name of the variable to extrapolate, or a cellstr of the variables to extrapolate. Default is to extrapolate all variables.
Caution: When 'method' is set to copula only the selected variables are included in the calculation of the extrapolated values.
- toDate : Extrapolate to the given date. If the date is before the end date of the given variable no changes will be made, and with no warning. Can also be a integer with the number of periods to extrapolate.

Optional inputs:

- 'method' :
 - > 'end' : Extrapolate series by using the last observation of each series. I.e. a random walk forecast. Default.
 - > 'copula' : This approach tries to estimate the unconditional marginal distribution of each series in the dataset and the (auto)correlation structure that describe the connection between these series. Some series may have more observations than others!

Caution : This method works when the unconditional distribution from which the series are assumed to be drawn from are the same over time. E.g. the series must have the same volatility over the period. The second assumption is that all the series are stationary. Use the 'check' input to test for non-stationarity by a ADF test for unit-root. If it is found to have a unit root the series will be differenced when forecasted, and then transformed back to level after that step.

- > 'ar' : Extrapolate each series individually using a fitted AR model.
- > 'var' : Extrapolate all series using a fitted VAR model. Max number of variables is set to 10 for this option.
- 'alpha' : Significance level of ADF test for stationary series. Only an option for the 'copula' method.
- 'check' : Check for stationary series. If not found to be stationary the series will be differenced and extrapolated with this transformation before transformed back to its old level. Only an option for the 'copula' method.
- 'nLags' : Number of lags to include when calculating the correlation matrix used by the copula. I.e. the number of historical observations to condition on when forming the conditional correlation matrix.
- 'draws' : The number of draws used to estimate the mean, when using the 'copula' method.
- 'constant' : Give true to include constant in the AR models used to extrapolate the individual series. Default is false.

Output:

- obj : An nb_ts object with extrapolate series.

Examples:

```
obj = nb_ts.rand('1900',50,2,1);
obj = extrapolate(obj,'Var1','1951');
```

Written by Kenneth S. Paulsen

► **extrapolateStock ↑**

```
obj = extrapolateStock(obj,stock,flow,depreciation)
```

Description:

Extrapolate stock with the flow from where the stock ends.

```
stock(t+1) = (1 - depreciation)*stock(t) + flow(t)
```

Input:

- obj : An object of class nb_dataSource.
- stock : A one line char with the name of the stock series.
- flow : A one line char with the name of the flow series.
- depreciation : A scalar number between 0 and 1.

Output:

- obj : An object of class nb_dataSource.

Written by Kenneth Sæterhagen Paulsen

► **fillNaN ↑**

```
obj = fillNaN(obj)
obj = fillNaN(obj,date,variables)
```

Description:

Fill in for nan values with last valid observation.

Input:

- obj : An object of class nb_ts.
- date : The end date of the returned dataset. Either a nb_date object or string with the date, or a number indicating how many periods back in time from the date today, i.e. 0 is today, -1 is past period and 1 is next period. Default is to use the end date of the object.
Caution : If the given date is before the end date of the data of the object no extrapolation is done.
- variables : A cellstr with the variables to fill in nan for. Default is all variables.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

► **floor** ↑

```
obj = floor(obj)
```

Description:

`floor(obj)` rounds the data elements of `obj` to the nearest integers towards minus infinity

Input:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Output:

- `obj` : An object of class `nb_ts`, `nb_cs` or `nb_data`

Examples:

```
out = floor(in);
```

Written by Andreas Haga Raavand

Inherited from superclass `NB_DATASOURCE`

► **fromRise_ts** ↑

```
data_ts = nb_ts.fromRise_ts(obj)
```

Description:

Transform from an RISE ts object or a struct of rise ts objects to an `nb_ts` object.

Input:

- `obj` : An object of class `ts`, or a structure of `ts` objects.

Output:

- `data_ts` : An `nb_ts` object.

Written by Kenneth S. Paulsen

► **ge** ↑

```
a = ge(a,b)
```

Description:

Test if the one object is greater than or equal to (\geq) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a >= b;  
obj = 2 >= b;  
obj = a >= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **get ↑**

```
propertyValue = get(obj,propertyName)
```

Description:

Get the properties of the object

Input:

- obj : An object of class nb_ts
- propertyName : Name of the property you want to get:
 - 'data' : The data of the object as a double
 - 'dataNames' : Name of the object datasets, as cellstr array
 - 'endDate' : The end date of the object as nb_date

```

- 'frequency'           : The frequency of the data, as
                           double
- 'numberOfDatasets'   : Number of datasets (pages) of the
                           object. Size of the third
                           dimension
- 'numberOfObservations' : Number of observations of the
                           object. Size of the first
                           dimension
- 'numberOfVariables'  : Number of variables of the object.
                           Size of the second dimension
- 'startDate'          : The start date of the object as
                           nb_date
- 'variables'          : The variables of the object, given
                           as a cellstr array

- 'links'               : A structure of the data source
                           links.

- 'sorted'              : true or false

- 'updateable'          : 1 if updateable, 0 otherwise.

```

Output:

```
propertyValue : The property value of the object for the wanted
                  property
```

Examples:

```
dataAsDouble = get(obj,'data');
variables    = get(obj,'variables')
```

Written by Kenneth S. Paulsen

► **getClassOfData ↑**

```
cl = getClassOfData(obj)
```

Description:

Get the class of the data stored by the object.

Input:

- obj : An object of class nb_dataSource.

Output:

- cl : Name of the class that the data of the object is stored as.

See also:

nb_ts.isDistribution, nb_ts.isDouble
nb_ts.isBoolean

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getCode** ↑

```
code = getCode(obj,preamble)
code = getCode(obj,preamble,'inputName', inputValue,...)
```

Description:

Get the LaTeX code of a table representing the data of the object

If the object consists of more pages (datasets) more tables will be created.

Input:

- obj : An object of class nb_ts
- preamble : Give 0 if you don't want to include the preamble in the returned output. Default is to include the preamble, i.e. 1.

Optional input:

- 'caption' : Adds a caption to the table. Must be a string.
- 'combine' : If the nb_ts object consist of two or three pages (datasets) this option can be used to combine all the data in one table. Either 1 or 0. Default is 0.
- 'colors' : Set it to 0 if the colored rows of the table should be turned off. Default is 1.
- 'dateformat' : Must be a string. 'default' is default.
 - > 'default'
 - > 'fame'
 - > 'xls'
 - > 'NBNorsk' ('NBNorwegian')
 - > 'NBEnglish' ('NBEngelsk')
- 'firstRowColor' : A string with the color, e.g. 'blue','white','black','blue!20!white'. Default is 'nbblue'.
- 'fontSize' : Sets the font size of the table. Either:
 - 'Huge', 'huge', 'LARGE', 'Large', 'large', 'normalsize' (default), 'small',

```

'footnotesize', 'scriptsize','tiny'.

Caution : This option is case sensitive.

- 'justification' : Sets the justification of the caption of the
table. Must be a string.

Either 'justified','centering' (default),
'raggedright', 'RaggedRight', 'raggedleft'.

Caution : This option is case sensitive.

- 'language'      : Either 'english' (default) or 'norwegian'
('norsk').

- 'lookUpMatrix'  :

Sets how the given mnemonics (variable names) should map to
different languages. Must be cell array on the form:

{'mnemonics1','englishDescription1','norwegianDescription1';
 'mnemonics2','englishDescription2','norwegianDescription2'};

Or a .m file name, as a string. The .m file must include
(and only include) what follows:

lookUpMatrix = {

'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};

Be aware : Each of the given description can be multi-lined
char, which will result in multi-line text of the
table.

- 'orientation'   : The orientation of the table. Either:

    > 'horizontal' : The dates as columns
    > 'vertical'   : The types as columns

- 'precision'     : Sets the precision of the numbers in the
table. Must be a string. Default is '%3.2f'.
I.e. two decimals.

- 'rotation'      : The rotation of the table in LaTeX. Either:

    > 'sidewaystable' : A sideways table
    > 'landscape'     : Rotate the whole page
    > ''              : No rotation

- 'rowColor1'      : Color of every second row of the table
starting from the second row. Same options
as was the case for the 'firstRowColor'
option.

- 'rowColor2'      : Color of every second row of the table
starting from the third row. Same options
as was the case for the 'firstRowColor'
option.

```

- 'rowColor3' : Color of every third row of the table starting from the fourth row. Only an option in combination with the 'combine' input set to 1 and that the nb_ts object has 3 pages. Same options as was the case for the 'firstRowColor' option.
- 'NaNrepl' : Replaces NaN's in a table by chosen symbol. Give as string, can be empty. Default: 'NaN', i.e. no replacement.

Output:

- code : A char with the tex code of the table

Examples:

```
obj = nb_ts(rand(10,3),'', '2012Q1', {'Var1','Var2','Var3'});
code = obj.getCode(1)
```

See also:

[nb_ts](#)

Written by Kenneth Sæterhagen Paulsen

► [getCreatedVariables ↑](#)

```
created = getCreatedVariables(obj)
```

Description:

Get a N x 2 table of the variables created using the createVariable method. The first column list the created variables, while the second column list the expressions.

Input:

- obj : An object that is a subclass of nb_dataSource.

Output:

- created : A N x 2 cell array. See description of this method for more.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► [getMethodCalls ↑](#)

```
[s,c] = getMethodCalls(obj)
```

Description:

Get all method calls as a cell matrix. The object needs to be updatable to get a list of methods called on the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.
- c : A cell matrix with a table of the method called on the object and its input. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getRealEndDate** ↑

```
realEndDate = getRealEndDate(obj)
realEndDate = getRealEndDate(obj,format,type)
realEndDate = getRealEndDate(obj,format,type,variables)
```

Description:

Get the real end date of the nb_ts object. I.e the last observation which is not nan or infinite.

Input:

- obj : An object of class nb_ts
- format : The date format returned.
 - Return a string:
 - > 'xls'
 - > 'pprnorsk' or 'mprnorwegian'
 - > 'pprengelsk' or 'mprenglish'
 - > 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
 - > 'nb_date'
- type : Either 'any' (default) or 'all'.
- variables : A cellstr of the variables to check.

Output:

- realEndDate : The last observation of the object which is not nan or infinite. As a string

Examples:

```
realEndDate = obj.getRealEndDate();  
realEndDate = obj.getRealEndDate('pprnorsk');
```

Written by Kenneth S. Paulsen

► getRealEndDatePages ↑

```
realEndDate = getRealEndDatePages(obj)  
realEndDate = getRealEndDatePages(obj,format,type)  
realEndDate = getRealEndDatePages(obj,format,type,variable,pages)
```

Description:

Get the real end date of each page of the nb_ts object. I.e the last observation which is not nan or infinite for each page.

Input:

- obj : An object of class nb_ts
- format : The date format returned.
 - Return a string:
 - > 'xls'
 - > 'pprnorsk' or 'mprnorwegian'
 - > 'pprengelsk' or 'mprenglish'
 - > 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
 - > 'nb_date'
- type : Either 'any' (default) or 'all'.
- variables : A cellstr of the variables to check.
- pages : A double array with whole numbers with the pages to check.

Output:

- realEndDate : The last observation of the object which is not nan or infinite for each page. Either a cellstr or a vector of objects which is of a subclass of the nb_date class.

Examples:

```
realEndDate = obj.getRealEndDatePages();  
realEndDate = obj.getRealEndDatePages('pprnorsk');
```

Written by Kenneth S. Paulsen

► **getRealEndDateVariables ↑**

```
realEndDate = getRealEndDateVariables(obj)  
realEndDate = getRealEndDateVariables(obj,format)  
realEndDate = getRealEndDateVariables(obj,format,type,page)
```

Description:

Get the real end date of each variable of the nb_ts object. I.e the last observation which is not nan or infinite for each variable.

Input:

- obj : An object of class nb_ts
- format : The date format returned.
 - Return a string:
 - > 'xls'
 - > 'pprnorsk' or 'mprnorwegian'
 - > 'pprengelsk' or 'mprenglish'
 - > 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
 - > 'nb_date'
- type : Either 'any' (default) or 'all'.
- pages : A double array with whole numbers with the pages to check.

Output:

- realEndDates : The last observation of the object which is not nan or infinite for each variable. Either a cellstr or a vecor of objects which is of a subclass of the nb_date class.

Examples:

```
realEndDates = obj.getRealEndDateVariables();  
realEndDates = obj.getRealEndDateVariables('nb_date');
```

Written by Kenneth S. Paulsen

► **getRealStartDate** ↑

```
realStartDate = getRealStartDate(obj)
realStartDate = getRealStartDate(obj,format,type,variables)
```

Description:

Get the real start date of the nb_ts object. I.e the first observation which is not nan or infinite.

Input:

- obj : An object of class nb_ts
- format : The date format returned.
 - Return a string:
> 'xls'
> 'pprnorsk' or 'mprnorwegian'
> 'pprengelsk' or 'mprenglish'
> 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
> 'nb_date'
- type : Either 'any' (default) or 'all'.
- variables : A cellstr of the variables to check.

Output:

- realStartDate : The first observation of the object which is not nan or infinite. As a string

Examples:

```
realStartDate = obj.getRealStartDate();
realStartDate = obj.getRealStartDate('pprnorsk');
```

Written by Kenneth S. Paulsen

► **getRealStartDatePages** ↑

```
realEndDate = getRealStartDatePages(obj)
realEndDate = getRealStartDatePages(obj,format,type)
realEndDate = getRealStartDatePages(obj,format,type,variable,pages)
```

Description:

Get the real end date of each page of the nb_ts object. I.e the last observation which is not nan or infinite for each page.

Input:

- obj : An object of class nb_ts
- format : The date format returned.
 - Return a string:
 - > 'xls'
 - > 'pprnorsk' or 'mprnorwegian'
 - > 'pprengelsk' or 'mprenglish'
 - > 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
 - > 'nb_date'
- type : Either 'any' (default) or 'all'.
- variables : A cellstr of the variables to check.
- pages : A double array with whole numbers with the pages to check.

Output:

- realEndDate : The first observation of the object which is not nan or infinite for each page. Either a cellstr or a vector of objects which is of a subclass of the nb_date class.

Examples:

```
realEndDate = obj.getRealStartDatePages();  
realEndDate = obj.getRealStartDatePages('pprnorsk');
```

Written by Kenneth S. Paulsen

► **getRealStartDateVariables ↑**

```
realEndDate = getRealStartDateVariables(obj)  
realEndDate = getRealStartDateVariables(obj,format)  
realEndDate = getRealStartDateVariables(obj,format,type,pages)
```

Description:

Get the real start date of each variable of the nb_ts object. I.e the first observation which is not nan or infinite for each variable.

Input:

- obj : An object of class nb_ts
- format : The date format returned.
 - Return a string:
 - > 'xls'
 - > 'pprnorsk' or 'mprnorwegian'
 - > 'pprengelsk' or 'mprenglish'
 - > 'default' (otherwise)
 - Return a date object which is of a subclass of the nb_date class:
 - > 'nb_date'
- type : Either 'any' (default) or 'all'.
- pages : A double array with whole numbers with the pages to check.

Output:

- realStartDates : The first observation of the object which is not nan or infinite for each variable. Either a cellstr or a vector of objects which is of a subclass of the nb_date class.

Examples:

```
realEndDates = obj.getRealStartDateVariables();
realEndDates = obj.getRealStartDateVariables('nb_date');
```

Written by Kenneth S. Paulsen

► **getRelease ↑**

```
obj = release(obj,num)
```

Description:

Get the wanted release from the real-time data of the object.

This method is not restricted to only updatable real-time data as is the case with nb_ts.release. Instead the dataNames property must be given with the 'yyyymmdd' format.

Caution : This method will break the link to the data source of updateable objects!

Input:

- obj : An object of class nb_ts. The vintages dates stored in the dataNames property on the format 'yyyymmdd'.

Caution: The number of variables stored is limited to one!

- num : The release number. 1 for the first release, and so on. 0 for final vintage.

Output:

- obj : An object of class nb_ts with only one page.

See also:

[nb_ts.release](#)

Written by Kenneth Sæterhagen Paulsen

► **getSource** ↑

```
sourceType = getSource(obj)
sourceType = getSource(obj,type)
```

Description:

Get source type.

Input:

- obj : An object of class nb_dataSource.
- type : Give 'program' to get the general source. Default is to give the specific type of source.

Output:

- sourceType : A one line char with the source.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getSourceList** ↑

```
s = getSourceList(obj)
```

Description:

Get the source list of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- s : List of sources, as a cellstr. Will return {} if the object is not updatable.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **getVariable ↑**

```
variableData = getVariable(obj,variableName,startDate,...  
                           endDate, pages)
```

Description:

Get the data of a variable, as a double

Input:

- obj : An object of class nb_ts
- variableName : The variable you want the data of. Must be given as a string (name of variable) or a cellstr.
- startDate : Start date of the return data of the given variable. As a string or an object which is of a subclass of nb_date
- endDate : End date of the return data of the given variable. As a string or an object which is of a subclass of nb_date
- pages : Pages of the return data of the given variable. As a double or logical array, e.e. [1:2] or [1,3,5].

Output:

- variableData : The data of the variable you have given. Return [] if not found.

Examples:

```
variableData = getVariable(obj,'Var1');  
variableData = getVariable(obj,'Var1','2012Q1');  
variableData = getVariable(obj,'Var1','2012Q1','2012Q4');  
variableData = getVariable(obj,'Var1','2012Q1','2012Q4',[1:3]);
```

Written by Kenneth S. Paulsen

► **growth** ↑

```
obj = growth(obj)
obj = growth(obj,lag,stripNaN)
```

Description:

Calculate approx growth, using the formula: $\log(x(t)) - \log(x(t-1))$ of all the timeseries of the nb_ts object.

Input:

- obj : An object of class nb_ts
- lag : The number of lags in the approx. growth formula, default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An nb_ts object with the calculated timeseries stored.

Examples:

```
obj = growth(obj);
obj = growth(obj,4);
```

See also:

[egrowth](#), [aegrowth](#), [agrowth](#)

Written by Kenneth S. Paulsen

► **gt** ↑

```
a = gt(a,b)
```

Description:

Test if the one object is greater then ($>$) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a > b;  
obj = 2 > b;  
obj = a > 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► h21 ↑

```
obj = h21(obj,freq,type)
```

Description:

Will for each observation calculate the weighted cumulative sum over the last N periods (Including the present). The weights will depend on the frequency and the selected type. Examples will be given in the case of monthly data and freq = 4;

- 'levelSummed' : $Y(q) = Y(m) + Y(m-1) + Y(m-2)$
- 'diffSummed' : $Y(q) = Y(m) + 2*Y(m-1) + 3*Y(m-2) + 2*Y(m-3) + Y(m-4)$
- 'levelAverage' : $Y(q) = 1/3*(Y(m) + Y(m-1) + Y(m-2))$
- 'diffAverage' : $Y(q) = 1/3*Y(m) + 2/3*Y(m-1) + Y(m-2) + 2/3*Y(m-3) + 1/3*Y(m-4)$

Input:

- obj : An object of class nb_ts.
- freq : The low frequency to convert high frequency observations to.
- type : See description of method. Default is 'levelAverage'

Output:

- obj : An object of class nb_ts. Caution: The frequency of the nb_ts will not be converted. See nb_ts.convert in this case.

See also:

[nb_ts.convert](#)

► **hasVariable** ↑

```
[ret,location] = hasVariable(obj,variable)
```

Description:

Test if an nb_cs object has a given variable

Input:

- obj : An object of class nb_cs
- variable : The variable name as a string. Can also be a cellstr with more variables.

Output:

- ret : 1 if found otherwise 0
- location : The location of the variable if found. Otherwise [].

Examples:

```
ret          = obj.hasVariable('Var1')
[ret,location] = hasVariable(obj,'Var1')
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **hdi** ↑

```
obj = hdi(obj,perc)
```

Description:

Calculate the highest density interval (hdi) over the third dimension of the data of the object.

Input:

- obj : An object of class nb_ts
- limits : A double with the wanted mass of the hdi of the data. E.g. 0.9, or [0.10,0.20].

Output:

- obj : A nb_ts object with the limits of the hdis stored as different pages of the object. See the dataNames property for the ordering.

Be aware that the hdis may not be overlapping! This means that the number of returned limits may be higher than the number of specified limits*2. So in the case of a bimodal distribution a the pages lb2_* and ub2_* represents the second area of the given limit.

Written by Kenneth Sæterhagen Paulsen

► head ↑

```
head(obj,nRows,page)
```

Description:

Display the first n rows of a nb_ts object.

Input:

- obj : An nb_ts object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_ts](#), [window](#), [tail](#)

Written by Per Bjarne Bye

► histogram ↑

```
data          = histogram(obj)
[data,plotter] = histogram(obj,M)
```

Description:

Create a histogram of a object containing only one variable and one page!

Input:

- obj : A nb_dataSource object with size N x 1 x 1.
- M : The number of bins of the histogram.

Output:

- data : A nb_cs object with size M x 1 x 1.
- plotter : A nb_graph_cs object with the histogram plotted.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATASOURCE

► horzcat ↑

```
obj = horzcat(a,b,varargin)
```

Description:

Horizontal concatenation of nb_ts objects. ([a,b]) This is only possible if the different objects contain different variables or have variables with the same values (start and/or end dates can differ). Uses the merge method.

If the start and/or end dates differ, nan values will be appended.

Input:

- a : An object of class nb_ts
- varargin : Optional number of nb_ts objects

Output:

- obj : An nb_ts object with all the variables from the different nb_ts object merge into one dataset

Examples:

```
obj = [a,b];  
obj = [a,b,c];
```

See also:

[merge](#)

Written by Kenneth S. Paulsen

► hpfilter ↑

```
obj = hpfilter(obj,lambda)  
obj = hpfilter(obj,lambda,perc,fcstLen)
```

Description:

Do hp-filtering of all the dataseries of the nb_ts object.
(Returns the gap). Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_ts
- lambda : The lambda of the hp-filter
- perc : Set to true to calculate the gap as (gap/trend)*100.
- fcstLen : The forecast length. Extrapolates the original series using the average of the last 4 periods. Default is 0.

Output:

- obj : An nb_ts object with the hp-filtered timeseries.

Examples:

```
gap = hpfilter(data,3000);
trend = data-gap;
```

See also:

[hpfilter](#)

Written by Kenneth S. Paulsen

► **hpfilterls** ↑

```
obj = hpfilterls(obj,lambda)
obj = hpfilterls(obj,lambda,perc,fcstLen)
```

Description:

Do one-sided hp-filtering of all the dataseries of the nb_ts object. (Returns the gap). Will strip nan values when calculating the filter.

Input:

- obj : An object of class nb_ts
- lambda : The lambda of the hp-filter
- perc : Set to true to calculate the gap as (gap/trend)*100.
- fcstLen : The forecast length. Extrapolates the original series using the average of the last 4 periods. Default is 0.

Output:

- obj : An nb_ts object with the hp-filtered timeseries.

Examples:

```
gap = hpfilterls(data,3000);
trend = data-gap;
```

See also:

[hpfilter](#)

Written by Kenneth S. Paulsen

► iegrowth ↑

```
obj = iegrowth(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of exact growth, i.e. the inverse method of the egrowth method of the nb_ts class

Input:

- obj : An object of class nb_ts
- InitialValues : A nb_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_ts object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.

- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_ts object with the indicies.

Examples:

```
obj = iegrowth(obj);
obj = iegrowth(obj,100);
obj = iegrowth(obj,[78,89]);

See also
nb_ts.egrowth, nb_ts.igrowth, nb_ts.growth
```

Written by Kenneth S. Paulsen

► **iepcn** ↑

```
obj = iepcn(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of exact percentage growth, i.e. the inverse method of the epcn method of the nb_ts class

Input:

- obj : An object of class nb_ts
- InitialValues : A nb_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_ts object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.

- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_ts object with the indicies.

Examples:

```
obj = iepcn(obj);
obj = iepcn(obj,100);
obj = iepcn(obj,[78,89]);
```

See also:

[nb_ts.epcn](#)

Written by Kenneth S. Paulsen

► **igrowth** ↑

```
obj = igrowth(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries wich represent the series growth. Inverse of log approx. growth, i.e. the inverse method of the growth method of the nb_ts class

Input:

- obj : An object of class nb_ts
- InitialValues : A nb_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_ts object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.
- periods : The number of periods the initial series has been taken growth over.

Output:

- Output : An nb_ts object with the indicies.

Examples:

```
obj = igrowth(obj);  
obj = igrowth(obj,100);  
obj = igrowth(obj,[78,89]);
```

See also
nb_ts.growth, nb_ts.egrowth, nb_ts.iegrowth

Written by Kenneth S. Paulsen

► **interpolate** ↑

```
obj = interpolate(obj,method)
```

Description:

Interpolate the data of the nb_data object. Will discard leading and trailing nan values.

Input:

- data : An nb_ts, nb_cs or nb_data object.
- method :
 - 'nearest' : Nearest neighbor interpolation
 - 'linear' : Linear interpolation. Default
 - 'spline' : Piecewise cubic spline interpolation (SPLINE)
 - 'pchip' : Shape-preserving piecewise cubic interpolation
 - 'cubic' : Same as 'pchip'
 - 'v5cubic' : The cubic interpolation from MATLAB 5, which does not extrapolate and uses 'spline' if X is not equally spaced.

Output:

- data : An nb_ts, nb_cs or nb_data object with the interpolated data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **ipcn ↑**

```
obj = ipcn(obj,initialValues)
obj = ipcn(obj,initialValues,periods,startAtNaN)
```

Description:

Construct indicies based on initial values and timeseries which represent the series growth. Inverse of percentage log approx. growth, i.e. the inverse method of the pcn method of the nb_ts class

Input:

- obj : An object of class nb_ts
- InitialValues : A nb_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_ts object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.

- periods : The number of periods the initial series

has been taken growth over.

- startAtNaN : true or false. If true it will start taking the inverse growth when the nb_ts object with initialValues are nan, instead using the first not nan observation in the same input. Default is false.

Output:

- Output : An nb_ts object with the indicies.

Examples:

```
obj = ipcN(obj);
obj = ipcN(obj,100);
obj = ipcN(obj,[78,89]);
```

See also:

[nb_ts.pcn](#)

Written by Kenneth S. Paulsen

► **isBoolean** ↑

```
ret = isBoolean(obj)
```

Description:

Check if the data of the nb_dataSource object is of class logical (boolean, i.e. true or false).

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isCrossSectional** ↑

```
ret = isCrossSectional(obj)
```

Description:

Test if this object is a cross sectional data object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_cs, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isDistribution** ↑

```
ret = isDistribution(obj)
```

Description:

Check if the data of the nb_dataSource object is of class nb_distribution

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isDouble** ↑

```
ret = isDouble(obj)
```

Description:

Check if the data of the nb_dataSource object is of class double (numeric)

Input:

- obj : An object of class nb_dataSource.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **isRealTime** ↑

ret = isRealTime(obj)

Description:

Is the dataset representing linked real-time data?

Input:

- obj : An object of class nb_ts.

Output:

- ret : true or false.

Written by Kenneth Sæterhagen Paulsen

► **isTimeseries** ↑

ret = isTimeseries(obj)

Description:

Test if a nb_dataSource object is a time series object.

Input:

- obj : An object of class nb_dataSource

Output:

- ret : true if object is of class nb_ts, otherwise false.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isUpdateable** ↑

```
ret = isUpdateable(obj)
```

Description:

Test if this object is updateable.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : 1 if updateable, otherwise 0.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if a nb_ts, nb_cs or nb_data object is empty. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isfinite** ↑

```
obj = isfinite(obj)
```

Description:

Test if each element of a nb_ts, nb_cs or nb_data object is finite.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is finite, otherwise 0.

Examples:

```
obj = isfinite(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isnan** ↑

```
obj = isnan(obj)
```

Description:

Test if each element of an nb_ts, nb_cs or nb_data object is nan.

Caution : Non-updateable operation.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : The object with data as logical. 1 if an element is nan, otherwise 0.

Examples:

```
obj = isnan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **isscalar** ↑

```
ret = isscalar(obj)
```

Description:

Test if a nb_ts, nb_cs or nb_data object is a scalar. Will always return 0, as an object of class nb_ts, nb_cs or nb_data is not a scalar.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- ret : false

Examples:

```
0 = isscalar(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **jbTest ↑**

```
[test,pval] = jbTest(obj)
```

Description:

Jargue-Bera test for normality. Null hypothesis of the test is that the series y is normal.

Input:

- obj : An object of class nb_ts.

- dim : The dimension to test for normality. Either 1, 2 or 3. Default is 1.

- out : If given as 'pval' the pval output is returned as the first output, otherwise the order is the standard way.

Output:

- test : The test statistics:
 > dim == 1: An object of class nb_cs with size 1 x nVars x nPage.
 > dim == 2: An object of class nb_ts with size nObs x 1 x nPage.
 > dim == 3: An object of class nb_ts with size nObs x nVars.

- pval : The test p-value.
 > dim == 1: An object of class nb_cs with size 1 x nVars x

```
nPage.  
> dim == 2: An object of class nb_ts with size nObs x 1 x nPage.  
> dim == 3: An object of class nb_ts with size nObs x nVars.
```

Written by Kenneth SÃ¶terhagen Paulsen

► **keepInitial** ↑

```
obj = keepInitial(obj, seasonalPattern, start)
```

Description:

Keep initial value for the variables in the object.

Input:

- obj : An object of class nb_ts.
- seasonalPattern : Give true to keep the seasonal pattern. Default is false.
- start : From the date to start.

Output:

- obj : An object of class nb_ts.

Written by Kenneth SÃ¶terhagen Paulsen

► **keepPages** ↑

```
obj = keepPages(obj, pages)
```

Description:

Keep pages of the current nb_ts object

Input:

- obj : An object of class nb_ts
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty a empty nb_ts object is returned.

Can also be a cellstr with the names to keep, or a logical array with length equal to the number of pages (datasets).

Output:

- obj : An nb_ts object with the pages specified in the input are kept.

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► keepVariables ↑

```
obj = keepVariables(obj,keptVar)
```

Description:

Keep variables from the current nb_ts object (letter size has something to say)

If some of the variables you specify in keptVar does not exist in the object, this will not have anything to say for the object. (The variables cannot be kept, because the variables do not exist.)

Input:

- obj : An object of class nb_ts
- keptVar : Must be a char or a cellstr

Keeps all the variable names, given in the char array or cellstr array keptVar, of current the nb_ts object.

NB! If keptVar is just one string and include a * as the last letter, this function will keep all the variable names, from the DB, that start with the letters which is in front of the * in the string.

i.e. obj = keepVariables(obj,'DPQ*');

Keep all the variables in the obj which has variable names starting with 'DPQ'.

If keptVar is just one string and include a * as the first letter, this function will keep all the variable names, from the DB, that include the letters which follows in the string.

i.e. obj = keepVariables(obj, '*shift');

Keeps all the variables in the obj which has variable names which include 'shift'.

Output:

- obj : An nb_ts object with the variables specified in input 'keptVar' kept, all the others are deleted.

Examples:

```
obj = keepVariables(obj, {'Var1','Var2'});
obj = keepVariables(obj, char('Var1','Var2'));
obj = keepVariables(obj, DB.variables);
```

Written by Kenneth S. Paulsen

► **ksdensity** ↑

```
obj = ksdensity(obj,varargin)
```

Description:

A method for creating an nb_ts object with the estimated kernel density of a sample. It can estimate a single probability density function, as well as recursive estimation.

Input:

- obj : An nb_ts object with the data.

Optional input:

- 'recursive' : True or false. If true, the CDF will be estimated recursively. Default is false.
- 'recStart' : Sets the start date for the recursive estimation. Default is the start date of the obj + 9 observations. As a string or as an object of class nb_date.
- 'recEnd' : Sets the end date for the recursive estimation. Default is the end date of the object. As a string or as an object of class nb_date.
- 'estStart' : Sets the start of the estimation sample. As a string or as an object of class nb_date.
- Rest of the optional input id given to the nb_ksdensity function.

Output:

- obj : A numIter x numVar nb_ts object where each observation point contains an nb_distribution object with the estimated parameters of the distribution.

Examples:

```
f    = nb_ts(randn(1000,1),'', '2010M1', {'v1'});
obj = f.ksdensity('recStart','2012M1','recEnd','2012M12', 'recursive',1);
```

See also:

[nb_ts.ecdf](#)

Written by Kenneth Sæterhagen Paulsen

► **kurtosis** ↑

`obj = kurtosis(obj,flag,outputType,dimension,varargin)`

Description:

Calculate the kurtosis of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their kurtosis.

The output can also be set to be a double or a nb_cs object consisting of the kurtosis values of the data.

Input:

- `obj` : An object of class nb_ts
- `flag` : > 0 : normalises by N-1 (Default)
> 1 : normalises by N
 - Where N is the sample length.
- `outputType` :
 - > 'nb_ts' : The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their kurtosis.
 - > 'double' : Get the kurtosis values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the kurtosis values as nb_cs object. The kurtosis will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- `dimension` : The dimension to calculate the kurtosis over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
nb_tsObj = kurtosis(obj);
double    = kurtosis(obj,0,'double');
nb_csObj = kurtosis(obj,0,'nb_cs');
```

Written by Kenneth S. Paulsen

► **lag ↑**

```
obj = lag(obj,periods,varargin)
```

Description:

Lag the data of the object. The input periods decides for how many periods.

Input:

- obj : An object of class nb_ts
- periods : Lag the data with this number of periods. Default is 1 period.

Optional input:

- 'cut' : true (cut sample to fit old sample length) or false (append new observations). Default is true.

Output:

- obj : An nb_ts object where the data laged by number of periods given by the input periods.

Examples:

```
obj = lag(obj,1);
```

Written by Kenneth S. Paulsen

► **lastObservation ↑**

```
obj = lastObservation(obj,number)
```

Description:

Get the last (real) observation(s) of the object.

Input:

- obj : An object of class nb_ts.
- number : Number of elements to return. Default is 1, i.e only the last.
As a integer.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

► le ↑

a = le(a,b)

Description:

Test if the one object is less than or equal to (\leq) the other object elementwise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a <= b;  
obj = 2 <= b;  
obj = a <= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **lead** ↑

```
obj = lead(obj,periods,varargin)
```

Description:

Lead the data of the object. The input periods decides for how many periods.

Input:

- obj : An object of class nb_ts
- periods : Lead the data with this number of periods. Default is 1 period.

Optional input:

- 'cut' : true (cut sample to fit old sample length) or false (append new observations at the start). Default is true.

Output:

- obj : An nb_ts object where the data leaded by number of periods given by the input periods.

Examples:

```
obj = lead(obj,1);
```

Written by Kenneth S. Paulsen

► **log** ↑

```
obj = log(obj)
```

Description:

Take log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on logs.

Examples:

```
obj = log(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **log10** ↑

```
obj = log10(obj)
```

Description:

Take the common (base 10) log of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where the data are on (base 10) logs.

Examples:

```
obj = log10(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **log1p** ↑

```
obj = log1p(obj)
```

Description:

log1p(obj) computes $\text{LOG}(1+xi)$, where xi are the elements of obj. Complex results are produced if $xi < -1$.

For small real xi, log1p(xi) should be approximately xi, whereas the computed value of $\text{LOG}(1+xi)$ can be zero or have high relative error.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = log1p(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► log2 ↑

```
obj = log2(obj)
```

Description:

log2(obj) is the base 2 logarithm of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = log2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► lt ↑

```
a = lt(a,b)
```

Description:

Test if the one object is less than (<) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a < b;  
obj = 2 < b;  
obj = a < 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► map2Distribution ↑

```
obj = map2Distribution(obj,dist)  
obj = map2Distribution(obj,dist,varargin)
```

Description:

Map observation to the distributions given by dist.

The current distribution of the data is estimated using a kernel density estimator. The data must be strongly stationary. I.e. the unknown distribution from where the data has been drawn must not depend on time.

Input:

- obj : An object of class nb_dataSource.
- dist : An object of class nb_distribution with size 1 x size(obj,2).

Optional inputs:

- See the optional inputs of the nb_distribution.estimate function.

Output:

- obj : An object of class nb_dataSource.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **mavg** ↑

```
obj = mavg(obj,backward,forward,flag)
```

Description:

Taking moving avarage of all the timeseries of the nb_ts object

Input:

- obj : An object of class nb_ts
- backward : Number of periods backward in time to calculate the moving average
- forward : Number of periods forward in time to calculate the moving average
- flag : If set to true the periods that does not have enough observations forward or backward should be set to nan. Default is false.

Output:

- obj : An nb_ts object storing the calculated moving average

Examples:

```
data = nb_ts(rand(50,2)*3,'','2011Q1',{'Var1','Var2'});  
mAvg10 = mavg(data,9,0); % (10 year moving average)
```

See also:

[nb_mavg](#)

Written by Kenneth S. Paulsen

► **max** ↑

```
obj = max(obj,outputType,dimension)
```

Description:

Calculate the max of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are beeing set to their max.

The output can also be set to be a double or a nb_cs object consisting of the max values of the data.

Input:

- obj : An object of class nb_ts
- outputType :
 - > 'nb_ts' : The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their max.
 - > 'double' : Get the max values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the max values as nb_cs object. The max will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the max over.

Output:

- obj : See the input outputType for more on the output from this method

Examples:

```
nb_tsObj = max(obj);
double   = max(obj,'double');
nb_csObj = max(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► mean ↑

```
obj = mean(obj,outputType,dimension,varargin)
```

Description:

Calculate the mean of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their mean.

The output can also be set to be a double or a nb_cs object consisting of the mean values of the data.

Input:

- obj : An object of class nb_ts

```

- outputType :

    > 'nb_ts'           : The result will be an object of class nb_ts
                           where all the non-nan values of all the
                           timeseries are being set to their mean.

    > 'nb_ts_scalar'   : The result will be an object of class nb_ts
                           where all the non-nan values of all the
                           timeseries are being set to their mean, but
                           where the dimension taking the mean over is
                           reduced to size 1. Not supported for dimension
                           1. The name of the variable/page will be
                           'mean'

    > 'double'          : Get the mean values as doubles, where
                           each column of the double matches the
                           variable location in the 'variables' property.
                           If the object consists of more pages the double
                           will also consist of more pages.

    > 'nb_cs'           : Get the mean values as nb_cs object.
                           The mean will when this option is used only be
                           calculated over the number of observations.
                           (I.e. dimension set to 1.)

- dimension : The dimension to calculate the mean over.

```

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more on the output from this method

Examples:

```

nb_tsObj = mean(obj);
double   = mean(obj,'double');
nb_csObj = mean(obj,'nb_cs');

```

Written by Kenneth S. Paulsen

► **meanDiff ↑**

```
obj = meanDiff(obj)
```

Description:

Construct level variables that has the mean change for each period.

Input:

- obj : An object of class nb_ts

Output:

- obj : A nb_ts object where the data has been updated.

Written by Kenneth S. Paulsen

► **meanGrowth** ↑

obj = meanGrowth(obj)

Description:

Construct level variables that has the mean growth for each period.

Input:

- obj : An object of class nb_ts

Output:

- obj : A nb_ts object where the data has been updated.

Written by Kenneth S. Paulsen

► **median** ↑

obj = median(obj,outputType,dimension,varargin)

Description:

Calculate the median of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are bbeing set to their median.

The output can also be set to be a double or a nb_cs object consisting of the median values of the data.

Input:

- obj : An object of class nb_ts

- outputType :

> 'nb_ts' : The result will be an object of class nb_ts where all the non-nan values of all the timeseries are bbeing set to their median.

```

> 'double' : Get the median values as doubles, where
each column of the double matches the
variable location in the 'variables' property.
If the object consist of more pages the double
will also consist of more pages.

> 'nb_cs'   : Get the median values as nb_cs object.
The median will when this option is used only
be calculated over the number of observations.
(I.e. dimension set to 1.)

- dimension : The dimension to calcualate the median over.

```

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from
this method

Examples:

```

nb_tsObj = median(obj);
double   = median(obj,'double');
nb_csObj = median(obj,'nb_cs');

```

Written by Kenneth S. Paulsen

► **merge ↑**

```

obj = merge(obj,DB)
obj = merge(obj,DB,interpolateDate,method,rename,append,type)

```

Description:

Merge two nb_ts objects. Same as obj = [obj,DB]

Caution:

- It is possible to merge datasets with the same variables as long as they represent the same data or have different timespans.
- If the datsets has different number of datasets and one of the merged objects only consists of one, this object will add as many datasets as needed (copies of the first dataset) so they can be merged.
- If any of the datasets are of type real-time, they cannot contain the same variables.

- If one dataset is of type real-time, then the other dataset will need to only have one page. The other dataset will get the same recursive structure as the real-time dataset.
- If two real-time datasets are merge the last vintage of the two dataset cannot differ, when it comes to the endDate, by more than one period. If thy differ by one period it is assumed that this is the case for all vintages backward in time as well, i.e. the regged edge of the last period is perserved for all vintages.
- If two real-time datasets are merge and one of them have more vintages backward in time, the one with the fewest vintages will be expanded with the same number of vintages as the other dataset. The first avilable vintage then be used to construct these vintages.
- If two real-time datasets are merged you should first use the method cleanRealTime on both inputs!

Input:

- obj : An object of class nb_ts
- DB : An object of class nb_ts
- interpolateDate :
 - How to transform the database with the lowest frequency.
 - 'start' : The interpolated data are taken as given at the start of the periods. I.e. use 01.01.2012 and 01.01.2013 when interpolating data with yearly frequency. (Default)
 - 'end' : The interpolated data are taken as given at the end of the periods. I.e. use 31.12.2012 and 31.12.2013 when interpolating data with yearly frequency.
- method : The method to use when converting:
 - 'linear' : Linear interpolation
 - 'cubic' : Shape-preserving piecewise cubic interpolation
 - 'spline' : Piecewise cubic spline interpolation
 - 'none' : No interpolation. All data in between is given by nans (missing values) (Default)
 - 'fill' : No interpolation. All periods of the higher frequency get the same value as that of the lower frequency.
- rename : > 'on' : Renames the prefixes (default)
 > 'off' : Do not rename the prefixes

For more see the 'rename' option of the convert method.

- append : > 0 : If data is conflicting an error will occur.
default.
> 1 : If data is conflicting data of the first database will be used.
- type : The type of series to merge. Only when append is equal to 1.
 - > 'levelGrowth' : Merge level data with growth rates. Must be one period growth. The merged series will be in level.
 - > 'growthLevel' : Merge growth rates with level data. Must be one period growth. The merged series will be in growth rates.
 - > 'levelLevel' : Merge level series, where the merging is done in growth rates, but the end result is still in levels.
 - > '' : Standard merging.

If two real-time datasets are merge:

- > 'pages' : In this case the merging of the real-time databases is taken page by page starting from the last page. If some of the datasets have more pages than the other a error will be given.
- > '' : Default merging of real-time datasets. See the description part.

Output:

- obj : An nb_ts object where the datasets from the two nb_ts objects are merged

Examples:

```
obj = merge(obj,DB)
obj = obj.merge(DB)
```

See also:

[nb_ts.append](#), [nb_dataSource.merge2Series](#)

Written by Kenneth S. Paulsen

► **merge2Series ↑**

```
obj = merge2Series(obj,var1,var2,new,method,varargin)
```

Description:

Merge 2 series. The var2 series is appended to the var1 series from where it is ending.

Input:

- obj : An object of class nb_dataSource.
- var1 : A one line char with the name of the base series.
- var2 : A one line char with the name of the appended series.
- new : Name of the new variable. If given as empty there will not be created a new series, but instead the var1 variable will be set to the new merged series. Default is empty.
- method : Either 'level', 'diff', 'growth', 'leveldiff' or 'levelgrowth'. Default is 'level'. For the cases 'level', 'diff' or 'growth' it is assumed the both series are in levels. 'leveldiff' assumes the first series is in level and the second in nLags-difference. 'levelgrowth' assumes the first series is in level and the second in growth rates over nLags periods, i.e. $(x(t) - x(t-nLags))/x(t-nLags)$.

Optional input:

- 'nLags' : The number of lages used for the methods 'diff' and 'growth'. Default is 1.
- 'date' : The date from where to use the second variable. Either a date as string or a nb_date object. If empty the merge will take place where the first variable end + 1 period.

Output:

- obj : An object of class nb_dataSource.

Examples:

```
obj           = nb_ts.rand('2012Q1',10,2,3);
obj(end-1:end,1,:) = nan;

obj1 = merge2Series(obj,'Var1','Var2','Var3')
obj2 = merge2Series(obj,'Var1','Var2')
obj3 = merge2Series(obj,'Var1','Var2','','diff','nLags',1)
obj4 = merge2Series(obj,'Var1','Var2','','diff','nLags',4)
obj5 = merge2Series(obj,'Var1','Var2','','level','date','2014Q1')
```

See also:

[nb_ts.merge](#), [nb_data.merge](#), [nb_cs.merge](#)

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **mergeContexts** ↑

```
obj = mergeContexts(varargin)
```

Description:

Merge real-time datasets that has the context dates stored in the dataNames property on the format 'yyyymmdd' and only represent one variable.

Caution: If the publishing calandar of one of the nb_ts objects is shorter than the other, the shortes of them will be expanded backwards with a quasi-real-time calandar. It will use the first publication date, and backcast the artifical publication dates by the time lag of this publication date. To construct the time series of these quasi-real-time data, it will use the first vintage, and recursivly remove one observation.

Caution : This method will break the link to the data source of updateable objects!

Optional input:

- varargin : Each object must be of class nb_ts on the specific format described in the Description of this method.

Output:

- obj : The updated set of contexts stored in a nb_ts object.

Written by Kenneth SÃ¶terhagen Paulsen

► **min** ↑

```
obj = min(obj,outputType,dimension)
```

Description:

Calculate the min of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are beeing set to their min.

The output can also be set to be a double or a nb_cs object consisting of the min values of the data.

Input:

```
- obj : An object of class nb_ts

- outputType :

    > 'nb_ts' : The result will be an object of class nb_ts
                  where all the non-nan values of all the
                  timeseries are being set to their min.

    > 'double' : Get the min values as doubles, where
                  each column of the double matches the
                  variable location in the 'variables' property.
                  If the object consists of more pages the double
                  will also consist of more pages.

    > 'nb_cs' : Get the min values as nb_cs object.
                  The min will when this option is used only
                  be calculated over the number of observations.
                  (I.e. dimension set to 1.)

- dimension : The dimension to calculate the min over.
```

Output:

```
- obj : See the input outputType for more one the output from
      this method
```

Examples:

```
nb_tsObj = min(obj);
double   = min(obj,'double');
nb_csObj = min(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► minus ↑

```
obj = minus(obj,DBOrNum)
```

Description:

Binary subtraction (-).

Caution: Will subtract the data of the corresponding variables from the two objects. All the variables not in common will result in series with nan values.

When one of the inputs are a scalar this function will subtract each element of the data by this number or each element of the data will be subtracted from the scalar.

Input:

- a : An object of class nb_ts or a scalar
- b : An object of class nb_ts or a scalar

Output:

- obj : An nb_ts object where all the variables are from the first object are substracted from the other.

Or

An nb_ts object where the scalar are substracted from all the elements of the input object

Or

An nb_ts object where all the elements of the input object are substracted from scalar.

Examples:

```
obj = obj - anotherObj;
obj = obj - 2;
obj = 2 - obj;
```

See also:

[nb_ts.plus](#), [nb_ts.callop](#), [nb_ts.callfun](#)

Written by Kenneth S. Paulsen

► **mldivide** ↑

```
obj = mldivide(a,b)
```

Description:

Matrix left division (\). See examples.

Input:

- a : An object of class nb_ts
- b : A scalar, a string or an nb_date object.

Output:

- obj : An nb_ts object.

Examples:

```
obj = nb_ts.rand('2012Q1',10,2)
obj = obj\1 % 1/obj
obj = obj\'2012Q1' % '2012Q1'/obj
obj = obj\'Var1' % 'Var1'/obj
obj = obj\obj.startDate % obj.startDate/obj
```

See also:

[nb_ts.mrdivide](#), [nb_ts.rdivide](#)

Written by Kenneth S. Paulsen

► **mode** ↑

```
obj = mode(obj,outputType,dimension,varargin)
```

Description:

Calculate the mode of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their mode.

The output can also be set to be a double or a nb_cs object consisting of the mode values of the data.

Input:

- obj : An object of class nb_ts
- outputType :
 - > 'nb_ts' : The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their mode.
 - > 'double' : Get the mode values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the mode values as nb_cs object. The mode will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the mode over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
nb_tsObj = mode(obj);
double    = mode(obj,'double');
nb_csObj = mode(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► **mpower** ↑

```
obj = mpower(a,b)
```

Description:

Matrix power (^). Defined when raised by a scalar, a string which either represent a variable or date or a nb_date object.

Input:

- a : An object of class nb_ts.
- b : A scalar, a string or an nb_date object.

Output:

- obj : An nb_ts object.

Examples:

```
obj  = nb_ts.rand('2012Q1',10,2)
obj1 = obj^'2012Q1'
obj2 = obj^'Var1'
obj3 = obj^obj.startDate
```

See also:

[nb_ts.power](#)

Written by Kenneth S. Paulsen

► **mrddivide** ↑

```
obj = mrddivide(a,b)
```

Description:

Matrix right division (/). See examples.

Input:

- a : An object of class nb_data, a scalar number, a string representing a variable name or a date, or a nb_date object.
- b : An object of class nb_data, a scalar number, a string representing a variable name or a date, or a nb_date object.

Output:

- obj : An nb_ts object.

Examples:

```
obj = nb_ts.rand('2012Q1',10,2)
obj1 = obj/1
obj2 = obj/'2012Q1'
obj3 = obj/'Var1';
obj4 = obj/obj.startDate
obj5 = 1/obj
obj6 = '2012Q1'/obj
obj7 = 'Var1'/obj;
obj8 = obj.startDate/obj
```

See also:

[nb_ts.mldivide](#), [nb_ts.rdivide](#)

Written by Kenneth S. Paulsen

► mstd ↑

```
obj = mstd(obj,backward,forward)
```

Description:

Taking moving standard deviation of all the timeseries of the nb_ts class

Input:

- obj : An object of class nb_ts
- backward : Number of periods backward in time to calculate the moving std
- forward : Number of periods forward in time to calculate the moving std

Output:

- obj : An nb_ts object storing the calculated moving standard deviation

Examples:

```
data = nb_ts(rand(50,2)*3,'','2011Q1',{'Var1','Var2'});
```

```
mstd10 = mstd(data,9,0); % (10 year moving std)
```

Written by Kenneth S. Paulsen

► mtimes ↑

```
obj = mtimes(obj,Num)
```

Description:

Matrix multiplication (*) Defined for multiplication with a constant, a string which either represent a variable or date or an nb_date object.

Input:

- obj : An object of class nb_ts or scalar
- b : An object of class nb_ts or a scalar, a string or an nb_date object.

Output:

- obj : An nb_ts object where the number (date or variable as a vector) is multiplied with all the elements of the input objects data

Examples:

```
obj = 2*obj;
obj = obj*2;
obj = obj*'2012Q1'
obj = obj*'Var1'
obj = obj*obj.startDate
```

See also:

[nb_ts.times](#)

Written by Kenneth S. Paulsen

► **nan** ↑

```
obj = nb_ts.nan()
obj = nb_ts.nan(start,obs,vars,pages,sorted)
```

Description:

Create an nb_ts object with all data set to nan.

Input:

- start : The start date of the created nb_ts object.
- obs : The number of observation of the created nb_ts object.
- vars : Either a cellstr with the variables of the nb_ts object, or a scalar with the number of variables of the nb_ts object.
- pages : Number of pages of the nb_ts object.
- sorted : true or false. Default is true.

Output:

- obj : An nb_ts object.

Examples:

```
obj = nb_ts.nan('1',10,{'Var1','Var2'});
obj = nb_ts.nan('2012Q1',2,2);
obj = nb_ts.nan('2012Q1',2,2,10);
```

See also:

[nb_ts](#)

Written by Kenneth Sæterhagen Paulsen

► **nan2var** ↑

```
obj = nan2var(obj,testedVariables,assignVariable)
```

Input:

- obj : An object of class nb_ts
- testedVariables : A cellstr with the variables you are setting equal to the assignVariable for the nan values found.
- assignVariable : A string with the name of the variable you are assigning the found nan values.

Output:

- obj : An nb_ts object where all the nan values of the variables in the testedVariables input is set to the matching value of the variable given by the assignVariable input.

Examples:

```
obj = nb_ts([1,2;nan,1;nan,3],'', '2012', {'Var1','Var2'});  
nan2var(obj,{'Var1'},'Var2')
```

```
ans =
```

'Time'	'Var1'	'Var2'
'2012'	[1]	[2]
'2013'	[1]	[1]
'2014'	[3]	[3]

Written by Kenneth S. Paulsen

► ne ↑

```
a = ne(a,b)
```

Description:

Test if the one object is not equal to ($\sim=$) the other object elemetswise and return a nb_dataSource object where each element are 1 if true, otherwise 0.

Caution: The objects must have the same dimension and variables!

It is also possible to test each element of an object to a scalar number.

Input:

- a : An object of class nb_dataSource or a scalar number.
- b : An object of class nb_dataSource, but must be of same subclass as a, or a scalar number.

Output:

- a : An nb_dataSource object where the data element are logical.

Examples:

```
obj = a ~= b;  
obj = 2 ~= b;  
obj = a ~= 2;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **not** ↑

```
a = not(a)
```

Description:

The not operator (~).

Input:

- a : An object of class nb_dataSource.

Output:

- a : An object of class nb_dataSource. Where the not operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

```
a = ~a;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **objSize** ↑

```
varargout = objSize(obj,dim)
```

Description:

Return the size(s) of the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- dim : - 1 : Number of observations
- 2 : Number of variables
- 3 : Number of datasets (pages)

Output:

- varargout : See the examples below

Examples:

```
dim = objSize(obj)

Where dim is 1 x 2 double where the first element
is the number of observations/types and the second element is
the number of variables
```

```
[dim1, dim2] = objSize(obj)

[dim1, dim2, dim3] = objSize(obj)

dim1 = objSize(obj,1)
dim2 = objSize(obj,2)
dim3 = objSize(obj,3)
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **ones** ↑

```
obj = nb_ts.ones()
obj = nb_ts.ones(start,obs,vars,pages,sorted)
```

Description:

Create an nb_ts object with all data set to 1.

Input:

- start : The start date of the created nb_ts object.
- obs : The number of observation of the created nb_ts object.
- vars : Either a cellstr with the variables of the nb_ts object, or a scalar with the number of variables of the nb_ts object.
- pages : Number of pages of the nb_ts object.
- sorted : true or false. Default is true.

Output:

- obj : An nb_ts object.

Examples:

```
obj = nb_ts.ones('1',10,['Var1','Var2']);
obj = nb_ts.ones('2012Q1',2,2);
obj = nb_ts.ones('2012Q1',2,2,10);
```

See also:

[nb_ts](#)

► **or** ↑

```
a = or(a,b)
```

Description:

The and operator (|).

Caution: The objects must have the same dimension and variables!

Input:

- a : An object of class nb_dataSource.
- b : An object of class nb_dataSource, but must be of same subclass as a!

Output:

- a : An object of class nb_dataSource. Where the or operator has evaluated all the data elements of the object.
The data will be a logical matrix.

Examples:

```
a = a | b;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **packing** ↑

```
obj = packing(obj,packages,varargin)
```

Description:

Package variables by applying the wanted function. Default is summin (sum).

Input:

- obj : An object of class nb_ts.
- packages : A 2 x N cell matrix with groups of variables and the names of the groups. If you have not listed a variable it will be grouped in a group called 'Rest' (as long as

'includeRest' is not set to false).

Must be given in the following format:

```
{'group_name_1','...','group_name_N';
 name_1           ,...,name_N}
```

Where name_x must be a string with a name of the variable or a cellstr array with the variable names. E.g 'Var1' or {'Var1','Var2'}.

Optional inputs:

- 'includeRest' : Give false to not include the 'Rest' variable, which will represent all the variable that has not been packed.
- 'func' : Either a function_handle or a one line char with the name of the function to use. The first input to this function is a nObs x nVar double, the second is the dimension (which is always 2). Examples; 'sum', 'prod', @sum or @prod.

Output:

- obj : A object of class nb_ts.

Examples:

```
data      = nb_ts.rand('2012Q1',10,4);
packages = {'group1','group2';
            {'Var1','Var2'},{'Var3'}};

dataP1 = packing(data,packages)
dataP2 = packing(data,packages,'includeRest',false)
dataP3 = packing(data,packages,'func',@prod)
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **parcorr ↑**

```
obj = parcorr(obj,numLags)
[obj,lBound,uBound] = parcorr(obj,numLags,errorBound,alpha)
```

Description:

Compute the sample partial autocorrelation function (PACF) of all the variables stored in the nb_ts object, and return a nb_data object with the results.

Reference:

[1] Box, G. E. P., G. M. Jenkins, and G. C. Reinsel. Time Series Analysis: Forecasting and Control. 3rd edition. Upper Saddle River, NJ: Prentice-Hall, 1994.

Input:

- obj : An object of class nb_ts.

Caution : This method does not handle nan or infinite for any of the stored data of the nb_ts object!

- numLags : Positive integer indicating the number of lags of the PACF to compute. If empty or missing, the default is to compute the PACF at lags 1. Since PACF is symmetric about lag zero, negative lags are ignored. Must be a scalar.

- errorBound : A string. The data must be stationary. Either:

> '' : No errorbounds calculated.

> 'asymtotic' : Using asymptotically derived formulas.

> 'paramBootstrap' : Calculated by estimating the data generating process. And use the fitted model to simulate artificial time-series. Then the error bands are constructed by the wanted percentile.

> 'blockBootstrap' : Calculated by blocking the observed series and using these blocks to simulate artificial time-series. Then the error bands are constructed by the wanted percentile.

> 'copulaBootstrap' : The observed series is boostraped based on a copula approach. See Paulsen (2017).

- alpha : Significance value. As a scalar. Default is 0.05.

Optional inputs:

- 'maxAR' : As an integer. See the nb_arima function. Defualt is 3.

- 'maxMA' : As an integer. See the nb_arima function. Default is 3.
- 'criterion' : As a string. See the nb_arima function. Default is 'aicc'.
- 'method' : As a string. See the nb_arima function. Default is 'hr'.

Output:

- obj : An nb_data object with the partial autocorrelations stored in the dataset 'Autocorrelations'.
If the errorbounds are to be calculated they are stored in the datasets 'Error bound (lower)' and 'Error bound (upper)'

Examples:

```
obj = parcorr(obj)
obj = parcorr(obj,10)
```

See also:

[nb_ts](#), [nb_data](#), [corr](#), [nb_parcorr](#)

Written by Kenneth Sæterhagen Paulsen

► [pca ↑](#)

```
F = pca(obj)
[F,LAMBDA,R,varF,expl,c,sigma,e,Z] = pca(obj,r,method,varargin)
```

Description:

Principal Component Analysis of the data of the object.

Input:

- obj : An object of class nb_ts.
 - r : The number of principal component. If empty this number will be found by the Bai and Ng (2002) test, see the optional option crit below, i.e choose the CT part of the selection criterion; $\log(V(ii,F)) + CT$. Where;
- $$V(ii,F) = \sum(\text{diag}(e_{ii}' * e_{ii}/T))/ii$$
- and e_{ii} is the residual when ii factors are used

```

- method : Either 'svd' or 'eig'. Default is 'svd'.

    > 'svd' : Uses single value deomposition to construct the
               principal components. This is the numerically best
               way, as the 'eig' method could be very unprecise!

    > 'eig' : Uses the eigenvalue decomposition approach instead

```

Optional inputs:

```

- 'crit' : You can choose between the follwing selection criterion

    > 1: log(NT/NT1)*ii*NT1/NT;

    > 2: (NT1/NT)*log(min([N;T]))*ii;

    > 3: ii*log(GCT)/GCT;

    > 4: 2*ii/T;

    > 5: log(T)*ii/T;

    > 6: 2*ii*NT1/NT;

    > 7: log(NT)*ii*NT1/NT; (default)

where NT1 = N + T, GCT = min(N,T), NT = N*T and ii = 1:rMax

- 'rMax' : The maximal number of factors to test for. Must be less than
            or equal to N. Default is N.

- 'trans' : Give 'demean' if you want to demean the data in the matrix
            X. Default. Give 'standardize' if you want to standardise the
            data in the matrix X. Gice 'none' to drop any kind of
            transformation of the data in the matrix X.

Caution: To get back X when 'demean' is given you need to add
          the constant terms in c. I.e;

X = c(ones(T,1),1) + F*LAMBDA + e, e ~ N(0,R) (1')

To get back X when 'standardise' you need to add
          the constant term and multiply with sigma. I.e.

X = c(ones(T,1),:) + F*LAMBDA.*sigma(ones(T,1),:) +
    eps, eps ~ N(0,R*) (1*)

Be aware that the eps differ from e, as e is the
          residual from the standardised regression.

'output' : A string with the wanted output. Either 'F', 'LAMBDA',
            'R', 'varF', 'expl', 'c', 'sigma', 'e'. See below for the
            matching output.

Caution: If provided it will be the only output from this
          function. I.e. return as F.

- 'unbalanced' : true or false. Set to true to allow for unbalanced
                 dataset. Default is false. If false all rows of the

```

dataset containing nan value are removed from calculations.

Output:

- F : The principal component, as a nb_ts object.
- LAMBDA : The estimated loadings, as a nb_cs object
- R : The covariance matrix of the residual in (1), as a nb_cs object.
- varF : As a nb_cs object. Each column will be the variance of the corresponding column of F.
- expl : The percentage of the total variance explained by each principal component. As a 1 x r nb_cs object
- c : Constant in the factor equation. nb_cs object with size 1 x nvar.
- sigma : See 'trans'. nb_cs object with size 1 x nvar.
- e : Residual of the equation (1) above. As a nb_ts object.
- Z : Normalized (and rebalanced) version of X.

Example:

```
load hald;
ingredients = nb_ts(ingredients,'',1,{'
    tricalcium_aluminate',...
    'tricalcium_silicate',...
    'tetracalcium_aluminoferrite',...
    'beta_dicalcium_silicate'});
[F,LAMBDA,R,varF,expl] = pca(ingredients)
```

See also:

[nb_pca](#)

Written by Kenneth SÃ¶terhagen Paulsen

► [pcn](#) ↑

```
obj = pcn(obj);
obj = pcn(obj,lag,stripNaN)
```

Description:

Calculate log approximated percentage growth. Using the formula
 $(\log(t+lag) - \log(t)) * 100$

Input:

- obj : An object of class nb_ts
- lag : The number of lags. Default is 1.
- stripNaN : Strip nan before calculating the growth rates.

Output:

- obj : An nb_ts object with the log approximated percentage growth data stored.

Examples:

```
obj = pcn(obj); % period-on-period log approx. growth
obj = pcn(obj,4); % 4-periods log approx. growth
```

See also:

[growth](#), [egrowth](#), [ipcn](#)

Written by Kenneth S. Paulsen

► **percentiles** ↑

```
obj = percentiles(obj,perc)
```

Description:

Take the percentile over the third dimension of the data of the object.

Input:

- obj : An object of class nb_ts
- perc : A double with the wanted percentiles of the data. E.g. 0.5 (median), or [0.05,0.15,0.25,0.35,0.5,0.65,0.75,0.85,0.95].

Output:

- obj : A nb_ts object with the percentiles stored as different pages of the object. See the dataNames property for the ordering.

Written by Kenneth Sæterhagen Paulsen

► **permute** ↑

```
obj = permute(obj,variables)
```

Description:

Switch the second and third dimension of the nb_ts, nb_cs or nb_data object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- variables : A cellstr with size 1 x numberOfDatasets. Default is to use dataNames property. I.e. when not provided or if empty.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► plot ↑

```
plot(obj,varargin)
plotter = plot(obj,varargin)
```

Description:

Plot the data of the nb_dataSource object.

Caution: If the data of the object is of class nb_distribution this method will redirect to plotDist.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- plotType : A string with either:
 - > 'graph' (Default)
 - > 'graphSubPlots'
 - > 'graphInfoStruct'The name of the graphing method of the class nb_graph_ts, nb_graph_cs or nb_graph_data.
- Caution: This is an optional input. If not given it is assumed that the optional input pairs are starting from the second input to this function.
- varargin : Same as the input to the method set() of the nb_graph_ts, nb_graph_cs or nb_graph_data class.

I.e. ..., 'inputName', inputValue, ...

Caution: If the data of the object is of class nb_distribution, see nb_ts.plotDist for the optional input pairs supported.

Output:

Plotted output

Examples:

```
plot(obj)  
plot(obj,'graphSubPlots')  
plot(obj,'','startGraph','2008Q1','endGraph','2011Q2')  
same as  
plot(obj,'graph','startGraph','2008Q1','endGraph','2011Q2')
```

See also:

[nb_graph_ts](#), [nb_ts.plotDist](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **plotDist** ↑

f = plotDist(obj, varargin)

Description:

A method for plotting the data of an nb_ts object when it is of type nb_distribution. It allows for both 2D and 3D plots.

Input:

- obj : An nb_ts object.

Optional input:

- '3d' : Either true or false. If true, the method will create a 3D-plot. Otherwise it will return 2D plots. Default is false.
- 'type' : What type of distribution to plot, either cdf or pdf. As string.
- 'function' : Either 'surf' or 'mesh', depending on how you want the

surface of the 3D-plot to look like.

- 'angle' : Allows for adjusting the angle of the X-labels. Default is 60.
- 'startGraph' : Sets the start date of the plot. Default is the start date of the data. As a string or as an object of class nb_date.
- 'endGraph' : Sets the end date of the plot. Default is the end date of the data. As a string or as an object of class nb_date.
- Other optional inputs: See the nb_graph_data class.

Output:

- f : Either a MATLAB figure or a nb_graph_data object.

Examples:

First create some data:

```
obj = nb_ts(randn(1000,2),'', '2010M1', {'v1','v2'})
```

Recursively estimate a pdf of the data:

```
rD = obj.ksdensity('recStart','2012M1','recEnd','2030M1', 'recursive',1)
```

Create a 3D-plot

```
rD.plotDist('3d',1)
```

See also:

[nb_ts.plot](#)

Written by Kenneth Sæterhagen Paulsen

► **plus ↑**

```
obj = plus(obj,DBOrNum)
```

Description:

Binary addition (+).

Caution: Will add the data of the corresponding variables from the two objects. All the variables not in common will result in series with nan values.

When one of the inputs are a scalar this function will add each element of the data by this number.

Input:

- a : An object of class nb_ts or a scalar
- b : An object of class nb_ts or a scalar

Output:

- obj : An nb_ts object where all the variables from the two objects are added.

Or

An nb_ts object where the scalar are added to all elements of the given nb_ts object

Examples:

```
obj = obj + anotherObj;  
obj = obj + 2;  
obj = 2 + obj;
```

See also:

[nb_ts.minus](#), [nb_ts.callop](#), [nb_ts.callfun](#)

Written by Kenneth S. Paulsen

► **pow2** ↑

```
obj = pow2(obj)
```

Description:

pow2(obj) raises the number 2 to the power of the elements of obj

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = pow2(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **power** ↑

```
obj = power(a,b)
```

Description:

Element-wise power (.^).

If both inputs are nb_ts objects this method will raise the data of the first object with the data from the second object. This will only be done for the variables which are found to be in both nb_ts objects. The rest of the variables will get nan values.

Input:

- obj : An object of class nb_ts or a scalar
- DBOrNum : An object of class nb_ts or a scalar

Output:

- obj : An nb_ts object where the data from th one object are raised with the data from the other object

or

An nb_ts object where all the elements are raised by the scalar DBOrNum.

or

An nb_ts object where the scalar obj are raised by all the elements of the object DBOrNum.

Examples:

```
obj = a.^b;
obj = a.^2;
obj = 2.^a;
```

See also:

[nb_ts.mpower](#), [nb_ts.callop](#), [nb_ts.callfun](#)

Written by Kenneth S. Paulsen

► **q2y** ↑

```
obj = q2y(obj)
```

Description:

Will for each quarter calculate the cumulative sum over the last 4 quarter (Including the present). The frequency of the return object will be quarterly.

Input:

- obj : An object of class nb_ts

Output:

- obj : An nb_ts object where the data are the sum over the last 4 quarters.

Written by Kenneth S. Paulsen

► **rand** ↑

```
obj = nb_ts.rand(start,obs,vars,pages,dist,sorted)
```

Description:

Create an nb_ts object with all data set to random number.

Input:

- start : The start date of the created nb_ts object.
- obs : The number of observation of the created nb_ts object.
- vars : Either a cellstr with the variables of the nb_ts object, or a scalar with the number of variables of the nb_ts object.
- pages : Number of pages of the nb_ts object.
- dist : A nb_distribution object to draw from.
- sorted : true or false. Default is true.

Output:

- obj : An nb_ts object.

Examples:

```
obj = nb_ts.rand('1',10,['Var1','Var2']);
obj = nb_ts.rand('2012Q1',2,2);
obj = nb_ts.rand('2012Q1',2,2,10,nb_distribution('type','normal'));
```

See also:

[nb_ts](#)

Written by Kenneth Sætherhagen Paulsen

► **rdivide** ↑

`obj = rdivide(obj,DB)`

Description:

Right element-wise division (./)

Do right element-wise division of the matching variables of the two nb_ts objects. If some variables are not found to be in both objects, the resulting object will have timeseries with nan values only for these variables.

Input:

- a : An object of class nb_ts
- b : An object of class nb_ts

Output:

- obj : An object of class nb_ts, where the data are the result of the element-wise division.

Examples:

`obj = obj./DB;`

See also:

[nb_ts.mldivide](#), [nb_ts.mrdivide](#), [nb_ts.callop](#), [nb_ts.callfun](#)

Written by Kenneth S. Paulsen

► **reIndex** ↑

`obj = reIndex(obj,date,baseValue)`

Description:

Reindex the data of the object to a new date. It is also possible to reindex the timeseries to a date with lower frequency. E.g. reindex quarterly data to be on average 100 in a given year.

Input:

- obj : An object of class nb_ts
- date : The date at which the data should be reindexed to.
(Reindexed to baseValue, default is 100)
- baseValue : A number to re-index the series to. Default is 100.

Output:

- obj : An object of class nb_ts where all the objects timeseries are reindexed to 100 at the given date

Examples:

```
obj = reIndex(obj,'2012Q2')
```

Written by Kenneth S. Paulsen

► real ↑

```
obj = real(obj)
```

Description:

real(obj) returns the real part of the elements in the nb_cs object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = real(obj);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► realTime2RecCondData ↑

```
out = realTime2RecCondData(obj,nSteps,freq,nowcast,vintages)
```

Description:

Takes real time data and converts it into recursive conditional data, with the number of steps of forecast that you want.

Input:

- obj : A nb_ts object.
- nSteps : The number of steps that you want to include in your recursive dataset.
- freq : The frequency of your data. Must be either 1, 2, 4, 12 or 365.
- nowcast : Either 0 or 1. If true you will include todays estimate as your first forecast. Default is true.
- vintages : Give false if the dataNames property do not store the vintage dates as is the case for data returned by nb_fetchRealTimeFromFame. Be aware that this assumes that each new page only give one and only one new observation.

Give 2 if the dataNames property store the end date of history for each vintage (instead of a vintage). This is the case if the nb_fetchRealTime is used.

Output:

- out : A nb_data object

See also:

[nb_fetchRealTime](#), [nb_fetchRealTimeFromFame](#)

Written by Tobias Ingebrigtsen

► reallog ↑

obj = reallog(obj)

Description:

Take the real natural logarithm of the data stored in the object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = reallog(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **realpow** ↑

obj = realpow(obj,DBOrNum)

Description:

Same as nb_ts.power.

See also:

[nb_ts.power](#)

Written by Kenneth S. Paulsen

► **realsqrt** ↑

obj = realsqrt(obj)

Description:

realsqrt(obj) is the square root of the elements of obj.
An error is produced if obj contains negative elements.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = realsqrt(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► rebalance ↑

```
obj = rebalance(obj,methods)
```

Description:

Rebalance the dataset with a spesific method for each variable.

Caution: If a variable is not assign a spesific method. A AR(1) model with automatic selection of the level of intergration is used to backcast and forecast trailing and leading nan, while a spline method is used to fill in the missing observations in-sample. See nb_arRebalance and spline for more.

Input:

- obj : An T x nVars object of class nb_ts. Can only have one page.

- methods : A nVars x 3 cell array. First column must be the variable name, the second column must be the function to backcast and forecast trailing and leading nan, while the third column must be the function to fill in for nan values in-sample.

E.g. {'Var1',@(x)nb_arRebalance(x),@(x)nb_spline(x)}

If 'all' is set as the variable name, the selected options will be applied to all variables.

If not given or given as empty the default methods will be used.

Output:

- obj : A T x nVars object of class nb_ts.

See also:

[nb_arRebalance](#), [nb_spline](#)

Written by Kenneth Sæterhagen Paulsen

► recursiveExtrapolate ↑

```
out = recursiveExtrapolate(obj,variables,nSteps,startDate)
out = recursiveExtrapolate(obj,variables,nSteps,startDate,varargin)
```

Description:

Recursively extrapolate last of observation of variables with the wanted number of periods.

Caution: This method only works on a single paged nb_ts object or objects that return true using the isRealTime method.

Input:

- obj : An object of class nb_ts
- variable : A string with the name of the variable to extrapolate, or a cellstr of the variables to extrapolate. Default is to extrapolate all variables.

Caution: When 'method' is set to copula only the selected variables are included in the calculation of the extrapolated values.

- nSteps : Must be an integer with the number of periods to extrapolate.
- startDate : Start date of recursive extrapolation. Either as a char or an object of which is of a subclass of the nb_date class. This option is only used when the dataset is not real-time.

Caution : If all other than the 'end' option is used for the 'method' option. This options must allow for a proper number of degrees of freedom for estimating the model to use to extrapolate.

Optional inputs:

- 'method' :
 - > 'end' : Extrapolate series by using the last observation of each series. I.e. a random walk forecast.
 - > 'copula' : This approach tries to estimate the unconditional marginal distribution of each series in the dataset and the (auto)correlation structure that describe the connection between these series. Some series may have more observations than others!

Caution : This method works when the unconditional distribution from which the series are assumed to be drawn from are the same over time. E.g. the series must have the same volatility over the period. The second assumption is that all the series are stationary. Use the 'check' input to test for non-stationarity by a ADF test for unit-root. If it is found to have a unit root the series will be differenced when forecasted, and then transformed back to level after that step.

- > 'ar' : Extrapolate each series individually using a fitted

AR model.

```
> 'var'      : Extrapolate all series using a fitted VAR model. Max  
               number of variables is set to 10 for this option.  
  
> 'actual'   : Extrapolate with actual data. This will lead to  
               nans for the last periods!  
  
- 'alpha'     : Significance level of ADF test for stationary series.  
               Only an option for the 'copula' method.  
  
- 'check'     : Check for stationary series. If not found to be  
               stationary the series will be differenced and  
               extrapolated with this transformation before transformed  
               back to its old level. Only an option for the 'copula'  
               method.  
  
- 'nLags'     : Number of lags to include when calculating the  
               correlation matrix used by the copula. I.e. the number  
               of historical observations to condition on when forming  
               the conditional correlation matrix.  
  
- 'draws'     : The number of draws used to estimate the mean, when  
               using the 'copula' method.  
  
- 'constant'  : Give true to include constant in the AR models used  
               to extrapolate the individual series. Default is false.
```

Output:

```
- out         : A nb_ts object with the recursively extrapolated series.
```

Examples:

```
obj = nb_ts.rand('1900',50,2,1);  
obj = recursiveExtrapolate(obj,'Var1',4,'1900');
```

Written by Kenneth S. Paulsen

► **release ↑**

```
obj = release(obj,num)
```

Description:

Get a specific realease from a real-time dataset.

```
Caution : cleanRealTime should be ran to secure that this method does  
          not throw an error.
```

Input:

- obj : An object of class nb_ts representing real-time data.
- num : An integer larger than 0 with the release number.

Output:

- obj : An object of class nb_ts.

See also:

[nb_ts.cleanRealTime](#), [nb_readExcelMorePages](#), [nb_fetchRealTimeFromFame](#)
[nb_ts.getRelease](#)

Written by Kenneth Sæterhagen Paulsen

► **removeObservations ↑**

obj = removeObservations(obj,numPer,vars)

Description:

Remove the number of wanted observation from each series, or a subset of variables. If one variable contain less observation than another it will still be removed another observation, so as to preserve the ragged edge of the data.

Input:

- obj : A nb_ts object
- numPer : The amount of observations to remove at the end of the sample for each series. By removal we mean setting it to nan.
- vars : A cellstr with the variables to perform the method on. Can be empty, in which case the method will be performed on all variables in the object, which is the default.

Output:

- obj : A nb_ts object

Examples:

```
obj = nb_ts.rand(1,4,3);
obj = removeObservations(obj,1)
obj = removeObservations(obj,1,['Var1','Var2'])
```

Written by Kenneth Sæterhagen Paulsen

► **rename ↑**

```
obj = rename(obj,type,oldName,newName)
```

Description:

Makes it possible to rename variables and datasets. For objects of class nb_cs types is also possible to rename.

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variable', but not when the input is 'dataset' or 'types'.

Input:

- obj : An object of class nb_dataSource
- type : Either:
 - 'variable' : To rename a variable(s)
 - 'dataset' : To rename a dataset(s) (The only input that is supported for nb_cell)
 - 'types' : To rename a type(s) (only nb_cs)

- oldName : Case 1;

> The old variable/dataset/type name, as a string

Case 2:

> The string which should be replaced in all the variable names of the database. And reorder things afterwards. This input must end with a *.

- newName : Case 1;

> The new variable/dataset/type name, as a string

Case 2;

> The string which should replace the old string part given by the input 'oldName'.

Output:

- obj : An nb_dataSource object with the renamed variable(s), type(s) or dataset(s).

Examples:

```
obj = nb_cs([2,2],'test',{'First'},{'Var1','Var2'});  
obj = obj.rename('variable','Var1','Var3');  
obj = obj.rename('variable','Var*','N_Var');  
obj = rename(obj,'variable',{'Var1','Var2'},{'VAR1','VAR2'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **renameMore** ↑

```
obj = renameMore(obj,type,oldNames,newNames)
```

Description:

Makes it possible to rename more variables, datasets and types (only nb_cs).

Caution : It will resort the variables and the data accordingly when the input type is equal to 'variables', but not when the input is 'datasets'.

Caution : This is the same as looping over nb_dataSource.rename, but more efficient.

Caution : * syntax is not supported as is the case for nb_dataSource.rename

Input:

- obj : An object of class nb_dataSource.
- type : Either:
 - 'variables' : To rename a variables
 - 'datasets' : To rename a datasets (The only input that is supported for nb_cell)
 - 'types' : To rename a type (Only nb_cs)
- oldNames : The old variable/dataset/type names, as a cellstr.
- newName : The new variable/dataset/type names, as a cellstr.

Output:

- obj : An nb_dataSource object where the variable(s)/dataname(s)/type(s) of the object given as input is/are renamed.

Examples:

```
obj = nb_cs([22,24;27,28],'Dataset1',{'Exp','Imp'},{'Nor','Swe'})  
obj = renameMore(obj,'dataset',{'Dataset1'},{'tradeBal'});  
obj = renameMore(obj,'variable',{'Nor','Swe'},{'Norway','Sweden'});  
obj = renameMore(obj,'type',{'Exp','Imp'},{'Export','Import'});
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **reorder ↑**

```
obj = reorder(obj,newOrder,type)
```

Description:

Re-order the variables/types/datasets of the object.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- newOrder : A cellstr with the new order of the variables/types/datasets.
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **ret ↑**

```
obj = ret(obj)
obj = ret(obj,nlag)
obj = ret(obj,nlag,skipNaN)
```

Description:

Calculate return, using the formula: $x(t)/x(t-lag)$ of all the timeseries of the nb_ts object.

Input:

- obj : An object of class nb_ts
- nlag : The number of lags in the return formula, default is 1.
- skipNaN : -1 : Skip nan while using the ret operator. (E.g. when dealing with working days.)
 - 0 : Do not skip nan values. Default.

Output:

- obj : An nb_ts object with the calculated timeseries stored.

Examples:

```
obj = ret(obj);
obj = ret(obj,4);
```

See also:

[nb_ts](#)

► **rlag** ↑

```
obj = rlag(obj,t,endDate)
```

Description:

Append data with use of the rolling lag operator

Input:

- obj : An object of class nb_ts
- t : The number of lags to use for the rolling window
- endDate : The new end date

Output:

- obj : An object of class ts

Examples:

```
obj = nb_ts(rand(20,1),'',1,'Var1')
obj = rlag(obj,4,'30')
```

► **round** ↑

```
obj = round(obj,value,startDate,endDate,variables)
```

Description:

Round to closes value. I.e. if value is 0.25 it will round to the closes 0.25. E.g. 0.67 will be rounded to 0.75.

Input:

- obj : A nb_ts object
- value : The rounding value. As a double. Default is 1.
- startDate : The start date of the rounding. As a date string or a nb_date object. Can be empty. Default is the start date of the data.

- endDate : The end date of the rounding. As a date string or a nb_date object. Can be empty. Default is the end date of the data.
- variables : The variables to round. Can be empty. Default is to round all variables.

Output:

- obj : A nb_ts object with the rounded numbers.

Written by Kenneth SÃ¶terhagen Paulsen

► **saveDataBase ↑**

saveDataBase(obj, varargin)

Description:

Save data of the object to (a) file(s)

If no optional input is given, i.e. obj.saveDataBase(). The data of the object is save down to xlsx file(s). Each dataset of the object is saved down to a excel spreadsheet with the name of the dataset (Taken from the 'dataNames' property)

Input:

- obj : An object of class nb_ts

Optional input (..., 'propertyName', PropertyValue, ...):

- 'saveName' : A string with the wanted name of the saved file.
- 'ext' : > 'xlsx' : Saves the object down to a excel spreadsheet. Default
 - > 'matold' : Saves the data down to a mat file. The data is transformed into a structure, with the variables as the fieldnames, and the data as its fields. If the data consist of more pages, each field will consist of the same number of pages. See the toStructure method with input old set to 1.
Must be combined with the optional input 'saveName'.
 - > 'mat' : Saves the data down to a mat file. The data is transformed into a structure, with the variables stored in the field 'variables', while the data of the variables will be saved as its fields with generic

names ('Var1','Var2' etc). If the data consist of more pages, each field will consist of the same number of pages. See the toStructure method.

Must be combined with the optional input 'saveName'.

> 'mats' : The object is saved down as a struct using the nb_ts.struct function.

> 'txt' : Saves the data down to a txt file.

- 'append' : > 1 : Saves all the datasets (pages of the data) to one excel spreadsheet, but in separate worksheets. (Where the names of the worksheets are given by the dataNames property of the object.)

Works only when 'ext' input is set to 'xlsx'. (The default)

> 0 : The default saving method.

- 'strip' : > 'on' : Strip all observation dates where all the variables has no value. (is nan)

> 'off' : Default

Caution : Only an option when saved to excel.

- 'dateformat' : Sets the date format of the saved output Only if 'ext' are set to 'xlsx', which is default.
The supported date formats are:

> 'default'
> 'fame'
> 'xls'
> 'NBNorsk' ('NBNorwegian')
> 'NBEnglish' ('NBEngelsk')

See the toDates methods of the classes nb_day, nb_month, nb_quarter, nb_semiAnnual and nb_year for more information on the date formats

- 'sheets' : Set the names of the sheets to write to, as a cellstr. The length must match the number of pages of the nb_ts object. Only supported if 'ext' is set to 'xlsx'.

Output:

The nb_ts object saved to the wanted file format.

Examples:

Save the data to excel with the name 'test':
saveDataBase(obj,'saveName','test');

```
Save the data to excel with another date format:  
saveDataBase(obj,'saveName','test','dateformat','xls');  
  
Save the data to excel spreadsheet with the datasets as different  
worksheets:  
saveDataBase(obj,'saveName','test','append',1);  
  
Save the data to a .mat with the name 'test':  
obj.savDataBase('ext','mat','saveName','test')
```

See also:

[asCell](#), [toStructure](#), [nb_readMat](#), [nb_readExcel](#)

Written by Kenneth S. Paulsen

► **sec** ↑

obj = sec(obj)

Description:

Secant of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

obj = sec(obj);

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **secd** ↑

obj = secd(obj)

Description:

Secant of argument in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = secd(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sech** ↑

```
obj = sech(obj)
```

Description:

Hyperbolic secant.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sech(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **set2nan** ↑

```
obj = set2nan(obj,testedVariable,settledVariable)
```

Input:

- obj : An object of class nb_ts
- testedVariable : A string with the name of the variable you are testing for nan values
- settedVariable : A string with the name of the variable you are setting equal to nan where the testedVariable are in fact nan.

Output:

- obj : An nb_ts object where the settedVariable are set equal to nan at all the same dates as the testedVariable is nan.

Examples:

```
obj = nb_ts([1,2;nan,1;2,3],'', '2012', {'Var1','Var2'});
```

```
obj = set2nan(obj,'Var1','Var2');
```

```
obj =
```

'Time'	'Var1'	'Var2'
'2012'	[1]	[2]
'2013'	[NaN]	[NaN]
'2014'	[2]	[3]

Written by Kenneth S. Paulsen

► **setDayOfWeek ↑**

```
obj = setDayOfWeek(obj,dayOfWeek)
```

Description:

Set the day the week represents when converted to daily frequency.

Input:

- obj : A nb_ts object representing weekly data.
- dayOfWeek : The day of the week. 1 is sunday, 2 is monday, ..., 7 is saturday.

Output:

- obj : A nb_ts object representing weekly data.

See also:

[nb_ts.convert](#)

► **setInfinite2NaN** ↑

```
obj = setInfinite2NaN(obj)
```

Description:

Set all elements that are infinite to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setMethodCalls** ↑

```
obj = setMethodCalls(obj,c)
```

Description:

Set all method calls of the object with a cell matrix. The object needs to be updatable.

Caution: To delete method calls use deleteMethodCalls

Caution: Call obj = update(obj) to interpret the changes made!

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.
- c : A cell matrix. See the output of getMethodCalls

Output:

- obj : An object of class nb_ts, nb_cs or nb_data.

See also:

[nb_ts.deleteMethodCalls](#), [nb_ts.getMethodCalls](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **setNewStartDate ↑**

`obj = setNewStartDate(obj,start)`

Description:

Set new start date of nb_ts object.

Input:

- `obj` : An object of class nb_ts.
- `start` : An object of class nb_date or a date string.

Output:

- `obj` : An object of class nb_ts with the new start date.

See also:

[nb_ts.lag](#), [nb_ts.lead](#)

Written by Kenneth Sæterhagen Paulsen

► **setToNaN ↑**

`obj = setToNaN(obj,startDateWin,endDateWin,variablesWin,Pages)`

Description:

Set a window of the object to nan

Input:

- `obj` : An object of class nb_ts
- `startDateWin` : The start date of the nan data of the object. Must be a string on the format; 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the start date of the data.

Can also be an object which is a subclass of the nb_date class.

- endDateWin : The end date of the nan data of the object. Must be a string on the format. 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the end date of the data.

Can also be an object which is a subclass of the nb_date class.

- variablesWin : A cellstr array of the variables you want to set to nan. If empty all the variables is set to nan.
- pages : A numerical index of the pages you want to set to nan.

Output:

- obj : An nb_ts object where the wanted data is set to nan.

See also:

[nb_ts](#)

Written by Kenneth S. Paulsen

► **setValue ↑**

```
obj = setValue(obj,VarName,Value,startDateOfValues, ...
endDateOfValues,pages)
```

Description:

Set some values of the dataset(s). (Only one variable at a time.) You cannot use dates outside the objects dates (i.e. outside obj.startDate:obj.endDate)

Input:

- obj : An object of class nb_ts
- VarName : The variable name of the variable you want to set some values of. As a string
- Value : The values you want to assign to the variable. Must be a numerical vector (with the same number of pages as given by pages or as the number of dataset the object consists of.) Cannot be outside the window of the data of the object.
- startDateOfValues : A date string with the start date of the data. If not given or given as a empty string it will assume that the setted data start at the startDate of the object.

This input could also be an object which is of a subclass of the nb_date class.

- endDateOfValues : A date string with the end date of the data. If not given or given as a empty string it will assume that the setted data end at the endDate of the object.

This input could also be an object which is of a subclass of the nb_date class

- pages : At which pages you want to set the values of a variable. Must be a numerical index of the pages you want to set.
E.g. if you want to set the values of the 3 first datasets (pages of the data) of the object. And the number of datasets of the object is larger then 3. You can use; 1:3. If empty all pages must be set.

Output:

- obj : An nb_ts object where the data of the given variable has been set.

Examples:

```
obj = nb_ts([2;3;4],'',,'2012',{'Var1'});  
  
obj = obj.setValue('Var1',[1;2;3]);  
obj = obj.setValue('Var1',2,'2013','2013',1);  
obj = obj.setValue('Var1',[1;2;3],'2012','2014');
```

See also
addVariable

Written by Kenneth S. Paulsen

► **setZero2NaN ↑**

```
obj = setZero2NaN(obj)
```

Description:

Set all elements that are 0 to nan.

Input:

- obj : An object of class nb_ts.

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► sgrowth ↑

```
obj = sgrowth(obj,horizon)
```

Description:

Calculates smoothed 12 or 6 months growth.

$x(*) = ((x13+x14+x15)/(x1+x2+x3)-1)*100$

$x(*) = ((x7+x8+x9)/(x1+x2+x3)-1)*100$

Note: Works only for monthly data.

Based on Anne Sofie Jores data transformation code.

Input:

- obj : A nb_ts object

- horizon : Either 1 or 2, depending on the frequency you want your growth to be calculated over. 1 is annual and 2 is semi-annual.

Output:

- out : A nb_ts object.

Examples:

```
a = nb_ts('forecast.db','','','{'NB.QUA_PCPIJAE'})  
a = sgrowth(a,1)
```

See also:

[nb_sgrowth](#)

Written by Tobias Ingebrigtsen

► shrinkSample ↑

```
obj = shrinkSample(obj,variables,periods)
```

Description:

Shrink sample to be balanced for a selected number of variables. (May tolerate trailing nan with the selected number of periods)

Input:

- obj : An object of class nb_ts
- variables : A cellstr with the variables of interest
- periods : A integer with the number of tolerate trailing nan. Default is 0.

Output:

- obj : An object of class nb_ts

See also:

[nb_ts.cutSample](#)

Written by Kenneth S. Paulsen

► **simulate ↑**

```
obj      = nb_ts.simulate()
obj      = nb_ts.simulate(start,obs,vars,pages,lambda,rho,dist,burn)
[obj,res] = nb_ts.simulate(start,obs,vars,pages,lambda,rho,dist,burn,...  
    varargin)
```

Description:

Simulate time-series data from a VAR-MA model

Input:

- start : The start date of the created nb_ts object.
- obs : The number of observation of the created nb_ts object.
- vars : Either a 1 x nVars cellstr with the variables of the nb_ts object, or a scalar with the number of variables of the returned nb_ts object.
- pages : Number of pages of the nb_ts object. I.e. the number of simulations from the process.
- lambda : The VAR coefficients. As a nVar x nVar*nLags double. Default is a zero matrix.
- rho : The MA coefficients (including the contemporaneous). As a nVar x nMA + 1. Default is a vector of ones. The weight on the contemporaneous innovation comes first, then the first

MA term and so on.

- dist : The distribution to draw the residuals from. As a 1 x svars nb_distribution object. Default is $N(0,1)$, i.e. when [] is given.
- burn : Number of observations used to simulate starting values. As an integer. Default is 10.

Optional input:

- 'exoData' : A obs * burn x nExo double with the simulated data of the exogenous variables.
- 'B' : A nVars x nExo double with the coefficients on the exogenous variables of the VAR.

Output:

- obj : A nb_ts object with the simulated data.
- res : A nb_ts object with the simulated innovations.

Examples:

```
% AR(2) model with std 0.5^2
obj = nb_ts.simulate('1994Q1',100,1,1000,[0.9,-0.2],0.5)

% A VAR with two variables and two lags
obj = nb_ts.simulate('1994Q1',100,2,1000, ...
    [0.9,-0.2,0.3,0;0.1,0,0.7,0.05],[0.5;0.3])
```

Written by Kenneth Sæterhagen Paulsen

► **sin ↑**

```
obj = sin(obj)
```

Description:

Sine of argument in radians.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = sin(obj);  
  
Written by Kenneth S. Paulsen  
  
Inherited from superclass NB_DATASOURCE
```

► **sind** ↑

```
obj = sind(obj)
```

Description:

sind(obj) is the sine of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sind(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **sinh** ↑

```
obj = sinh(obj)
```

Description:

sinh(obj) is the hyperbolic sine of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = sinh(in);  
  
Written by Andreas Haga Raavand  
  
Inherited from superclass NB_DATASOURCE
```

► **skewness ↑**

```
obj = skewness(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the skewness of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their skewness.

The output can also be set to be a double or a nb_cs object consisting of the skewness values of the data.

Input:

- obj : An object of class nb_ts
- flag : Same as for the function skewness created by MATLAB.
- outputType :
 - > 'nb_ts' : The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their skewness.
 - > 'double' : Get the skewness values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consist of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the skewness values as nb_cs object. The skewness will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the skewness over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method
- dimension : The dimension to calculate the skewness over.

Examples:

```
nb_tsObj = skewness(obj);
double    = skewness(obj,0,'double');
nb_csObj = skewness(obj,0,'nb_cs');
```

Written by Kenneth S. Paulsen

► **sort ↑**

```
obj = sort(obj,mode,dim,variable)
```

Description:

Sort the wanted dimension (observations) of the data in the order given by the order input.

Caution : Sorting does not reorder the dataNames, variables or dates!

Input:

- obj : An object of class nb_ts
- mode : 'descend' (default)
'ascend'
- dim : The dimension to sort. Either 1, 2 or 3. Default is 3.
- variable : Give a string with the variable to sort. The rest of the variables will then be reordered accordingly.
If empty (default), all variables are sorted.

Caution: Only an option for dim == 1

Output:

- obj : An object of class nb_ts

Examples:

```
in  = nb_ts(rand(10,2,10),'',1,{'Var1','Var2'});
out = sort(in);
out = sort(in,'descend')
```

Written by Kenneth S. Paulsen

► **sortProperty ↑**

```
obj = sortProperty(obj,type)
```

Description:

Sort the variables/types/datasets of the object alphabetically.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data
- type : Either 'variables' (default), 'types' or 'datasets'. 'types' is only supported for nb_cs objects.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **splitByPublishDates** ↑

```
out = splitByPublishDates(obj,publishDates,lag,format)
```

Description:

Input:

- obj : An object of class nb_ts with only one page!
- publishDates : A cellstr or nb_day vector with the dates that the series has been published backward in time.
- lag : The number of periods the series are when published. E.g. if the observation for the last month of a monthly series is published at the 10th of each month, then give 1 (default). Give 2 if it is published with lag of two months, and so on.
- format : The format of the publishing dates stored in the dataNames property of the output. See the nb_date.format2string method. Default is 'yyyymmdd'.

Output:

- out : An object of class nb_ts with pages given by the series up to the given date.

Written by Kenneth Sæterhagen Paulsen

► **splitSample** ↑

```
data = splitSample(obj,nSteps,appendNaN)
```

Description:

Split a sample into a multipaged nb_data object with size nSteps x nvar x nobs. Will append nan values for the last observations as default.

Input:

- data : An object of class nb_ts.
- nSteps : The number of period of the splitted data. As a scalar integer.
- appendNaN : true or false. Default is true.

Output:

- data : An object of class nb_data with size nSteps x nvar x nobs.

Examples:

```
data = splitSample(nb_ts.rand(1,20,2),4)
```

See also:

[nb_ts](#), [nb_ts.splitSeries](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **splitSeries ↑**

```
obj = splitSeries(obj,variable,date,postfix,overlapping)
```

Description:

Split a series into two variables at a given date.

Input:

- obj : An object of class nb_ts
- variable : The variable(s) to split. Either a string or a cellstr.
- date : The date to split the series. Either as a string or a nb_date object. Local variables syntax is supported.
- postfix : A string with the postfix of the new variable(s).
- overlapping : Indicate if you want the splitted series to be overlapping or not. As a logical. Default is true.

Output:

- obj : An object of class nb_ts with the splitted series added.

See also:

[nb_ts](#), [nb_ts.splitSample](#)

Written by Kenneth SÃ¶terhagen Paulsen

► **sqrt** ↑

obj = sqrt(obj)

Description:

sqrt(obj) is the square root of the elements of obj. Complex results are produced for non-positive elements.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

out = sqrt(in);

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **squeeze** ↑

obj = squeeze(obj)

Description:

Squeezes the different datasets (pages) of the given nb_ts object. It will append the variables in each dataset with the given data name

Input:

- obj : An nb_ts object. If the object has only one dataset (page) this method has nothing to do.

Output:

- obj : An nb_ts object, where all the pages are squeezed together. I.e. all data will be stored in one dataset, and all variable names will get the dataset name appended.

Example:

```
obj = nb_ts(ones(1,1,2),{'b','c'},'2012',{'Var1'})
```

```
obj =
```

```
(:,:,1) =
```

'Time'	'Var1'
'2012'	[1]

```
(:,:,2) =
```

'Time'	'Var1'
'2012'	[1]

```
sObj = squeeze(obj)
```

```
sObj =
```

'Time'	'Var1_b'	'Var1_c'
'2012'	[1]	[1]

Written by Kenneth Sæterhagen Paulsen

► **std ↑**

```
obj = std(obj,flag,outputType,dimension,varargin)
```

Description:

Calculate the std of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their std.

The output can also be set to be a double or a nb_cs object consisting of the std values of the data.

Input:

- obj : An object of class nb_ts
- flag : > 0 : normalises by N-1 (Default)
> 1 : normalises by N

Where N is the sample length.

- outputType :
 - > 'nb_ts' : The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their std.
 - > 'double' : Get the std values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the std values as nb_cs object. The std will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the std over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
nb_tsObj = std(obj);
double   = std(obj,0,'double');
nb_csObj = std(obj,0,'nb_cs');
```

Written by Kenneth S. Paulsen

► **stdise** ↑

```
obj = stdise(obj,flag)
```

Description:

Standardise data of the object by subtracting mean and dividing by std deviation.

Input :

- obj : An object of class nb_ts
- flag : - 0 : normalises by N-1 (Default)

- 1 : normalises by N

Where N is the sample length.

Output:

- obj : An nb_ts object with the standardised data

Examples:

```
obj = stdise(obj);
```

Written by Kenneth S. Paulsen

► **stopSorting** ↑

```
obj = stopSorting(obj)
```

Description:

Stop sorting of variables.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data.

Output:

- obj : An object of class nb_ts, nb_cs or nb_data where sorting is turned off.

Example:

```
obj = obj.addPrefix('NEMO.');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **strip** ↑

```
obj = strip(obj,startDate,endDate,variables)
```

Description:

Sets all values of the given variables of a nb_ts object, between two given dates, to nan.

Input:

- obj : A nb_ts object
- startDate : The starting point of the strip, must be either an nb_date object or a valid input to the toDate method of the nb_date class
- endDate : The starting point of the strip, must be either an nb_date object or a valid input to the toDate method of the nb_date class
- variables : A cellstring with the variables to perform the method on. Can be empty, in which case the method will be performed on all variables in the object.

Output:

- obj : A nb_ts object

Examples:

```
strippedObj = strip(obj,'2011Q1','2012Q3',{'Var1','Var2'})  
strippedObj = strip(obj,'2011Q1','2012Q3')
```

See also:

[nb_ts.setToNaN](#)

Written by Eyo Herstad

► **stripButLast** ↑

```
obj = stripButLast(obj,numPeriods,variables)
```

Description:

Sets all values of the given variables of a nb_ts object, except a given amount of observations at the end, to nan.

Input:

- obj : A nb_ts object
- numPeriods : The amount of observations to be left as-is in the object. If the input is given to 2, the returned object will have all it's observations set to nan except the last two observations.
- variables : A cellstring with the variables to perform the method on. Can be empty, in which case the method will be performed on all variables in the object.

Output:

- obj : A nb_ts object

Examples:

```
strippedObj = stripButLast(obj,5,['Var1','Var2'])  
strippedObj = stripButLast(obj,'5')
```

Written by Eyo Herstad

► **stripFcstFromRealTime** ↑

```
obj = stripFcstFromRealTime(obj,type)
```

Description:

Remove conditional information from a real-time dataset

Caution : It is assumed that each page give rise to a new historical observation, i.e. the dataNames property must not increase by more than one period when it is traversed.

Input:

- obj : An object of class nb_ts. The dataNames property must either store the vintages or the end of history dates.
- type : Give 1 if the dataNames property stores vintages, otherwise use 2 if it stores the end of history dates. Default is 2:

Output:

- obj : An object of class nb_ts.

Written by Kenneth Sæterhagen Paulsen

► **struct** ↑

```
s = struct(obj)
```

Description:

Object to struct.

Input:

- obj : An nb_ts object.

Output:

- s : A structure representing an nb_ts object.

Written by Kenneth Sæterhagen Paulsen

► structure2Dataset ↑

```
obj = structure2Dataset(obj,givenStruct,NameOfDataset,startDate)
```

Description:

When you give a struct to the constructor of this class all the fields af that struct will be added as a new dataset, but this method add all the fields of the input struct as a variable in one dataset

If you only want to add a dataset from a structure in this way (no other datasets) intitialize an empty object, and then use this method.

Caution : The structure must include a field 'startDate', which must be a string with the start date of the data to add.

Inputs:

- obj : An nb_ts object, could be empty.
- givenStruct : The structure which contains the data of the added variable. Where the fieldnames will be the variables name of the added dataset + plus one field 'startDate' with the start date of the dataset.
- NameOfDataset : Name of the added dataset. If not provided a default name will be given
- startDate : The start date of the added structure. Only needed if the provided structure has no field 'startDate'.

Outputs:

- obj : An nb_ts object with the added structure as a dataset.

Examples:

```
s          = struct();  
s.startDate = '2012';  
s.var1      = [2;2;2];  
data       = nb_ts();  
data       = data.structure2Dataset(s)  
  
data =
```

```
'Time'      'var1'  
'2012'      [    2]  
'2013'      [    2]  
'2014'      [    2]
```

Written by Kenneth S. Paulsen

► **subAvg** ↑

```
obj = subAvg(obj,k)  
obj = subSum(obj,k,w)
```

Description:

Will for the last k periods (including the present) calculate the cumulative sum and then divide by the amount of periods, which gives you the average over those periods.

Input:

- obj : An object of class nb_ts.
- k : Lets you choose what frequency you want to calculate the average over. As a double. E.g. 4 if you have quarterly data and want to calculate the average over the last 4 quarters.

Output:

- obj : An nb_ts object where the data are the average over the last k periods.

Examples:

```
dataquarter = nb_ts('histdata.db', '', '2000Q1', {'QSA_PCPIJAE'});  
growth12Q   = pcn(dataquarter,4);  
growth12Q   = subAvg(growth12Q,4);
```

See also:

[growth](#), [q2y](#), [pcn](#)

Written by Tobias Ingebrigtsen

► **subSum** ↑

```
obj = subSum(obj,k)  
obj = subSum(obj,k,w)
```

Description:

Calculates the cumulative sum over the last k periods (including the present period).

Input:

- obj : An object of class nb_ts.
- k : Lets you choose what frequency you want to calculate the cumulative sum over. As a double. E.g. 4 if you have quarterly data and want to calculate the average over the last 4 quarters.
- w : Weights applies to the k periods to sum over. Default is equal weights! As a double vector with length k.

Output:

- obj : An object of class nb_ts.

Examples:

```
dataquarter = nb_ts('histdata.db', '', '2000Q1', {'QSA_PCPIJAE'});  
growth12Q = pcn(dataquarter,4);  
growth12Q = subSum(growth12Q,4);
```

See also:

[pcn](#), [growth](#), [subAvg](#)

Written by Tobias Ingebrigtsen

► subsasgn ↑

```
varargout = subsasgn(obj,s,b)
```

Description:

Makes it possible to do subscripted assignment of the data of an object

Input:

- obj : An object of class nb_ts
- s : The same input as when you do subscripted assignment one a double matrix
- b : The assign data at the given index s.

Output:

- obj : The assign data property setted of the given object.

Examples:

```
obj      = nb_ts([2;3;4],'', '2012', {'Var1'});
obj(1:3,1) = [1;2;3]
obj =
    'Time'    'Var1'
    '2012'    [ 1]
    '2013'    [ 2]
    '2014'    [ 3]
```

Written by Kenneth S. Paulsen

► subsref ↑

```
varargout = subsref(obj,s)
```

Description:

Makes it possible to do subscripted reference of the data of an object. See the examples for more.

Using the method window, just using indexing instead.

Input:

- obj : An object of class nb_ts.
- s : A structure on how to index the object.

Output:

- obj : The indexed object.

Examples:

```
obj = obj(1,2:4,1)
```

same as

```
obj = obj(1,2:4)
```

Be aware that that obj(1,:) and obj(1,2:end) will also work

```
obj = obj('1994Q1')
```

same as

```

obj.window('1994Q1','1994Q1')

obj = obj('1994Q1','1994Q4')

same as

obj.window('1994Q1','1994Q4')

obj = obj('1994Q1','1994Q4',{'Var1','Var2',...})

same as

obj.window('1994Q1','1994Q4',{'Var1','Var2',...})

obj = obj('1994Q1','1994Q4',{'Var1','Var2',...},1:2)

same as

obj.window('1994Q1','1994Q4',{'Var1','Var2',...},1:2)

obj = obj('Var1','Var2',...)

same as

obj.window('','','',{'Var1','Var2',...},1:obj.numberOfDatasets)

```

Written by Kenneth S. Paulsen

► sum ↑

```
obj = sum(obj,dim)
```

Description:

Takes the sum of the object timeseries

Caution : All sums ignore nan values. If not all values is nan.

Input:

- obj : An object of class nb_ts
- dim : The dimension to sum over, returns:
 - > dim = 1: Either :
 - > An nb_ts object with all the elements of each variable set to their sum over the time horizon.

```

> An nb_cs with one type representing the sum
over the time horizon). The type is named
'sum'.

> dim = 2: An nb_ts object with one variable representing
the sum (Take the sum over the variables)
(Default)

> dim = 3: An nb_ts object with only on page, representing
the sum over all pages.

- output : Either 'nb_ts' (default) or 'nb_cs'. Only important
when summing over the 1 dimension.

```

Output:

- obj : Either an nb_ts object or an nb_cs object representing
the sum.

Examples:

```

obj      = nb_ts([2,1;3,2;4,3],'', '2012', {'Var1','var2'})
obj =
    'Time'      'Var1'      'var2'
    '2012'      [ 2]      [ 1]
    '2013'      [ 3]      [ 2]
    '2014'      [ 4]      [ 3]

s1 = sum(obj,1,'nb_ts')

s1 =
    'Time'      'Var1'      'var2'
    '2012'      [ 9]      [ 6]
    '2013'      [ 9]      [ 6]
    '2014'      [ 9]      [ 6]

s1_cs = sum(obj,1,'nb_cs')

s1_cs =
    'Types'      'Var1'      'var2'
    'sum'        [ 9]      [ 6]

s2 = sum(obj,2)

s2 =
    'Time'      'sum'
    '2012'      [ 3]
    '2013'      [ 5]
    '2014'      [ 7]

s2 = sum(obj,3)

s2 =

```

```
'Time'      'Var1'      'var2'  
'2012'      [    2]      [    1]  
'2013'      [    3]      [    2]  
'2014'      [    4]      [    3]
```

Written by Kenneth S. Paulsen

► **sumOAF** ↑

```
obj = sumOAF(obj,sumFreq)
```

Description:

Take the sum over a lower frequency.

I.e. if frequency is quartely, this function can sum over all the quarters of a year. And it will return the sum over the year in all quarters of the that year

Input:

- obj : An object of class nb_ts
- sumFreq : The frequency to sum over

Output:

- obj : An object of class nb_ts where the data is summed over a lower frequency

Examples:

```
obj = nb_ts.ones('2012Q1',8,1);  
obj = obj.sumOAF(1)
```

Written by Kenneth S. Paulsen

► **summary** ↑

```
obj = summary(obj)
```

Description:

Summary of the timesseries of the nb_ts object

Input:

- obj : An object of class nb_ts

Output:

- obj : The summary statistics - min, max, std, var, skewness and kurtosis, as a nb_cs object

Written by Kenneth S. Paulsen

► **tail** ↑

`tail(obj,nRows,page)`

Description:

Display the last n rows of a nb_ts object.

Input:

- obj : An nb_ts object.
- nRows : An integer with the number of rows to display. Defaults to 6.
- page : An integer with what page to display. Defaults to 1.

See also:

[nb_ts](#), [window](#), [head](#)

Written by Per Bjarne Bye

► **tan** ↑

`obj = tan(obj)`

Description:

Take the tangent of the data stored in the nb_ts, nb_cs or nb_data object

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
obj = tan(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **tand** ↑

```
obj = tand(obj)
```

Description:

tand(obj) is the tangent of the elements of obj, expressed in degrees.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = tand(in);
```

Written by Andreas Haga Raavand

Inherited from superclass NB_DATASOURCE

► **tanh** ↑

```
obj = tanh(obj)
```

Description:

tanh(obj) is the hyperbolic tangent of the elements of obj.

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An object of class nb_ts, nb_cs or nb_data

Examples:

```
out = tanh(in);  
  
Written by Andreas Haga Raavand  
  
Inherited from superclass NB_DATASOURCE
```

► **times** ↑

```
obj = times(obj,DB)
```

Description:

Element-wise multiplication (.*)

Caution : Will only multiply the data of corresponding variables of the two objects. I.e. variable not found to be in both object will result in timeseries with all nan values.

Input:

- obj : An object of class nb_ts
- DB : An object of class nb_ts

Output:

- obj : An nb_ts object the data results from element-wise multiplication of the data of the input objects.

Examples:

```
obj = obj.*DB;
```

See also:

[nb_ts.mtimes](#), [nb_ts.callop](#), [nb_ts.callfun](#)

Written by Kenneth S. Paulsen

► **timesCS** ↑

```
obj = timesCS(obj,DB)
```

Description:

Element-wise multiplication (.*) between a nb_ts and nb_cs object.

Caution : Will multiply the data of variables in obj that match does one variable in DB. The variable that does not match are not changed. The variables found in DB, but not in obj are ignored. No warning will be given if no matches are found.

Two cases:

> obj has as many pages as DB, and the number of pages are > 1, then the multiplication will be done page by page. DB can only have one type (row) in this case.

> DB has only one page, but has more than one type (row). Then obj must either have one page or as many pages as there are types of DB. If obj has one page th multiplication will be done for each type (row) of DB. The output will have as many pages as there are types of the DB input. If obj has the same number of types as DB, then each page of obj will be multiplied with the matching type of DB, i.e. page one is multiplied by type one and so on.

Input:

- obj : An object of class nb_ts.
- DB : An object of class nb_cs, can only have one type.

Output:

- obj : A nb_ts object the data results from element-wise multiplication of the data of the input objects.

Examples:

obj = obj.*DB;

See also:

[nb_ts.times](#)

Written by Kenneth S. Paulsen

► **toMFile ↑**

```
string = toMFile(obj)
toMFile(obj,filename)
string = toMFile(obj,filename,varName)
```

Description:

Write a .m file to generate the current object.

Input:

- obj : An nb_ts object.
- filename : The filename to write the code to. If empty no file will be written.
- varName : Name of decleared variable by this code. Default is data.

Output:

- string : A cellstr with the .m code to generate the current object.

Written by Kenneth Sæterhagen Paulsen

► **toRise_ts ↑**

```
data_ts = toRise_ts(obj)
data_ts = toRise_ts(obj,'struct')
```

Description:

Transform from an nb_ts object to an RISE ts object, or a struct of rise ts object representing each variable (Where the pages are added as dimension 2. I.e. the input to the data property of the rise_generic object).

Input:

- obj : An object of class nb_ts
- type : Either 'struct' or 'object'.

Output:

- data_ts : An object of class ts or a struct of ts objects

Examples:

```
ts = obj.toRise_ts();
```

Written by Kenneth S. Paulsen

► **toStructure ↑**

```
retStruct = toStructure(obj)
retStruct = toStructure(obj,old)
```

Description:

Transform an nb_ts obj to a structure

Input:

- obj : An object of class nb_ts
- old : Indicate if old mat file format is wanted. Default is 0 (false).

Output:

- retStruct : A structure with fieldsnames given by the object variables and field given by the variables data. (Can have more than one page). And a own field with the start date of the data. (As a string.)

Examples:

```
obj = nb_ts(ones(8,1),'', '2012Q1', {'Var1'});  
s = obj.toStructure()  
  
s =  
  
    Var1: [8x1 double]  
variables: {'Var1'}  
startDate: '2012Q1'  
    class: 'nb_ts'  
  userData: ''  
localVariables: []  
      sorted: 1
```

Written by Kenneth S. Paulsen

► **toTseries ↑**

tseries_DB = toTseries(obj)

Description:

Transform from an nb_ts object to an tseries object

To use this function you need to add the IRIS package to the MATLAB path.

Input:

- obj : An nb_ts object

Output:

- tseries_DB : An tseries object

Examples:

```
tseries_DB = obj.toTseries();
```

Written by Kenneth S. Paulsen

► **todyn_ts** ↑

```
dyn_ts_DB = todyn_ts(obj)
```

Description:

Transform from an nb_ts object to an dyn_ts object

Input:

- obj : An object of class nb_ts

Output:

- dyn_ts_DB : An object of class dyn_ts

Examples:

```
dyn_ts_DB = obj.todyn_ts();
```

Written by Kenneth S. Paulsen

► **tonb_cell** ↑

```
nb_cell_DB = tonb_cell(obj,dateFormat)
```

Description:

Transform from a nb_ts object to a nb_cell object

Input:

- obj : An object of class nb_ts
- dateFormat : The date format of the dates of the return nb_cell object.
 - > 'default' (default)
 - > 'fame'
 - > 'NBEnglish' or 'NBEngelsk'
 - > 'NBNorsk' or 'NBNorwegian'
 - > 'xls'
- strip : - 'on' : Strip all observation dates where all the variables has no value.
- 'off' : Does not strip all observation dates where all the variables has no value. Default.

Output:

- nb_cell_DB : An object of class nb_cell

Examples:

```
nb_cell_DB = obj.tonb_cell();
```

Written by Kenneth S. Paulsen

► **tonb_cs ↑**

```
nb_cs_DB = tonb_cs(obj,dateFormat)
```

Description:

Transform from an nb_ts object to an nb_cs object

Input:

- obj : An object of class nb_ts
- dateFormat : The date format of the dates of the return nb_cs object.
 - > 'default' (default)
 - > 'fame'
 - > 'NBEnglish' or 'NBEngelsk'
 - > 'NBNorsk' or 'NBNorwegian'
 - > 'xls'
- strip : - 'on' : Strip all observation dates where all the variables has no value.
- 'off' : Does not strip all observation dates where all the variables has no value. Default.

Output:

- nb_cs_DB : An object of class nb_cs

Examples:

```
nb_cs_DB = obj.tonb_cs();
```

Written by Kenneth S. Paulsen

► **tonb_data** ↑

```
nb_data_DB = tonb_data(obj)
nb_data_DB = tonb_data(obj,start)
```

Description:

Transform from a nb_ts object to a nb_data object. The startObs will automatically be set to 1, if not the start input is provided.

Input:

- obj : An object of class nb_ts
- start : Start observation.

Output:

- nb_data_DB : An object of class nb_data

Examples:

```
nb_data_DB = obj.tonb_data();
```

Written by Kenneth S. Paulsen

► **uminus** ↑

```
obj = uminus(obj)
```

Description:

Unary minus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : A nb_ts, nb_cs or nb_data object where all the data are the unary minus of the input objects data

Examples:

```
obj = -obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► undiff ↑

```
obj = undiff(obj,initialValues,periods)
```

Description:

Construct indicies based on initial values and timeseries which represent the series diff. Inverse of the diff method.

Input:

- obj : An object of class nb_ts
- initialValues : A nb_ts object with a bigger window than obj, or a scalar or a double with the initial values of the indicies. Must be of the same size as the number of variables of the nb_ts object. If not provided 100 is default.

Caution : If periods > 1 the initialValues input must be given, and has at least have periods number of rows.
- periods : The number of periods the initial series has been taken diff over.

Output:

- Output : An nb_ts object with the indicies.

Examples:

```
obj = undiff(obj);
obj = undiff(obj,100);
obj = undiff(obj,[78,89]);
```

See also
nb_ts.diff

Written by Kenneth S. Paulsen

► **unstruct** ↑

```
obj = nb_ts.unstruct(s)
```

Description:

Reverse of the struct method.

Input:

- s : See the s output of the struct method.

Output:

- obj : An nb_ts object.

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj,warningOff,inGUI)
```

Description:

This method will try to update the data of the nb_ts object.

Caution : It is only possible to update an nb_dataSource object which has updateable links to a FAME database or a full directory (path) to an excel spreadsheet or .mat file or the SMART database.

Caution : If you want to create a link to a specific worksheet of a excel file you must provide the extension!

Caution : All method calls done on the object are preserved.
(There exist some exception; and, or etc.)

Input:

- obj : An object of class nb_dataSource which are updatable.

- warningOff : 'on' or 'off'. If 'on' only warnings are given while the data source is updated, else an error will be given. Default is 'on'.

- inGUI : 'on' or 'off'. Indicate if the update command is called in the GUI or not. Default is 'off'.

Output:

- obj : An object of class nb_dataSource with the data updated. If it is not possible a warning will be given.

Examples:

```
obj = nb_ts(['N:\Matlab\Utvikling\MATLAB_LIB\NEMO\'...
             'Documentation\Examples\example_ts_quarterly']);
obj = obj.update
```

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_DATASOURCE

► **uplus** ↑

```
obj = uplus(obj)
```

Description:

Unary plus

Input:

- obj : An object of class nb_ts, nb_cs or nb_data

Output:

- obj : An nb_ts, nb_cs or nb_data object where all the data are the unary plus of the input objects data

Examples:

```
obj = +obj;
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_DATASOURCE

► **var** ↑

```
obj = var(obj,outputType,dimension,varargin)
```

Description:

Calculate the var of each timeseries. The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their var.

The output can also be set to be a double or a nb_cs object consisting of the var values of the data.

Input:

- obj : An object of class nb_ts
- outputType :
 - > 'nb_ts' : The result will be an object of class nb_ts where all the non-nan values of all the timeseries are being set to their var.
 - > 'double' : Get the var values as doubles, where each column of the double matches the variable location in the 'variables' property. If the object consists of more pages the double will also consist of more pages.
 - > 'nb_cs' : Get the var values as nb_cs object. The variance will when this option is used only be calculated over the number of observations. (I.e. dimension set to 1.)
- dimension : The dimension to calculate the var over.

Optional input:

- 'notHandleNaN' : Give this to not handle nan values.

Output:

- obj : See the input outputType for more one the output from this method

Examples:

```
nb_tsObj = var(obj);
double   = var(obj,'double');
nb_csObj = var(obj,'nb_cs');
```

Written by Kenneth S. Paulsen

► vertcat ↑

```
obj = vertcat(a,b,varargin)
```

Description:

Vertical concatenation ([a;b])

Input:

- a : An object of class nb_ts
- b : An object of class nb_ts
- varargin : Optional numbers of objects of class nb_ts

Output:

- a : An nb_ts object where the data from the different objects are appended to each other.

Examples:

```
obj = nb_ts(ones(2,1),'', '2012Q1', {'Var1'});  
aObj = nb_ts(ones(2,1),'', '2012Q3', {'Var1'});  
m = [obj;aObj]
```

m =

```
'Time'      'Var1'  
'2012Q1'    [ 1]  
'2012Q2'    [ 1]  
'2012Q3'    [ 1]  
'2012Q4'    [ 1]
```

Written by Kenneth S. Paulsen

► whiten ↑

```
F = whiten(obj)  
F = whiten(obj,r)
```

Description:

Calculate of factors from X that have variance one and covariances 0.

Input:

- obj : An object of class nb_ts with size nObs x nVar x nPage.
- r : The number of principal component. If empty nVar factors are returned.

Output:

- F : The principal component, as a nb_ts object.

Example:

```
load hald;  
ingredients = nb_ts(ingredients,'',1,{'tricalcium_aluminate',...  
                                'tricalcium_silicate',...  
                                'tetracalcium_aluminoferrite',...  
                                'beta_dicalcium_silicate'});  
F = whiten(ingredients)
```

See also:

[nb_whiten](#), [nb_ts.pca](#)

► **window** ↑

```
obj = window(obj,startDateWin,endDateWin,variablesWin,pages)
```

Description:

Narrow down window of the data of the nb_ts object

Input:

- obj : An object of class nb_ts
- startDateWin : The new wanted start date of the data of the object. Must be a string on the format; 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the start date of the data.
Can also be an object which is a subclass of the nb_date class.
- endDateWin : The new wanted end date of the data of the object. Must be a string on the format. 'yyyyQq', 'yyyyMmm' or 'yyyy'. If empty, i.e. '', nothing is done to the end date of the data.
Can also be an object which is a subclass of the nb_date class.
- variablesWin : A cellstr array of the variables you want to keep of the given object. If empty all the variables is kept.
- pages : A numerical index of the pages you want to keep. E.g. if you want to keep the first 3 datasets (pages of the data) of the object. And the number of datasets of the object is larger than 3. You can use; 1:3. If empty all pages is kept.
I.e. obj = obj.window('',{},1:3)

Output:

- obj : An nb_ts object where the datasets of the object is narrowed down to the specified window.

Examples:

```
obj = nb_ts(ones(10,2,2),'', '2012Q1', {'Var1','Var2'});  
obj = obj.window('2012Q2')
```

```
obj = obj.window('','2013Q4')
obj = obj.window('','','',{'Var1'})
obj = obj.window('','','{}',1)
```

See also:

Written by Kenneth S. Paulsen

► **writeTex** ↑

```
writeTex(obj,filename)
writeTex(obj,filename,'inputName', inputValue,...)
```

Description:

Writes the object data to a LaTeX table saved to a .tex file.

If the object consists of more pages (datasets) more tables will be created.

Input:

- obj : An object of class nb_ts
- filename : The name of the saved .tex file. With or without the extension.

Optional input:

See optional inputs to nb_ts.getCode.

Output:

A saved .tex file with the LaTeX table

Examples:

```
obj = nb_ts(rand(10,3),'','2012Q1',{'Var1','Var2','Var3'});
obj.writeTex('test')
```

See also:

► **x12Census** ↑

```
obj = x12Census(obj)
[obj,x,outputfile,errorfile,model] = x12Census(obj)
[obj,x,outputfile,errorfile,model] = x12Census(obj,varargin)
```

Description:

Do x12 Census adjustement to an nb_ts object using x12awin.exe.

This is a file copied from the IRIS Toolbox an adapted to the NB Toolbox. (I.e. using nb_ts instead of tseries)

x12awin.exe is a program developed by:

U. S. Department of Commerce, U. S. Census Bureau

X-12-ARIMA quarterly seasonal adjustment Method,
Release Version 0.3 Build 192

This method modifies the X-11 variant of Census Method II
by J. Shiskin A.H. Young and J.C. Musgrave of February, 1967.
and the X-11-ARIMA program based on the methodological research
developed by Estela Bee Dagum, Chief of the Seasonal Adjustment
and Time Series Staff of Statistics Canada, September, 1979.

This version of X-12-ARIMA includes an automatic ARIMA model
selection procedure based largely on the procedure of Gomez and
Maravall (1998) as implemented in TRAMO (1996).

Caution : The object must be of quarterly or monthly frequency!!

Input:

- obj : Input data that will seasonally adjusted or filtered
by the Census X12 Arima. Must be an nb_ts object.

Optional input (..., 'propertyName', PropertyValue, ...):

- 'backcast' : Run a backcast based on the fitted ARIMA model
for this number of periods back to improve on the
seasonal adjustment. The backcast is included
in the output argument x. Must be a scalar.

- 'log' : Logarithmise the input data before, and
de-logarithmise the output data back after,
running x12. {1} | 0

- 'forecast' : Run a forecast based on the fitted ARIMA model
for this number of periods ahead to improve on
the seasonal adjustment. The forecast is included
in the output argument x. Must be a scalar.

- 'display' : Display X12 output messages in command window.
{0} | 1. Default is not.

- 'dummy' : Dummy variable or variables (in case of a
multivariate nb_ts object) used in X12-ARIMA
regression; the dummy variables can also include
values for forecasts and backcasts if you request

them. Either an nb_ts object or empty.

- 'dummyType' : Type of dummy. Either 'ao' | {'holiday'} | 'td'
- 'mode' : Seasonal adjustment mode. 'auto' means that series with only positive or only negative numbers will be adjusted in the 'mult' (multiplicative) mode, while series with combined positive and negative numbers in the 'add' (additive) mode. {'auto'} | 'add' | 'logadd' | 'mult' | 'pseudoadd' | 'sign'
- 'maxIter' : Maximum number of iterations for the X12 estimation procedure. Must be numeric. Default is 1500.
- 'maxOrder' : A 1-by-2 vector with maximum order for the regular ARMA model (can be 1, 2, 3, or 4) and maximum order for the seasonal ARMA model (can be 1 or 2). Must be numeric. Default is [1,2].
- 'missing' : Allow for in-sample missing observations, and fill in values predicted by an estimated ARIMA process; if false, the seasonal adjustment will not run and a warning will be thrown. 1 | {0}.
- 'output' : Requested output data, as a string. Either:
 - 'irregular' : For the irregular component,
 - 'seasadj' : For the final seasonally adjusted series. Default.
 - 'seasonal' : For seasonal factors.
 - 'trendcycle' : For the trend-cycle.
 - 'missingvaladj' : For the original series with missing observations replaced with ARIMA estimates.
- 'specFile' : Name of the X12-ARIMA spec file. Must be a char. Default is 'default'.
- 'tdays' : Correct for the number of trading days. 1 | {0}
- 'tolerance' : Convergence tolerance for the X12 estimation procedure. Must be numeric. Default is 1e-5.
- 'startDate' : Start date of seasonally adjustment.
- 'endDate' : End date of seasonally adjustment.

Output:

- obj : An nb_ts object with the seasonally/trend adjusted/component of all the stored series of the object.

- **x** : The original object with the backcast and forecast appended.

Caution : If the object is link to a data source this object will still not be updateable.

- **outputfile** : A cellstr array with the output files from the seasonal/trend adjustment.
- **errorfile** : A cellstr array with error files from the seasonal/trend adjustment.
- **mdl** : A struct with ARIMA model estimates.

Written by Kenneth SÃ¶terhagen Paulsen

► **zeros** ↑

```
obj = nb_ts.zeros()
obj = nb_ts.zeros(start,obs,vars,pages,sorted)
```

Description:

Create a nb_ts object with all data set to 0.

Input:

- **start** : The start date of the created nb_ts object.
- **obs** : The number of observation of the created nb_ts object.
- **vars** : Either a cellstr with the variables of the nb_ts object, or a scalar with the number of variables of the nb_ts object.
- **pages** : Number of pages of the nb_ts object.
- **sorted** : true or false. Default is true.

Output:

- **obj** : An nb_ts object.

Examples:

```
obj = nb_ts.zeros('1',10,{'Var1','Var2'});
obj = nb_ts.zeros('2012Q1',2,2);
obj = nb_ts.zeros('2012Q1',2,2,10);
```

See also:

[nb_ts](#)

◆ nb_cell2obj

```
data = nb_cell2obj(cellMatrix)
```

Description:

This is a function tries to transform an cell matrix to an nb_data, nb_ts or nb_cs object.

Input:

- cellMatrix : A cell matrix. Must have size(1) > 1 and size(2) > 1
- excel : true or false. Default is false.
- sorted : true or false. Default is false.

Formats:

- Timeseries :

```
{'dates',      'Var1', 'Var2';  
'30.06.2012', 3,    4;  
'30.09.2012', 5,    6}
```

- Cross sectional data :

```
{'types', 'Var1', 'Var2';  
'var',   1,     4;  
'std',   1,     2}
```

- Dimensionless (Indicated by having 'obs'/'observations' in the element {1,1} of the cell matrix)

```
{'obs',      'Var1', 'Var2';  
1,          1,     4;  
2,          1,     2}
```

- Business days / timeseries with missing observations (Indicated by having 'bd'/'businessdays'/'md'/'missingdates' in the element {1,1} of the cell matrix)

```
{'md',      'Var1', 'Var2';  
1,          1,     4;  
2,          1,     2}
```

- excel : If the cell comes from a excel spreadsheet, sometimes the data needs to be stripped.

Output:

- data : An object of class nb_data, nb_ts or nb_cs

See also:

◆ **[nb_checkPostFix](#)**

message = nb_checkPostFix(postfix)

Description:

Check the postfix for unsupported chars

Written by Kenneth Sætherhagen Paulsen

◆ **[nb_checkPreFix](#)**

message = nb_checkPreFix(postfix)

Description:

Check the prefix for unsupported chars

Written by Kenneth Sætherhagen Paulsen

◆ **[nb_covidDates](#)**

[dates,drop] = nb_covidDates(freq)

Description:

Get the dates of the covid episode.

Input:

- freq : The frequency of the covid episodes.

Output:

- dates : A 1 x nDates nb_date array.

- drop : Number of dummies set to all 0, i.e. the X number of dummies at the end.

See also:

[nb_ts.covidDummy](#), [nb_covidDummyNames](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_covidDummyNames**

```
names = nb_covidDummyNames(freq)
names = nb_covidDummyNames(freq, covidDummyDates)
```

Description:

The dummy names for the covid-19 episode.

Input:

- freq : The frequency of the covid dummy.
- covidDummyDates : A cellstr with the dates of the covid-19 crisis.
Default is the period 16.03.2020 – 31.12.2021.
Hint: Use nb_month(3,2020):nb_month(12,2021).

Output:

- names : A cellstr with the names of the covid dummies.

See also:

[nb_ts.covidDummy](#), [nb_covidDates](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_createDefaultLink**

```
newLink = nb_createDefaultLink()
```

Description:

Creates a default link (i.e. empty) used by the nb_ts and nb_cs classes

Output:

- newLink : A structure with all the fields of an link.

See also:

[nb_ts](#), [nb_cs](#), [nb_data](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_deleteDefaultWorksheets

```
nb_deleteDefaultWorksheets(filename)
```

Description:

Delete the 'Sheet1','Sheet2','Sheet3' worksheets of an excel spreadsheet

Input:

- filename : The excel filename, as a string.

Written by Kenneth Sæterhagen Paulsen

◆ nb_eval

```
out = nb_eval(expression,variables,data)
out = nb_eval(expression,variables,data,macro)
```

Description:

Evaluate a expression as a string.

Input:

- expression : A string with the expression to evaluate. E.g.
 'lag(exp(Var1/(Var2^1^3))*4,1)*Var4 + Var1*(exp(Var1/2))'
- variables : The variables of the dataset. As a cellstr with size
 1 x nvars.
- data : The dataset. A double or a nb_math_ts object with the
 data of the variables. Must have size nobs x nvars.
- macro : Set to true to also handle the NB Toolbox macro processing
 language as well. Default is false.

Output:

- out : The result of the evaluation of the string

[nb_data.createVariable](#), [eval](#)

Written by Kenneth Sæterhagen Paulsen

◆ nb_excelCellOffset

```
xlcell = nb_excelCellOffset(base,x,y)
```

Description:

Get the excel cell index the number of increments up/down and to the left/right of the cell given by start.

Input:

- base : A string with the base cell. E.g. 'A1'
- x : A number of increments up (negative), or down (positive).
- y : A number of increments to the left (negative), or to the right (positive).

Output:

- xlcell : A string on the format 'A1'.

See also:

[nb_excelRange](#), [nb_letter2num](#), [nb_num2letter](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_excelRange**

```
range = nb_excelRange(base,r,c,br,bc)
```

Description:

Get excel range from a base cell on the format 'A1' and different combinations of offsets.

Input:

- base : A String on the format 'A1', 'ZZ123' or 'A1:B1'.
- If nargin == 2:
 - r : The range will be returned from the base with this number of row offsets. As a strictly positiv scalar integer.
 - c : The range will be returned from the base with this number of column offsets. As a strictly positiv scalar integer.
- If nargin == 4:
 - r : The range will be returned from the base with this number of row offsets. As a strictly positive scalar integer. 1 imply no movement.

- c : The range will be returned from the base with this number of column offsets. As a strictly positive scalar integer. 1 imply no movement.
- br : First move the base these number of rows. As a scalar integer. 0 imply no movement.
- bc : First move the base these number of columns. As a scalar integer. 0 imply no movement.

Output:

- range : A excel range on the format 'A1:C2' or 'B1:C2'.

Examples:

```
nb_excelRange('A1',2,2)
nb_excelRange('A1',2,2,1,1)
```

See also:

◆ nb_findIndex

```
index = nb_findIndex(cellstr1,cellstr2)
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_input2String

```
string = nb_input2String(anyObject)
```

Description:

Converts a input into a string. This function is used by the method `getMethodCalls` of the classes `nb_ts`, `nb_cs` and `nb_data`.

Caution : Some inputs that are classified as not editable will be returned as a string, i.e. 'Not editable'.

Input:

- anyObject : Any type of object

Output:

- string : A string

Written by Kenneth Sæterhagen Paulsen

◆ nb_isQorM

```
[ind,frequency] = nb_isQorM(date)
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_letter2num

```
num = nb_letter2num(letter)
```

Description:

Convert from 'A', 'AA', 'AZZ' to a number. The letter must be in the set ['A', 'Z'].

Input:

- letter : A one line char with length from 1-3.

Output:

- num : A number representing the letter combination.

Examples:

```
num1 = nb_letter2num('A')
num2 = nb_letter2num('Z')
num3 = nb_letter2num('AA')
num4 = nb_letter2num('AZ')
num5 = nb_letter2num('BA')
num6 = nb_letter2num('AZZ')
num7 = nb_letter2num('BAA')
num8 = nb_letter2num('ZZZ')
```

◆ nb_lookUpVariables

```
[vars,numberOfLines] = nb_lookUpVariables(variables,lookUpMatrix,language,numberOfLinesOutput)
```

Written by Kenneth Sæterhagen Paulsen

◆ nb_mergeSources

```
[sources,vintages,variables ] = ...
    nb_mergeSources(dbNames,vintages,variables)
```

Description:

A function to avoid duplicate sources in a dataset.

Input:

- dbNames : The names of the databases of the object.
- vintages : The vintages of the different variables of the object.
- variables : The variablenames of the object.

Output:

- sources : The databases, without duplicates
- vintages : The vintages returned without duplicates
- variables : The variables of the object with correct sources.

See also:

[nb_ts.merge](#)

Original code by Kenneth Sætherhagen Paulsen, tweaks by Eyo I. Herstad

◆ **nb_num2letter**

```
letter = nb_num2letter(num)
```

Description:

Convert a number to a letter. Must be a postive integer in [1,18278].

Input:

- num : A number representing the letter combination.

Output:

- letter : A one line char with length from 1-3.

Examples:

```
11 = nb_num2letter(nb_letter2num('A'))
12 = nb_num2letter(nb_letter2num('Z'))
13 = nb_num2letter(nb_letter2num('AA'))
14 = nb_num2letter(nb_letter2num('AZ'))
15 = nb_num2letter(nb_letter2num('BA'))
16 = nb_num2letter(nb_letter2num('AZZ'))
17 = nb_num2letter(nb_letter2num('BAA'))
18 = nb_num2letter(nb_letter2num('ZZZ'))

◆ **nb_readExcel**

```
data = nb_readExcel(filename)
data = nb_readExcel(filename,sheet)
data = nb_readExcel(filename,sheet,range)
data = nb_readExcel(filename,sheet,range,transpose)
data = nb_readExcel(filename,sheet,range,transpose,sorted)
```

Description:

This is a function for reading an excel spreadsheet and return, a nb_data object (dimensionless data), a nb_ts object (timeseries data) or a nb_cs object (cross sectional data).

Input:

- filename : A string with the filename of the excel spreadsheet.
If full path is given the data will be updateable.
- sheet : A string with the sheet name you want to read.
- range : A cell with the range of the dates/types/obs,
variables and data. (1 x 3 cell array).
E.g. {'A2:A5','B1:C1','B2:C5'}
- transpose : 1 (true) or 0 (false). Default is 0.
- sorted : 1 (true) or 0 (false). Default is 1.
- c : A cell with already read data from excel

Formats:

- Dimensionless:

obs	Var1	Var2
1	3	4
2	5	6

Caution : obs in the cell A1:A1 is required!!!

Caution : Nothing else could be included in the worksheet as
long as the range is not specified!!

- Timeseries :

dates	Var1	Var2
30.06.2012	3	4
30.09.2012	5	6

```
Caution : Nothing else could be included in the worksheet as
long as the range is not specified!!
```

- Cross sectional data :

```
types Var1  Var2
var      1      4
std      1      2
```

```
Caution : Nothing else could be included in the worksheet as
long as the range is not specified!!
```

Output:

- data : An object of class nb_data, nb_ts or nb_cs

See also:

[nb_data](#), [nb_ts](#), [nb_cs](#)

Written by Kenneth S. Paulsen

◆ **nb_readExcelMorePages**

```
data = nb_readExcelMorePages(filename)
data = nb_readExcelMorePages(filename, sorted, sheets)
```

Description:

This is a function for reading each sheet of an excel spreadsheet and return, a nb_data object (dimensionless data), a nb_ts object (timeseries data) or a nb_cs object (cross sectional data).

This function can then be utilized to read real-time or panel data from excel spreadsheets.

If you want to read the data as real-time, each sheet must be given the name of the end date of that vintage series. The format of the date must be supported by NB toolbox. Each vintage must give rise to one new observation (and only one!).

Input:

- filename : A string with the filename of the excel spreadsheet.
If full path is given the data will be updateable.
- sorted : 1 (true) or 0 (false). Default is 1.
- sheets : A cellstr with the sheet names you want to read. Default is all.

Formats (of each sheet):

- Dimensionless:

```
obs      Var1 Var2
1        3     4
2        5     6
```

Caution : obs in the cell A1:A1 is required!!!

Caution : Nothing else could be included in the worksheet as long as the range is not specified!!

- Timeseries :

```
dates      Var1 Var2
30.06.2012    3     4
30.09.2012    5     6
```

Caution : Nothing else could be included in the worksheet as long as the range is not specified!!

- Cross sectional data :

```
types Var1  Var2
var      1     4
std      1     2
```

Caution : Nothing else could be included in the worksheet as long as the range is not specified!!

Output:

- data : An object of class nb_data, nb_ts or nb_cs, where each sheet is added as a separate dataset (page). The sheetnames will appear in the dataNames property of the output.

See also:

[nb_data](#), [nb_ts](#), [nb_cs](#)

Written by Kenneth S. Paulsen

◆ **nb_readExcelMoreSheets**

```
data = nb_readExcelMoreSheets(filename)
```

Description:

Read all the sheets of an excel file given by the input filename and return it as an object of class nb_DataCollection.

Input:

- filename : A string with the filename of the excel spreadsheet.

Output:

- data : An nb_DataCollection object. (Much like an spreadsheet in excel, with each worksheets given as an nb_ts object or an nb_cs objects.)

Format of the worksheets of the excel spreadsheet:

- Timeseries :

dates	Var1	Var2
30.06.2012	3	4
30.09.2012	5	6

Caution : Nothing else could be included in the page!!

- Cross sectional data :

types	Var1	Var2
var	1	4
std	1	2

Caution : Nothing else could be included in the page!!

Output:

- data : An object of class nb_DataCollection

See also:

[nb_DataCollection](#), [nb_ts](#), [nb_cs](#), [nb_readExcel](#)

Written by Kenneth S. Paulsen

◆ **nb_readMat**

data = nb_readMat(filename,sorted)

Description:

This is a function for reading a mat file, and checks if the stored information in that file can be converted to either a nb_data, nb_ts, nb_cs or nb_modelDataSource object

Input:

- filename : A string with the filename of the .mat file.

Formats:

See `nb_data.toStructure`, `nb_ts.toStructure`, `nb_cs.toStructure`,
`nb_data.struct`, `nb_ts.struct` or `nb_cs.struct`

Output:

- data : An object of class nb_data, nb_ts, nb_cs or nb_modelDataSource.

See also:

[nb_ts](#), [nb_cs](#), [nb_data](#), [nb_modelDataSource](#)

Written by Kenneth S. Paulsen

◆ **nb_struct2nb.DataSource**

obj = nb_struct2nb.DataSource(s)

Description:

Convert a struct with nb.DataSource objects as fields to an object of a subclass of the nb.DataSource class.

Input:

- s : A struct with nb.DataSource as fields.

Output:

- obj : A nb.DataSource object

Written by Kenneth Sætherhagen Paulsen

◆ **nb_validpath**

[found,filePath,ext] = nb_validpath(filename,mode)

Description:

Identify if the excel file with name filename is a valid excel file.

Input:

- filename : Must be a string containing a partial path ending in a file or directory name. May contain \ or / or \\. Extension may or may not be included. Tested extensions are '.xls','.xlsx' or '.xlsm'.

- mode : Set to 'write' to prevent it looking for files on the matlab path to locate the path if no path is given. Default is ''.

Output:

```
- found      : true if found, otherwise false.  
- filePath  : A string with the full path of the file.  
- ext       : The file extension. Either '.xls','.xlsx' or '.xlsm'.
```

See also:

[nb_xlsread](#), [nb_xlswrite](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_xlsGetSheets**

```
[sheets,Excel] = nb_xlsGetSheets(file)
```

Description:

Get sheets of an excel file.

Input:

```
- file : Either a filename as a string or a  
        actxserver('Excel.Application') object, see nb_xlsread.
```

Output:

```
- sheets : A cellstr with the sheets of the selected excel file.  
- Excel  : A actxserver('Excel.Application') object.
```

See also:

[nb_xlsread](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_xlsNum2Column**

◆ **nb_xlsread**

```
c = nb_xlsread(filename)  
c = nb_xlsread(filename,sheet)  
c = nb_xlsread(filename,sheet,range)  
c = nb_xlsread(filename,sheet,range,transpose)  
c = nb_xlsread(filename,sheet,range,transpose,mode)  
[c,sheets,Excel] = nb_xlsread(filename,sheet,range,transpose,mode,Excel)
```

Description:

Read an excel file and return an cell matrix representing the selected worksheet.

Caution : xls files

Input:

- filename : The name of the excel file. If extension not provided, .xlsx is assumed.

- sheet : Name of the read sheet. If empty (default) the first sheet of the file is read.

- range : The range to read. Must be given as 'A1:B2', or a 1 x M cell of ranges. If it is given as a cell of ranges the output will also be a cell with the same size as range.

Caution: range must be empty for mode 'nb'.

- mode : > 'default' : Will read the excel sheet as is.

> 'nb' : If the range input is a cell with size 1 x 3 with the range of the dates/types/obs, variables and data.

E.g. {'A2:A5','B1:C1','B2:C5'}

The output will be a cell matrix instead of nested cell. Of course the dimensions of the range must match!

- Excel : Handle to the Excel application. Same as the Excel ouput. It is assumed that a excel file has been opened with this application!

Output:

- c : Either a cell matrix or a nested cell row. See range input.

- sheets : The sheets of the excel spreadsheet, as a cellstr.

- Excel : Handle to the Excel application used for reading the excel spreadsheet. The Excel application has the selected file open for reading!

Examples:

```
c = nb_xlsread('data.xlsx')
```

See also:

[xlsread](#)

Written by Kenneth Sæterhagen Paulsen

◆ **nb_xlswrite**

```
nb_xlswrite(filename,c,sheet)
```

Description:

Write data to excel spreadsheet.

Input:

- filename : Name of excel file to write to, as a string.
- c : Cell matrix to write to excel
- sheet : The name of the sheet to save the data to, as a string.
- del : Give true to delete default sheet names ('Sheet1','Sheet2','Sheet3'). Default is false.
Caution: This only works for files that are created with this function (for some reason).
- Excel : An Excel application object (actxserver('Excel.Application')). May be smart to only initialize once if writing data to an excel file in a loop!
Caution: It is assumed that the excel file has already been opened by the application for writing!

Examples:

```
nb_xlswrite('test.xlsx',num2cell(rand(3,3)))
```

■ nb_graph_adv

Go to: [Properties](#) | [Methods](#)

```
obj = nb_graph_adv(plotter,varargin)
```

Superclasses:

handle

Description:

This is a class for making graphs with figure titles and footers.
(MPR styled graphs)

Objects of this class can be given to an object of class
nb_graph_package to create a graph package.

Constructor:

```
obj = nb_graph_adv(plotter,varargin)
```

Input:

- plotter : An object of class nb_graph.
- varargin : 'propertyName',PropertyValue,...

Output:

- obj : An object of class nb_graph_adv

Examples:

```
data      = nb_ts('test');
plotter  = nb_graph_ts(data);
advPlotter = nb_graph_adv(plotter,'figureTitleNor',...
                         'A title','footerNor','A footer');
```

or

```
advPlotter = nb_graph_adv(plotter,'figureTitleNor',...
                           char('A title','A new line'),...
                           'footerNor',...
                           char('A footer','A new line'));
```

or

```
advPlotter = nb_graph_adv(plotter,'figureTitleNor',...
                           {'A title','A new line'},...
                           'footerNor',...
                           {'A footer','A new line'});
```

nb_graph_package

Written by Kenneth Sæterhagen Paulsen

Properties:

- a4Portrait
- chapter
- counter
- defaultFigureNumbering
- excelFooterEng
- excelFooterNor
- figureNameEng
- figureNameNor
- figureTitleAlignment
- figureTitleFontSize
- figureTitleInterpreter
- figureTitlePlacement
- figureTitleWrapping
- flip
- fontName
- fontUnits
- footerAlignment
- footerEng
- footerFontSize
- footerFontWeight
- footerInterpreter
- footerNor
- footerPlacement
- footerWrapping
- forecastDate
- forecastTypes
- jump
- legendsEng
- letter
- letterRestart
- localVariables
- number
- plotter
- remove
- roundoff
- saveName
- tooltipEng
- tooltipNor
- tooltipWrapping
- userData

- a4Portrait ↑

Save PDF to A4 portrait format. 0 or 1

- chapter ↑

Overrun the chapter property of the nb_graph_package it is included in. Default is [], i.e. use the chapter of the nb_graph_package. Must be set to a number.

- counter ↑

Sets the figure counter to this number when included in a nb_graph_package object. Nice property to have if some graphs of the package is created with other tools. Must be a scalar.

- **defaultFigureNumbering** ↑

Set to true to add Figur 1 to the first line of figureTitleNor and Graph 1 to figureTitleEng.

- **excelFooterEng** ↑

Deprecated

- **excelFooterNor** ↑

Deprecated

- **figureNameEng** ↑

Sets the english name of the figure. This name will be used on the englsg index page of the excel spreadsheet.

- **figureNameNor** ↑

Sets the norwegian name of the figure. This name will be used on the norwegian index page of the excel spreadsheet.

- **figureTitleAlignment** ↑

Sets the alignment of the figure title. As a string. Either 'left', 'center' or 'right'. 'left' is default.

- **figureTitleEng** ↑

Sets the english figure title of the graph. Either a string ('A figure title'), char (char('A figure title', 'A new line')) or a cellstr ({'A figure title', 'A new line'})

6 lines of the figure title is supported.

- **figureTitleFontSize** ↑

Sets the figure title font size. 0.0511 is default.

- **figureTitleFontWeight** ↑

Sets the figure title font weight. Must be a string. Either 'bold', 'light', 'normal' or 'demi'. 'normal' is default

- **figureTitleInterpreter** ↑

Sets the interpreter of the figure title text. Must be a string. Either 'latex' (mathematical expressions), 'tex' (Normal latex interpreter) or 'none' (No interpreter). Default is 'tex'.

- **figureTitleNor** ↑

Sets the norwegian figure title of the graph. Either a string ('A figure title'), char (char('A figure title', 'A new line')) or a cellstr ({'A figure title', 'A new line'})

6 lines of the figure title is supported.

- **figureTitlePlacement** ↑

Sets where to place the figure title in the x-axis direction, either 'center', 'leftaxes', 'right' or the default value 'left'.

- **figureTitleWrapping** ↑

Wrap text of figure title automatic. Default is false, i.e. no wrapping.

- **flip** ↑

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

- **fontName** ↑

Sets the font name used for the text of graph. As a string. Default is 'arial'.

- **fontUnits** ↑

Sets the font units of all the fonts of the graph. Either {'points'} | 'normalized' | 'inches' | 'centimeters'. Default is 'points'.

Caution : If you set the fontUnits property in a method call to the set method, all the font properties set before the fontUnits property will be set in the old fontUnits, while all the font properties set after will be in the new fontUnits.

Caution : When the legType is set to 'MATLAB' this property will not set the font units of the legend.

Caution : Don't use this property in combination with one of the graph styles defined by this class. I.e. 'mpr', 'mpr_white', 'presentation' and

'presentation_white' They will set this property to 'normalized'.

Caution : 'normalized' font units must be between 0 and 1.
The normalized units are not the same as the MATLAB
normalized units. This normalized units are not
only normalized to the axes size, but also across
resolution of the screen. (But only vertically)

- **footerAlignment** ↑

Sets the alignment of the footer. As a string. Either
'left', 'center' or 'right'. 'left' is default.

- **footerEng** ↑

Sets the english footer of the graph. Either a string
('A footer'), char (char('A footer','A new line')) or
a cellstr ({'A footer','A new line'})

6 lines of the footer is supported.

- **footerFontSize** ↑

Sets the footer font size. 0.0397 is default.

- **footerFontWeight** ↑

Sets the footer font weight. Must be a string. Either
'bold', 'light', 'normal' or 'demi'. 'normal' is default.

- **footerInterpreter** ↑

Sets the interpreter of the footer text. Must be a string.
Either 'latex' (mathematical expressions), 'tex' (Normal
latex interpreter) or 'none' (No interpreter). Default is
'tex'.

- **footerNor** ↑

Sets the norwegian footer of the graph. Either a string
('A footer'), char (char('A footer','A new line')) or a
cellstr ({'A footer','A new line'})

6 lines of the footer is supported.

- **footerPlacement** ↑

Sets where to place the footer in the x-axis direction,
either 'center', 'leftaxes', 'right' or the default
value 'left'.

- **footerWrapping** ↑

Wrap text of footer automatic. Default is false, i.e. no wrapping.

- **forecastDate** ↑

Sets from where to color the text of the excel output file as forecast. Either a string with the date ('2012Q1') or a cellstr ({'Var1','2012Q1','Var2','2012Q2'}).

- **forecastTypes** ↑

Sets from where to color the text of the excel output file as forecast. Either a cellstr with the types which is "forecast".

- **jump** ↑

Sets the number of graphs the counter should jump. As a scalar. Default is 1.

- **legendsEng** ↑

Sets the english legends of the produced graph. I.e. overrun the legends property of the given nb_graph_ts or nb_graph_cs object. Must be a cellstr. I.e. {'legend1','legend2'}

Caution : This will set the legAuto property of the nb_graph_ts or nb_graph_cs object to 'off'. I.e. You must also provided the legends for the patches and fake legends by this property. See the documentation of the nb_graph_ts or nb_graph_cs for more on the legAuto property.

- **letter** ↑

Give 1 if the graph should be "numbered" with a letter instead of an number. I.e. 'Figur 1.1a' or 'Chart 1.1a'. Default is 0 (Numbering the graph as 'Figur 1.1' or 'Chart 1.1')

- **letterRestart** ↑

Restart letter counting. {0} (false) | 1 (true).

- **localVariables** ↑

A handle to an nb_struct object storing the local variables

- **number** ↑

Sets the number of the graph. As a scalar. E.g. 'Figure 1' or 'Chart 1' if the number property is set to 1.

- **plotter** ↑

Sets the underlying graph object. Must be of class nb_graph_ts, nb_graph_cs, nb_graph_data, nb_table_ts, nb_table_cs nb_table_data or nb_table_cell.

- **remove** ↑

Sets the variables which can not be published. I.e. will not written to the excel output file. Must be a cellstr. E.g. {'Var1','Var2',...}.

- **roundoff** ↑

When included in a nb_graph_package object this property will overrun the nb_graph_package.roundoff property if not empty. Must be an integer greater or equal to 0, or empty (uses the property of the package). Default is empty.

- **saveName** ↑

Sets the savename of the saved output file. Mainly used by the nb_graph_package class. Must be a string.

- **tooltipEng** ↑

Text to be displayed as a tooltip with technical comments when reading electronic report. If empty, excel footer is used when writing text. English.

- **tooltipNor** ↑

Text to be displayed as a tooltip with technical comments when reading electronic report. If empty, excel footer is used when writing text. Norwegian.

- **tooltipWrapping** ↑

Boolean indicating whether to wrap the tooltip. Default is false.

- **userData** ↑

User data, can be set to anything you want.

Methods:

- | | | | |
|--|--------------------------------|-------------------------------|------------------------------|
| • addGraph | • getData | • graphEng | • graphNor |
| • helpAdvancedMenuCallback | • realTimespan | • removeGraph | • saveFigure |
| • set | • setSpecial | • timespan | • update |

► **addGraph** ↑

```
addGraph(obj,another)
```

Description:

Add another graph to a 1 x 2 panel.

Input:

- obj : A nb_graph_adv object.
- another : A nb_graph object.

Written by Kenneth Sæterhagen Paulsen

► **getData** ↑

```
data = getData(obj)
```

Description:

Get the data of the graph

Input:

- obj : An object of class nb_graph_adv

Output:

- data : As a nb_ts, nb_cs or nb_data object.

Example:

```
data = obj.getData();
```

Written by Kenneth S. Paulsen

► **graphEng** ↑

```
graphEng(obj)
```

Description:

Plot the graph (english version)

Input:

- obj : An object of class nb_graph_adv

Output:

The graph plotted on the screen (english version)

Examples:

```
obj.graphEng()
```

Written by Kenneth S. Paulsen

► **graphNor** ↑

```
graphNor(obj)
```

Description:

Plot the graph (norwegian)

Input:

- obj : An object of class nb_graph_adv

Output:

The graph plotted on the screen (norwegian version)

Examples:

```
obj.graphNor()
```

Written by Kenneth S. Paulsen

► **helpAdvancedMenuCallback** ↑

```
nb_graph_adv.helpAdvancedMenuCallback(uiHandle, event)
```

Description:

Part of DAG

Opens a nb_helpWindow with useful comments on the advanced graph menu.

Written by Per Bjarne Bye

► **realTimespan** ↑

```
dateString = realTimespan(obj)
```

Description:

Get the timespan of the data behind a graph which is not nan or infinite, as a string. On the PPR format.

Input :

- obj : An object of class nb_graph_ts

Output :

- dateString : A string with the timespan of the graph represented by this object. The language of this string will depend on the language of the language property of the plotter object.

Written by Kenneth S. Paulsen

► **removeGraph** ↑

```
removeGraph(obj)
```

Description:

Add another graph to a 1 x 2 panel.

Input:

- obj : A nb_graph_adv object.
- another : A nb_graph object.

Written by Kenneth SÃ!terhagen Paulsen

► **saveFigure** ↑

```
saveFigure(obj)
```

Description:

Save the figure to a pdf file

Input:

- obj : An object of class nb_graph_adv

Output:

The plotted graph saved to a pdf file, given by the saveName property of the object.

Examples:

```
obj.saveFigure()
```

Written by Kenneth S. Paulsen

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of the nb_graph_adv object.

See the documentation of the nb_graph_adv class for more on the different properties.

Input:

- obj : An object of class nb_graph_adv
- varargin : 'propertyName',PropertyValue,...

Output:

- obj : The input object with the updated properties.

Examples:

```
set(obj,'propertyName',PropertyValue);
obj.set('propertyName',PropertyValue,...)
obj = obj.set('footerfontsize',14);
```

Written by Kenneth S. Paulsen

► **setSpecial** ↑

```
setSpecial(obj,varargin)
```

Written by Kenneth S. Paulsen

► **timespan** ↑

```
dateString = timespan(obj)
```

Description:

Get the timespan of the graph as a string. On the PPR format.

Input :

- obj : An object of class nb_graph_adv, with the property plotter set to an nb_graph_ts object. Will return an empty string otherwise.

Output :

- dateString : A string with the timespan of the graph represented by this object. The language of this string will depend on the language of the language property of the plotter object.

Examples:

Written by Kenneth S. Paulsen

► **update ↑**

```
obj = update(obj)
```

Description:

Update the data source of the nb_graph_adv object. I.e update the data source of the plotter property.

See the update method of the nb_cs or nb_ts class for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_graph_adv

Output:

- obj : An object of class nb_graph_adv, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

■ nb_graph_bd

Go to: [Properties](#) | [Methods](#)

```
obj = nb_graph_bd(varargin)
```

Superclasses:

handle, nb_graph

Description:

This is a class for making business days (sparse time-series) graphics.

Constructor:

```
obj = nb_graph_bd(data)
```

Input:

- data : The input must one of the following:

> An object of class nb_bd. E.g. nb_graph_bd(data)

> A excel spreadsheet which could be read by the nb_bd class. E.g. nb_graph_bd('excelName1')

It is also possible to initialize an empty nb_graph_bd object. (Do not provide any inputs to the constructor)

Output:

- obj : An object of class nb_graph_bd

- **`DB`** 

All the data given to the `nb_graph_ts` object collected in a `nb_bd` object. Should not be set using `obj.DB = data!` Instead see the `nb_graph_bd.resetDataSource` method.

- **`GraphStruct`** 

Sets the information on which variables and how to plot them when using the `graphInfoStruct(...)` method of this class.

Must be an .m-file with the code on how the structure of graphing information should be initialized or as a structure with the graphing information.

Only the `graphInfoStruct(...)` method uses this property. See the documentation of the NB toolbox for more on this input.

Inherited from superclass `NB_GRAPH`

- **`a4Portrait`** 

Save PDF to A4 portrait format. 0 or 1

Inherited from superclass `NB_GRAPH`

- **`addAdvanced`** 

Set to false to prevent adding advanced components.

Inherited from superclass `NB_GRAPH`

- **`addSpace`** 

Sets the space before and/or after in the x direction of the graph [`addedSpaceBefore` `addedSpaceAfter`]. E.g. add one period before and after [1,1].

Inherited from superclass `NB_GRAPH`

- **alignAxes** ↑

Align axes at a given base value. Must be set to a scalar double.
E.g. 0.

Inherited from superclass NB_GRAPH

- **annotation** ↑

Sets the plotted annotations of the graph.

Must be one or more nb_annotation objects. See the documentation of the nb_annotation class for more. If you give more objects they must be collected in a cell array.

Examples can be found here:

\NBTOOLBOX\Examples\Graphics\nb_annotationExamples.m

Inherited from superclass NB_GRAPH

- **areaAbrupt** ↑

Set this property to true to make the areas abruptly finish when given as nan. Default is false.

Inherited from superclass NB_GRAPH

- **areaAccumulate** ↑

Set if the areas should be accumulated or not. Default is true.

Inherited from superclass NB_GRAPH

- **areaAlpha** ↑

Sets the transparency of the area chart. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

Inherited from superclass NB_GRAPH

- **axesFast** ↑

Set the if you want graphs to be produced fast with a loss of functionality and look or not. When empty default for the graph method is false, while for the graphSubPlots and graphInfoStruct methods are true.

Inherited from superclass NB_GRAPH

- **axesFontSize** ↑

Sets the font size of the axes tick mark labels, default is 12. Must be a scalar.

Inherited from superclass NB_GRAPH

- **axesFontSizeX** ↑

Sets the font size of the x-axis tick mark labels, default is []. I.e. use the axesFontSize property instead. Must be a scalar.

This property will not be scaled when fontUnits are changed, as is the case for axesFontSize.

Caution: Will not set the x-axis font size when plotType is set to scatter.

Inherited from superclass NB_GRAPH

- **axesFontWeight** ↑

Sets the font weight of the axes tick mark labels. Must be a string. Default is 'normal'. Either 'normal', 'bold', 'light' or 'demi'

Inherited from superclass NB_GRAPH

- **axesLineWidth** ↑

Sets the the line width of the axes, default is 0.5. Must be a set to a scalar double greater than 0.

Inherited from superclass NB_GRAPH

- **axesPrecision** ↑

Sets the precision/format of the rounding of number on the axes.

See the precision input to the nb_num2str function. Default is [], i.e. to call num2str without additional inputs.

Inherited from superclass NB_GRAPH

- **axesScaleFactor** ↑

Set the scaling factor used when axesScaleLineWidth is set to true.

Inherited from superclass NB_GRAPH

- **axesScaleLineWidth** ↑

Scale line width to axes height. true or false (default). If axesScaleFactor is set to a scalar number this will be the scaling factor used instead of the automatic scaling factor.

Inherited from superclass NB_GRAPH

- **barAlpha1** ↑

Set the alpha blending parameter 1, when barBlend is set to true. See nb_alpha. Default is 0.5

Inherited from superclass NB_GRAPH

- **barAlpha2** ↑

Set the alpha blending parameter 2, when barBlend is set to true. See nb_alpha. Default is 0.5

Inherited from superclass NB_GRAPH

- **barBlend** ↑

Set to true to do alpha blending instead of shading if shading options is used. Default is false.

Inherited from superclass NB_GRAPH

- **barLineWidth** ↑

Set the bar line width without affecting any other line widths. Default is empty, i.e. use the lineWidth property.

Inherited from superclass NB_GRAPH

- **barShadingColor** ↑

The color shaded bars are interpolated with. Default is 'white'. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **barShadingDate** ↑

Sets the date from which the bar plot should be shaded. Either a string or an object which is of a subclass of the nb_date class.

- **barShadingDirection** ↑

Sets the angle the shading should be vertical of. Either {'north'} | 'south' | 'west' | 'east'. As a string. Default is 'north'.

Inherited from superclass NB_GRAPH

- **barWidth** ↑

Sets the width of the bar plot. As a scalar. Default is 0.45.

Inherited from superclass NB_GRAPH

- **baseLine** ↑

If 0 is given the base line will not be plotted, otherwise it will be plotted.

Inherited from superclass NB_GRAPH

- **baseLineColor** ↑

Sets the color of the base line. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **baseLineStyle** ↑

Sets the line style of the base line. As a string. Either {'-' } | '--' | '---' | ':' | '-.' | 'none'.

Inherited from superclass NB_GRAPH

- **baseLineWidth** ↑

Sets the width of the base line. Must be a scalar.

Inherited from superclass NB_GRAPH

- **baseValue** ↑

Sets the base value used for bar and area plot. (Sest also the y-axis base value for the base line)

Inherited from superclass NB_GRAPH

- **candleIndicatorColor** ↑

Sets the color of the indicator of the candle. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **candleIndicatorLineStyle** ↑

Sets the line style of the indicator of the candle. Must be a string. Default is '-'.

Inherited from superclass NB_GRAPH

- **candleMarker** ↑

Sets the marker of the indicator of the candle. Must be a string. Default is 'none'.

Inherited from superclass NB_GRAPH

- **candleVariables** ↑

Sets which variables are going to be plotted as open, close, high, low and indicator. Must be a cellstr. E.g.

{'open','var1','close','var2',...}

If a type (e.g. 'low') is not given it will not be plotted.

Meaning of each type:

- > 'close' : The lowest values of the plotted patches of the candle.
- > 'high' : The highest values of the plotted candles.
- > 'indicator' : The value for where to plot a horizontal line (across the patch). E.g. the mean value.
- > 'open' : The highest values of the plotted patches of the candle.
- > 'low' : The lowest values of the plotted candles.

Inherited from superclass NB_GRAPH

- **candleWidth** ↑

Sets the width of the candle plot. As a scalar. Default is 0.45.

Inherited from superclass NB_GRAPH

- **code** ↑

If you set this to a file name, this file will be evaluated after all the plotting is done. Must be a string.

This could be nice for adding special annotation, lines and so on. In this file you can use any MATLAB function, but some strange error message can occur if you use local variables which is already defined (So use long and descriptive variable names in the provided code to prevent this).

This property is only an option for the method graph.

Nice to know:

> The current nb_figure object can be reached with
get(obj,'figureHandle')

> The current nb_axes object can be reached with
get(obj,'axesHandle')

Caution : Be aware that the name of the file must be unique and cannot be a MATLAB function or a local variable.

Caution : The file must be a MATLAB .m file

Inherited from superclass NB_GRAPH

- **colorMap** ↑

Sets the colormap used when plotType is set to 'image' and fanMethod is set to 'graded'. Must be given as n x 3 double or the path to a .mat file that contain the colormap. Default is given by nb_axes.defaultColorMap.

For an example of a supported MAT file see:

- ...\\Examples\\Graphics\\colorMapNB.mat

Inherited from superclass NB_GRAPH

- **colorOrder** ↑

Sets the color order of the plotted data (Left axes). Either a cellstr with the color names (size; 1xM) or a double with RGB colors (Size; Mx3). Where M is the number of plotted variables against the left axes.

Inherited from superclass NB_GRAPH

- **colorOrderRight** ↑

Sets the color order of the plotted data (Right axes). Either a cellstr with the color names (size; 1xM) or a double with RGB colors (Size; Mx3). Where M is the number of plotted variables against the right axes.

Inherited from superclass NB_GRAPH

- **colors** ↑

Sets the colors of the given variable(s). Must be a cell array on the form: {'var1', 'black', 'var2', [0.2 0.2 0.2],...}. Here we set the colors of the variables 'var1' and 'var2' to 'black' and [0.2 0.2 0.2] (RGB color) respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Caution: For the graphInfoStruct() method you need to select the variables from obj.DB.dataNames instead!

Inherited from superclass NB_GRAPH

- **crop** ↑

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

Inherited from superclass NB_GRAPH

- **dashedLine** ↑

Sets the date at which all the plotted lines will be dashed. Must be given as a string or an object which is of a subclass of the nb_date class.

- **dataType** ↑

The data type to plot, either 'stripped' (default) or 'full'. If 'stripped' only periods where any of the variables have data is plotted, otherwise all periods of the timespan of the data is plotted.

- **dateFormat** ↑

The date format used for the dates on the x-axis labels. Default is 'nbNorwegian' for norwegian and 'nbEnglish' for english (i.e. when set to '').

- **dateInterpreter** ↑

Sets how to interpreter the dates. I.e. where to place the datapoints in relation to the tick mark labels. Must be a string. {'start'} | 'end' | 'middle'.

- **displayValue** ↑

Set to false to not display observation values when holding the mouse over the graph. Default is true.

Inherited from superclass NB_GRAPH

- **endGraph** [↑](#)

Sets the end date of the graph. Either as string or an object which is of a subclass of the nb_date class. If the given date is after the end date of the data, the data will be appended with nan values. I.e. the graph will be blank for these dates.

- **excelFooterEng** [↑](#)

If you want a extended footer to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to include the same footer as in the graph. English version.

Inherited from superclass NB_GRAPH

- **excelFooterNor** [↑](#)

If you want a extended footer to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to include the same footer as in the graph. Norwegian version.

Inherited from superclass NB_GRAPH

- **excelTitleEng** [↑](#)

If you want a custom title to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to use the same title as in the graph (panel if multiple graphs). English version.

Inherited from superclass NB_GRAPH

- **excelTitleNor** [↑](#)

If you want a custom title to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to use the same title as in the graph (panel if multiple graphs). Norwegian version.

Inherited from superclass NB_GRAPH

- **factor** [↑](#)

Set this property to multiply the data with a given factor. Must be a scalar.

Inherited from superclass NB_GRAPH

- **fakeLegend** [↑](#)

Set this property if you want to add a legend of none plotted variable. You can set this property. Must be a cell on the form: {'legendName', settings,...}, where the legendName will be text of the fake legend. And the settings input must also be a cell array with the optional inputs {...,'propertyName', propertyName,...}. These settings will set the appearance of the fake legend. The following propertyNames are supported:

```
> 'type'      : Either 'line' or 'patch'.

> 'color'     : Sets the color of the fake legend. Default is
                 'black'. Must either be a 1 x 3 double with
                 the RGB colors or a string with the color
                 name. If shaded patch is wanted it must be
                 2 x 3 double with the RGB colors or a 1 x 2
                 cellstr with the color names to use.

> 'direction' : Sets the direction of the shading. Either
                 {'north'} | 'south' | 'west' | 'east'. As a
                 string. Default is 'north'. Only an option
                 when 'type' is set to 'patch'.

> 'edgeColor'  : Sets the color of the edge of the patch.
                 Default is the same as the 'color' option.
                 Only an option when 'type' is set to 'patch'.

> 'lineStyle'   : Sets the line style of the fake legend. As a
                 string. Either {'-' } | '--' | '---' | ':' |
                 '-.' | 'none'. Default is a normal line.

                 Will set the edge line style if the 'type'
                 is set to 'patch'.

> 'lineWidth'   : Sets the line width of the fake legend.
                 Default is 2.5. Must be a scalar.

> 'marker'     : Sets the marker of the fake legend. Default is
                 'none'. Only an option when 'type' is set to
                 'line'. Lookup LineSpec in the MATLAB help
                 meny for more on the supported marker types.
```

Caution : Even if you don't want to set any of the optional input. The settings input must be given. I.e an empty cell, i.e. {}.

Inherited from superclass NB_GRAPH

- **fanAlpha** ↑

Sets the transparency of the fan chart. May be needed if you add fan charts to more than one variable at the time. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

- **fanColor** ↑

Sets the colors of the fan charts. Must be a matrix of size; number of fan layer x 3, with the RGB color specifications.

or

A string with the basis color for the fan colors. Either 'red', 'blue', 'green', 'yellow', 'magenta', 'cyan' or 'white'.

Be aware that the classification of the color of the given "basecolor" is based on the property fanPercentiles, so if you have more or less than 4 layers you must change this property to have the same size as the number of layers. (This is the case even if you don't use it to calculate the percentiles of a given datasets. Given by the property fanDatasets)

Default is the nb colors.

Caution: If fanMethod is set to 'graded' the color used are those assign to the colorMap property.

- **fanDatasets** ↑

Sets the data of the added fan layers.

If you have the data of the different layer in separate datasets. Then the input to this property must be a 2 * number of layers cell matrix. Can be excel spreadsheets, .mat files or dyn_ts objects.

or

You can also give the data with all the simulated data or fan layers in an dyn_ts object or an nb_ts object. (Each page one simulation or each page one layer). (FASTEST with an nb_ts object as input.)

Remember that the percentiles for the fan charts is set by the property fanPercentiles, default is [.3, .5, .7, .9].

The fan layers are added differently given the method you use.

> graph(...): Adds the fan given in this property to the last variable given in the property variablesToPlot. (If not the fanVariable property is set.) If you graph more datasets (in separate figures), the fan layers will be the same for all of them. Set the fanVariables property if that is not wanted.

> graphSubPlots(...): Adds the fan given in this property to the corresponding variable in the last given datasets (last page of the nb_ts object given by the property DB) of each each subplot.

-graphInfoStruct(...): Adds the fan given by this property to each variable of each subplot. Added for the last given dataset. (Last page of the nb_ts object given by the

property DB.)

- **fanFile** ↑

The file to get the default fan layers from. As a string.

- **fanGradedLineWidth** ↑

Line width used but the graded fan chart is set to

- **fanGradedStyle** ↑

Line width used but the graded fan chart is set to

- **fanLegend** ↑

Set this property if you want to add a MPR styled legend of the fan layers. Set it to 1 if wanted. Default is not (0).

- **fanLegendFontSize** ↑

Sets the font size of the fan legend. Default is 12. Must be a scalar.

- **fanLegendLocation** ↑

Sets the location of the fan legend. Locations are:

```
> 'Best', (same as 'North'.)
> 'NorthWest'
> 'North'
> 'NorthEast'
> 'SouthEast'
> 'South'
> 'SouthWest'
> 'outside' : Places the legend outside the axes, one the right side. (If you create subplots, this is the only option which will look good.)
```

You can also give a 1 x 2 double vector with the location of where to place the legend. First column is the x-axis location and the second column is the y-axis location. Both must be between 0 and 1.

- **fanLegendText** ↑

Set this property if you want to give the text over the colored boxes of the MPR looking fan legend, you must give them as a cell. (Must have same size as number of layers.) Default is the percentiles with the % sign added. E.g. {'30%','50%','70%','90%'}.

- **fanMethod** ↑

{'percentiles'} | 'hdi' | 'graded'; Which type of fan chart is going to be made. 'percentiles' are produced by using percentiles, 'hdi' use highest density intervals, while 'graded' creates a graded fan chart of the colors specified with the colorMap property.

- **fanPercentiles** ↑

Sets the percentiles you want to calculate (if the fanDatasets property is representing simulation) or specify the percentiles you have given (if the fanDatasets property is representing already calculated percentiles). Must be given as a double vector. Default is [0.3 0.5 0.7 0.9].

This property is also the default base for the text of the fan legend. (Where the percentiles are given in percent.)

- **fanVariable** ↑

Sets the variable you want to add the fan layers to. Must be given as a string with the variable name. Default is to use the last variable in the variablesToPlot property.

If this input is a cellstr with more than one variable, the 'fanPercentiles' input must be a scalar double. Fan chart will then be added to more than one variable.

- **fanVariables** ↑

If you have the fan layers included in the same dataset as your other plotted variables you can use this property. The input must then be given as 1 x 2 * number of layers cell array with the fan layers names (as strings). I.e. both the upper and lower layers must be given as separate variables.
(Need not be ordered though.)

E.g. {'LowPerc 90%', 'LowPerc 70%', 'UppPerc 90%', 'UppPerc 70%'}

Caution: Must fit the number of percentiles given by the property fanPercentiles (Remember to include both upper and lower bounds!).

Only an input to the method graph(...): Adds the given fan layers to the last variable given by the property variablesToPlot or the variable given by fanVariable property.

- **figureColor** ↑

Color of the figure as a 1x3 double. Default is [1 1 1].

Inherited from superclass NB_GRAPH

- **figureName** ↑

Sets the name of figure (only in MATLAB), default is no name.

Inherited from superclass NB_GRAPH

- **figurePosition** ↑

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

Inherited from superclass NB_GRAPH

- **figureTitle** ↑

Sets if figure titles is wanted on the figures when using the method graphInfoStruct. The fieldnames of the GraphStruct property will be used as figure title. Default is 0 (not include).

If set to a one line char this property can be used for the plotting method graphSubPlots.

Inherited from superclass NB_GRAPH

- **fileFormat** ↑

Sets the save file format. Either 'eps', 'jpg', 'pdf' or 'png'. 'pdf' is default.

Inherited from superclass NB_GRAPH

- **findAxisLimitMethod** ↑

Sets the method used for finding the axis limits, and y-ticks.

- > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
- > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
- > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
- > 4 : Uses the MATLAB algorithm for finding the axis limits.

Inherited from superclass NB_GRAPH

- **flip** ↑

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

Inherited from superclass NB_GRAPH

- **fontName** ↑

Sets the name of font used. Default is 'arial'.

Inherited from superclass NB_GRAPH

- **fontScale** ↑

Sets the parameter that scales all the font sizes of the graphs. Must be scalar. Default is 1 (do not scale).

Inherited from superclass NB_GRAPH

- **fontUnits** ↑

Sets the font units of all the fonts of the graph. Either
{'points'} | 'normalized' | 'inches' | 'centimeters'.
Default is 'points'.

Caution : If you set the fontUnits property in a method call
to the set method, all the font properties set
before the fontUnits property will be set in the
old fontUnits, while all the font properties set
after will be in the new fontUnits.

Caution : Don't use this property in combination with one of
the graph styles defined by this class. I.e.
'mpr', 'mpr_white', 'presentation' and
'presentation_white' They will set this property
to 'normalized'.

Caution : 'normalized' font units must be between 0 and 1.
The normalized units are not the same as the MATLAB
normalized units. This normalized units are not
only normalized to the axes size, but also across
resolution of the screen. (But only vertically)

Inherited from superclass NB_GRAPH

- **graphStyle** ↑

Sets the graphing style of the plots. Give 'mpr' if you want
the MPR looking style, or 'presentation' for
graphs for the presentation (see nb_Presentation). If you
don't want the grey shaded background you can use 'mpr_white'
and 'presentation_white' instead.

You can also add your own graph style setting through a .m
file. I.e. give the filename (without extension) as a string.

E.g. In the file you can type in something like:

```
set(obj,'titleFontSize',12,'legInterpreter','tex');
```

Caution: If you give this as the first input to the set method
it is possible to overrun some of the default
settings if that is wanted. E.g. font size of the
text, the shading of the plot and so on.

Inherited from superclass NB_GRAPH

- **grid** ↑

Set it to 'on' if grid lines are wanted otherwise set it to
'off'. Default is 'off'.

Inherited from superclass NB_GRAPH

- **gridLineStyle** ↑

Sets the line style of the grid lines. Either '-' , '--' , ':'
or '-.'.

Inherited from superclass NB_GRAPH

- **highlight** ↑

If highlighted area between two dates of the graph is wanted set this property.

One highlighted area:

A cell array on the form {'date1', 'date2'}

More highlighted areas:

A nested cell array on the form

{{'date1(1)', 'date2(1)'}, {'date1(2)', 'date2(2)'}, ...}

If plotType is set to 'scatter' scalars can be used instead.

- **highlightColor** ↑

Sets the colors of the background patches. Must be one of the following:

- > A string with the color name to use when plotting (all) the patch(es)
- > A cell array of strings with the color names
- > A cell with 1 x 3 doubles with the RGB color specification.

When given as a cell this property must match the highlight property. I.e. the number of highlighted areas added.

The default color of the highlighted areas is 'light blue'.

- **horizontalLine** ↑

If you want to include some extra horizontal lines, beside the base line, you can set this property. Must be set to a scalar or a double vector with the y-axis value(s) on where to place the horizontal line(s).

Inherited from superclass NB_GRAPH

- **horizontalLineColor** ↑

Sets the color(s) of the given horizontal line(s).

Must either be an M x 3 double with the RGB color(s) or a 1 x M cell array of strings with the color name(s). Where M must be less than the number of plotted horizontal lines.

If less or no color(s) is/are set by this property the default colors for the rest or all the horizontal line(s) is/are [0 0 0], i.e. MATLAB black.

Inherited from superclass NB_GRAPH

- **horizontalLineStyle** ↑

Sets the style(s) of the given horizontal line(s).

Must either be a string or a 1 x M cell array of strings with the style(s). Where M must be less than the number of plotted

horizontal lines.

If less or no style(s) is/are set by this property the default lines for the rest or all the horizontal line(s) is/are '-'.

Inherited from superclass NB_GRAPH

- **horizontalLineWidth** ↑

Sets the line width of the horizontal line(s). Must be a scalar. Default is 1.

Inherited from superclass NB_GRAPH

- **language** ↑

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

Inherited from superclass NB_GRAPH

- **legAuto** ↑

'on' | {'off'}. As a string.

> 'on' : The strings given through the fakeLegend and patch properties are automatically added to the legend.

> 'off' : The strings given through the fakeLegend and patch properties are not automatically added to the legend. Which means that you must provide all the legend information through the legends property. The patch descriptions must be given first and the fake legend description must be given last in the legends property. Default.

Inherited from superclass NB_GRAPH

- **legBox** ↑

Set if a box should be drawn around the legend. Either {'on'} | 'off'.

Caution : When removing the box you make it impossible to move it around afterwards.

Inherited from superclass NB_GRAPH

- **legColor** ↑

Sets the color of the background of the box of the legend. Either as 1x3 double with the RGB or as a string). Default is 'none', i.e. transparent.

Inherited from superclass NB_GRAPH

- **legColumnWidth** ↑

Sets the width of the columns of the legend. Default is to let MATLAB find the width itself. If given it must be a scalar with the width of all columns of the legend or a $1 \times \text{legColumns}$ double with the width of each individual column.

Should be between 0 and 1. Use the try and fail method to find out what fits.

Inherited from superclass NB_GRAPH

- **legColumns** [↑](#)

Sets the number of columns of the legends. Must be a scalar.

Inherited from superclass NB_GRAPH

- **legFontColor** [↑](#)

Sets the font color(s) of the legend text. Must either be a 1×3 double or a string with the color name of all legend text objects, or a $M \times 3$ double or a cellstr array with size $1 \times M$ with color names to use of each legend text object.

Inherited from superclass NB_GRAPH

- **legFontSize** [↑](#)

Sets the font size of the legend. Must be a scalar default is 10.

Inherited from superclass NB_GRAPH

- **legInterpreter** [↑](#)

Sets the interpreter of the legend text. Must be a string.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **legLocation** [↑](#)

Sets the location of the legend, must be string. The location can be:

> 'Best' : Same as 'NorthWest'.
> 'NorthWest'
> 'North'
> 'NorthEast'
> 'SouthEast'
> 'South'
> 'SouthWest'
> 'below' : Below the plot (when many subplots, it will place the legend below all of them)
> 'middle' : Could only be use for 2×2 subplot, and then it places the legend between the upper and lower subplots.

Location that only works for the graph() method:

```

> 'outsideright'      : Legend is placed outside the axes on the
                         right side, and the axes is resized, so
                         the axes and legend does not take up more
                         space than the axes did in the first place.
                         The legend is vertically centered.
> 'outsiderighttop'   : Same as 'outsideright', but placed
                         vertically top.

```

Inherited from superclass NB_GRAPH

- **legPosition** ↑

Sets the position of the legend. Must be a 1x2 double. Where the first element is the x-axis location and the second is the y-axis location. [xPosition yPosition]

Caution : Both elements must be between 0 and 1. And where we have that [0, 0] will be the bottom left location of the axes and [1, 1] is the top right position of the axes. (This position will be the top left position of the legend itself.)

Caution : This option overruns the legLocation property.

Inherited from superclass NB_GRAPH

- **legReorder** ↑

Set this property to reorder the legend. Either a string with {'default'} | 'inverse' or a double with how to reorder the legend. E.g. if you have 3 legends to plot the default index will be [1,2,3], the inverse ('inv') will be [3,2,1]. If you want to decide that the 3. legend should be first, then the 1. and 2., you can type in [3,1,2].

Caution : If a double is given it must have as many elements as there is plotted legends. I.e. if you give a empty string to one of the legends it will be excluded. Say you provide the property legends as {'s','t','f'} then the double must have size 1x3.

Inherited from superclass NB_GRAPH

- **legSpace** ↑

The vertical space between the texts of the legend. Must be a scalar. Default is 0.

Inherited from superclass NB_GRAPH

- **legendText** ↑

Sets the legend(s) of the given variable(s). Must be a cell array on the form: {'var1', 'Name', 'var2', 'Name2', ...}. Here we set the legends of the variables 'var1' and 'var2' to 'Name' and 'Name2' respectively. (The rest will be given the variable names as default).

To give a legend to a splitted line (second part) give;

```

{....,'Var1(second)','LegendSplitted',...} (Is case sensitiv)

Caution : legAuto should be set to 'on'. Which is not default.
          This is only important if the patch or fakeLegend
          property is used.

Caution : When given this property will overwrite the legends
          property

Caution : If the variable, scattergroup or candle is not found
          no error will occure!

Caution : If you have used the patch or fakeLegend property these
          can be translated as well with this property

```

Inherited from superclass NB_GRAPH

- legends ↑

Give the legends of the plot. Must be given as a cell array
of strings.

Default (it depends on the method you use) :

```

> 'graph'           : The variable names are used as the
                      default legends. (Given by the
                      variableToPlot and variableToPlotRight
                      properties)

> 'graphSubPlot'   : The dataset names are used as the
                      default legends. (Given by the
                      dataNames of the DB property.)

> 'graphInfoStruct' : The dataset names are used as the
                      default legends. (Given by the
                      dataNames of the DB property.)

```

Caution : The ordering of the legends is as follows:

- patch : See the patch property (only when legAuto is set to 'off')
- variablesToPlot : Then the all the variablesToPlot variables. When You have splitted lines, i.e. either using the dashedLine property or the lineStyles property, these can be set after all the variablesToPlot. Have in mind that the ordering is kept.
- variablesToPlotRight : Then the comes all the variables provided by the variablesToPlotRight. Then the splitted lines.
- fakeLegend : Then you can provide the legend text for the fake legend. (only when legAuto is set to 'off')

Example:

```

data      = nb_ts.rand('2012',10,2);
plotter = nb_graph_ts(data);
plotter.set('variablesToPlot',{'Var1'},...
            'variablesToPlotRight',{'Var2'},...
            'lineStyles',{'Var1',{'-','2014','--'},...
                         'Var2',{'-','2014','--'},...
            'legends',{'Test','Test (--)','Test2','Test2 (--)'});
plotter.graph()

```

Inherited from superclass NB_GRAPH

- **lineStyles** [↑](#)

Sets the line styles of the given variable(s). Must be a cell array on the form: {'var1', '-' , 'var2', '--', ...}. Here we set the line styles of the variables 'var1' and 'var2' to '-' and '--' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Supported line styles are '-','--',':','.-','---

Caution : For nb_graph_ts and nb_graph_data it is possible to split the plotted line using the following syntax;
{'var1',{'-','2000Q1','--'}} and {'var1',{'-',2,'--'}}
respectively

Inherited from superclass NB_GRAPH

- **lineWidth** [↑](#)

Sets the line width of the line plots. Must be a scalar.
Default is 2.5.

Inherited from superclass NB_GRAPH

- **lineWidths** [↑](#)

Sets the line widths of the given variables. Must be a cell array on the form: {'var1', 1, 'var2', 1.5,...}. Here we set the line widths of the variables 'var1' and 'var2' to 1 and 1.5 respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Inherited from superclass NB_GRAPH

- **localVariables** [↑](#)

A nb_struct with the local variables of the nb_graph object. I.e. a field with name 'test' can be reach with the string input %#test.

Inherited from superclass NB_GRAPH

- **lookUpMatrix** [↑](#)

Sets how the given mnemonics (variable and type names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {  
    'mnemonics1','englishDescription1','norwegianDescription1';  
    'mnemonics2','englishDescription2','norwegianDescription2'};
```

Inherited from superclass NB_GRAPH

- **mYLim** ↑

Sets the max/min y-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Both or one of them can be set to nan, i.e. the default limits will be used) E.g. [0 6], [nan, 6] or [0, nan].

Caution: If the variablesToPlotRight property is not empty this setting only sets the left y-axis limits.

Only an option for the graphInfoStruct(...) method.

- **markerSize** ↑

Sets the size of the all markers. Must be a scalar. Default is 8.

Inherited from superclass NB_GRAPH

- **markers** ↑

Sets the markers of the given variables. Must be a cell array on the form: {'var1', '^', 'var2', 'o', ...}. Here we set the markers of the variables 'var1' and 'var2' to '^' and 'o' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

See the table below on which markers that are supported.

'+'	: Plus sign
'o'	: Circle
'*'	: Asterisk
'.'	: Point
'x'	: Cross
's'	: Square
'd'	: Diamond
'^'	: Upward-pointing triangle
'v'	: Downward-pointing triangle
'>'	: Right-pointing triangle
'<'	: Left-pointing triangle
'p'	: Five-pointed star (pentagram)
'h'	: Six-pointed star (hexagram)

Inherited from superclass NB_GRAPH

- **missingValues** ↑

Set how to interpret missing observations. Must be a string. Either;

```
> 'interpolate' : Linearly interpolate the missing values.  
> 'none'          : No interpolation (default)
```

- **noLabel** ↑

Set it to 1 if no label(s) is/are wanted on the graphs, otherwise set it to 0. Both on the y-axis and x-axis. Default is 0. This is of course only have an effect if the nb_graph object have been given the xLabel or yLabel properties. (These are empty by default.)

Inherited from superclass NB_GRAPH

- **noLegend** ↑

Set it to 1 if no legend is wanted, otherwise set it to 0. Default is 0.

Inherited from superclass NB_GRAPH

- **noTickMarkLabels** ↑

Set to true (1) to remove tick marks and tick marks label of axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTickMarkLabelsLeft** ↑

Set to true (1) to remove tick marks and tick marks label of the left side of the axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTickMarkLabelsRight** ↑

Set to true (1) to remove tick marks and tick marks label of the right side of the axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTitle** ↑

Set it to 1 if you don't want title(s) of the graphs, otherwise set it to 0. Default is 0.

Set it to 2 if you want the dataNames{ii} as the title of the graph when using the graph method.

Inherited from superclass NB_GRAPH

- **normalized** ↑

If the font should be normalized to the figure or axes. Either 'figure' or 'axes'.

Inherited from superclass NB_GRAPH

- **numberOfGraphs** ↑

Number of graph produced by the graph methods. Not settable.

Inherited from superclass NB_GRAPH

- **page** ↑

Sets the page of the data object to plot. Only an option for graph() method. Default is [], i.e. plot all pages in separate figures.

Inherited from superclass NB_GRAPH

- **parameters** ↑

A struct with the parameters that can be used in evaluation of expressions in the graphSubPlots and graphInfoStruct methods.

Inherited from superclass NB_GRAPH

- **patch** ↑

Sets the patch property of the object. If set this will add a patch (color fill) between two variables.

Only one patch :

```
{'patchName','var1','var2',color}
```

More patches :

```
{'patchName1','var1Patch1','var2Patch1',color1 ,...  
'patchName2','var1Patch2','var2Patch2',color2,...}
```

Where the the color option(s) must either be a 1 x 3 double with the RGB colors or a string with the color name.

The first input will be the legend text of the patch. I.e. 'patchName', 'patchName1' and 'patchName2' will be the description text included in the legend. (If not the property legAuto is set to 'off'.)

Inherited from superclass NB_GRAPH

- **patchAlpha** ↑

Sets the transparency of the patches. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

Inherited from superclass NB_GRAPH

- **pdfBook** ↑

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be use in combination with the saveName property.

Inherited from superclass NB_GRAPH

- **plotAspectRatio** ↑

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3, or when '[16,9]' the aspect ratio of the figure is 16 to 9

Inherited from superclass NB_GRAPH

- **plotType** ↑

Sets the plot type. Either:

- > 'line' : If line plot(s) is wanted. Default.
- > 'stacked' : If stacked bar plot(s) is wanted. Not an option for the graphSubPlots(...) method.
- > 'grouped' : If grouped bar plot(s) is wanted.
- > 'dec' : If decomposition plot(s) is wanted. Which is a bar plot with also a line with the sum of the stacked bars. Not an option for the graphSubPlots(...) method.
- > 'area' : If area plot(s) is wanted.
- > 'candle' : If candle plot(s) is wanted.
- > 'scatter' : If scatter plot(s) is wanted.

- **plotTypes** ↑

Sets the plot type of the given variables. Must be a cell array on the form: {'var1', 'line', 'var2', 'grouped', ...}. Here we set the plot type of the variables 'var1' and 'var2' to 'line' and 'grouped' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

See the property plotType above on which plot types that are supported.

- **position** ↑

Sets the position of the axes, must be an 1x4 double. [leftMostPoint lowestPoint width height]. Only an option for the graph() method. Default is [0.1 0.1 0.8 0.8].

For the graph method graphSubPlots the position input can be given a 1 x N cell array, where each element is a 1x4 double.
N = obj.subPlotSize(1)*obj.subPlotSize(2).

Inherited from superclass NB_GRAPH

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are produced. Must be a string.

Default is to save each graph produced in separate files. Set the pdfBook property to 1 if you want to save all the produced graphs in one pdf file. (To save all figures in one file is only possible for pdf files. I.e. the fileFormat property must be 'pdf'.)

Inherited from superclass NB_GRAPH

- **scatterDates** ↑

Sets the start and end to be used for the scatter plot plotted against the left axes. Must be a nested cell array. The dates can be given as strings or date objects. E.g:

```
{'scatterGroup1',{ 'startDate1','endDate1'},...  
 'scatterGroup2',{ 'startDate2','endDate2'},...}
```

Caution : This property must be provided to produce a scatter plot! (Or of course scatterDatesRight)

Be aware : Each date will result in one point in the scatter.

- **scatterDatesRight** ↑

Sets the start and end to be used for the scatter plot plotted against the right axes. Must be a nested cell array. The dates can be given as strings or date objects. E.g:

```
{'scatterGroup1',{ 'startDate1','endDate1'},...  
 'scatterGroup2',{ 'startDate2','endDate2'},...}
```

Caution : This property must be provided to produce a scatter plot! (Or of course scatterDates)

Be aware : Each date will result in one point in the scatter.

- **scatterLineStyle** ↑

Sets the scatter line style. Must be string. See 'lineStyles' for supported inputs. (Sets the line style of all scatter plots)

- **scatterVariables** ↑

The variables used for the scatter plot. Must be a 1x2 cellstr array. The first element will be the variable plotted against the x-axis, while the second element will be the variable plotted against the left y-axis. E.g:

```
{'var1','var2'}
```

- **scatterVariablesRight** ↑

The variables used for the scatter plot. Must be a 1x2 cellstr array. The first element will be the variable plotted against the x-axis, while the second element will be the variable plotted against the right y-axis. E.g:

```
{'var1','var2'}
```

- **shading** ↑

The shading option of the axes background:

- 'grey' : Shaded grey background
- 'none' : Background color given by the color property.
- A n x m x 3 double with the background color. n is the number of horizontal pixels, m is the number of vertical pixels and 3 means the RGB colors.

Inherited from superclass NB_GRAPH

- **spacing** ↑

Sets the x-ticks spacing. Must be a scalar. Refers to the given x-axis tick frequency.

- **startGraph** ↑

Sets the start date of the graph. Must be a string or an object which of a subclass of the nb_date class. If this date is before the start date of the data, the data will be expanded with nan (blank values) for these periods.

- **subPlotSize** ↑

Sets the number of subplots per figure. Must be a 1 x 2 double with the number of subplot rows as the first element and the number of subplot columns as the second element. Only an option of the graphSubPlots() and graphInfoStruct() methods.

Default is [2, 2].

Inherited from superclass NB_GRAPH

- **subPlotSpecial** ↑

Set it to 1 if you want the 1x2 and 2x1 subplots to better fit for usage in presentations. Default is 0, i.e. use MATLAB default positions.

When set to 1 this class uses the nb_subplotSpecial instead of nb_subplot to find the positions of the subplots.

Inherited from superclass NB_GRAPH

- **subPlotsOptions** ↑

Use this property to set subplot spesific options of each variable while using the the method graphSubPlots(). Each field must be the name of the variable. The options are:

```
- yLabel      : The y-axis label.
- yLim       : Sets the y-axis limits. As a 1x2 double.
- ySpacing   : Spacing between y-axis tick marks.
- dashedLine : The date to start the dashed line for the given
               variable.
```

Example:

```
s.Var1 = struct('yLim',[0,1]);
s.Var2 = struct('yLim',[0,1]);
```

- **sumTo** ↑

Sets a number which the area or the stacked bar plot should sum to. Must be a scalar. I.e. if 100 is given. The sizes of the bars will be the percentage share of the total sum.

Inherited from superclass NB_GRAPH

- **tag** ↑

Used by the nb_graph_subplot class to locate the nb_graph object in the subplot. Should not be used. Use userData instead.

Inherited from superclass NB_GRAPH

- **title** ↑

Sets the title of the plot. Must be a char. Only an option for the graph(...) method.

Inherited from superclass NB_GRAPH

- **titleAlignment** ↑

Sets the figure title text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_GRAPH

- **titleFontSize** ↑

Sets the font size of the titles which is placed above the (sub)plot(s). Must be scalar. Default is 14.

Inherited from superclass NB_GRAPH

- **titleFontWeight** ↑

Sets the font weight of the titles which is placed above the (sub)plot(s). Must be a string. Default is 'bold'.

Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **titleInterpreter** ↑

Sets the interpreter used for the given string given by the title property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_GRAPH

- **titlePlacement** ↑

Sets the placement of the title. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_GRAPH

- **userData** ↑

User data, can be set to anything you want.

Inherited from superclass NB_GRAPH

- **variablesToPlot** ↑

Sets the variables to plot against the left (or both) axes. Must be a cell array of strings with the variable names. I.e. {'var1', 'var2',...}.

Not an option for the graphInfoStruct(...), which use the property GraphStruct instead.

Inherited from superclass NB_GRAPH

- **variablesToPlotRight** ↑

Sets the variables to plot against the right axes. Must be a cell array of strings with the variable names. I.e. {'var1', 'var2',...}.

Not an option for the graphInfoStruct(...), which use the property GraphStruct instead.

Inherited from superclass NB_GRAPH

- **verticalLine** ↑

Sets the date(s) of where to place a vertical line(s). (Dotted orange line is default). Must be a string or a cell array of strings with the date(s) for where to place the vertical line(s). I.e. 'date1' or {'date1','date2',...}

Each element of the cell could also be given as a cell with two dates, i.e. {'date1', 'date2' }. Then the vertical line will be placed between the given dates.

If plotType is set to 'scatter' scalars can be used instead.

- **verticalLineColor** ↑

Sets the color(s) of the given vertical line(s). Must either be an $M \times 3$ double with the RGB color(s) or a $1 \times M$ cell array of strings with the color name(s). Where M must be less than the number of plotted vertical lines.

If less or no color(s) is/are set by this property the default color(s) for the rest or all the vertical line(s) is/are [0 0 0]. I.e. MATLAB black.

- **verticalLineLimit** ↑

Sets the y-axis limit(s) of the given vertical line(s). Must either be a $1 \times M$ cell array of 1×2 double with the upper and lower y-axis limit(s). Where M must be less than the number of plotted vertical lines.

If less or no limit(s) is/are set by this property the default limit for the rest or all the vertical line(s) is/are the full height of the graph.

- **verticalLineStyle** ↑

Sets the line style(s) of the given vertical line(s). Must either be a $1 \times M$ cell array of strings with the style(s). Where M must be less than the number of plotted vertical lines.

If less or no style(s) is/are set by this property the default line style is/are used for the rest or all the vertical line(s) is/are '--'.

- **verticalLineWidth** ↑

Sets the line width of (all) the vertical line(s). Must be a scalar. Default is 1.5.

- **xLabel** ↑

Sets (add) the text of the x-axis label. Must be a string.

Inherited from superclass NB_GRAPH

- **xLabelAlignment** ↑

Sets the x-axis label text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_GRAPH

- **xLabelFontSize** ↑

Sets the font size of the x-axis label. Must be scalar. Default is 12.

Inherited from superclass NB_GRAPH

- **xLabelFontWeight** ↑

Sets the font weight of the x-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **xLabelInterpreter** ↑

The interpreter used for the given string given by the xlabel
property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_GRAPH

- **xLabelPlacement** ↑

Sets the placement of the x-axis label. {'center'} | 'left' |
'right' | 'leftaxes'.

Inherited from superclass NB_GRAPH

- **xLim** ↑

Sets the x-axis limits of the plot. Must be 1 x 2 double
vector, where the first number is the lower limit and the
second number is the upper limit. (Both or one of them can be
set to nan, i.e. the default limits will be used) E.g. [0 6],
[nan, 6] or [0, nan].

Only an option when the plotType property is set to 'scatter'.

- **xScale** ↑

Sets the scale of the x-axis. Either {'linear'} | 'log'.

Only an option when plotType is set to 'scatter'.

- **xTickLabelAlignment** ↑

The alignment of the x-axis tick marks labels. {'normal'} |
'middle'.

- **xTickLabelLocation** ↑

The location of the x-axis tick marks labels. Either
{'bottom'} | 'top' | 'baseline'. 'baseline' will only work in
combination with the xtickLocation property set to a double
with the basevalue.

- **xTickLabels** ↑

Sets the x-axis tick mark labels. To translate the default tick
mark label 'Var1' and 'Var2' you can use;

```
{'Var1','Label1','Var2','Label2'}
```

If given as a empty cell, default x-axis tick marks will be used, which is default.

This property can be used to create multi-lined x-axis tick mark labels. To do this give a multi-row char to the labels you want to make multi-lined.

Inherited from superclass NB_GRAPH

- **xTickLocation** ↑

The location of the x-axis tick marks. Either {'bottom'} | 'top' | double. If given as a double the tick marks will be placed at this value (where the number represent the y-axis value).

- **xTickRotation** ↑

Sets the rotation of the x-axis tick mark labels. Must be a scalar with the number of degrees the labels should be rotated. Positive angles cause counterclockwise rotation.

- **yDir** ↑

Sets the direction of the y-axis of the plot. Must be a string. Either 'normal' or 'reverse'. Default is 'normal'.

Caution: If the variablesToPlotRight is not empty this setting only sets the left y-axis direction.

- **yDirRight** ↑

Sets the direction of the right y-axis of the plot. Either 'normal' or 'reverse'. Default is 'normal'. (Only when the variablesToPlotRight property is not empty.)

- **yLabel** ↑

Sets (add) the text of the y-axis label. Must be a string.

Inherited from superclass NB_GRAPH

- **yLabelFontSize** ↑

Sets the font size of the y-axis label. Must be scalar. Default is 12.

Inherited from superclass NB_GRAPH

- **yLabelFontWeight** ↑

Sets the font weight of the y-axis label. Must be string. Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **yLabelInterpreter** ↑

The interpreter used for the given string given by the `xLabel` property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass `NB_GRAPH`

- **yLabelRight** ↑

Sets the text of the y-axis label. (Only on the right side.)
Must be a string. Takes the same font option as the `yLabel` property

Inherited from superclass `NB_GRAPH`

- **yLim** ↑

Sets the y-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Both or one of them can be set to nan, i.e. the default limits will be used) E.g. [0 6], [nan, 6] or [0, nan].

Caution: If the `variablesToPlotRight` property is not empty this setting only sets the left y-axis limits.

Only an option for the `graph(...)` and `graphSubPlots()` methods.
(For the `graphInfoStruct(...)` method use the property `GraphStruct`.)

- **yLimRight** ↑

Sets the right y-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Only when the `variablesToPlotRight` property is not empty.) (Both or one of them can be set to nan, i.e. the default limits will be used)
E.g. [0 6], [nan, 6] or [0, nan].

Only an option for the `graph(...)` and `graphSubPlots()` methods.
(For the `graphInfoStruct(...)` method use the property `GraphStruct`.)

- **yOffset** ↑

The y-axis tick mark labels offset from the axes

- **yScale** ↑

Sets the scale of the y-axis. {'linear'} | 'log'. (Both the left and the right axes if nothing is plotted on the right axes.)

- **yScaleRight** ↑

Sets the scale of the right y-axis. {'linear'} | 'log'.
(Has only something to say if something is plotted on the
right axes)

- **ySpacing** ↑

Sets the spacing between y-axis tick mark labels of the
y-axis. Must be scalar.

Caution: The spacing will be the number of periods between the
tick marks labels. The number of periods will follow
the frequency of the xTickFrequency property if
setted, else it will follow the frequency of the
data provided. (Except when dealing with daily data,
because then the default xTickFrequency is 'yearly')

Caution: If the variablesToPlotRight property is not empty
this property only sets the spacing between ticks of
the left y-axis.

- **ySpacingRight** ↑

Sets the spacing between y-axis tick mark labels of the
right y-axis. Must be scalar.

Caution: The spacing will be the number of periods between the
tick marks labels. The number of periods will follow

Methods:

- | | | | |
|-----------------------------------|-------------------------------------|---------------------------------------|------------------------------|
| • createFigure | • get | • getBDOOptions | • getCode |
| • getData | • getGenericOptions | • getPlottedVariables | • graph |
| • graphInfoStruct | • graphSubPlots | • isempty | • merge |

| • set | • struct | • timespan | • update |

► **createFigure** ↑

`createFigure(obj)`

Description:

Create figure to plot in.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_GRAPH

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_graph_bd

Input:

- obj : An object of class nb_graph_bd
- propertyName : A string with the name of the wanted property.

Output:

- propertyValue : The property value of the given property.

Examples:

Get the last axes handle of the nb_graph_ts object. Be aware that all the axes handles are stored in the figurehandle property of the object.

```
axeshandle = obj.get('axeshandle');
```

Get the handle of all the current figures of the nb_graph_bd object.

```
figurehandle = obj.get('figurehandle');
```

See also:

[nb_figure](#), [nb_axes](#), [nb_bd](#)

Written by Kenneth S. Paulsen

► **getBDOptions ↑**

```
options = getBDOptions(obj)
```

Description:

Container with the properties specific to nb_graph_bd

Input:

- none

Output:

- options : A numSettings name 4 cell array with names in first column, default inputs in second, logical checks in the third, and a function handle with the set function in the fourth.

Examples:

```
options = getBDOptions(obj);
```

See also:

[set](#), [getGenericOptions](#), [nb_parseInputs](#)

Written by Kenneth Sæterhagen Paulsen

► **getCode** ↑

```
[code,numOfGraphs] = getCode(obj,frameTitle,frameSubTitle,...  
                               footer,source,pageNumber,theme)
```

Description:

Get the latex code when including a graph in a slide object produced by an object of class nb_graph_ts.

This method is called from the nb_Slide class, when making a beamer slide in latex.

Input:

- obj : An object of class nb_graph_ts
- frameTitle : A string with the frame title of the slide.
- frameSubTitle : A string with the frame subtitle of the slide.
- footer : A cellstr with the footers of the slide
- source : A cellstr with the sources of the slide
- pageNumber : Give 1 if the page number should be included.
- theme : The beamer theme used. Default is '' (use default beamer theme).

Output:

- code : The latex code as a char.
- numOfGraphs : The number of graphs produced by the input object of class nb_graph_ts. As an integer.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_GRAPH

► **getData** ↑

```
data = getData(obj)
```

Description:

Get the data of the graph

Input:

- obj : An object of class nb_graph_bd

Output:

- data : As an nb_bd object.

Written by Kenneth S. Paulsen

► **getGenericOptions** ↑

```
options = getGenericOptions(obj)
```

Description:

A static method of nb_graph.

Container with the intersect of options for subclasses of nb_graph.

Input:

- none

Output:

- options : A numSettings x 4 cell array with names in first column, default inputs in second, logical checks in the third, and a function handle with the set function in the fourth.

Examples:

```
options = getGenericOptions(obj);
```

See also:

[set](#), [nb_parseInputs](#)

Written by Per Bjarne Bye

Inherited from superclass NB_GRAPH

► **getPlottedVariables** ↑

```
vars = getPlottedVariables(obj,forLegend)
```

Description:

Get the plotted variables of the graph

Input:

- obj : An object of class nb_graph_bd
- forLegend : true or false (default)

When forLegend is used the variables are listed as needed for the legend, but without fake legends and patches, and duplicates are not removes.

Output:

- vars : As a cellstr

Example:

```
vars = obj.getPlottedVariables();
```

Written by Kenneth S. Paulsen

► **graph** ↑

```
graph(obj)
```

Description:

Create a graph or more graphs

Graphs all the variables given by the variablesToPlot and the variablesToPlotRight properties in one plot, and does that for all the datasets of the DB property. I.e. one new plot for each dataset (page) of the DB property of the nb_graph_ts object.

Input:

- obj : An object of class nb_graph_bd

Output:

The graph plotted on the screen.

Examples:

```
data = nb_bd([2;1;2],'', '2012Q1', 'Var1');
obj = nb_graph_bd(data);
obj.graph();
```

See also:

[nb_graph_bd.set](#)

Written by Kenneth S. Paulsen

► **graphInfoStruct** ↑

`graphInfoStruct(obj)`

Description:

Create graphs based on the property `GraphStruct`. (Or the default `GraphStruct` given by the method `defaultGraphStruct`)

This method makes it easy to set up graph packages. For example graphing output from models.

See the documentation NB toolbox for more on this method.

Input:

- `obj` : An object of class `nb_graph_bd`, where the property `GraphStruct` contains the information on how to plot the objects data.

Output:

The wanted graphs plotted on the screen.

Written by Kenneth S. Paulsen

► **graphSubPlots** ↑

`graphSubPlots(obj)`

Description:

Create graphs of all the variables given in `variablesToPlot` property, in different subplots. (Each dataset against each other). The number of subplot is given by the property `subPlotSize`.

Input:

- obj : An object of class nb_graph_bd

Output:

The wanted graphs plotted on the screen.

Written by Kenneth S. Paulsen

► isempty ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_graph_bd object is empty. I.e. if no data is stored in the object. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_graph_bd

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► merge ↑

```
out = merge(obj,varargin)
```

Description:

Default: This tries to merge the data of plotter objects that uses the graphSubPlots, or the graphInfoStruct.

Caution: All objects must share the exact same variables!

'graph' is given: In this case it will try to merge the data of all nb_graph objects, and concatenate the variableToPlot property. If the property variableToPlot is empty for all objects, it will also be returned as empty, i.e. plot all series in the data.

Caution : Merging of any of the other properties then DB and variableToPlot is not done!

Input:

- obj : An object of class nb_graph, which includes the classes nb_graph_ts, nb_graph_cs and nb_graph_data.

Optional input:

- 'graph' : Give this input to merge the graphs in the way that is described in the description of this method.
- varargin : Each input must be an object of class nb_graph.

Output:

- out : An object of class nb_graph.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_GRAPH

► **realTimespan** ↑

```
dateString = realTimespan(obj,language,freq)
```

Description:

Get the timespan of the data behind a graph which is not nan or infinite, as a string. On the PPR format.

Input :

- obj : An object of class nb_graph_bd
- language : 'english' or 'norwegian'. 'norwegian' is default
- freq : The wanted frequency of the timespan

Output :

- dateString : A string with the timespan of the graph represented by this object.

Written by Kenneth S. Paulsen

► **resetDataSource** ↑

```
[message,err] = resetDataSource(obj,dataSource,updateProps)
```

Description:

Reset the data source of the nb_graph_bd object.

Input:

- obj : An object of class nb_graph_bd
- dataSource : An nb_bd object with the new data.
- updateProps : If the variablesToPlot should be updated to be equal to dataSource.variables + the startGraph and endGraph properties are set to the startDate and endDate of the new data source.

Can also be 'gui'. Then all properties will be checked against the new dataset, and if the new dataset does not comply with the properties, the properties will be updated!

Written by Kenneth S. Paulsen

► **saveData** ↑

```
obj = saveData(obj,filename)
```

Description:

Saves the data of the figure

Input:

- obj : An object of class nb_graph_bd
- filename : A string with the saved output name

Example:

```
obj.saveData('test');
```

Written by Kenneth S. Paulsen

► **saveFigure** ↑

```
saveFigure(obj,extraName,format)
```

Description:

Save the figure(s) produced by the nb_graph object to (a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_graph
- extraName : If you want to add some extra name to the saveName property of the nb_graph_data object before saving the file. (If the saveName property of the nb_graph_ts object is empty this will be the full name of the output file.)
- format : The format of the saved output. Default is given by the property fileFormat of the nb_graph. Either 'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.

Output:

The produced figure(s) saved to the wanted formats.

Examples:

```
data = nb_data([2;1;2],'', '1', 'Var1');
obj = nb_graph_data(data);
obj.graph();
saveFigure(obj,'test','pdf');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_GRAPH

► set ↑

```
set(obj,varargin)
```

Description:

Set properties of the nb_graph class and its subclasses.

See documentation NB Toolbox or type help('nb_graph') for more on the properties of the class.

Input:

- obj : An object that is a subclass of nb_graph
- varargin : 'propertyName',PropertyValue,...

Output:

No actual output, but the input objects properties will have been set to their new value.

Examples:

```
data = nb_ts([2;1;2],'', '2012Q1', 'Var1');
obj = nb_graph_ts(data);
obj.set('startGraph', '2012Q1', 'endGraph', '2012Q3');
obj.set('crop', 1);
```

Written by Per Bjarne Bye

Inherited from superclass NB_GRAPH

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct

Input:

- obj : An object of class nb_graph_ts

Output:

- s : A struct

Written by Kenneth Sæterhagen Paulsen

► **timespan** ↑

```
dateString = timespan(obj,language,freq)
```

Description:

Get the timespan of the graph as a string. On the PPR format.

Input :

- obj : An object of class nb_graph_bd
- language : 'english' or 'norwegian'. 'norwegian' is default
- freq : The wanted frequency of the timespan

Output :

- dateString : A string with the timespan of the graph represented by this object.

Written by Kenneth S. Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the figure

See the update method of the nb_ts classes for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_graph_bd

Output:

- obj : An object of class nb_graph_bd, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

■ **nb_graph_cs**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_graph_cs(varargin)
```

Superclasses:

handle, nb_graph

Description:

This is a class for making graphics of cross sectional data.

Constructor:

```
obj = nb_graph_cs(data)
```

Constructor of the nb_graph_cs class

Input:

- data : If you have one source you want to collect the data from you can give it as a input to this constructor. I.e:

```
> nb_cs           : nb_graph_cs(data)
> excel          : nb_graph_cs('excelName1')
```

It is also possible to initialize an empty nb_graph_cs object. (Do not provide any inputs to the constructor)

Output:

- obj : An object of class nb_graph_cs

See also:

- **`DB`** 

All the data given to the `nb_graph_cs` object collected in a `nb_cs` object. Should not be set using `obj.DB = data!` Instead see the `nb_graph_cs.resetDataSource` method.

- **`GraphStruct`** 

Sets the information on which variables and how to plot them when using the `graphInfoStruct(...)` method of this class.

Must be an .m-file with the code on how the structure of graphing information should be initialized or as a structure with the graphing information.

Only the `graphInfoStruct(...)` method uses this property. See the documentation of the NB toolbox for more on this input.

Inherited from superclass `NB_GRAPH`

- **`a4Portrait`** 

Save PDF to A4 portrait format. 0 or 1

Inherited from superclass `NB_GRAPH`

- **`addAdvanced`** 

Set to false to prevent adding advanced components.

Inherited from superclass `NB_GRAPH`

- **`addSpace`** 

Sets the space before and/or after in the x direction of the graph [`addedSpaceBefore` `addedSpaceAfter`]. E.g. add one period before and after [1,1].

Inherited from superclass `NB_GRAPH`

- **alignAxes** ↑

Align axes at a given base value. Must be set to a scalar double.
E.g. 0.

Inherited from superclass NB_GRAPH

- **annotation** ↑

Sets the plotted annotations of the graph.

Must be one or more nb_annotation objects. See the documentation of the nb_annotation class for more. If you give more objects they must be collected in a cell array.

Examples can be found here:

\NBTOOLBOX\Examples\Graphics\nb_annotationExamples.m

Inherited from superclass NB_GRAPH

- **areaAbrupt** ↑

Set this property to true to make the areas abruptly finish when given as nan. Default is false.

Inherited from superclass NB_GRAPH

- **areaAccumulate** ↑

Set if the areas should be accumulated or not. Default is true.

Inherited from superclass NB_GRAPH

- **areaAlpha** ↑

Sets the transparency of the area chart. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

Inherited from superclass NB_GRAPH

- **axesFast** ↑

Set the if you want graphs to be produced fast with a loss of functionality and look or not. When empty default for the graph method is false, while for the graphSubPlots and graphInfoStruct methods are true.

Inherited from superclass NB_GRAPH

- **axesFontSize** ↑

Sets the font size of the axes tick mark labels, default is 12. Must be a scalar.

Inherited from superclass NB_GRAPH

- **axesFontSizeX** ↑

Sets the font size of the x-axis tick mark labels, default is []. I.e. use the axesFontSize property instead. Must be a scalar.

This property will not be scaled when fontUnits are changed, as is the case for axesFontSize.

Caution: Will not set the x-axis font size when plotType is set to scatter.

Inherited from superclass NB_GRAPH

- **axesFontWeight** ↑

Sets the font weight of the axes tick mark labels. Must be a string. Default is 'normal'. Either 'normal', 'bold', 'light' or 'demi'

Inherited from superclass NB_GRAPH

- **axesLineWidth** ↑

Sets the line width of the axes, default is 0.5. Must be a set to a scalar double greater than 0.

Inherited from superclass NB_GRAPH

- **axesPrecision** ↑

Sets the precision/format of the rounding of number on the axes.

See the precision input to the nb_num2str function. Default is [], i.e. to call num2str without additional inputs.

Inherited from superclass NB_GRAPH

- **axesScaleFactor** ↑

Set the scaling factor used when axesScaleLineWidth is set to true.

Inherited from superclass NB_GRAPH

- **axesScaleLineWidth** ↑

Scale line width to axes height. true or false (default). If axesScaleFactor is set to a scalar number this will be the scaling factor used instead of the automatic scaling factor.

Inherited from superclass NB_GRAPH

- **barAlpha1** ↑

Set the alpha blending parameter 1, when barBlend is set to true. See nb_alpha. Default is 0.5

Inherited from superclass NB_GRAPH

- **barAlpha2** ↑

Set the alpha blending parameter 2, when barBlend is set to true. See nb_alpha. Default is 0.5

Inherited from superclass NB_GRAPH

- **barBlend** ↑

Set to true to do alpha blending instead of shading if shading options is used. Default is false.

Inherited from superclass NB_GRAPH

- **barLineWidth** ↑

Set the bar line width without affecting any other line widths. Default is empty, i.e. use the lineWidth property.

Inherited from superclass NB_GRAPH

- **barOrientation** ↑

Sets the orientation of the bar plot. This property is discarded when using the plotTypes property. Must be a string with either 'vertical' (default) or 'horizontal'

- **barShadingColor** ↑

The color shaded bars are interpolated with. Default is 'white'. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **barShadingDirection** ↑

Sets the angle the shading should be vertical of. Either {'north'} | 'south' | 'west' | 'east'. As a string. Default is 'north'.

Inherited from superclass NB_GRAPH

- **barShadingTypes** ↑

Sets the types which should have shaded bars. Must be a cellstr, with the names of the types to be shaded. E.g. {'Type1','Type2',...}

- **barWidth** ↑

Sets the width of the bar plot. As a scalar. Default is 0.45.

Inherited from superclass NB_GRAPH

- **baseLine** ↑

If 0 is given the base line will not be plotted, otherwise it will be plotted.

Inherited from superclass NB_GRAPH

- **baseLineColor** ↑

Sets the color of the base line. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **baseLineStyle** ↑

Sets the line style of the base line. As a string.
Either {'-' | '--' | '---' | ':' | '-.' | 'none'.

Inherited from superclass NB_GRAPH

- **baseLineWidth** ↑

Sets the width of the base line. Must be a scalar.

Inherited from superclass NB_GRAPH

- **baseValue** ↑

Sets the base value used for bar and area plot. (Sest also the
y-axis base value for the base line)

Inherited from superclass NB_GRAPH

- **candleIndicatorColor** ↑

Sets the color of the indicator of the candle. Must either be a
1 x 3 double with the RGB colors or a string with the color
name.

Inherited from superclass NB_GRAPH

- **candleIndicatorLineStyle** ↑

Sets the line style of the indicator of the candle. Must be a
string. Default is '-'.

Inherited from superclass NB_GRAPH

- **candleMarker** ↑

Sets the marker of the indicator of the candle. Must be a
string. Default is 'none'.

Inherited from superclass NB_GRAPH

- **candleVariables** ↑

Sets which variables are going to be plotted as open, close,
high, low and indicator. Must be a cellstr. E.g.

{'open','var1','close','var2',...}

If a type (e.g. 'low') is not given it will not be plotted.

Meaning of each type:

> 'close' : The lowest values of the plotted patches of
the candle.

> 'high' : The highest values of the plotted candles.

> 'indicator' : The value for where to plot a horizontal line
(across the patch). E.g. the mean value.

> 'open' : The highest values of the plotted patches of the candle.

> 'low' : The lowest values of the plotted candles.

Inherited from superclass NB_GRAPH

- **candleWidth** [↑](#)

Sets the width of the candle plot. As a scalar. Default is 0.45.

Inherited from superclass NB_GRAPH

- **code** [↑](#)

If you set this to a file name, this file will be evaluated after all the plotting is done. Must be a string.

This could be nice for adding special annotation, lines and so on. In this file you can use any MATLAB function, but some strange error message can occur if you use local variables which is already defined (So use long and descriptive variable names in the provided code to prevent this).

This property is only an option for the method graph.

Nice to know:

> The current nb_figure object can be reached with
get(obj,'figureHandle')

> The current nb_axes object can be reached with
get(obj,'axesHandle')

Caution : Be aware that the name of the file must be unique and cannot be a MATLAB function or a local variable.

Caution : The file must be a MATLAB .m file

Inherited from superclass NB_GRAPH

- **colorMap** [↑](#)

Sets the colormap used when plotType is set to 'image' and fanMethod is set to 'graded'. Must be given as n x 3 double or the path to a .mat file that contain the colormap. Default is given by nb_axes.defaultColorMap.

For an example of a supported MAT file see:

- ...\\Examples\\Graphics\\colorMapNB.mat

Inherited from superclass NB_GRAPH

- **colorOrder** [↑](#)

Sets the color order of the plotted data (Left axes). Either a cellstr with the color names (size; 1xM) or a double with

RGB colors (Size; Mx3). Where M is the number of plotted variables against the left axes.

Inherited from superclass NB_GRAPH

- **colorOrderRight** [↑](#)

Sets the color order of the plotted data (Right axes). Either a cellstr with the color names (size; 1xM) or a double with RGB colors (Size; Mx3). Where M is the number of plotted variables against the right axes.

Inherited from superclass NB_GRAPH

- **colors** [↑](#)

Sets the colors of the given variable(s). Must be a cell array on the form: {'var1', 'black', 'var2', [0.2 0.2 0.2],...}. Here we set the colors of the variables 'var1' and 'var2' to 'black' and [0.2 0.2 0.2] (RGB color) respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Caution: For the graphInfoStruct() method you need to select the variables from obj.DB.dataNames instead!

Inherited from superclass NB_GRAPH

- **crop** [↑](#)

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

Inherited from superclass NB_GRAPH

- **displayValue** [↑](#)

Set to false to not display observation values when holding the mouse over the graph. Default is true.

Inherited from superclass NB_GRAPH

- **donutInnerRadius** [↑](#)

Sets the realtive length of the inner circle of the donut. -0.5 mean that the donut has an inner circle with the same radius as half the outer circle of the donut.

- **donutRadius** [↑](#)

Sets the radius of the donut. Default is 1.

- **excelFooterEng** [↑](#)

If you want a extended footer to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to include the same footer as in the graph. English version.

Inherited from superclass NB_GRAPH

- **excelFooterNor** ↑

If you want a extended footer to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to include the same footer as in the graph. Norwegian version.

Inherited from superclass NB_GRAPH

- **excelTitleEng** ↑

If you want a custom title to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to use the same title as in the graph (panel if multiple graphs). English version.

Inherited from superclass NB_GRAPH

- **excelTitleNor** ↑

If you want a custom title to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to use the same title as in the graph (panel if multiple graphs). Norwegian version.

Inherited from superclass NB_GRAPH

- **factor** ↑

Set this property to multiply the data with a given factor. Must be a scalar.

Inherited from superclass NB_GRAPH

- **fakeLegend** ↑

Set this property if you want to add a legend of none plotted variable. You can set this property. Must be a cell on the form: {'legendName', settings,...}, where the legendName will be text of the fake legend. And the settings input must also be a cell array with the optional inputs {...,'propertyName', propertyName,...}. These settings will set the appearance of the fake legend. The following propertyNames are supported:

```
> 'type'      : Either 'line' or 'patch'.  
  
> 'color'     : Sets the color of the fake legend. Default is  
  'black'. Must either be a 1 x 3 double with  
  the RGB colors or a string with the color  
  name. If shaded patch is wanted it must be  
  2 x 3 double with the RGB colors or a 1 x 2  
  cellstr with the color names to use.  
  
> 'direction' : Sets the direction of the shading. Either  
  {'north'} | 'south' | 'west' | 'east'. As a  
  string. Default is 'north'. Only an option  
  when 'type' is set to 'patch'.  
  
> 'edgeColor' : Sets the color of the edge of the patch.  
  Default is the same as the 'color' option.
```

Only an option when 'type' is set to 'patch'.

> 'lineStyle' : Sets the line style of the fake legend. As a string. Either {'-' | '--' | '---' | ':' | '-.' | 'none'. Default is a normal line.

Will set the edge line style if the 'type' is set to 'patch'.

> 'lineWidth' : Sets the line width of the fake legend. Default is 2.5. Must be a scalar.

> 'marker' : Sets the marker of the fake legend. Default is 'none'. Only an option when 'type' is set to 'line'. Lookup LineSpec in the MATLAB help meny for more on the supported marker types.

Caution : Even if you don't want to set any of the optional input. The settings input must be given. I.e an empty cell, i.e. {}.

Inherited from superclass NB_GRAPH

- **fanColor** [↑](#)

Sets the colors of the fan charts. Must be a matrix of size; number of fan layer x 3, with the RGB color specifications.

or

A string with the basis color for the fan colors. Either 'red', 'blue', 'green', 'yellow', 'magenta', 'cyan' or 'white'.

Be aware that the classification of the color of the given "basecolor" is based on the property fanPercentiles, so if you have more or less than 4 layers you must change this property to have the same size as the number of layers. (This is the case even if you don't use it to calculate the percentiles of a given datasets. Given by the property fanDatasets)

Default is the nb colors.

Caution: If fanMethod is set to 'graded' the color used are those assign to the colorMap property.

- **fanDatasets** [↑](#)

Sets the data of the added fan layers.

If you have the data of the different layer in separate datasets. Then the input to this property must be a 2 * number of layers cell matrix. Can be excel spreadsheets or .mat files.

or

You can also give the data with all the simulated data or fan layers in a nb_cs object. (Each page one simulation or each

page one layer).

Remember that the percentiles for the fan charts is set by the property `fanPercentiles`, default is `[.3, .5, .7, .9]`.

The fan layers are added differently given the method you use.

```
> graph(...): Adds the fan given in this property to the last
   variable given in the property variablesToPlot.
   (If not the fanVariable property is set.) If you
   graph more datasets (in separate figures), the
   fan layers will be the same for all of them.
   Set the fanVariables property if that is not
   wanted.

> graphSubPlots(...): Adds the fan given in this property to
   the corresponding variable in the last
   given datasets (last page of the nb_cs
   object given by the property DB) of each
   each subplot.

-graphInfoStruct(...): Adds the fan given by this property to
   each variable of each subplot. Added
   for the last given dataset. (Last page
   of the nb_cs object given by the
   property DB.)
```

- **fanLegend** [↑](#)

Set this property if you want to add a MPR styled legend of the fan layers. Set it to 1 if wanted. Default is not (0).

- **fanLegendFontSize** [↑](#)

Sets the font size of the fan legend. Default is 12. Must be a scalar.

- **fanLegendLocation** [↑](#)

Sets the location of the fan legend. Locations are:

```
> 'Best', (same as 'North'.)
> 'NorthWest'
> 'North'
> 'NorthEast'
> 'SouthEast'
> 'South'
> 'SouthWest'
> 'outside' : Places the legend outside the axes, one the
   right side. (If you create subplots, this is
   the only option which will look good.)
```

You can also give a 1×2 double vector with the location of where to place the legend. First column is the x-axis location and the second column is the y-axis location. Both must be between 0 and 1.

- **fanLegendText** ↑

Set this property if you want to give the text over the colored boxes of the MPR looking fan legend, you must give them as a cell. (Must have same size as number of layers.) Default is the percentiles with the % sign added. E.g. {'30%', '50%', '70%', '90%'}.

- **fanMethod** ↑

{'percentiles' | 'hdi' | 'graded'}; Which type of fan chart is going to be made. 'percentiles' are produced by using percentiles, 'hdi' use highest density intervals, while 'graded' creates a graded fan chart of the colors specified with the colorMap property.

- **fanPercentiles** ↑

Sets the percentiles you want to calculate (if the fanDatasets property is representing simulation) or specify the percentiles you have given (if the fanDatasets property is representing already calculated percentiles). Must be given as a double vector. Default is [0.3 0.5 0.7 0.9].

This property is also the default base for the text of the fan legend. (Where the percentiles are given in percent.)

- **fanVariable** ↑

Sets the variable you want to add the fan layers to. Must be given as a string with the variable name. Default is to use the last variable in the variablesToPlot property.

- **figureColor** ↑

Color of the figure as a 1x3 double. Default is [1 1 1].

Inherited from superclass NB_GRAPH

- **figureName** ↑

Sets the name of figure (only in MATLAB), default is no name.

Inherited from superclass NB_GRAPH

- **figurePosition** ↑

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

Inherited from superclass NB_GRAPH

- **figureTitle** ↑

Sets if figure titles is wanted on the figures when using the method graphInfoStruct. The fieldnames of the GraphStruct property will be used as figure title. Default is 0 (not include).

If set to a one line char this property can be used for the plotting method graphSubPlots.

Inherited from superclass NB_GRAPH

- **fileFormat** [↑](#)

Sets the save file format. Either 'eps', 'jpg', 'pdf' or 'png'. 'pdf' is default.

Inherited from superclass NB_GRAPH

- **findAxisLimitMethod** [↑](#)

Sets the method used for finding the axis limits, and y-ticks.

- > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
- > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
- > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
- > 4 : Uses the MATLAB algorithm for finding the axis limits.

Inherited from superclass NB_GRAPH

- **flip** [↑](#)

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

Inherited from superclass NB_GRAPH

- **fontName** [↑](#)

Sets the name of font used. Default is 'arial'.

Inherited from superclass NB_GRAPH

- **fontScale** [↑](#)

Sets the parameter that scales all the font sizes of the graphs. Must be scalar. Default is 1 (do not scale).

Inherited from superclass NB_GRAPH

- **fontUnits** [↑](#)

Sets the font units of all the fonts of the graph. Either {'points'} | 'normalized' | 'inches' | 'centimeters'. Default is 'points'.

Caution : If you set the fontUnits property in a method call to the set method, all the font properties set

before the fontUnits property will be set in the old fontUnits, while all the font properties set after will be in the new fontUnits.

Caution : Don't use this property in combination with one of the graph styles defined by this class. I.e. 'mpr', 'mpr_white', 'presentation' and 'presentation_white'. They will set this property to 'normalized'.

Caution : 'normalized' font units must be between 0 and 1. The normalized units are not the same as the MATLAB normalized units. This normalized units are not only normalized to the axes size, but also across resolution of the screen. (But only vertically)

Inherited from superclass NB_GRAPH

- **graphStyle** [↑](#)

Sets the graphing style of the plots. Give 'mpr' if you want the MPR looking style, or 'presentation' for graphs for the presentation (see nb_Presentation). If you don't want the grey shaded background you can use 'mpr_white' and 'presentation_white' instead.

You can also add your own graph style setting through a .m file. I.e. give the filename (without extension) as a string.

E.g. In the file you can type in something like:

```
set(obj,'titleFontSize',12,'legInterpreter','tex');
```

Caution: If you give this as the first input to the set method it is possible to overrun some of the default settings if that is wanted. E.g. font size of the text, the shading of the plot and so on.

Inherited from superclass NB_GRAPH

- **grid** [↑](#)

Set it to 'on' if grid lines are wanted otherwise set it to 'off'. Default is 'off'.

Inherited from superclass NB_GRAPH

- **gridLineStyle** [↑](#)

Sets the line style of the grid lines. Either '-', '--', ':' or '-.'.

Inherited from superclass NB_GRAPH

- **highlight** [↑](#)

If highlighted area between two types of the graph is wanted set this property.

One highlighted area:

A cell array on the form {'type1', 'type2'}

More highlighted areas:

A nested cell array on the form

{{'type1(1)', 'type2(1)'}, {'type1(2)', 'type2(2)'}, ...}

If plotType is set to 'scatter' scalars can be used instead.

- **highlightColor** ↑

Sets the colors of the background patches. Must be one of the following:

- > A string with the color name to use when plotting (all) the patch(es)
- > A cell array of strings with the color names
- > A cell with 1 x 3 doubles with the RGB color specification.

When given as a cell this property must match the highlight property. I.e. the number of highlighted areas added.

The default color of the highlighted areas is 'light blue'.

- **horizontalLine** ↑

If you want to include some extra horizontal lines, beside the base line, you can set this property. Must be set to a scalar or a double vector with the y-axis value(s) on where to place the horizontal line(s).

Inherited from superclass NB_GRAPH

- **horizontalLineColor** ↑

Sets the color(s) of the given horizontal line(s).

Must either be an M x 3 double with the RGB color(s) or a 1 x M cell array of strings with the color name(s). Where M must be less than the number of plotted horizontal lines.

If less or no color(s) is/are set by this property the default colors for the rest or all the horizontal line(s) is/are [0 0 0], i.e. MATLAB black.

Inherited from superclass NB_GRAPH

- **horizontalLineStyle** ↑

Sets the style(s) of the given horizontal line(s).

Must either be a string or a 1 x M cell array of strings with the style(s). Where M must be less than the number of plotted horizontal lines.

If less or no style(s) is/are set by this property the default lines for the rest or all the horizontal line(s) is/are '-'.

Inherited from superclass NB_GRAPH

- **horizontalLineWidth** ↑

Sets the line width of the horizontal line(s). Must be a scalar. Default is 1.

Inherited from superclass NB_GRAPH

- **language** ↑

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

Inherited from superclass NB_GRAPH

- **legAuto** ↑

'on' | {'off'}. As a string.

> 'on' : The strings given through the fakeLegend and patch properties are automatically added to the legend.

> 'off' : The strings given through the fakeLegend and patch properties are not automatically added to the legend. Which means that you must provide all the legend information through the legends property. The patch descriptions must be given first and the fake legend description must be given last in the legends property. Default.

Inherited from superclass NB_GRAPH

- **legBox** ↑

Set if a box should be drawn around the legend. Either {'on'} | 'off'.

Caution : When removing the box you make it impossible to move it around afterwards.

Inherited from superclass NB_GRAPH

- **legColor** ↑

Sets the color of the background of the box of the legend. Either as 1x3 double with the RGB or as a string). Default is 'none', i.e. transparent.

Inherited from superclass NB_GRAPH

- **legColumnWidth** ↑

Sets the width of the columns of the legend. Default is to let MATLAB find the width itself. If given it must be a scalar with the width of all columns of the legend or a 1 x legColumns double with the width of each individual column.

Should be between 0 and 1. Use the try and fail method to find out what fits.

Inherited from superclass NB_GRAPH

- **legColumns** ↑

Sets the number of columns of the legends. Must be a scalar.

Inherited from superclass NB_GRAPH

- **legFontColor** ↑

Sets the font color(s) of the legend text. Must either be a 1x3 double or a string with the color name of all legend text objects, or a M x 3 double or a cellstr array with size 1 x M with color names to use of each legend text object.

Inherited from superclass NB_GRAPH

- **legFontSize** ↑

Sets the font size of the legend. Must be a scalar default is 10.

Inherited from superclass NB_GRAPH

- **legInterpreter** ↑

Sets the interpreter of the legend text. Must be a string.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **legLocation** ↑

Sets the location of the legend, must be string. The location can be:

> 'Best' : Same as 'NorthWest'.
> 'NorthWest'
> 'North'
> 'NorthEast'
> 'SouthEast'
> 'South'
> 'SouthWest'
> 'below' : Below the plot (when many subplots, it will place the legend below all of them)
> 'middle' : Could only be use for 2 x 2 subplot, and then it places the legend between the upper and lower subplots.

Location that only works for the graph() method:

> 'outsideright' : Legend is placed outside the axes on the right side, and the axes is resized, so the axes and legend does not take up more space than the axes did in the first place. The legend is vertically centered.
> 'outsiderighttop' : Same as 'outsideright', but placed vertically top.

Inherited from superclass NB_GRAPH

- **legPosition** ↑

Sets the position of the legend. Must be a 1x2 double. Where the first element is the x-axis location and the second is the y-axis location. [xPosition yPosition]

Caution : Both elements must be between 0 and 1. And where we have that [0, 0] will be the bottom left location of the axes and [1, 1] is the top right position of the axes. (This position will be the top left position of the legend itself.)

Caution : This option overruns the legLocation property.

Inherited from superclass NB_GRAPH

- **legReorder** ↑

Set this property to reorder the legend. Either a string with {'default'} | 'inverse' or a double with how to reorder the legend. E.g. if you have 3 legends to plot the default index will be [1,2,3], the inverse ('inv') will be [3,2,1]. If you want to decide that the 3. legend should be first, then the 1. and 2., you can type in [3,1,2].

Caution : If a double is given it must have as many elements as there is plotted legends. I.e. if you give a empty string to one of the legends it will be excluded. Say you provide the property legends as {'s','t','f'} then the double must have size 1x3.

Inherited from superclass NB_GRAPH

- **legSpace** ↑

The vertical space between the texts of the legend. Must be a scalar. Default is 0.

Inherited from superclass NB_GRAPH

- **legendText** ↑

Sets the legend(s) of the given variable(s). Must be a cell array on the form: {'var1', 'Name', 'var2', 'Name2', ...}. Here we set the legends of the variables 'var1' and 'var2' to 'Name' and 'Name2' respectively. (The rest will be given the variable names as default).

To give a legend to a splitted line (second part) give; {...,'Var1(second)', 'LegendSplitted', ...} (Is case sensitiv)

Caution : legAuto should be set to 'on'. Which is not default. This is only important if the patch or fakeLegend property is used.

Caution : When given this property will overwrite the legends property

Caution : If the variable, scattergroup or candle is not found

```
no error will occure!
```

Caution : If you have used the patch or fakeLegend property these can be translated as well with this property

Inherited from superclass NB_GRAPH

- **legends** ↑

Give the legends of the plot. Must be given as a cell array of strings.

Default (it depends on the method you use) :

```
> 'graph'           : The variable names are used as the
                      default legends. (Given by the
                      variableToPlot and variableToPlotRight
                      properties)

> 'graphSubPlot'   : The dataset names are used as the
                      default legends. (Given by the
                      dataNames of the DB property.)

> 'graphInfoStruct' : The dataset names are used as the
                      default legends. (Given by the
                      dataNames of the DB property.)
```

Caution : The ordering of the legends is as follows:

- patch : See the patch property (only when legAuto is set to 'off')
- variablesToPlot : Then the all the variablesToPlot variables. When You have splitted lines, i.e. either using the dashedLine property or the lineStyles property, these can be set after all the variablesToPlot. Have in mind that the ordering is kept.
- variablesToPlotRight : Then the comes all the variables provided by the variablesToPlotRight. Then the splitted lines.
- fakeLegend : Then you can provide the legend text for the fake legend. (only when legAuto is set to 'off')

Example:

```
data      = nb_ts.rand('2012',10,2);
plotter = nb_graph_ts(data);
plotter.set('variablesToPlot',{'Var1'},...
            'variablesToPlotRight',{'Var2'},...
            'lineStyles',{'Var1',{'-'},{'2014','--'}},...
            'Var2',{'-'},{'2014','--'});
            'legends',{'Test','Test (--)','Test2','Test2 (--)'});
plotter.graph()
```

Inherited from superclass NB_GRAPH

- **lineStyles** ↑

Sets the line styles of the given variable(s). Must be a cell array on the form: {'var1', '--', 'var2', '---', ...}. Here we set the line styles of the variables 'var1' and 'var2' to '--' and '---' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Supported line styles are '--','--',':','.-','---

Caution : For nb_graph_ts and nb_graph_data it is possible to split the plotted line using the following syntax;
{'var1',{ '--', '2000Q1', '--' }} and {'var1',{ '--', 2, '--' }} respectively

Inherited from superclass NB_GRAPH

- **lineWidth** ↑

Sets the line width of the line plots. Must be a scalar.
Default is 2.5.

Inherited from superclass NB_GRAPH

- **lineWidths** ↑

Sets the line widths of the given variables. Must be a cell array on the form: {'var1', 1, 'var2', 1.5,...}. Here we set the line widths of the variables 'var1' and 'var2' to 1 and 1.5 respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Inherited from superclass NB_GRAPH

- **localVariables** ↑

A nb_struct with the local variables of the nb_graph object. I.e. a field with name 'test' can be reach with the string input %#test.

Inherited from superclass NB_GRAPH

- **lookUpMatrix** ↑

Sets how the given mnemonics (variable and type names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {
'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Inherited from superclass NB_GRAPH

- **markerSize** ↑

Sets the size of the all markers. Must be a scalar. Default is 8.

Inherited from superclass NB_GRAPH

- **markers** [↑](#)

Sets the markers of the given variables. Must be a cell array on the form: {'var1', '^', 'var2', 'o', ...}. Here we set the markers of the variables 'var1' and 'var2' to '^' and 'o' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

See the table below on which markers that are supported.

'+'	: Plus sign
'o'	: Circle
'*'	: Asterisk
'.'	: Point
'x'	: Cross
's'	: Square
'd'	: Diamond
'^'	: Upward-pointing triangle
'v'	: Downward-pointing triangle
'>'	: Right-pointing triangle
'<'	: Left-pointing triangle
'p'	: Five-pointed star (pentagram)
'h'	: Six-pointed star (hexagram)

Inherited from superclass NB_GRAPH

- **noLabel** [↑](#)

Set it to 1 if no label(s) is/are wanted on the graphs, otherwise set it to 0. Both on the y-axis and x-axis. Default is 0. This is of course only have an effect if the nb_graph object have been given the xLabel or yLabel properties. (These are empty by default.)

Inherited from superclass NB_GRAPH

- **noLegend** [↑](#)

Set it to 1 if no legend is wanted, otherwise set it to 0. Default is 0.

Inherited from superclass NB_GRAPH

- **noTickMarkLabels** [↑](#)

Set to true (1) to remove tick marks and tick marks label of axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTickMarkLabelsLeft** [↑](#)

Set to true (1) to remove tick marks and tick marks label of the left side of the axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTickMarkLabelsRight** ↑

Set to true (1) to remove tick marks and tick marks label of the right side of the axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTitle** ↑

Set it to 1 if you don't want title(s) of the graphs, otherwise set it to 0. Default is 0.

Set it to 2 if you want the dataNames{ii} as the title of the graph when using the graph method.

Inherited from superclass NB_GRAPH

- **normalized** ↑

If the font should be normalized to the figure or axes. Either 'figure' or 'axes'.

Inherited from superclass NB_GRAPH

- **numberOfGraphs** ↑

Number of graph produced by the graph methods. Not settable.

Inherited from superclass NB_GRAPH

- **page** ↑

Sets the page of the data object to plot. Only an option for graph() method. Default is [], i.e. plot all pages in separate figures.

Inherited from superclass NB_GRAPH

- **parameters** ↑

A struct with the parameters that can be used in evaluation of expressions in the graphSubPlots and graphInfoStruct methods.

Inherited from superclass NB_GRAPH

- **patch** ↑

Sets the patch property of the object. If set this will add a patch (color fill) between two variables.

Only one patch :

```
{'patchName','var1','var2',color}
```

More patches :

```
{'patchName1','var1Patch1','var2Patch1',color1 ,...  
'patchName2','var1Patch2','var2Patch2',color2,...}
```

Where the the color option(s) must either be a 1 x 3 double with the RGB colors or a string with the color name.

The first input will be the legend text of the patch. I.e. 'patchName', 'patchName1' and 'patchName2' will be the description text included in the legend. (If not the property legAuto is set to 'off'.)

Inherited from superclass NB_GRAPH

- **patchAlpha** ↑

Sets the transparency of the patches. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

Inherited from superclass NB_GRAPH

- **pdfBook** ↑

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be used in combination with the saveName property.

Inherited from superclass NB_GRAPH

- **pieAxisVisible** ↑

Make the axes box visible ('on') or not ('off'), when doing pie or donut plot. 'on' is default.

- **pieEdgeColor** ↑

Sets the pie and donut edge color. Default is to not display edges (same as setting to 'none'). Can be a one line char with the colors that can be interpreted by nb_plotHandle.interpretColor, or a double with size 1x3 with the RGB colors.

- **pieExplode** ↑

Sets the element(s) of the pie or donut chart which should explode. Must be a cellstr of the variables to explode. E.g. {'Var1','Var2',...}

- **pieLabelsExtension** ↑

Extension of the pie or donut labels, e.g. 'mrd.kr' or '%'. Must be a string.

- **pieOrigoPosition** ↑

Set the origo position of pie or donut plot. Default is [-0.5,0]. Must either be empty or a 1x2 double.

- **pieTextExplode** ↑

Set this property to make text labels move more from the center of the pie or donut chart. Must be a cellstr of the variables to explode the text of. E.g. {'Var1','Var2',...}

- **plotAspectRatio** ↑

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3, or when '[16,9]' the aspect ratio of the figure is 16 to 9

Inherited from superclass NB_GRAPH

- **plotType** ↑

Sets the plot type. Either:

- > 'line' : If line plot(s) is wanted. Default.
- > 'stacked' : If stacked bar plot(s) is wanted.
- > 'grouped' : If grouped bar plot(s) is wanted.
- > 'dec' : If decomposition plot(s) is wanted. Which is a bar plot with also a line with the sum of the stacked bars.
- > 'area' : If area plot(s) is wanted.
- > 'radar' : If radar plot(s) is wanted.
- > 'candle' : If candle plot(s) is wanted.
- > 'scatter' : If scatter plot(s) is wanted.
- > 'pie' : If pie plot(s) is wanted.
- > 'donut' : If donut plot(s) is wanted.
- > 'image' : If you want to plot the data as an image mapped to the colors found by the property colorMap.

- **plotTypes** ↑

Sets the plot type of the given variables. Must be a cell array on the form: {'var1', 'line', 'var2', 'grouped', ...}. Here we set the plot type of the variables 'var1' and 'var2' to 'line' and 'grouped' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Only the plot types 'line', 'stacked', 'grouped', 'dec' and 'area' are supported.

- **position** ↑

Sets the position of the axes, must be an 1x4 double. [leftMostPoint lowestPoint width height]. Only an option for the graph() method. Default is [0.1 0.1 0.8 0.8].

For the graph method graphSubPlots the position input can be given a $1 \times N$ cell array, where each element is a 1×4 double.
 $N = \text{obj}.\text{subPlotSize}(1) * \text{obj}.\text{subPlotSize}(2)$.

Inherited from superclass NB_GRAPH

- **radarFontColor** ↑

The color of the font of the labels. Either a 1×3 double with the color of all the labels or a $\text{size}(xData, 1) \times 3$ with the color of each label (RGB colors). Can also be a string with the color names to use on all labels or a cellstr with the color names of each label. Size must be $1 \times \text{size}(xData, 1)$

- **radarNumberOfIsoLines** ↑

The number of isocurves of the radar plot. Must be an integer. Default is 10.

- **radarRotate** ↑

Rotate the radar. In radians. Must be a scalar. Default is 0.

- **radarScale** ↑

Sets the axes limits, so the radar plot is scaled properly. (Also set the size of the plotted radar). Must be a 1×2 double. Default is [2, 1.25].

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are produced. Must be a string.

Default is to save each graph produced in separate files. Set the pdfBook property to 1 if you want to save all the produced graphs in one pdf file. (To save all figures in one file is only possible for pdf files. I.e. the fileFormat property must be 'pdf'.)

Inherited from superclass NB_GRAPH

- **scatterLineStyle** ↑

Sets the scatter line style. Must be string. See 'lineStyles' for supported inputs. (Sets the line style of all scatter plots)

- **scatterTypes** ↑

The types used for the scatter plot. Must be a 1×2 cellstr array. The first element will be the type plotted against the x-axis, while the second element will be the type plotted against the left y-axis. E.g:

```
{'type1','type2'}
```

- **scatterTypesRight** ↑

The types used for the scatter plot. Must be a 1x2 cellstr array. The first element will be the type plotted against the x-axis, while the second element will be the type plotted against the right y-axis. E.g:

```
{'type1','type2'}
```

- **scatterVariables** ↑

Sets the variables to be used for the scatter plot plotted against the left axes. Must either be a nested cell array. E.g:

```
{'scatterGroup1',{'var1','var2','...'},...
'scatterGroup2',{'var10','var11','...'})
```

Be aware : Each variable will result in one point in the scatter.

- **scatterVariablesRight** ↑

Sets the variables to be used for the scatter plot plotted against the right axes. Must either be a nested cell array. E.g:

```
{'scatterGroup1',{'var1','var2','...'},...
'scatterGroup2',{'var10','var11','...'})
```

Be aware : Each variable will result in one point in the scatter.

- **shading** ↑

The shading option of the axes background:

- 'grey' : Shaded grey background
- 'none' : Background color given by the color property.
- A n x m x 3 double with the background color. n is the number of horizontal pixels, m is the number of vertical pixels and 3 means the RGB colors.

Inherited from superclass NB_GRAPH

- **subPlotSize** ↑

Sets the number of subplots per figure. Must be a 1 x 2 double with the number of subplot rows as the first element and the number of subplot columns as the second element. Only an option of the graphSubPlots() and graphInfoStruct() methods.

Default is [2, 2].

Inherited from superclass NB_GRAPH

- **subPlotSpecial** ↑

Set it to 1 if you want the 1x2 and 2x1 subplots to better fit for usage in presentations. Default is 0, i.e. use MATLAB default positions.

When set to 1 this class uses the nb_subplotSpecial instead of nb_subplot to find the positions of the subplots.

Inherited from superclass NB_GRAPH

- **sumTo** ↑

Sets a number which the area or the stacked bar plot should sum to. Must be a scalar. I.e. if 100 is given. The sizes of the bars will be the percentage share of the total sum.

Inherited from superclass NB_GRAPH

- **tag** ↑

Used by the nb_graph_subplot class to locate the nb_graph object in the subplot. Should not be used. Use userData instead.

Inherited from superclass NB_GRAPH

- **title** ↑

Sets the title of the plot. Must be a char. Only an option for the graph(...) method.

Inherited from superclass NB_GRAPH

- **titleAlignment** ↑

Sets the figure title text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_GRAPH

- **titleFontSize** ↑

Sets the font size of the titles which is placed above the (sub)plot(s). Must be scalar. Default is 14.

Inherited from superclass NB_GRAPH

- **titleFontWeight** ↑

Sets the font weight of the titles which is placed above the (sub)plot(s). Must be a string. Default is 'bold'.

Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **titleInterpreter** ↑

Sets the interpreter used for the given string given by the title property.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **titlePlacement** ↑

Sets the placement of the title. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_GRAPH

- **typesToPlot** ↑

Sets the types to plot for each plotted variables. Must be a cellstr. E.g. {'type1','type2',...}

If the plotType property is set to 'pie', selecting more plot types will create more graphs (one per type).

- **typesToPlotRight** ↑

Sets the types to plot for each plotted variables on the right axes. Must be a cellstr. E.g. {'type1','type2',...}. Only an option if plotType is set to 'grouped', and barOrientation is set to horizontal, and some variables are given to the variablesToPlotRight property.

- **userData** ↑

User data, can be set to anything you want.

Inherited from superclass NB_GRAPH

- **variablesToPlot** ↑

Sets the variables to plot against the left (or both) axes. Must be a cell array of strings with the variable names. I.e. {'var1', 'var2',...}.

Not an option for the graphInfoStruct(...), which use the property GraphStruct instead.

Inherited from superclass NB_GRAPH

- **variablesToPlotRight** ↑

Sets the variables to plot against the right axes. Must be a cell array of strings with the variable names. I.e. {'var1', 'var2',...}.

Not an option for the graphInfoStruct(...), which use the property GraphStruct instead.

Inherited from superclass NB_GRAPH

- **verticalLine** ↑

Sets the type(s) of where to place a vertical line(s). Must be a cellstr array with all the types which should have a vertical line, either 'type' or {'type1','type2',...}.

Each element of the cell could also be given as a cell with two types, i.e. {'type1','type2'}. Then the vertical line

will be placed between the given types.

If plotType is set to 'scatter' scalars can be used instead.

- **verticalLineColor** ↑

Sets the color(s) of the given vertical line(s). Must either be an M x 3 double with the RGB color(s) or a 1 x M cell array of strings with the color name(s). Where M must be less than the number of plotted vertical lines.

If less or no color(s) is/are set by this property the default color(s) for the rest or all the vertical line(s) is/are [0 0 0]. I.e. MATLAB black.

- **verticalLineLimit** ↑

Sets the y-axis limit(s) of the given vertical line(s). Must either be a 1 x M cell array of 1 x 2 double with the upper and lower y-axis limit(s). Where M must be less than the number of plotted vertical lines.

If less or no limit(s) is/are set by this property the default limit for the rest or all the vertical line(s) is/are the full height of the graph.

- **verticalLineStyle** ↑

Sets the line style(s) of the given vertical line(s). Must either be a 1 x M cell array of strings with the style(s). Where M must be less than the number of plotted vertical lines.

If less or no style(s) is/are set by this property the default line style is/are used for the rest or all the vertical line(s) is/are '--'.

- **verticalLineWidth** ↑

Sets the line width of (all) the vertical line(s). Must be a scalar. Default is 1.5.

- **xLabel** ↑

Sets (add) the text of the x-axis label. Must be a string.

Inherited from superclass NB_GRAPH

- **xLabelAlignment** ↑

Sets the x-axis label text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_GRAPH

- **xLabelFontSize** ↑

Sets the font size of the x-axis label. Must be scalar.
Default is 12.

Inherited from superclass NB_GRAPH

- **xLabelFontWeight** ↑

Sets the font weight of the x-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **xLabelInterpreter** ↑

The interpreter used for the given string given by the xlabel
property.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **xLabelPlacement** ↑

Sets the placement of the x-axis label. {'center'} | 'left' |
'right' | 'leftaxes'.

Inherited from superclass NB_GRAPH

- **xLim** ↑

Sets the x-axis limits of the plot. Must be 1 x 2 double
vector, where the first number is the lower limit and the
second number is the upper limit. (Both or one of them can be
set to nan, i.e. the default limits will be used) E.g. [0 6],
[nan, 6] or [0, nan].

Only an option when the plotType property is set to 'scatter'.

- **xScale** ↑

Sets the scale of the x-axis. Either {'linear'} | 'log'.

Only an option when plotType is set to 'scatter'.

- **xSpacing** ↑

Sets the x-ticks spacing. Must be a scalar.

- **xTickLabelAlignment** ↑

The alignment of the x-axis tick marks labels. {'below'} |
'middle'.

- **xTickLabelLocation** ↑

The location of the x-axis tick marks labels. Either {'bottom'} | 'top' | 'baseline'. 'baseline' will only work in combination with the xtickLocation property set to a double with the basevalue.

- **xTickLabels** ↑

Sets the x-axis tick mark labels. To translate the default tick mark label 'Var1' and 'Var2' you can use;

```
{'Var1','Label1','Var2','Label2'}
```

If given as a empty cell, default x-axis tick marks will be used, which is default.

This property can be used to create multi-lined x-axis tick mark labels. To do this give a multi-row char to the labels you want to make multi-lined.

Inherited from superclass NB_GRAPH

- **xTickLocation** ↑

The location of the x-axis tick marks. Either {'bottom'} | 'top' | double. If given as a double the tick marks will be placed at this value (where the number represent the y-axis value).

- **xTickRotation** ↑

Sets the rotation of the x-axis tick mark labels. Must be a scalar with the number of degrees the labels should be rotated. Positive angles cause counterclockwise rotation.

- **yDir** ↑

Sets the direction of the y-axis of the plot. Must be a string. Either 'normal' or 'reverse'. Default is 'normal'.

Caution: If the variablesToPlotRight is not empty this setting only sets the left y-axis direction.

- **yDirRight** ↑

Sets the direction of the right y-axis of the plot. Either 'normal' or 'reverse'. Default is 'normal'. (Only when the variablesToPlotRight property is not empty.)

- **yLabel** ↑

Sets (add) the text of the y-axis label. Must be a string.

Inherited from superclass NB_GRAPH

- **yLabelFontSize** ↑

Sets the font size of the y-axis label. Must be scalar.
Default is 12.

Inherited from superclass NB_GRAPH

- **yLabelFontWeight** ↑

Sets the font weight of the y-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **yLabelInterpreter** ↑

The interpreter used for the given string given by the xLabel
property.

```
> 'latex' : For mathematical expression
> 'tex'   : Latex text interpreter,
> 'none'  : Do nothing
```

Inherited from superclass NB_GRAPH

- **yLabelRight** ↑

Sets the text of the y-axis label. (Only on the right side.)
Must be a string. Takes the same font option as the yLabel
property

Inherited from superclass NB_GRAPH

- **yLim** ↑

Sets the y-axis limits of the plot. Must be 1 x 2 double
vector, where the first number is the lower limit and the
second number is the upper limit. (Both or one of them can be
set to nan, i.e. the default limits will be used) E.g. [0 6],
[nan, 6] or [0, nan].

Caution: If the variablesToPlotRight property is not empty
this setting only sets the left y-axis limits.

Only an option for the graph(...) and graphSubPlots() methods.
(For the graphInfoStruct(...) method use the property
GraphStruct.)

- **yLimRight** ↑

Sets the right y-axis limits of the plot. Must be 1 x 2 double
vector, where the first number is the lower limit and the
second number is the upper limit. (Only when the
variablesToPlotRight property is not empty.) (Both or one of
them can be set to nan, i.e. the default limits will be used)
E.g. [0 6], [nan, 6] or [0, nan].

Only an option for the graph(...) and graphSubPlots() methods.
(For the graphInfoStruct(...) method use the property
GraphStruct.)

- **yOffset** ↑

The y-axis tick mark labels offset from the axes

- **yScale** ↑

Sets the scale of the y-axis. {'linear'} | 'log'. (Both the left and the right axes if nothing is plotted on the right axes.)

- **yScaleRight** ↑

Sets the scale of the right y-axis. {'linear'} | 'log'. (Has only something to say if something is plotted on the right axes)

- **ySpacing** ↑

Sets the spacing between y-axis tick mark labels of the y-axis. Must be scalar.

Caution: The spacing will be the number of periods between the tick marks labels. The number of periods will follow the frequency of the xTickFrequency property if setted, else it will follow the frequency of the data provided. (Except when dealing with daily data, because then the default xTickFrequency is 'yearly')

Caution: If the variablesToPlotRight property is not empty this property only sets the spacing between ticks of the left y-axis.

- **ySpacingRight** ↑

Sets the spacing between y-axis tick mark labels of the right y-axis. Must be scalar.

Caution: The spacing will be the number of periods between the tick marks labels. The number of periods will follow

► **createFigure** ↑

```
createFigure(obj)
```

Description:

Create figure to plot in.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_GRAPH

► **get ↑**

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_graph_cs

Input:

- obj : An object of class nb_graph_cs
- propertyName : A string with the name of the wanted property.

Output:

- propertyValue : The property value of the given property.

Examples:

Get the last axes handle of the nb_graph_cs object. Be aware that all the the axes handles are stored in the figurehandle property of the object.

```
axeshandle = obj.get('axeshandle');
```

Get the handle of all the current figures of the nb_graph_cs object.

```
figurehandle = obj.get('figurehandle');
```

See also:

[nb_figure](#), [nb_axes](#)

Written by Kenneth S. Paulsen

► **getCSOptions ↑**

```
options = getCSOptions(obj)
```

Description:

A static method of nb_graph_cs.

Container with the properties specific to nb_graph_cs

Input:

- none

Output:

- options : A numSettings x 4 cell array with names in first column, default inputs in second, logical checks in the third, and function handles with the set function in the fourth.

Examples:

```
options = getCSOptions(obj);
```

See also:

[set](#), [getGenericOptions](#), [nb_parseInputs](#)

Written by Per Bjarne Bye

► getCode ↑

```
[code,numOfGraphs] = getCode(obj,frameTitle,frameSubTitle,...  
footer,source,pageNumber,theme)
```

Description:

Get the latex code when including a graph in a slide object produced by an object of class nb_graph_ts.

This method is called from the nb_Slide class, when making a beamer slide in latex.

Input:

- obj : An object of class nb_graph_ts
- frameTitle : A string with the frame title of the slide.
- frameSubTitle : A string with the frame subtitle of the slide.
- footer : A cellstr with the footers of the slide
- source : A cellstr with the sources of the slide
- pageNumber : Give 1 if the page number should be included.
- theme : The beamer theme used. Default is '' (use default beamer theme).

Output:

- code : The latex code as a char.
- numOfGraphs : The number of graphs produced by the input object of class nb_graph_ts. As an integer.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_GRAPH

► getData ↑

```
data = getData(obj)
```

Description:

Get the data of the graph

Input:

- obj : An object of class nb_graph_cs

Output:

- data : As an nb_cs object

Example:

```
data = obj.getData();
```

Written by Kenneth S. Paulsen

► getGenericOptions ↑

```
options = getGenericOptions(obj)
```

Description:

A static method of nb_graph.

Container with the intersect of options for subclasses of nb_graph.

Input:

- none

Output:

- options : A numSettings x 4 cell array with names in first column, default inputs in second, logical checks in the third, and a function handle with the set function in the fourth.

Examples:

```
options = getGenericOptions(obj);
```

See also:

[set](#), [nb_parseInputs](#)

Written by Per Bjarne Bye

Inherited from superclass `NB_GRAPH`

► **getPlottedTypes** ↑

```
types = getPlottedTypes(obj)
```

Description:

Get the plotted types of the graph

Input:

- obj : An object of class `nb_graph_cs`

Output:

- types : As a cellstr

Example:

```
types = obj.getPlottedTypes();
```

Written by Kenneth S. Paulsen

► **getPlottedVariables** ↑

```
vars = getPlottedVariables(obj, forLegend)
```

Description:

Get the plotted variables of the graph

Input:

- obj : An object of class nb_graph_cs
- forLegend : true or false (default)

When forLegend is used the variables are listed as needed for the legend, but without fake legends and patches, and duplicates are not removes.

Output:

- vars : A cellstr

Example:

```
vars = obj.getPlottedVariables();
```

Written by Kenneth S. Paulsen

► **graph ↑**

```
graph(obj)
```

Description:

Create a graph or more graphs

Graphs all the variables given by the variablesToPlot and the variablesToPlotRight properties in one plot, and does that for all the datasets of the DB property. I.e. one new plot for each dataset (page) of the DB property of the nb_graph_cs object.

Input:

- obj : An object of class nb_graph_cs

Output:

The graph plotted on the screen.

Examples:

```
data = nb_cs([2;1;2],'',{'type1','type2','type3'},'Var1');
obj = nb_graph_cs(data);
obj.graph();
```

See also:

[nb_graph_cs.set](#)

Written by Kenneth S. Paulsen

► graphInfoStruct ↑

```
graphInfoStruct(obj)
```

Description:

Create graphs based on the property GraphStruct. If it is empty nothing wil happen.

This method makes it easy to set up graph packages. For example graphing output from models.

See the documentation NB toolbox for more on this method.

Input:

- obj : An object of class nb_graph_cs, where the property GraphStruct contains the information on how to plot the objects data.

Output:

The wanted graphs plotted on the screen.

Examples:

```
obj.graphInfoStruct();
```

Written by Kenneth S. Paulsen

► graphSubPlots ↑

```
graphSubPlots(obj)
```

Description:

Create graphs of all the variables given in variablesToPlot property, in different subplots. (Each dataset against each other). The number of subplot is given by the property subPlotSize.

Input:

- obj : An object of class nb_graph_cs

Output:

The wanted graphs plotted on the screen.

Examples:

```
data = nb_cs([2 3 2;1 4 5;2 3 2],'',{'type1','type2','type3'},...  
            {'Var1','Var2','Var3'});  
obj = nb_graph_cs(data);  
obj.graphSubPlots();
```

Written by Kenneth S. Paulsen

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_graph_cs object is empty. I.e. if no data is stored in the object. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_graph_cs

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **merge** ↑

```
out = merge(obj,varargin)
```

Description:

Default: This tries to merge the data of plotter objects that uses the graphSubPlots, or the graphInfoStruct.

Caution: All objects must share the exact same variables!

'graph' is given: In this case it will try to merge the data of all nb_graph objects, and concatenate the variableToPlot property. If the property variableToPlot is empty for all objects, it will also be returned as empty, i.e. plot all series in the data.

Caution : Merging of any of the other properties then DB and variableToPlot is not done!

Input:

- obj : An object of class nb_graph, which includes the classes nb_graph_ts, nb_graph_cs and nb_graph_data.

Optional input:

- 'graph' : Give this input to merge the graphs in the way that is described in the description of this method.
- varargin : Each input must be an object of class nb_graph.

Output:

- out : An object of class nb_graph.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_GRAPH

► resetDataSource ↑

```
[message,err] = resetDataSource(obj,varargin)
```

Description:

Reset the data source of the nb_graph_cs object.

Input:

- obj : An object of class nb_graph_cs
- dataSource : An object of class nb_cs.
- updateProps : If the variablesToPlot should be updated to be equal to dataSource.variables + typesToPlot should be updated to be equal to dataSource.types.

Can also be 'gui'. Then all properties will be checked against the new dataset, and if the new dataset does not comply with the properties, the properties will be updated!

Written by Kenneth S. Paulsen

► saveData ↑

```
obj = saveData(obj,filename)
```

Description:

Saves the data of the figure

Input:

- obj : An object of class nb_graph_cs
- filename : A string with the saved output name

Example:

```
obj.saveData('test');
```

Written by Kenneth S. Paulsen

► **saveFigure ↑**

```
saveFigure(obj,extraName,format)
```

Description:

Save the figure(s) produced by the nb_graph object to
(a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_graph
- extraName : If you want to add some extra name to the saveName property of the nb_graph_data object before saving the file. (If the saveName property of the nb_graph_ts object is empty this will be the full name of the output file.)
- format : The format of the saved output. Default is given by the property fileFormat of the nb_graph. Either 'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.

Output:

The produced figure(s) saved to the wanted formats.

Examples:

```
data = nb_data([2;1;2],'',1,'Var1');
obj = nb_graph_data(data);
obj.graph();
saveFigure(obj,'test','pdf');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_GRAPH

► **set** ↑

```
set(obj,varargin)
```

Description:

Set properties of the nb_graph class and its subclasses.

See documentation NB Toolbox or type `help('nb_graph')` for more on the properties of the class.

Input:

- `obj` : An object that is a subclass of nb_graph
- `varargin` : `'propertyName'`,`propertyValue`,...

Output:

No actual output, but the input objects properties will have been set to their new value.

Examples:

```
data = nb_ts([2;1;2],'', '2012Q1', 'Var1');
obj = nb_graph_ts(data);
obj.set('startGraph','2012Q1','endGraph','2012Q3');
obj.set('crop',1);
```

Written by Per Bjarne Bye

Inherited from superclass NB_GRAPH

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct

Input:

- `obj` : An object of class nb_graph_cs

Output:

- `s` : A struct

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the figure

See the update method of the nb_cs class for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_graph_cs

Output:

- obj : An object of class nb_graph_cs, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

■ **nb_graph_data**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_graph_data(data)
```

Superclasses:

handle, nb_graph

Description:

This is a class for making dataseries graphics.

Constructor:

```
obj = nb_graph_data(data)
```

Input:

- data :

The input must be one of the following:

> An object of class nb_data. E.g. nb_graph_data(data)

> A excel spreadsheet which could be read by the nb_data
class. E.g. nb_graph_data('excelName')

Output:

- obj : An object of class nb_graph_data

- **`DB`** 

All the data given to the `nb_graph_data` object collected in a `nb_data` object. Should not be set using `obj.DB = data!` Instead see the `nb_graph_data.resetDataSource` method.

- **`GraphStruct`** 

Sets the information on which variables and how to plot them when using the `graphInfoStruct(...)` method of this class.

Must be an .m-file with the code on how the structure of graphing information should be initialized or as a structure with the graphing information.

Only the `graphInfoStruct(...)` method uses this property. See the documentation of the NB toolbox for more on this input.

Inherited from superclass `NB_GRAPH`

- **`a4Portrait`** 

Save PDF to A4 portrait format. 0 or 1

Inherited from superclass `NB_GRAPH`

- **`addAdvanced`** 

Set to false to prevent adding advanced components.

Inherited from superclass `NB_GRAPH`

- **`addSpace`** 

Sets the space before and/or after in the x direction of the graph [`addedSpaceBefore` `addedSpaceAfter`]. E.g. add one period before and after [1,1].

Inherited from superclass `NB_GRAPH`

- **alignAxes** ↑

Align axes at a given base value. Must be set to a scalar double.
E.g. 0.

Inherited from superclass NB_GRAPH

- **annotation** ↑

Sets the plotted annotations of the graph.

Must be one or more nb_annotation objects. See the documentation of the nb_annotation class for more. If you give more objects they must be collected in a cell array.

Examples can be found here:

\NBTOOLBOX\Examples\Graphics\nb_annotationExamples.m

Inherited from superclass NB_GRAPH

- **areaAbrupt** ↑

Set this property to true to make the areas abruptly finish when given as nan. Default is false.

Inherited from superclass NB_GRAPH

- **areaAccumulate** ↑

Set if the areas should be accumulated or not. Default is true.

Inherited from superclass NB_GRAPH

- **areaAlpha** ↑

Sets the transparency of the area chart. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

Inherited from superclass NB_GRAPH

- **axesFast** ↑

Set the if you want graphs to be produced fast with a loss of functionality and look or not. When empty default for the graph method is false, while for the graphSubPlots and graphInfoStruct methods are true.

Inherited from superclass NB_GRAPH

- **axesFontSize** ↑

Sets the font size of the axes tick mark labels, default is 12. Must be a scalar.

Inherited from superclass NB_GRAPH

- **axesFontSizeX** ↑

Sets the font size of the x-axis tick mark labels, default is []. I.e. use the axesFontSize property instead. Must be a scalar.

This property will not be scaled when fontUnits are changed, as is the case for axesFontSize.

Caution: Will not set the x-axis font size when plotType is set to scatter.

Inherited from superclass NB_GRAPH

- **axesFontWeight** ↑

Sets the font weight of the axes tick mark labels. Must be a string. Default is 'normal'. Either 'normal', 'bold', 'light' or 'demi'

Inherited from superclass NB_GRAPH

- **axesLineWidth** ↑

Sets the line width of the axes, default is 0.5. Must be a set to a scalar double greater than 0.

Inherited from superclass NB_GRAPH

- **axesPrecision** ↑

Sets the precision/format of the rounding of number on the axes.

See the precision input to the nb_num2str function. Default is [], i.e. to call num2str without additional inputs.

Inherited from superclass NB_GRAPH

- **axesScaleFactor** ↑

Set the scaling factor used when axesScaleLineWidth is set to true.

Inherited from superclass NB_GRAPH

- **axesScaleLineWidth** ↑

Scale line width to axes height. true or false (default). If axesScaleFactor is set to a scalar number this will be the scaling factor used instead of the automatic scaling factor.

Inherited from superclass NB_GRAPH

- **barAlpha1** ↑

Set the alpha blending parameter 1, when barBlend is set to true. See nb_alpha. Default is 0.5

Inherited from superclass NB_GRAPH

- **barAlpha2** ↑

Set the alpha blending parameter 2, when barBlend is set to true. See nb_alpha. Default is 0.5

Inherited from superclass NB_GRAPH

- **barBlend** ↑

Set to true to do alpha blending instead of shading if shading options is used. Default is false.

Inherited from superclass NB_GRAPH

- **barLineWidth** ↑

Set the bar line width without affecting any other line widths. Default is empty, i.e. use the lineWidth property.

Inherited from superclass NB_GRAPH

- **barPeriods** ↑

The periods for where to plot the bar. E.g 3 or [3,4]. Only an option for the graphSubPlots() method. The lineStop must be set to make this option work. Default is [].

- **barShadingColor** ↑

The color shaded bars are interpolated with. Default is 'white'. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **barShadingDirection** ↑

Sets the angle the shading should be vertical of. Either {'north'} | 'south' | 'west' | 'east'. As a string. Default is 'north'.

Inherited from superclass NB_GRAPH

- **barShadingObs** ↑

Sets the date from which the bar plot should be shaded. As an integer. Default is [].

- **barWidth** ↑

Sets the width of the bar plot. As a scalar. Default is 0.45.

Inherited from superclass NB_GRAPH

- **baseLine** ↑

If 0 is given the base line will not be plotted, otherwise it will be plotted.

Inherited from superclass NB_GRAPH

- **baseLineColor** ↑

Sets the color of the base line. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **baseLineStyle** ↑

Sets the line style of the base line. As a string.
Either {'-' | '--' | '---' | ':' | '-.' | 'none'.

Inherited from superclass NB_GRAPH

- **baseLineWidth** ↑

Sets the width of the base line. Must be a scalar.

Inherited from superclass NB_GRAPH

- **baseValue** ↑

Sets the base value used for bar and area plot. (Sest also the
y-axis base value for the base line)

Inherited from superclass NB_GRAPH

- **candleIndicatorColor** ↑

Sets the color of the indicator of the candle. Must either be a
1 x 3 double with the RGB colors or a string with the color
name.

Inherited from superclass NB_GRAPH

- **candleIndicatorLineStyle** ↑

Sets the line style of the indicator of the candle. Must be a
string. Default is '-'.

Inherited from superclass NB_GRAPH

- **candleMarker** ↑

Sets the marker of the indicator of the candle. Must be a
string. Default is 'none'.

Inherited from superclass NB_GRAPH

- **candleVariables** ↑

Sets which variables are going to be plotted as open, close,
high, low and indicator. Must be a cellstr. E.g.

{'open','var1','close','var2',...}

If a type (e.g. 'low') is not given it will not be plotted.

Meaning of each type:

> 'close' : The lowest values of the plotted patches of
the candle.

> 'high' : The highest values of the plotted candles.

> 'indicator' : The value for where to plot a horizontal line
(across the patch). E.g. the mean value.

> 'open' : The highest values of the plotted patches of the candle.

> 'low' : The lowest values of the plotted candles.

Inherited from superclass NB_GRAPH

- **candleWidth** [↑](#)

Sets the width of the candle plot. As a scalar. Default is 0.45.

Inherited from superclass NB_GRAPH

- **code** [↑](#)

If you set this to a file name, this file will be evaluated after all the plotting is done. Must be a string.

This could be nice for adding special annotation, lines and so on. In this file you can use any MATLAB function, but some strange error message can occur if you use local variables which is already defined (So use long and descriptive variable names in the provided code to prevent this).

This property is only an option for the method graph.

Nice to know:

> The current nb_figure object can be reached with
get(obj,'figureHandle')

> The current nb_axes object can be reached with
get(obj,'axesHandle')

Caution : Be aware that the name of the file must be unique and cannot be a MATLAB function or a local variable.

Caution : The file must be a MATLAB .m file

Inherited from superclass NB_GRAPH

- **colorBarAtEnd** [↑](#)

A string with the color specification to use for the bars when the line with bars at the end plot type is triggered. One of 'nb' | 'red' | 'green' | 'yellow' | ''. Default is 'nb'. Use the lineStop and barPeriods properties to trigger this plot type.

- **colorMap** [↑](#)

Sets the colormap used when plotType is set to 'image' and fanMethod is set to 'graded'. Must be given as n x 3 double or the path to a .mat file that contain the colormap. Default is given by nb_axes.defaultColorMap.

For an example of a supported MAT file see:

- ...\\Examples\\Graphics\\colorMapNB.mat

Inherited from superclass NB_GRAPH

- **colorOrder** [↑](#)

Sets the color order of the plotted data (Left axes). Either a cellstr with the color names (size; 1xM) or a double with RGB colors (Size; Mx3). Where M is the number of plotted variables against the left axes.

Inherited from superclass NB_GRAPH

- **colorOrderRight** [↑](#)

Sets the color order of the plotted data (Right axes). Either a cellstr with the color names (size; 1xM) or a double with RGB colors (Size; Mx3). Where M is the number of plotted variables against the right axes.

Inherited from superclass NB_GRAPH

- **colors** [↑](#)

Sets the colors of the given variable(s). Must be a cell array on the form: {'var1', 'black', 'var2', [0.2 0.2 0.2],...}. Here we set the colors of the variables 'var1' and 'var2' to 'black' and [0.2 0.2 0.2] (RGB color) respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Caution: For the graphInfoStruct() method you need to select the variables from obj.DB.dataNames instead!

Inherited from superclass NB_GRAPH

- **crop** [↑](#)

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

Inherited from superclass NB_GRAPH

- **dashedLine** [↑](#)

Sets the date at which all the plotted lines will be dashed. Must be given as an integer with the obs (or a double when the variableToPlotX is given)

- **displayValue** [↑](#)

Set to false to not display observation values when holding the mouse over the graph. Defualt is true.

Inherited from superclass NB_GRAPH

- **endBarWidth** [↑](#)

The width of the bars when the line with bars at the end plot type is triggered. Use the lineStop and barPeriods properties to trigger this plot type. Default is 3.

- **endGraph** ↑

Sets the end obs of the graph. Either as an integer. If the given obs is after the end obs of the data, the data will be appended with nan values. I.e. the graph will be blank for these obs.

Not used when variableToPlotX property is set, use xLim instead.

- **excelFooterEng** ↑

If you want a extended footer to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to include the same footer as in the graph. English version.

Inherited from superclass NB_GRAPH

- **excelFooterNor** ↑

If you want a extended footer to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to include the same footer as in the graph. Norwegian version.

Inherited from superclass NB_GRAPH

- **excelTitleEng** ↑

If you want a custom title to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to use the same title as in the graph (panel if multiple graphs). English version.

Inherited from superclass NB_GRAPH

- **excelTitleNor** ↑

If you want a custom title to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to use the same title as in the graph (panel if multiple graphs). Norwegian version.

Inherited from superclass NB_GRAPH

- **factor** ↑

Set this property to multiply the data with a given factor.
Must be a scalar.

Inherited from superclass NB_GRAPH

- **fakeLegend** ↑

Set this property if you want to add a legend of none plotted variable. You can set this property. Must be a cell on the form: {'legendName', settings,...}, where the legendName will be text of the fake legend. And the settings input must also be a cell array with the optional inputs {...,'propertyName', propertyName,...}. These settings will set the appearance of the fake legend. The following propertyNames are supported:

```
> 'type'      : Either 'line' or 'patch'.

> 'color'     : Sets the color of the fake legend. Default is
                 'black'. Must either be a 1 x 3 double with
                 the RGB colors or a string with the color
                 name. If shaded patch is wanted it must be
                 2 x 3 double with the RGB colors or a 1 x 2
                 cellstr with the color names to use.

> 'direction' : Sets the direction of the shading. Either
                 {'north'} | 'south' | 'west' | 'east'. As a
                 string. Default is 'north'. Only an option
                 when 'type' is set to 'patch'.

> 'edgeColor'  : Sets the color of the edge of the patch.
                 Default is the same as the 'color' option.
                 Only an option when 'type' is set to 'patch'.

> 'lineStyle'   : Sets the line style of the fake legend. As a
                 string. Either {'-' } | '--' | '---' | ':' |
                 '-.' | 'none'. Default is a normal line.

                 Will set the edge line style if the 'type'
                 is set to 'patch'.

> 'lineWidth'   : Sets the line width of the fake legend.
                 Default is 2.5. Must be a scalar.

> 'marker'     : Sets the marker of the fake legend. Default is
                 'none'. Only an option when 'type' is set to
                 'line'. Lookup LineSpec in the MATLAB help
                 meny for more on the supported marker types.
```

Caution : Even if you don't want to set any of the optional input. The settings input must be given. I.e an empty cell, i.e. {}.

Inherited from superclass NB_GRAPH

- **fanColor** ↑

Sets the colors of the fan charts. Must be a matrix of size; number of fan layer x 3, with the RGB color specifications.

or

A string with the basis color for the fan colors. Either 'red', 'blue', 'green', 'yellow', 'magenta', 'cyan' or 'white'.

Be aware that the classification of the color of the given

"basecolor" is based on the property fanPercentiles, so if you have more or less than 4 layers you must change this property to have the same size as the number of layers. (This is the case even if you don't use it to calculate the percentiles of a given datasets. Given by the property fanDatasets)

Default is the nb colors.

Caution: If fanMethod is set to 'graded' the color used are those assign to the colorMap property.

- **fanDatasets** ↑

Sets the data of the added fan layers.

If you have the data of the different layer in separate datasets. Then the input to this property must be a 2 * number of layers cell matrix. Can be excel spreadsheets or .mat files.

or

You can also give the data with all the simulated data or fan layers in a nb_cs object. (Each page one simulation or each page one layer).

Remember that the percentiles for the fan charts is set by the property fanPercentiles, default is [.3, .5, .7, .9].

The fan layers are added differently given the method you use.

> graph(...): Adds the fan given in this property to the last variable given in the property variablesToPlot.
(If not the fanVariable property is set.) If you graph more datasets (in separate figures), the fan layers will be the same for all of them.
Set the fanVariables property if that is not wanted.

> graphSubPlots(...): Adds the fan given in this property to the corresponding variable in the last given datasets (last page of the nb_cs object given by the property DB) of each subplot.

-graphInfoStruct(...): Adds the fan given by this property to each variable of each subplot. Added for the last given dataset. (Last page of the nb_cs object given by the property DB.)

- **fanLegend** ↑

Set this property if you want to add a MPR styled legend of the fan layers. Set it to 1 if wanted. Default is not (0).

- **fanLegendFontSize** ↑

Sets the font size of the fan legend. Default is 12. Must be a scalar.

- **fanLegendLocation** ↑

Sets the location of the fan legend. Locations are:

```
> 'Best', (same as 'North'.)
> 'NorthWest'
> 'North'
> 'NorthEast'
> 'SouthEast'
> 'South'
> 'SouthWest'
> 'outside' : Places the legend outside the axes, one the
               right side. (If you create subplots, this is
               the only option which will look good.)
```

You can also give a 1×2 double vector with the location of where to place the legend. First column is the x-axis location and the second column is the y-axis location. Both must be between 0 and 1.

- **fanLegendText** ↑

Set this property if you want to give the text over the colored boxes of the MPR looking fan legend, you must give them as a cell. (Must have same size as number of layers.) Default is the percentiles with the % sign added. E.g.
{'30%', '50%', '70%', '90%'}.

- **fanMethod** ↑

{'percentiles' | 'hdi' | 'graded'}; Which type of fan chart is going to be made. 'percentiles' are produced by using percentiles, 'hdi' use highest density intervals, while 'graded' creates a graded fan chart of the colors specified with the colorMap property.

- **fanPercentiles** ↑

Sets the percentiles you want to calculate (if the fanDatasets property is representing simulation) or specify the percentiles you have given (if the fanDatasets property is representing already calculated percentiles). Must be given as a double vector. Default is [0.3 0.5 0.7 0.9].

This property is also the default base for the text of the fan legend. (Where the percentiles are given in percent.)

- **fanVariable** ↑

Sets the variable you want to add the fan layers to. Must be given as a string with the variable name. Default is to use the last variable in the variablesToPlot property.

- **figureColor** ↑

Color of the figure as a 1x3 double. Default is [1 1 1].

Inherited from superclass NB_GRAPH

- **figureName** ↑

Sets the name of figure (only in MATLAB), default is no name.

Inherited from superclass NB_GRAPH

- **figurePosition** ↑

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

Inherited from superclass NB_GRAPH

- **figureTitle** ↑

Sets if figure titles is wanted on the figures when using the method graphInfoStruct. The fieldnames of the GraphStruct property will be used as figure title. Default is 0 (not include).

If set to a one line char this property can be used for the plotting method graphSubPlots.

Inherited from superclass NB_GRAPH

- **fileFormat** ↑

Sets the save file format. Either 'eps', 'jpg', 'pdf' or 'png'. 'pdf' is default.

Inherited from superclass NB_GRAPH

- **findAxisLimitMethod** ↑

Sets the method used for finding the axis limits, and y-ticks.

- > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
- > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
- > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
- > 4 : Uses the MATLAB algorithm for finding the axis limits.

Inherited from superclass NB_GRAPH

- **flip** ↑

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

Inherited from superclass NB_GRAPH

- **fontName** ↑

Sets the name of font used. Default is 'arial'.

Inherited from superclass NB_GRAPH

- **fontScale** ↑

Sets the parameter that scales all the font sizes of the graphs. Must be scalar. Default is 1 (do not scale).

Inherited from superclass NB_GRAPH

- **fontUnits** ↑

Sets the font units of all the fonts of the graph. Either {'points'} | 'normalized' | 'inches' | 'centimeters'. Default is 'points'.

Caution : If you set the fontUnits property in a method call to the set method, all the font properties set before the fontUnits property will be set in the old fontUnits, while all the font properties set after will be in the new fontUnits.

Caution : Don't use this property in combination with one of the graph styles defined by this class. I.e. 'mpr', 'mpr_white', 'presentation' and 'presentation_white' They will set this property to 'normalized'.

Caution : 'normalized' font units must be between 0 and 1. The normalized units are not the same as the MATLAB normalized units. This normalized units are not only normalized to the axes size, but also across resolution of the screen. (But only vertically)

Inherited from superclass NB_GRAPH

- **graphStyle** ↑

Sets the graphing style of the plots. Give 'mpr' if you want the MPR looking style, or 'presentation' for graphs for the presentation (see nb_Presentation). If you don't want the grey shaded background you can use 'mpr_white' and 'presentation_white' instead.

You can also add your own graph style setting through a .m file. I.e. give the filename (without extension) as a string.

E.g. In the file you can type in something like:

```
set(obj,'titleFontSize',12,'legInterpreter','tex');
```

Caution: If you give this as the first input to the set method it is possible to overrun some of the default settings if that is wanted. E.g. font size of the text, the shading of the plot and so on.

Inherited from superclass NB_GRAPH

- **grid** ↑

Set it to 'on' if grid lines are wanted otherwise set it to 'off'. Default is 'off'.

Inherited from superclass NB_GRAPH

- **gridLineStyle** ↑

Sets the line style of the grid lines. Either '-' , '--' , ':' or '-.' .

Inherited from superclass NB_GRAPH

- **highlight** ↑

If highlighted area between two observations of the graph is wanted set this property.

One highlighted area:

A cell array on the form {obs1, obs2}

More highlighted areas:

A nested cell array on the form
{ {obs1(1), obs2(1)}, {obs1(2), obs2(2)}, ... }

- **highlightColor** ↑

Sets the colors of the background patches. Must be one of the following:

- > A string with the color name to use when plotting (all) the patch(es)
- > A cell array of strings with the color names
- > A cell with 1 x 3 doubles with the RGB color specification.

When given as a cell this property must match the highlight property. I.e. the number of highlighted areas added.

The default color of the highlighted areas is 'light blue'.

- **horizontalLine** ↑

If you want to include some extra horizontal lines, beside the base line, you can set this property. Must be set to a scalar or a double vector with the y-axis value(s) on where to place the horizontal line(s).

Inherited from superclass NB_GRAPH

- **horizontalLineColor** ↑

Sets the color(s) of the given horizontal line(s).

Must either be an M x 3 double with the RGB color(s) or a 1 x M cell array of strings with the color name(s). Where M must be less than the number of plotted horizontal lines.

If less or no color(s) is/are set by this property the default

colors for the rest or all the horizontal line(s) is/are [0 0 0], i.e. MATLAB black.

Inherited from superclass NB_GRAPH

- **horizontalLineStyle** ↑

Sets the style(s) of the given horizontal line(s).

Must either be a string or a 1 × M cell array of strings with the style(s). Where M must be less than the number of plotted horizontal lines.

If less or no style(s) is/are set by this property the default lines for the rest or all the horizontal line(s) is/are '-'.

Inherited from superclass NB_GRAPH

- **horizontalLineWidth** ↑

Sets the line width of the horizontal line(s). Must be a scalar. Default is 1.

Inherited from superclass NB_GRAPH

- **language** ↑

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

Inherited from superclass NB_GRAPH

- **legAuto** ↑

'on' | {'off'}. As a string.

> 'on' : The strings given through the fakeLegend and patch properties are automatically added to the legend.

> 'off' : The strings given through the fakeLegend and patch properties are not automatically added to the legend. Which means that you must provide all the legend information through the legends property. The patch descriptions must be given first and the fake legend description must be given last in the legends property. Default.

Inherited from superclass NB_GRAPH

- **legBox** ↑

Set if a box should be drawn around the legend. Either {'on'} | 'off'.

Caution : When removing the box you make it impossible to move it around afterwards.

Inherited from superclass NB_GRAPH

- **legColor** ↑

Sets the color of the background of the box of the legend.
Either as 1x3 double with the RGB or as a string).
Default is 'none', i.e. transparent.

Inherited from superclass NB_GRAPH

- **legColumnWidth** ↑

Sets the width of the columns of the legend. Default is to let MATLAB find the width itself. If given it must be a scalar with the width of all columns of the legend or a 1 x legColumns double with the width of each individual column.

Should be between 0 and 1. Use the try and fail method to find out what fits.

Inherited from superclass NB_GRAPH

- **legColumns** ↑

Sets the number of columns of the legends. Must be a scalar.

Inherited from superclass NB_GRAPH

- **legFontColor** ↑

Sets the font color(s) of the legend text. Must either be a 1x3 double or a string with the color name of all legend text objects, or a M x 3 double or a cellstr array with size 1 x M with color names to use of each legend text object.

Inherited from superclass NB_GRAPH

- **legFontSize** ↑

Sets the font size of the legend. Must be a scalar default is 10.

Inherited from superclass NB_GRAPH

- **legInterpreter** ↑

Sets the interpreter of the legend text. Must be a string.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **legLocation** ↑

Sets the location of the legend, must be string. The location can be:

> 'Best' : Same as 'NorthWest'.
> 'NorthWest'
> 'North'
> 'NorthEast'

```
> 'SouthEast'  
> 'South'  
> 'SouthWest'  
> 'below'      : Below the plot (when many subplots, it will  
                  place the legend below all of them)  
> 'middle'     : Could only be used for 2 x 2 subplot, and then  
                  it places the legend between the upper and  
                  lower subplots.
```

Location that only works for the graph() method:

```
> 'outsideright'   : Legend is placed outside the axes on the  
                     right side, and the axes is resized, so  
                     the axes and legend does not take up more  
                     space than the axes did in the first place.  
                     The legend is vertically centered.  
> 'outsiderighttop' : Same as 'outsideright', but placed  
                     vertically top.
```

Inherited from superclass NB_GRAPH

- **legPosition** [↑](#)

Sets the position of the legend. Must be a 1x2 double. Where
the first element is the x-axis location and the second is the
y-axis location. [xPosition yPosition]

Caution : Both elements must be between 0 and 1. And where we
have that [0, 0] will be the bottom left location of
the axes and [1, 1] is the top right position of the
axes. (This position will be the top left
position of the legend itself.)

Caution : This option overruns the legLocation property.

Inherited from superclass NB_GRAPH

- **legReorder** [↑](#)

Set this property to reorder the legend. Either a string
with {'default'} | 'inverse' or a double with how to reorder
the legend. E.g. if you have 3 legends to plot the default
index will be [1,2,3], the inverse ('inv') will be [3,2,1].
If you want to decide that the 3. legend should be first, then
the 1. and 2., you can type in [3,1,2].

Caution : If a double is given it must have as many elements
as there are plotted legends. I.e. if you give a
empty string to one of the legends it will be
excluded. Say you provide the property
legends as {'s','t','f'} then the double
must have size 1x3.

Inherited from superclass NB_GRAPH

- **legSpace** [↑](#)

The vertical space between the texts of the legend. Must be a
scalar. Default is 0.

Inherited from superclass NB_GRAPH

- **legendText** ↑

Sets the legend(s) of the given variable(s). Must be a cell array on the form: {'var1', 'Name', 'var2', 'Name2', ...}. Here we set the legends of the variables 'var1' and 'var2' to 'Name' and 'Name2' respectively. (The rest will be given the variable names as default).

To give a legend to a splitted line (second part) give;
{...,'Var1(second)', 'LegendSplitted', ...} (Is case sensitiv)

Caution : legAuto should be set to 'on'. Which is not default.
This is only important if the patch or fakeLegend property is used.

Caution : When given this property will overwrite the legends property

Caution : If the variable, scattergroup or candle is not found no error will occure!

Caution : If you have used the patch or fakeLegend property these can be translated as well with this property

Inherited from superclass NB_GRAPH

- **legends** ↑

Give the legends of the plot. Must be given as a cell array of strings.

Default (it depends on the method you use):

> 'graph' : The variable names are used as the default legends. (Given by the variableToPlot and variableToPlotRight properties)

> 'graphSubPlot' : The dataset names are used as the default legends. (Given by the dataNames of the DB property.)

> 'graphInfoStruct' : The dataset names are used as the default legends. (Given by the dataNames of the DB property.)

Caution : The ordering of the legends is as follows:

- patch : See the patch property (only when legAuto is set to 'off')
- variablesToPlot : Then all the variablesToPlot variables. When You have splitted lines, i.e. either using the dashedLine property or the lineStyles property, these can be set after all the variablesToPlot. Have in mind that the ordering is kept.
- variablesToPlotRight : Then comes all the variables

provided by the variablesToPlotRight.
Then the splitted lines.

- fakeLegend : Then you can provide the legend text for the fake legend. (only when legAuto is set to 'off')

Example:

```
data      = nb_ts.rand('2012',10,2);
plotter = nb_graph_ts(data);
plotter.set('variablesToPlot',{'Var1'},...
            'variablesToPlotRight',{'Var2'},...
            'lineStyles',{'Var1',{'-','2014','--'},...
                         'Var2',{'-','2014','--'},...
            'legends',{'Test','Test (--)','Test2','Test2 (--)'});
plotter.graph()
```

Inherited from superclass NB_GRAPH

- **lineStop** ↑

The period that the line should be stopped. E.g. 2. This will trigger the plot type line with bars at end. See also the barPeriods property. Default is [].

- **lineStyles** ↑

Sets the line styles of the given variable(s). Must be a cell array on the form: {'var1', '- ', 'var2', '---', ...}. Here we set the line styles of the variables 'var1' and 'var2' to '-' and '---' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Supported line styles are '-','--','::','.-','---

Caution : For nb_graph_ts and nb_graph_data it is possible to split the plotted line using the following syntax;
{'var1',{'-','2000Q1','--'}} and {'var1',{'-',2,'--'}} respectively

Inherited from superclass NB_GRAPH

- **lineWidth** ↑

Sets the line width of the line plots. Must be a scalar.
Default is 2.5.

Inherited from superclass NB_GRAPH

- **lineWidths** ↑

Sets the line widths of the given variables. Must be a cell array on the form: {'var1', 1, 'var2', 1.5,...}. Here we set the line widths of the variables 'var1' and 'var2' to 1 and 1.5 respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Inherited from superclass NB_GRAPH

- **localVariables** ↑

A nb_struct with the local variables of the nb_graph object. I.e. a field with name 'test' can be reach with the string input %#test.

Inherited from superclass NB_GRAPH

- **lookUpMatrix** ↑

Sets how the given mnemonics (variable and type names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {
'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Inherited from superclass NB_GRAPH

- **mYLim** ↑

Sets the max/min y-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Both or one of them can be set to nan, i.e. the default limits will be used) E.g. [0 6], [nan, 6] or [0, nan].

Caution: If the variablesToPlotRight property is not empty this setting only sets the left y-axis limits.

Only an option for the graphInfoStruct(...) method.

- **markerSize** ↑

Sets the size of the all markers. Must be a scalar. Default is 8.

Inherited from superclass NB_GRAPH

- **markers** ↑

Sets the markers of the given variables. Must be a cell array on the form: {'var1', '^', 'var2', 'o', ...}. Here we set the markers of the variables 'var1' and 'var2' to '^' and 'o' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

See the table below on which markers that are supported.

'+'	: Plus sign
'o'	: Circle
'*'	: Asterisk
'.'	: Point
'x'	: Cross

```

's' : Square
'd' : Diamond
'^' : Upward-pointing triangle
've' : Downward-pointing triangle
'>' : Right-pointing triangle
'<' : Left-pointing triangle
'p' : Five-pointed star (pentagram)
'h' : Six-pointed star (hexagram)

Inherited from superclass NB_GRAPH

- missingValues ↑

Set how to interpret missing observations. Must be a string.
Either;

> 'interpolate' : Linearly interpolate the missing values.

> 'none'           : No interpolation (default)

- nanAfterObs ↑

If setted this property would make the graph blank after the
provided obs, but the x-axis would still keeps its axis
limits. Must be an integer.

Caution: Not possible to combine with variablesToPlotX

- nanBeforeObs ↑

If setted this property would make the graph blank before the
provided obs, but the x-axis would still keeps its axis
limits. Must be an integer.

Caution: Not possible to combine with variablesToPlotX

- nanVariables ↑

Sets the nan option for individual variables. Must be given
as a cell. I.e. {'var1', {2, 4}, ...
'var2', {2, 4}, ...}. This will make both 'var1' and 'var2'
variables blank before 2 and after 4 (Not including.)
in the given graph.

Caution: Not possible to combine with variablesToPlotX

- noLabel ↑

Set it to 1 if no label(s) is/are wanted on the graphs,
otherwise set it to 0. Both on the y-axis and x-axis.
Default is 0. This is of course only have an effect if the
nb_graph object have been given the xLabel or yLabel
properties. (These are empty by default.)

Inherited from superclass NB_GRAPH

- noLegend ↑

```

Set it to 1 if no legend is wanted, otherwise set it to 0.
Default is 0.

Inherited from superclass NB_GRAPH

- **noTickMarkLabels** ↑

Set to true (1) to remove tick marks and tick marks label of axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTickMarkLabelsLeft** ↑

Set to true (1) to remove tick marks and tick marks label of the left side of the axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTickMarkLabelsRight** ↑

Set to true (1) to remove tick marks and tick marks label of the right side of the axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTitle** ↑

Set it to 1 if you don't want title(s) of the graphs, otherwise set it to 0. Default is 0.

Set it to 2 if you want the dataNames{ii} as the title of the graph when using the graph method.

Inherited from superclass NB_GRAPH

- **normalized** ↑

If the font should be normalized to the figure or axes.
Either 'figure' or 'axes'.

Inherited from superclass NB_GRAPH

- **numberOfGraphs** ↑

Number of graph produced by the graph methods. Not settable.

Inherited from superclass NB_GRAPH

- **obs** ↑

All the dates of the plot as a cellstr. Not settable.

- **page** ↑

Sets the page of the data object to plot. Only an option for graph() method. Default is [], i.e. plot all pages in separate figures.

Inherited from superclass NB_GRAPH

- **parameters** ↑

A struct with the parameters that can be used in evaluation of expressions in the graphSubPlots and graphInfoStruct methods.

Inherited from superclass NB_GRAPH

- **patch** ↑

Sets the patch property of the object. If set this will add a patch (color fill) between two variables.

Only one patch :

```
{'patchName','var1','var2',color}
```

More patches :

```
{'patchName1','var1Patch1','var2Patch1',color1 ,...  
'patchName2','var1Patch2','var2Patch2',color2,...}
```

Where the the color option(s) must either be a 1 x 3 double with the RGB colors or a string with the color name.

The first input will be the legend text of the patch. I.e. 'patchName', 'patchName1' and 'patchName2' will be the description text included in the legend. (If not the property legAuto is set to 'off'.)

Inherited from superclass NB_GRAPH

- **patchAlpha** ↑

Sets the transparency of the patches. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

Inherited from superclass NB_GRAPH

- **pdfBook** ↑

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be use in combination with the saveName property.

Inherited from superclass NB_GRAPH

- **plotAspectRatio** ↑

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3, or when '[16,9]' the aspect ratio of the figure is 16 to 9

Inherited from superclass NB_GRAPH

- **plotType** ↑

Sets the plot type. Either:

```
> 'line'           : If line plot(s) is wanted. Default.  
> 'stacked'       : If stacked bar plot(s) is wanted. Not an  
                     option for the graphSubPlots(...) method.  
> 'grouped'       : If grouped bar plot(s) is wanted.  
> 'dec'            : If decomposition plot(s) is wanted. Which is  
                     a bar plot with also a line with the sum of  
                     the stacked bars. Not an option for the  
                     graphSubPlots(...) method.  
> 'area'           : If area plot(s) is wanted.  
> 'candle'          : If candle plot(s) is wanted.  
> 'scatter'         : If scatter plot(s) is wanted.
```

- **plotTypes** ↑

Sets the plot type of the given variables. Must be a cell array on the form: {'var1', 'line', 'var2', 'grouped', ...}. Here we set the plot type of the variables 'var1' and 'var2' to 'line' and 'grouped' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

See the property plotType above on which plot types that are supported.

- **position** ↑

Sets the position of the axes, must be an 1x4 double. [leftMostPoint lowestPoint width height]. Only an option for the graph() method. Default is [0.1 0.1 0.8 0.8].

For the graph method graphSubPlots the position input can be given a 1 x N cell array, where each element is a 1x4 double. N = obj.subPlotSize(1)*obj.subPlotSize(2).

Inherited from superclass NB_GRAPH

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are produced. Must be a string.

Default is to save each graph produced in separate files. Set the pdfBook property to 1 if you want to save all the produced graphs in one pdf file. (To save all figures in one file is only possible for pdf files. I.e. the fileFormat property must be 'pdf'.)

Inherited from superclass NB_GRAPH

- **scatterLineStyle** ↑

Sets the scatter line style. Must be string. See 'lineStyles' for supported inputs. (Sets the line style of all scatter plots)

- **scatterObs** ↑

Sets the start and end to be used for the scatter plot plotted against the left axes. Must be a nested cell array. The obs can be given as integers. E.g:

```
{'scatterGroup1',{'startObs1','endObs1'},...  
'scatterGroup2',{'startObs2','endObs2'},...}
```

Caution : This property must be provided to produce a scatter plot! (Or of course scatterObsRight)

Be aware : Each obs will result in one point in the scatter.

- **scatterObsRight** ↑

Sets the start and end to be used for the scatter plot plotted against the right axes. Must be a nested cell array. The obs can be given as integers. E.g:

```
{'scatterGroup1',{'startObs1','endObs1'},...  
'scatterGroup2',{'startObs2','endObs2'},...}
```

Caution : This property must be provided to produce a scatter plot! (Or of course scatterObs)

Be aware : Each obs will result in one point in the scatter.

- **scatterVariables** ↑

The variables used for the scatter plot. Must be a 1x2 cellstr array. The first element will be the variable plotted against the x-axis, while the second element will be the variable plotted against the left y-axis. E.g:

```
{'var1','var2'}
```

- **scatterVariablesRight** ↑

The variables used for the scatter plot. Must be a 1x2 cellstr array. The first element will be the variable plotted against the x-axis, while the second element will be the variable plotted against the right y-axis. E.g:

```
{'var1','var2'}
```

- **shading** ↑

The shading option of the axes background:

- 'grey' : Shaded grey background
- 'none' : Background color given by the color property.

- A $n \times m \times 3$ double with the background color. n is the number of horizontal pixels, m is the number of vertical pixels and 3 means the RGB colors.

Inherited from superclass NB_GRAPH

- **spacing** ↑

Sets the x-ticks spacing. Must be an integer (or a double when variableToPlotX is used)

- **startGraph** ↑

Sets the start obs of the graph. Must be a string or an integer. If this obs is before the start obs of the data, the data will be expanded with nan (blank values) for these periods.

Not used when variableToPlotX property is set, use xLim instead.

- **subPlotSize** ↑

Sets the number of subplots per figure. Must be a 1×2 double with the number of subplot rows as the first element and the number of subplot columns as the second element. Only an option of the graphSubPlots() and graphInfoStruct() methods.

Default is [2, 2].

Inherited from superclass NB_GRAPH

- **subPlotSpecial** ↑

Set it to 1 if you want the 1×2 and 2×1 subplots to better fit for usage in presentations. Default is 0, i.e. use MATLAB default positions.

When set to 1 this class uses the nb_subplotSpecial instead of nb_subplot to find the positions of the subplots.

Inherited from superclass NB_GRAPH

- **sumTo** ↑

Sets a number which the area or the stacked bar plot should sum to. Must be a scalar. I.e. if 100 is given. The sizes of the bars will be the percentage share of the total sum.

Inherited from superclass NB_GRAPH

- **tag** ↑

Used by the nb_graph_subplot class to locate the nb_graph object in the subplot. Should not be used. Use userData instead.

Inherited from superclass NB_GRAPH

- **title** ↑

Sets the title of the plot. Must be a char. Only an option for the graph(...) method.

Inherited from superclass NB_GRAPH

- **titleAlignment** ↑

Sets the figure title text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_GRAPH

- **titleFontSize** ↑

Sets the font size of the titles which is placed above the (sub)plot(s). Must be scalar. Default is 14.

Inherited from superclass NB_GRAPH

- **titleFontWeight** ↑

Sets the font weight of the titles which is placed above the (sub)plot(s). Must be a string. Default is 'bold'.

Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **titleInterpreter** ↑

Sets the interpreter used for the given string given by the title property.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **titlePlacement** ↑

Sets the placement of the title. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_GRAPH

- **userData** ↑

User data, can be set to anything you want.

Inherited from superclass NB_GRAPH

- **variableToPlotX** ↑

Set the variable to use as the x-axes variable. I.e. when you want to plot one or more variables against this one. As a string.

If the graphSubPlots method is used this input can be set to cellstr with the same size as the variablesToPlot input.
You can use this to set individual domains for each subplot.

- **variablesToPlot** ↑

Sets the variables to plot against the left (or both) axes.
Must be a cell array of strings with the variable names. I.e.
{'var1', 'var2', ...}.

Not an option for the graphInfoStruct(...), which use the
property GraphStruct instead.

Inherited from superclass NB_GRAPH

- **variablesToPlotRight** ↑

Sets the variables to plot against the right axes. Must be
a cell array of strings with the variable names. I.e.
{'var1', 'var2', ...}.

Not an option for the graphInfoStruct(...), which use the
property GraphStruct instead.

Inherited from superclass NB_GRAPH

- **verticalLine** ↑

Sets the obs(s) of where to place a vertical line(s).
(Dotted orange line is default). Must be a number or a cell
array of numbers with the obs(s) for where to place the
vertical line(s). I.e. obs1 or {obs1,obs2,...}

- **verticalLineColor** ↑

Sets the color(s) of the given vertical line(s). Must either
be an M x 3 double with the RGB color(s) or a 1 x M cell array
of strings with the color name(s). Where M must be less than
the number of plotted vertical lines.

If less or no color(s) is/are set by this property the default
color(s) for the rest or all the vertical line(s) is/are
[0 0 0]. I.e. MATLAB black.

- **verticalLineLimit** ↑

Sets the y-axis limit(s) of the given vertical line(s). Must
either be a 1 x M cell array of 1 x 2 double with the upper
and lower y-axis limit(s). Where M must be less than the
number of plotted vertical lines.

If less or no limit(s) is/are set by this property the default
limit for the rest or all the vertical line(s) is/are the full
height of the graph.

- **verticalLineStyle** ↑

Sets the line style(s) of the given vertical line(s). Must
either be a 1 x M cell array of strings with the style(s).
Where M must be less than the number of plotted vertical
lines.

If less or no style(s) is/are set by this property the default line style is/are used for the rest or all the vertical line(s) is/are '--'.

- **verticalLineWidth** ↑

Sets the line width of (all) the vertical line(s). Must be a scalar. Default is 1.5.

- **xLabel** ↑

Sets (add) the text of the x-axis label. Must be a string.

Inherited from superclass NB_GRAPH

- **xLabelAlignment** ↑

Sets the x-axis label text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_GRAPH

- **xLabelFontSize** ↑

Sets the font size of the x-axis label. Must be scalar. Default is 12.

Inherited from superclass NB_GRAPH

- **xLabelFontWeight** ↑

Sets the font weight of the x-axis label. Must be string. Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **xLabelInterpreter** ↑

The interpreter used for the given string given by the xlabel property.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **xLabelPlacement** ↑

Sets the placement of the x-axis label. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_GRAPH

- **xLim** ↑

Sets the x-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Both or one of them can be set to nan, i.e. the default limits will be used) E.g. [0 6], [nan, 6] or [0, nan].

Only an option when the plotType property is set to 'scatter' or when variableToPlotX is used.

- **xScale** ↑

Sets the scale of the x-axis. Either {'linear'} | 'log'.

Only an option when plotType is set to 'scatter' or when variableToPlotX is used.

- **xTickLabelAlignment** ↑

The alignment of the x-axis tick marks labels. {'normal'} | 'middle'.

- **xTickLabelLocation** ↑

The location of the x-axis tick marks labels. Either {'bottom'} | 'top' | 'baseline'. 'baseline' will only work in combination with the xtickLocation property set to a double with the basevalue.

- **xTickLabels** ↑

Sets the x-axis tick mark labels. To translate the default tick mark label 'Var1' and 'Var2' you can use;

```
{'Var1','Label1','Var2','Label2'}
```

If given as a empty cell, default x-axis tick marks will be used, which is default.

This property can be used to create multi-lined x-axis tick mark labels. To do this give a multi-row char to the labels you want to make multi-lined.

Inherited from superclass NB_GRAPH

- **xTickLocation** ↑

The location of the x-axis tick marks. Either {'bottom'} | 'top' | double. If given as a double the tick marks will be placed at this value (where the number represent the y-axis value).

- **xTickRotation** ↑

Sets the rotation of the x-axis tick mark labels. Must be a scalar with the number of degrees the labels should be rotated. Positive angles cause counterclockwise rotation.

- **xTickStart** ↑

Sets the start obs of where to start the x-tick mark labels.
Must be an integer (a double when variableToPlotX is used).

- **yDir** ↑

Sets the direction of the y-axis of the plot. Must be a string. Either 'normal' or 'reverse'. Default is 'normal'.

Caution: If the variablesToPlotRight is not empty this setting only sets the left y-axis direction.

- **yDirRight** ↑

Sets the direction of the right y-axis of the plot. Either 'normal' or 'reverse'. Default is 'normal'. (Only when the variablesToPlotRight property is not empty.)

- **yLabel** ↑

Sets (add) the text of the y-axis label. Must be a string.

Inherited from superclass NB_GRAPH

- **yLabelFontSize** ↑

Sets the font size of the y-axis label. Must be scalar.
Default is 12.

Inherited from superclass NB_GRAPH

- **yLabelFontWeight** ↑

Sets the font weight of the y-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **yLabelInterpreter** ↑

The interpreter used for the given string given by the xLabel property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_GRAPH

- **yLabelRight** ↑

Sets the text of the y-axis label. (Only on the right side.)
Must be a string. Takes the same font option as the yLabel property

Inherited from superclass NB_GRAPH

- **yLim** ↑

Sets the y-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Both or one of them can be set to nan, i.e. the default limits will be used) E.g. [0 6], [nan, 6] or [0, nan].

Caution: If the variablesToPlotRight property is not empty this setting only sets the left y-axis limits.

Only an option for the graph(...) and graphSubPlots() methods. (For the graphInfoStruct(...) method use the property GraphStruct.)

- **yLimRight** ↑

Sets the right y-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Only when the variablesToPlotRight property is not empty.) (Both or one of them can be set to nan, i.e. the default limits will be used) E.g. [0 6], [nan, 6] or [0, nan].

Only an option for the graph(...) and graphSubPlots() methods. (For the graphInfoStruct(...) method use the property GraphStruct.)

- **yOffset** ↑

The y-axis tick mark labels offset from the axes

- **yScale** ↑

Sets the scale of the y-axis. {'linear'} | 'log'. (Both the left and the right axes if nothing is plotted on the right axes.)

- **yScaleRight** ↑

Sets the scale of the right y-axis. {'linear'} | 'log'. (Has only something to say if something is plotted on the right axes)

- **ySpacing** ↑

Sets the spacing between y-axis tick mark labels of the y-axis. Must be scalar.

Caution: The spacing will be the number of periods between the tick marks labels. The number of periods will follow the frequency of the xTickFrequency property if setted, else it will follow the frequency of the data provided. (Except when dealing with daily data, because then the default xTickFrequency is 'yearly')

Caution: If the variablesToPlotRight property is not empty this property only sets the spacing between ticks of the left y-axis.

- **ySpacingRight** ↑

Sets the spacing between y-axis tick mark labels of the right y-axis. Must be scalar.

Caution: The spacing will be the number of periods between the tick marks labels. The number of periods will follow

Methods:

► **createFigure** ↑

```
createFigure(obj)
```

Description:

Create figure to plot in.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_GRAPH

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_graph_data

Input:

- obj : An object of class nb_graph_data
- propertyName : A string with the name of the wanted property.

Output:

- propertyValue : The property value of the given property.

Examples:

Get the last axes handle of the nb_graph_data object. Be aware that all the axes handles are stored in the figurehandle property of the object.

```
axeshandle = obj.get('axeshandle');
```

Get the handle of all the current figures of the nb_graph_data object.

```
figurehandle = obj.get('figurehandle');
```

Written by Kenneth S. Paulsen

► **getCode** ↑

```
[code,numOfGraphs] = getCode(obj,frameTitle,frameSubTitle,...  
                               footer,source,pageNumber,theme)
```

Description:

Get the latex code when including a graph in a slide object produced by an object of class nb_graph_ts.

This method is called from the nb_Slide class, when making a beamer slide in latex.

Input:

- obj : An object of class nb_graph_ts
- frameTitle : A string with the frame title of the slide.
- frameSubTitle : A string with the frame subtitle of the slide.
- footer : A cellstr with the footers of the slide
- source : A cellstr with the sources of the slide
- pageNumber : Give 1 if the page number should be included.
- theme : The beamer theme used. Default is '' (use default beamer theme).

Output:

- code : The latex code as a char.
- numOfGraphs : The number of graphs produced by the input object of class nb_graph_ts. As an integer.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_GRAPH

► **getData** ↑

```
data = getData(obj)
```

Description:

Get the data of the graph

Input:

- obj : An object of class nb_graph_data

Output:

- data : As an nb_data object

Example:

```
data = obj.getData();
```

Written by Kenneth S. Paulsen

► **getDataOptions** ↑

```
options = getDataOptions(obj)
```

Description:

Container with the properties specific to nb_graph_data

Input:

- none

Output:

- options : A numSettings x 4 cell array with names in first column, default inputs in second, logical checks in the third, and a function handle with the set function in the fourth.

Examples:

```
options = getDataOptions(obj);
```

See also:

[set](#), [getGenericOptions](#), [nb_parseInputs](#)

Written by Per Bjarne Bye

► **getGenericOptions** ↑

```
options = getGenericOptions(obj)
```

Description:

A static method of nb_graph.

Container with the intersect of options for subclasses of nb_graph.

Input:

- none

Output:

- options : A numSettings x 4 cell array with names in first column, default inputs in second, logical checks in the third, and a function handle with the set function in the fourth.

Examples:

```
options = getGenericOptions(obj);
```

See also:

[set](#), [nb_parseInputs](#)

Written by Per Bjarne Bye

Inherited from superclass NB_GRAPH

► **getPlottedVariables** ↑

```
vars = getPlottedVariables(obj, forLegend)
```

Description:

Get the plotted variables of the graph

Input:

- obj : An object of class nb_graph_data
- forLegend : true or false (default)

When forLegend is used the variables are listed as needed for the legend, but without fake legends and patches, and duplicates are not removes.

Output:

- vars : As a cellstr

Example:

```
vars = obj.getPlottedVariables();
```

Written by Kenneth S. Paulsen

► **graph ↑**

```
graph(obj)
```

Description:

Create a graph or more graphs

Graphs all the variables given by the variablesToPlot and the variablesToPlotRight properties in one plot, and does that for all the datasets of the DB property. I.e. one new plot for each dataset (page) of the DB property of the nb_graph_data object.

Input:

- obj : An object of class nb_graph_data

Output:

The graph plotted on the screen.

Examples:

```
data = nb_data([2;1;2],'',1,'Var1');  
obj = nb_graph_ts(data);  
obj.graph();
```

See also:

[nb_graph_data](#), [nb_graph_data.set](#)

Written by Kenneth S. Paulsen

► graphInfoStruct ↑

```
graphInfoStruct(obj)
```

Description:

Create graphs based on the property GraphStruct. (Or the default GraphStruct given by the method defaultGraphStruct)

This method makes it easy to set up graph packages. For example graphing output from models.

See the documentation NB toolbox for more on this method.

Input:

- obj : An object of class nb_graph_data, where the property GraphStruct contains the information on how to plot the objects data.

Output:

The wanted graphs plotted on the screen.

Examples:

```
obj.graphInfoStruct();
```

Written by Kenneth S. Paulsen

► graphSubPlots ↑

```
graphSubPlots(obj)
```

Description:

Create graphs of all the variables given in variablesToPlot property, in different subplots. (Each dataset against each other). The number of subplot is given by the property subPlotSize.

Input:

- obj : An object of class nb_graph_data

Output:

The wanted graphs plotted on the screen.

Examples:

```
data = nb_data([2 3 2;1 4 5;2 3 2],'',1,...  
              {'Var1','Var2','Var3'});  
obj = nb_graph_data(data);  
obj.graphSubPlots();
```

Written by Kenneth S. Paulsen

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_graph_data object is empty. I.e. if no data is stored in the object. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_graph_data

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► **merge** ↑

```
out = merge(obj,varargin)
```

Description:

Default: This tries to merge the data of plotter objects that uses the graphSubPlots, or the graphInfoStruct.

Caution: All objects must share the exact same variables!

'graph' is given: In this case it will try to merge the data of all nb_graph objects, and concatenate the variableToPlot property. If the property variableToPlot is empty for all objects, it will also be returned as empty, i.e. plot all series in the data.

Caution : Merging of any of the other properties then DB and variableToPlot is not done!

Input:

- obj : An object of class nb_graph, which includes the classes nb_graph_ts, nb_graph_cs and nb_graph_data.

Optional input:

- 'graph' : Give this input to merge the graphs in the way that is described in the description of this method.
- varargin : Each input must be an object of class nb_graph.

Output:

- out : An object of class nb_graph.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_GRAPH

► realTimespan ↑

```
dateString = realTimespan(obj)
```

Description:

Get the timespan of the data behind a graph which is not nan or infinite, as a string. On the PPR format.

Input :

- obj : An object of class nb_graph_data
- language : Has nothing to say

Output :

- obsString : A string with the span of the graph represented by this object.

Examples:

```
data      = nb_data([2;1;2],',','1','Var1');
obj      = nb_graph_data(data);
dateString = realTimespan(obj);
```

Written by Kenneth S. Paulsen

► resetDataSource ↑

```
[message,err] = resetDataSource(obj,varargin)
```

Description:

Reset the data source of the nb_graph_data object.

Input:

- obj : An object of class nb_graph_data
- dataSource : An nb_data object with the new data.
- updateProps : If the variablesToPlot should be updated to be equal to dataSource.variables + the startGraph and endGraph properties are set to the startDate and endDate of the new data source.

Can also be 'gui'. Then all properties will be checked against the new dataset, and if the new dataset does not comply with the properties, the properties will be updated!

Written by Kenneth S. Paulsen

► **saveData** ↑

```
obj = saveData(obj,filename,strip)
```

Description:

Saves the data of the figure

Input:

- obj : An object of class nb_graph_data
- filename : A string with the saved output name
- strip : - 'on' : Strip all observation dates where all the variables has no value. Default.
- 'off' : Does not strip all observation dates where all the variables has no value

Example:

```
obj.saveData('test');
```

Written by Kenneth S. Paulsen

► **saveFigure** ↑

```
saveFigure(obj,extraName,format)
```

Description:

Save the figure(s) produced by the nb_graph object to
(a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_graph
- extraName : If you want to add some extra name to the saveName property of the nb_graph_data object before saving the file. (If the saveName property of the nb_graph_ts object is empty this will be the full name of the output file.)
- format : The format of the saved output. Default is given by the property fileFormat of the nb_graph. Either 'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.

Output:

The produced figure(s) saved to the wanted formats.

Examples:

```
data = nb_data([2;1;2],'', '1', 'Var1');  
obj = nb_graph_data(data);  
obj.graph();  
saveFigure(obj,'test','pdf');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_GRAPH

► **set ↑**

```
set(obj,varargin)
```

Description:

Set properties of the nb_graph class and its subclasses.

See documentation NB Toolbox or type help('nb_graph') for more on the properties of the class.

Input:

- obj : An object that is a subclass of nb_graph
- varargin : 'propertyName',PropertyValue,...

Output:

No actual output, but the input objects properties will have been set to their new value.

Examples:

```
data = nb_ts([2;1;2],'', '2012Q1', 'Var1');
obj = nb_graph_ts(data);
obj.set('startGraph', '2012Q1', 'endGraph', '2012Q3');
obj.set('crop', 1);
```

Written by Per Bjarne Bye

Inherited from superclass NB_GRAPH

► struct ↑

```
s = struct(obj)
```

Description:

Convert object to struct

Input:

- obj : An object of class nb_graph_cs

Output:

- s : A struct

Written by Kenneth Sæterhagen Paulsen

► timespan ↑

```
dateString = timespan(obj, language)
```

Description:

Get the timespan of the graph as a string. On the PPR format.

Input :

- obj : An object of class nb_graph_data
- language : Has nothing to say

Output :

- dateString : A string with the span of the graph represented by this object.

Examples:

```
data      = nb_data([2;1;2],'',1,'Var1');
obj      = nb_graph_data(data);
dateString = timespan(obj);
```

Written by Kenneth S. Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the figure

See the update method of the nb_data for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_graph_data

Output:

- obj : An object of class nb_graph_data, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

■ **nb_graph_package**
Go to: [Properties](#) | [Methods](#)

```
obj = nb_graph_package(start,chapter)
```

Superclasses:

handle

Description:

Class for creating a graph package (MPR styled graphs)

Constructor:

```
obj = nb_graph_package(start,chapter)
```

Input:

- start : The start number of the package. As a scalar.
- chapter : The chapter of the package. As a scalar.

Output:

- obj : An object of class nb_graph_package

Examples:

Start with the first graph of the chapter 1.

```
obj = nb_graph_package(1,1);
```

See also:

[nb_graph_adv](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- a4Portrait
- advanced
- bigLetter
- chapter
- excelStyle
- firstPageNameEng
- firstPageNameNor
- flip
- graphs
- identifiers
- lookUpMatrix
- roundoff
- start
- userData
- zeroLowerBound

- **a4Portrait** [↑](#)

Save PDF to A4 portrait format. 0 or 1

- **advanced** [↑](#)

Set the window size to fit the advanced graphs (i.e. nb_graph_adv objects). Default is true. When set to false the normally produced graphs will be on the correct scale (i.e. nb_graph_ts, nb_graph_cs, nb_graph_data and nb_graph_subplot)

- **bigLetter** [↑](#)

Give 1 the numbering should be done with a big letter instead of a number. I.e. 'Figur 1.A' or 'Chart 1.A', instead of 'Figure 1.1' or 'Chart 1.1'.

- **chapter** [↑](#)

The chapter of the graph package. As an integer.

- **excelStyle** [↑](#)

Sets the style of the Excel sheet the data is being exported into using saveData.
Options are MPR (Monetary Policy Rapport) and FSR (Financial Stability Rapport). Default is MPR.

- **firstPageNameEng** ↑

Sets the heading on the index page of the excel spreadsheet. When the language input to the method saveData is 'english' or 'both' this will be the heading of the english index page (Or else this property does nothing). Must be given as a string or as an cellstr. A cellstr will give a multilined heading. E.g. 'Index page' or {'Index page','second line'}. Default is empty.

- **firstPageNameNor** ↑

Sets the heading on the index page of the excel spreadsheet. When the language input to the method saveData is 'norwegian' or 'both' this will be the heading of the norwegian index page. Must be given as a string or as an cellstr. A cellstr will give a multilined heading. E.g. 'Index page' or {'Index page','second line'}. Default is empty.

- **flip** ↑

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

- **graphs** ↑

All the graphs of the package, as a cell of nb_graph_adv and nb_graph_subplot objects.

- **identifiers** ↑

A cellstr with the graph objects identifiers

- **lookUpMatrix** ↑

A cell matrix on how to translate the mnemonics to variable description in the excel output spreadsheet. Both in english and norwegian. Use the set method of this class for setting this property.

Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {

'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

- **roundoff** ↑

Give the number of decimals of the excel output produced by the saveData method. Default is 2. Must be an integer greater or equal to 0, or empty (no round-off).

- **start** ↑

The starting number of the figure package. As an integer.

- **userData** ↑

User data, can be set to anything you want.

- **zeroLowerBound** ↑

Zero lower bound QUA_RNFOLIO and QUA_RNFOLIO_LATESTMPR

Methods :

- add
- getSupportedTemplates
- moveDown
- moveLast
- preview
- remove
- set
- update
- writePDFExtended
- writeSeparateExtended
- exportExcelChangeLog
- importExcelChangeLog
- moveFirst
- moveUp
- previewExtended
- saveData
- switchLocation
- writePDF
- writeSeparate
- writeText

► **add** ↑

add(obj, graph, identifier)

Description:

Add a graph to package. Must be an object of class nb_graph_adv or nb_graph_subplot.

Input:

- obj : An object of class nb_graph_package
- graph : An object of class nb_graph_adv or nb_graph_subplot

```
- identifier : A string to link to the object. Used by the
    reorder, remove and reset methods.

    If given as empty, a default identifier is given.
    I.e. 'GraphX'. Where X is the already added graph
    + 1.

    Caution : The identifier must be unique.
```

Examples:

```
obj.add(nb_graph_advObj)
obj.add(nb_graph_advObj,'Test')
```

Written by Kenneth S. Paulsen

► **exportExcelChangeLog** ↑

```
exportExcelChangeLog(obj,saveName,packageName)
```

Description:

Exports the written information in a graph package to an Excel file.
The exported file will contain titles, footers, and excel footers with
all DAG formatting visible.
Changes can be made to the exported file. This file can be imported to
DAG and all changes will take place.

Input:

- obj : An object of class nb_graph_package.
- saveName : The name of the Excel file to write.
- packageName : The name of the graph package.

Examples:

```
obj.writeText('MyGraphPackage');
```

Written by Per Bjarne Bye

► **getSupportedTemplates** ↑

```
templates = getSupportedTemplates(obj)
```

Description:

Get the the templates that are shared among the graph. If some graphs does not have an assigned template the output will be {}.

Input:

- obj : An object of class nb_graph_package.

Output:

- templates : A cellstr with the shared templates.

See also:

[nb_graph_package](#)

Written by Kenneth Sæterhagen Paulsen

► **importExcelChangeLog** ↑

`exportExcelChangeLog(obj,excelFile)`

Description:

Reads the Excel file and updates the written information in the graph package based on the Excel file. Note that the file must be structured such that it is identical to a file created by `exportExcelChangeLog`.

Input:

- obj : An object of class nb_graph_package.
- excelFile : 1 x n char. The Excel file with the information.

Examples:

`obj.importExcelChangeLog('myExcelFile.xls');`

Written by Per Bjarne Bye

► **moveDown** ↑

`moveDown(obj,identifier)`

Description:

Moves the graph stored with the identifier provided 1 step down in the package. (If it is the last nothing will happen.)

Input:

- obj : An object of class nb_graph_package.
- identifier : A String with the identifier to the graph to move down one step.

Examples:

```
obj.moveDown('Graph1')
```

See also:

[nb_graph_package](#)

Written by Kenneth Sæterhagen Paulsen

► **moveFirst** ↑

```
moveFirst(obj, identifier)
```

Description:

Moves the graph stored with the identifier provided first in the package.

Input:

- obj : An object of class nb_graph_package.
- identifier : A String with the identifier to the graph to move last.

Examples:

```
obj.moveFirst('Graph1')
```

See also:

[nb_graph_package](#)

Written by Kenneth Sæterhagen Paulsen

► **moveLast** ↑

```
moveLast(obj, identifier)
```

Description:

Moves the graph stored with the identifier provided last in the package.

Input:

- obj : An object of class nb_graph_package.
- identifier : A String with the identifier to the graph to move last.

Examples:

```
obj.moveLast('Graph1')
```

See also:

[nb_graph_package](#)

Written by Kenneth Sæterhagen Paulsen

► **moveUp** ↑

```
moveUp(obj,identifier)
```

Description:

Moves the graph stored with the identifier provided 1 step up in the package. (If it is the first nothing will happen.)

Input:

- obj : An object of class nb_graph_package.
- identifier : A String with the identifier to the graph to move up one step.

Examples:

```
obj.moveUp('Graph1')
```

See also:

[nb_graph_package](#)

Written by Kenneth Sæterhagen Paulsen

► **preview** ↑

```
preview(obj,language/gui,template)
```

Description:

Preview of the graph package.

Input:

- obj : An object of class nb_graph_package
- language : The language as a string, 'english' or {'norsk'}
- gui : true or false
- template : A one line char with the applied template. Default is 'current', i.e. do specific template.

Examples:

```
obj.preview('english');
```

Written by Kenneth S. Paulsen

► **previewExtended** ↑

```
previewExtended(obj,language/gui)
```

Description:

Preview of the graph package.

Input:

- obj : An object of class nb_graph_package
- language : The language as a string, 'english' or {'norsk'}
- gui : true or false

Examples:

```
obj.previewExtended('english');
```

Written by Kenneth S. Paulsen

► **remove** ↑

```
remove(obj, identifier)
```

Description:

Removes the graph stored with the identifier provided.

Input:

- obj : An object of class nb_graph_package.
- identifier : A String with the identifier to the graph to remove.

Examples:

```
obj.remove('Graph1')
```

See also:

[nb_graph_package](#)

Written by Kenneth Sæterhagen Paulsen

► **saveData** ↑

```
saveData(obj, saveName, language)
saveData(obj, saveName, language, firstPageName, firstPageName2, roundoff, ...
         excelStyle)
```

Description:

Save the data behind the graphs of the graph package to excel.

Input:

- obj : An object of class nb_graph_package
- saveName : The excel file name as a string
- language : The language as a string. One of the following:
 - > 'english' : The data are written to a excel spreadsheet with only english text.
 - > 'norsk' : The data are written to a excel spreadsheet with only norwegian text.
 - > 'both' : The data are written to a excell spreadsheet with both norwegian and english text.

- firstPageName : Sets the heading on the index page of the excel spreadsheet. When the language input is 'norwegian' or 'both' this will be the heading of the norwegian index page. Must be given as a string or as an cellstr. A cellstr will give a multilined heading. E.g. 'Index page' or {'Index page','second line'}.
- firstPageName2 : Sets the heading on the index page of the excel spreadsheet. When the language input is 'english' or 'both' this will be the heading of the english index page. Must be given as a string or as an cellstr. A cellstr will give a multilined heading. E.g. 'Index page' or {'Index page','second line'}.
- roundoff : Give 1 if you want to round off to 2 decimals, 0 otherwise. Default is obj.roundoff.

Examples:

```
package.saveData('test','both',{'Rapport',...
    'med noe nyttig'},...
{'A report',...
    'with something useful'},...
1);
```

Written by Per Bjarne Bye and Kenneth S. Paulsen

► **set ↑**

```
set(obj,varargin)
```

Description:

Set the properties of the nb_graph_package object

Input:

- obj : An object of class nb_graph_package
- varargin :,'propertyName',PropertyValue,...

Output :

- obj : The input objects properties are updated.

Examples:

```
obj.set('propertyName',PropertyValue,...)
obj = obj.set('lookupmatrix',{'QUA_PCPI','CPI','KPI'});
```

Written by Kenneth S. Paulsen

► **switchLocation** ↑

```
switchLocation(obj, identifier1, identifier2)
```

Description:

Moves the graph stored with the identifier provided last in the package.

Input:

- obj : An object of class nb_graph_package.
- identifier1 : A String with the identifier to the graph to switched.
- identifier2 : A String with the identifier to the graph to switched.

Examples:

```
obj.switchLocation('Graph1','Graph2')
```

See also:

[nb_graph_package](#)

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the nb_graph_package object. I.e update the data source of the graphs property.

See the update method of the nb_cs or nb_ts class for more on how to make the data of the graphs updateable.

Input:

- obj : An object of class nb_graph_package
- addWaitBar : Add wait bar if 1, otherwise no. Default is not.

Output:

- obj : An object of class nb_graph_package, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

► **writePDF** ↑

```
writePDF(obj,saveName,language/gui,template)
```

Description:

Save the graph package to a pdf file

Input:

- obj : An object of class nb_graph_package
- saveName : The name of the pdf file as a string. If empty no file is made.
- language : The language as a string, 'english' or {'norsk'}
- gui : true or false
- template : A one line char with the applied template. Default is 'current', i.e. do specific template.

Examples:

```
obj.writePDF('test', 'english');
```

Written by Kenneth S. Paulsen

► **writePDFExtended** ↑

```
writePDFExtended(obj,saveName,language/gui)
```

Description:

Save the graph package to a pdf file with more information on the graphs.

Input:

```

- obj : An object of class nb_graph_package

- saveName : The name of the pdf file as a string. If empty no file
is made.

- language : The language as a string, 'english' or
{'norsk'}

- gui : true or false

```

Examples:

```
obj.writePDFExtended('test', 'english');
```

Written by Kenneth S. Paulsen

► **writeSeparate ↑**

```
writeSeparate(obj, folder, language, format, index, gui, template, ...
includeFigureNumber, crop)
```

Description:

Save the graph package to files. Each graph will be save with the name of the assign identifier. See the nb_graph_package.add for more on the identifiers.

Input:

```

- obj : An object of class nb_graph_package

- folder : The folder to save the graphs to.

- language : The language as a string, 'english' or
{'norsk'}. Will also be appended the save names.

- format : The file format to save the graph to. See the nb_saveas
function for the supported formats. Default is 'pdf'.

- index : Either a 1 x numGraphs logical or empty. Set the matching
element of a graph to false to skip printing the specific
graph. Default is empty, i.e. to print all graphs of the
package.

- gui : true or false

- template : The template of the graphs to use. Default is 'current'.

- includeFigureNumber : Include figure number in file names. Default
is false.

- crop : true or false. Default is true.

- skipConfirmation : Skip the confirmation window and go straight to
writing or not. Default is false.

```

Examples:

```
obj.writeSeparate('test', 'english', 'pdf');
```

Written by Kenneth S. Paulsen

► **writeSeparateExtended** ↑

```
writeSeparateExtended(obj, folder, language, format, index, gui, ...  
                      includeFigureNumber)
```

Description:

Save the graph package to files. Each graph will be save with the name of the assign identifier. See the nb_graph_package.add for more on the identifiers. Tooltip, excel title and footer will be added to the graph.

Input:

- obj : An object of class nb_graph_package
- folder : The folder to save the graphs to.
- language : The language as a string, 'english' or {'norsk'}. Will also be appended the save names.
- format : The file format to save the graph to. See the nb_saveas function for the supported formats. Default is 'pdf'.
- index : Either a 1 x numGraphs logical or empty. Set the matching element of a graph to false to skip printing the specific graph. Default is empty, i.e. to print all graphs of the package.
- gui : true or false
- includeFigureNumber : Include figure number in file names. Default is false.
- skipConfirmation : Skip the confirmation window and go straight to writing or not. Default is false.

Examples:

```
obj.writeSeparate('test', 'english', 'pdf');
```

Written by Kenneth S. Paulsen

► **writeText** ↑

```
writeText(obj, folder, language, index, includeFigureNumber)
```

Description:

Write text of graphs to .txt files. One for the figure title and one for the footer for each graph separately. Each graph will be save with the name of the assign identifier. See the nb_graph_package.add for more on the identifiers.

Input:

- obj : An object of class nb_graph_package
- folder : The folder to save the text of the graphs to.
- language : The language as a string, 'english' or {'norsk'}. Will also be appended the save names.
- index : Either a 1 x numGraphs logical or empty. Set the matching element of a graph to false to skip writing the text of that graph. Default is empty, i.e. to write the text of all graphs of the package.
- includeFigureNumber : Include figure number in file names. Default is false.
- singleFolder : Save files to a single folder or make two subfolders and save text to one and extended text to the other. Default is true.
- lazyWriting : Write only the text files that have changed (cannot find the file or the file content is identical to what is about to be written). The files that are written are reported in a separate window. Default is false
- skipConfirmation : Skip the confirmation window and go straight to writing or not. Default is false.

Examples:

```
obj.writeText('test', 'english');
```

Written by Kenneth S. Paulsen

■ nb_graph_subplot

Go to: [Properties](#) | [Methods](#)

```
obj = nb_graph_subplot(varargin)
```

Superclasses:

handle

Description:

This is a class for making subplots of nb_graph_ts and nb_graph_cs objects (graphs).

Constructor:

```
obj = nb_graph_subplot(varargin)
```

Input:

- varargin : Arbitrary number of objects of class nb_graph_ts or nb_graph_cs.

Output:

- obj : An object of class nb_graph_subplot

See also:

[nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- a4Portrait
- figureNameEng
- fileFormat
- graphStyle
- numberOfGraphs
- saveName
- subPlotSize
- axesScaleLineWidth
- figureNameNor
- flip
- language
- pdfBook
- scale
- subPlotSpecial
- crop
- figurePosition
- graphObjects
- manualAxesPosition
- plotAspectRatio
- shading
- userData

- **a4Portrait** ↑

Save PDF to A4 portrait format. 0 or 1

- **axesScaleLineWidth** ↑

Scale line width to axes height. true or false (default).

- **crop** ↑

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

- **figureNameEng** ↑

Sets the english name of the figure. This name will be used on the englisp index page of the excel spreadsheet.

- **figureNameNor** ↑

Sets the norwegian name of the figure. This name will be used on the norwegian index page of the excel spreadsheet.

- **figurePosition** ↑

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

- **fileFormat** ↑

Sets the save file format. Either 'eps', 'jpg', 'pdf' or 'png'. 'pdf' is default.

- **flip** ↑

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

- **graphObjects** ↑

The graphs to include in the figure as subplots. As nb_graph_ts, nb_graph_data, nb_graph_cs or nb_graph_adv objects.

- **graphStyle** ↑

Will if set to 'presentation' or 'presentation_white' only decide the some figure option. Use the graphStyle property of the added graph objects to set the graph style.

- **language** ↑

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

- **manualAxesPosition** ↑

Set the axes position to manual. Default is false

- **numberOfGraphs** ↑

Number of graph produced by the graph methods. Not settable

- **pdfBook** ↑

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be use in combination with the saveName property.

- **plotAspectRatio** ↑

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3.

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are produced. Must be a string.

Default is to save each graph produced in separate files. Set the pdfBook property to 1 if you want to save all the produced graphs in one pdf file. (To save all figures in one file is only possible for pdf files. I.e. the fileFormat property must be 'pdf'.)

- **scale** ↑

Scale all the font sizes of the plotted graphs of the subplot. (Except nb_annotation objects). Default is 0.7.

- **shading** ↑

Sets the shading of the background. Either 'grey' or 'none'. 'none' will give a white colored background.

- **subPlotSize** ↑

Sets the number of subplots per figure. Must be a 1 x 2 double with the number of subplot rows as the first element and the number of subplot columns as the second element. Only an option of the graphSubPlots() method.

Default is [2, 2].

- **subPlotSpecial** ↑

Set it to 1 if you want the 1x2 and 2x1 subplots to better fit for usage in presentations. Default is 0, i.e. use MATLAB default positions.

When set to 1 this class uses the nb_subplotSpecial instead of nb_subplot to find the positions of the subplots.

- **userData** ↑

User data, can be set to anything you want.

Methods:

- add
 - delete
 - get
 - getCode
 - graph
 - graphEng
 - graphNor
 - remove
 - reset
 - saveData
 - saveFigure
 - set
 - update
-

► add ↑

```
add(obj,graphObj)
```

Description:

Adds a graph object to the subplot object.

Caution : This function will copy the provided object before its adds the object to the nb_graph_subplot object.

Input:

- obj : An object of class nb_graph_subplot
- graphObj : An object of class nb_graph_ts or nb_graph_cs.

Example:

```
obj.add(graphObj);
```

Written by Kenneth S. Paulsen

► delete ↑

```
obj = delete(obj,graphObj)
```

Description:

Delete specified graph object if found.

Caution : When an nb_graph_ts or nb_graph_cs object is added to an nb_graph_subplot object, it will be copied. So if you provided the same object as you add, it will not be found and deleted.

Input:

- obj : An object of class nb_graph_subplot
- graphObj : An object of class nb_graph_ts or nb_graph_cs.

Example:

```
obj.delete(graphObj);
```

Written by Kenneth S. Paulsen

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_graph_subplot

Input:

- obj : An object of class nb_graph_subplot
- propertyName : A string with the name of the wanted property.

Output:

- propertyValue : The property value of the given property.

Examples:

See also:

Written by Kenneth S. Paulsen

► **getCode** ↑

```
[code,numOfGraphs] = getCode(obj,frameTitle,frameSubTitle,...  
                               footer,source,pageNumber,theme)
```

Description:

Get the latex code when including a graph in a slide object produced by an object of class nb_graph_subplot.

This method is called from the nb_Slide class, when making a beamer slide in latex.

Input:

- obj : An object of class nb_graph_subplot
- frameTitle : A string with the frame title of the slide.

- frameSubTitle : A string with the frame subtitle of the slide.
- footer : A cellstr with the footers of the slide
- source : A cellstr with the sources of the slide
- pageNumber : Give 1 if the page number should be included.
- theme : The beamer theme used. Default is '' (use default beamer theme).

Output:

- code : The latex code as a char.
- numOfGraphs : The number of graphs produced by the input object of class nb_graph_subplot. As an integer.

Examples:

Written by Kenneth S. Paulsen

► **graph ↑**

`graph(obj)`

Description:

Create a graph or more graphs

Graphs all the objects given to the nb_graph_subplot object.

Input:

- obj : An object of class nb_graph_subplot

Output:

The graph(s) plotted on the screen.

Examples:

`obj.graph();`

See also:

[nb_graph_subplot](#)

Written by Kenneth S. Paulsen

► **graphEng** ↑

graphEng(obj)

Description:

Plot the graph (english version)

Input:

- obj : An object of class nb_graph_adv

Output:

The graph plotted on the screen (english version)

Examples:

obj.graphEng()

Written by Kenneth S. Paulsen

► **graphNor** ↑

graphNor(obj)

Description:

Plot the graph (norwegian)

Input:

- obj : An object of class nb_graph_adv

Output:

The graph plotted on the screen (norwegian version)

Examples:

obj.graphNor()

Written by Kenneth S. Paulsen

► **remove** ↑

```
remove(obj,graphToRemove)
```

Description:

Remove specified graph object if found. Will give an error if not found.

Caution : When a nb_graph_obj or nb_graph_adv object is added to an nb_graph_subplot object, it will be copied. So if you provided the same object as you added (as the graphToRemove), it will not be found and a error will occure.

Input:

- obj : An object of class nb_graph_subplot
- graphToRemove : An object of class nb_graph_obj or nb_graph_adv.

Written by Kenneth S. Paulsen

► **reset** ↑

```
copiedGraph = reset(obj,oldGraphObj,newGraphObj)
```

Description:

Reset specified graph object if found, with the newGraphObj. Will give an error if not found.

Caution : If the resetting succeds the newGraphObj will be copied.

Caution : When an nb_graph_ts or nb_graph_cs object is added to an nb_graph_subplot object, it will be copied. So if you provided the same object as you add (as the oldGraphObj), it will not be found and a error will occure.

Input:

- obj : An object of class nb_graph_subplot
- oldGraphObj : An object of class nb_graph.
- newGraphObj : An object of class nb_graph.

Output:

- copiedGraph : The copied graph as an nb_graph object.

Written by Kenneth S. Paulsen

► **saveData** ↑

```
obj = saveData(obj,filename,strip,sheetName)
```

Description:

Saves the data of the figure

Input:

- obj : An object of class nb_graph_subplot
- filename : A string with the saved output name
- strip : > 'on' : Strip all observation dates where all the variables has no value. Default.
 > 'off' : Does not strip all observation dates where all the variables has no value.
- sheetName : A string with the name of the saved worksheets. I.e. the data of the subplots will be saved in the sheets with name [sheetName '<jj>']. E.g. if sheetName is given as 'GDP' the worksheet for the first subplot will get the name 'GDP(1)', while the second will get the name 'GDP(2)'. Default is 'Graph'.

Example:

```
obj.saveData('test');  
obj.saveData('test','on');  
obj.saveData('test','on','Name of figure');
```

Written by Kenneth S. Paulsen

► **saveFigure** ↑

```
saveFigure(obj,extraName,format)
```

Description:

Save the figure(s) produced by the nb_graph_subplot object to (a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_graph_subplot
- extraName : If you want to add some extra name to the saveName property of the nb_graph_ts object before saving

the file. (If the saveName property of the nb_graph_ts object is empty this will be the full name of the output file.)

- format : The format of the saved output. Default is given by the property fileFormat of the nb_graph. Either 'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.

Output:

The produced figure(s) saved to the wanted formats.

Examples:

```
saveFigure(obj,'test','pdf');
```

Written by Kenneth S. Paulsen

► **set** ↑

```
set(obj,varargin)
```

Description:

Set properties of the nb_graph_subplot class.

See documentation NB Toolbox or type help('nb_graph_subplot') for more on the properties of the class.

Input:

- obj : An object of class nb_graph_subplot
- varargin : 'propertyName',PropertyValue,...

Output:

The input objects properties set to their new value.

Examples:

```
obj.set('subPlotSize',[2,2]);
```

Written by Kenneth S. Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the figure(s)

Input:

- obj : An object of class nb_graph_subplot

Output:

- obj : An object of class nb_graph_subplot, where the data is updated for the different graph objects.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

■ nb_graph_ts

Go to: [Properties](#) | [Methods](#)

```
obj = nb_graph_ts(varargin)
```

Superclasses:

handle, nb_graph

Description:

This is a class for making timeseries graphics.

Constructor:

```
obj = nb_graph_ts(data)
```

Input:

- data : The input must one of the following:

> An object of class nb_ts. E.g. nb_graph_ts(data)

> A excel spreadsheet which could be read by the nb_ts class. E.g. nb_graph_ts('excelName1')

It is also possible to initialize an empty nb_graph_ts object. (Do not provide any inputs to the constructor)

Output:

- obj : An object of class nb_graph_ts

See also:

nb_graph, nb_graph_data, nb_graph_cs, nb_graph_adv, nb_graph_subplot

- **DB** ↑

All the data given to the nb_graph_ts object collected in a nb_ts object. Should not be set using obj.DB = data! Instead see the nb_graph_ts.resetDataSource method.

- **GraphStruct** ↑

Sets the information on which variables and how to plot them when using the graphInfoStruct(...) method of this class.

Must be an .m-file with the code on how the structure of graphing information should be initialized or as a structure with the graphing information.

Only the graphInfoStruct(...) method uses this property. See the documentation of the NB toolbox for more on this input.

Inherited from superclass NB_GRAPH

- **a4Portrait** ↑

Save PDF to A4 portrait format. 0 or 1

Inherited from superclass NB_GRAPH

- **addAdvanced** ↑

Set to false to prevent adding advanced components.

Inherited from superclass NB_GRAPH

- **addSpace** ↑

Sets the space before and/or after in the x direction of the graph [addedSpaceBefore addedSpaceAfter]. E.g. add one period before and after [1,1].

Inherited from superclass NB_GRAPH

- **alignAxes** ↑

Align axes at a given base value. Must be set to a scalar double. E.g. 0.

Inherited from superclass NB_GRAPH

- **annotation** ↑

Sets the plotted annotations of the graph.

Must be one or more nb_annotation objects. See the documentation of the nb_annotation class for more. If you give more objects they must be collected in a cell array.

Examples can be found here:

\NBTOOLBOX\Examples\Graphics\nb_annotationExamples.m

Inherited from superclass NB_GRAPH

- **areaAbrupt** ↑

Set this property to true to make the areas abruptly finish when given as nan. Default is false.

Inherited from superclass NB_GRAPH

- **areaAccumulate** ↑

Set if the areas should be accumulated or not. Default is true.

Inherited from superclass NB_GRAPH

- **areaAlpha** ↑

Sets the transparency of the area chart. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

Inherited from superclass NB_GRAPH

- **averageLine** ↑

Set this property if you want to plot some average line(s).

Must be given as a cell, i.e. {var, settings, ...}:

> var : A string with the variable name you want to take the average of.

```

> settings : {'propertyName',PropertyValue,...}

The property names options are:

> 'calcStart' : The start date for when to start the
    calculation of the mean. Default is the
    date given by the 'startGraph' property.

> 'calcEnd'   : The end date for when to end the
    calculation of the mean. Default is the
    date given by the 'endGraph' property.

> 'color'     : Color of the average line. Default is
    [0 0 0] (MATLAB black).

> 'lineStyle' : Line style of the average line. Default is
    line style '-'. (Normal line)

> 'lineWidth' : Line width of the average line. Default
    line width is 2.5.

> 'plotStart' : The start date for when to start the
    plotting of the mean. Default is the
    date given by the 'startGraph' property.

> 'plotEnd'   : The end date for when to end the
    plotting of the mean. Default is the
    date given by the 'endGraph' property.

> 'side'       : The axes side. Either 'left' or 'right'.

If the variable is not found a proper error message will
occur.

```

- **axesFast** ↑

Set the if you want graphs to be produced fast with a loss of functionality and look or not. When empty default for the graph method is false, while for the graphSubPlots and graphInfoStruct methods are true.

Inherited from superclass NB_GRAPH

- **axesFontSize** ↑

Sets the font size of the axes tick mark labels, default is 12. Must be a scalar.

Inherited from superclass NB_GRAPH

- **axesFontSizeX** ↑

Sets the font size of the x-axis tick mark labels, default is []. I.e. use the axesFontSize property instead. Must be a scalar.

This property will not be scaled when fontUnits are changed, as is the case for axesFontSize.

Caution: Will not set the x-axis font size when plotType is set to scatter.

Inherited from superclass NB_GRAPH

- **axesFontWeight** ↑

Sets the font weight of the axes tick mark labels. Must be a string. Default is 'normal'. Either 'normal', 'bold', 'light' or 'demi'

Inherited from superclass NB_GRAPH

- **axesLineWidth** ↑

Sets the the line width of the axes, default is 0.5. Must be a set to a scalar double greater than 0.

Inherited from superclass NB_GRAPH

- **axesPrecision** ↑

Sets the precision/format of the rounding of number on the axes.

See the precision input to the nb_num2str function. Default is [], i.e. to call num2str without additional inputs.

Inherited from superclass NB_GRAPH

- **axesScaleFactor** ↑

Set the scaling factor used when axesScaleLineWidth is set to true.

Inherited from superclass NB_GRAPH

- **axesScaleLineWidth** ↑

Scale line width to axes height. true or false (default). If axesScaleFactor is set to a scalar number this will be the scaling factor used instead of the automatic scaling factor.

Inherited from superclass NB_GRAPH

- **barAlpha1** ↑

Set the alpha blending parameter 1, when barBlend is set to true. See nb_alpha. Default is 0.5

Inherited from superclass NB_GRAPH

- **barAlpha2** ↑

Set the alpha blending parameter 2, when barBlend is set to true. See nb_alpha. Default is 0.5

Inherited from superclass NB_GRAPH

- **barBlend** ↑

Set to true to do alpha blending instead of shading if shading options is used. Default is false.

Inherited from superclass NB_GRAPH

- **barLineWidth** ↑

Set the bar line width without affecting any other line widths. Default is empty, i.e. use the lineWidth property.

Inherited from superclass NB_GRAPH

- **barShadingColor** ↑

The color shaded bars are interpolated with. Default is 'white'. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **barShadingDate** ↑

Sets the date from which the bar plot should be shaded. Either a string or an object which is of a subclass of the nb_date class.

- **barShadingDirection** ↑

Sets the angle the shading should be vertical of. Either {'north'} | 'south' | 'west' | 'east'. As a string. Default is 'north'.

Inherited from superclass NB_GRAPH

- **barWidth** ↑

Sets the width of the bar plot. As a scalar. Default is 0.45.

Inherited from superclass NB_GRAPH

- **baseLine** ↑

If 0 is given the base line will not be plotted, otherwise it will be plotted.

Inherited from superclass NB_GRAPH

- **baseLineColor** ↑

Sets the color of the base line. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **baseLineStyle** ↑

Sets the line style of the base line. As a string. Either {'-' } | '--' | '---' | ':' | '-.' | 'none'.

Inherited from superclass NB_GRAPH

- **baseLineWidth** ↑

Sets the width of the base line. Must be a scalar.

Inherited from superclass NB_GRAPH

- **baseValue** ↑

Sets the base value used for bar and area plot. (Sest also the y-axis base value for the base line)

Inherited from superclass NB_GRAPH

- **candleIndicatorColor** ↑

Sets the color of the indicator of the candle. Must either be a 1 x 3 double with the RGB colors or a string with the color name.

Inherited from superclass NB_GRAPH

- **candleIndicatorLineStyle** ↑

Sets the line style of the indicator of the candle. Must be a string. Default is '-'.

Inherited from superclass NB_GRAPH

- **candleMarker** ↑

Sets the marker of the indicator of the candle. Must be a string. Default is 'none'.

Inherited from superclass NB_GRAPH

- **candleVariables** ↑

Sets which variables are going to be plotted as open, close, high, low and indicator. Must be a cellstr. E.g.

{'open','var1','close','var2',...}

If a type (e.g. 'low') is not given it will not be plotted.

Meaning of each type:

- > 'close' : The lowest values of the plotted patches of the candle.
- > 'high' : The highest values of the plotted candles.
- > 'indicator' : The value for where to plot a horizontal line (across the patch). E.g. the mean value.
- > 'open' : The highest values of the plotted patches of the candle.
- > 'low' : The lowest values of the plotted candles.

Inherited from superclass NB_GRAPH

- **candleWidth** ↑

Sets the width of the candle plot. As a scalar. Default is 0.45.

Inherited from superclass NB_GRAPH

- **code** ↑

If you set this to a file name, this file will be evaluated after all the plotting is done. Must be a string.

This could be nice for adding special annotation, lines and so on. In this file you can use any MATLAB function, but some strange error message can occur if you use local variables which is already defined (So use long and descriptive variable names in the provided code to prevent this).

This property is only an option for the method graph.

Nice to know:

> The current nb_figure object can be reached with
get(obj,'figureHandle')

> The current nb_axes object can be reached with
get(obj,'axesHandle')

Caution : Be aware that the name of the file must be unique and cannot be a MATLAB function or a local variable.

Caution : The file must be a MATLAB .m file

Inherited from superclass NB_GRAPH

- **colorMap** ↑

Sets the colormap used when plotType is set to 'image' and fanMethod is set to 'graded'. Must be given as n x 3 double or the path to a .mat file that contain the colormap. Default is given by nb_axes.defaultColorMap.

For an example of a supported MAT file see:

- ...\\Examples\\Graphics\\colorMapNB.mat

Inherited from superclass NB_GRAPH

- **colorOrder** ↑

Sets the color order of the plotted data (Left axes). Either a cellstr with the color names (size; 1xM) or a double with RGB colors (Size; Mx3). Where M is the number of plotted variables against the left axes.

Inherited from superclass NB_GRAPH

- **colorOrderRight** ↑

Sets the color order of the plotted data (Right axes). Either a cellstr with the color names (size; 1xM) or a double with RGB colors (Size; Mx3). Where M is the number of plotted variables against the right axes.

Inherited from superclass NB_GRAPH

- **colors** ↑

Sets the colors of the given variable(s). Must be a cell array on the form: {'var1', 'black', 'var2', [0.2 0.2 0.2],...}. Here we set the colors of the variables 'var1' and 'var2' to 'black' and [0.2 0.2 0.2] (RGB color) respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Caution: For the graphInfoStruct() method you need to select the variables from obj.DB.dataNames instead!

Inherited from superclass NB_GRAPH

- **crop** ↑

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

Inherited from superclass NB_GRAPH

- **dashedLine** ↑

Sets the date at which all the plotted lines will be dashed. Must be given as a string or an object which is of a subclass of the nb_date class.

- **dateInterpreter** ↑

Sets how to interpreter the dates. I.e. where to place the datapoints in relation to the tick mark labels. Must be a string. {'start'} | 'end' | 'middle'.

- **dates** ↑

All the dates of the plot as a cellstr. Not settable.

- **datesToPlot** ↑

Dates to plot as a cellstr of dates (strings). Can also use local variables.

This property can be used if you want to compare time observations against eachother. See nb_graph_tsExamples.m for more.

- **defaultFans** ↑

If a date is given default fans for the one of the variables 'QSA_GAPNB_Y', 'QSA_GAP_Y', 'QUA_DPY_PCPI', 'QUA_DPY_PCPIJAE', 'QUA_DPY_PCPIXE', 'QUA_DPY_PCPIXE_R' and 'QUA_RNFOOLIO' is added, otherwise not. The frequency of the provided data must be quarterly (4). Either as a string or an nb_quarter object. Only one of the aforementioned variables should be plotted at a time.

- **displayValue** [↑](#)

Set to false to not display observation values when holding the mouse over the graph. Default is true.

Inherited from superclass NB_GRAPH

- **endGraph** [↑](#)

Sets the end date of the graph. Either as string or an object which is of a subclass of the nb_date class. If the given date is after the end date of the data, the data will be appended with nan values. I.e. the graph will be blank for these dates.

- **excelFooterEng** [↑](#)

If you want a extended footer to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to include the same footer as in the graph. English version.

Inherited from superclass NB_GRAPH

- **excelFooterNor** [↑](#)

If you want a extended footer to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to include the same footer as in the graph. Norwegian version.

Inherited from superclass NB_GRAPH

- **excelTitleEng** [↑](#)

If you want a custom title to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to use the same title as in the graph (panel if multiple graphs). English version.

Inherited from superclass NB_GRAPH

- **excelTitleNor** [↑](#)

If you want a custom title to the graph in the excel spreadsheet produced by the nb_graph_package.saveData method, this property can be used. The default is to use the same title as in the graph (panel if multiple graphs). Norwegian version.

Inherited from superclass NB_GRAPH

- **factor** [↑](#)

Set this property to multiply the data with a given factor.
Must be a scalar.

Inherited from superclass NB_GRAPH

- **fakeLegend** ↑

Set this property if you want to add a legend of none plotted variable. You can set this property. Must be a cell on the form: {'legendName', settings,...}, where the legendName will be text of the fake legend. And the settings input must also be a cell array with the optional inputs {...,'propertyName', propertyName,...}. These settings will set the appearance of the fake legend. The following propertyNames are supported:

```
> 'type'      : Either 'line' or 'patch'.  
  
> 'color'     : Sets the color of the fake legend. Default is  
    'black'. Must either be a 1 x 3 double with  
    the RGB colors or a string with the color  
    name. If shaded patch is wanted it must be  
    2 x 3 double with the RGB colors or a 1 x 2  
    cellstr with the color names to use.  
  
> 'direction' : Sets the direction of the shading. Either  
    {'north'} | 'south' | 'west' | 'east'. As a  
    string. Default is 'north'. Only an option  
    when 'type' is set to 'patch'.  
  
> 'edgeColor'  : Sets the color of the edge of the patch.  
    Default is the same as the 'color' option.  
    Only an option when 'type' is set to 'patch'.  
  
> 'lineStyle'   : Sets the line style of the fake legend. As a  
    string. Either {'-' } | '--' | '---' | ':' |  
    '-.' | 'none'. Default is a normal line.  
  
    Will set the edge line style if the 'type'  
    is set to 'patch'.  
  
> 'lineWidth'   : Sets the line width of the fake legend.  
    Default is 2.5. Must be a scalar.  
  
> 'marker'     : Sets the marker of the fake legend. Default is  
    'none'. Only an option when 'type' is set to  
    'line'. Lookup LineSpec in the MATLAB help  
    meny for more on the supported marker types.  
  
Caution : Even if you don't want to set any of the optional  
    input. The settings input must be given. I.e an  
    empty cell, i.e. {}.
```

Inherited from superclass NB_GRAPH

- **fanAlpha** ↑

Sets the transparency of the fan chart. May be needed if you add fan charts to more than one variable at the time. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

- **fanColor** ↑

Sets the colors of the fan charts. Must be a matrix of size; number of fan layer x 3, with the RGB color specifications.

or

A string with the basis color for the fan colors. Either 'red', 'blue', 'green', 'yellow', 'magenta', 'cyan' or 'white'.

Be aware that the classification of the color of the given "basecolor" is based on the property fanPercentiles, so if you have more or less than 4 layers you must change this property to have the same size as the number of layers. (This is the case even if you don't use it to calculate the percentiles of a given datasets. Given by the property fanDatasets)

Default is the nb colors.

Caution: If fanMethod is set to 'graded' the color used are those assign to the colorMap property.

- **fanDatasets** ↑

Sets the data of the added fan layers.

If you have the data of the different layer in separate datasets. Then the input to this property must be a 2 * number of layers cell matrix. Can be excel spreadsheets, .mat files or dyn_ts objects.

or

You can also give the data with all the simulated data or fan layers in an dyn_ts object or an nb_ts object. (Each page one simulation or each page one layer). (FASTEST with an nb_ts object as input.)

Remember that the percentiles for the fan charts is set by the property fanPercentiles, default is [.3, .5, .7, .9].

The fan layers are added differently given the method you use.

> graph(...): Adds the fan given in this property to the last variable given in the property variablesToPlot. (If not the fanVariable property is set.) If you graph more datasets (in separate figures), the fan layers will be the same for all of them. Set the fanVariables property if that is not wanted.

> graphSubPlots(...): Adds the fan given in this property to the corresponding variable in the last given datasets (last page of the nb_ts object given by the property DB) of each each subplot.

-graphInfoStruct(...): Adds the fan given by this property to each variable of each subplot. Added for the last given dataset. (Last page of the nb_ts object given by the property DB.)

- **fanFile** ↑

The file to get the default fan layers from. As a string.

- **fanGradedLineWidth** ↑

Line width used but the graded fan chart is set to

- **fanGradedStyle** ↑

Line width used but the graded fan chart is set to

- **fanLegend** ↑

Set this property if you want to add a MPR styled legend of the fan layers. Set it to 1 if wanted. Default is not (0).

- **fanLegendFontSize** ↑

Sets the font size of the fan legend. Default is 12. Must be a scalar.

- **fanLegendLocation** ↑

Sets the location of the fan legend. Locations are:

```
> 'Best', (same as 'North'.)
> 'NorthWest'
> 'North'
> 'NorthEast'
> 'SouthEast'
> 'South'
> 'SouthWest'
> 'outside' : Places the legend outside the axes, one the right side. (If you create subplots, this is the only option which will look good.)
```

You can also give a 1 x 2 double vector with the location of where to place the legend. First column is the x-axis location and the second column is the y-axis location. Both must be between 0 and 1.

- **fanLegendText** ↑

Set this property if you want to give the text over the colored boxes of the MPR looking fan legend, you must give them as a cell. (Must have same size as number of layers.) Default is the percentiles with the % sign added. E.g. {'30%','50%','70%','90%'}.

- **fanMethod** ↑

{'percentiles'} | 'hdi' | 'graded'; Which type of fan chart is going to be made. 'percentiles' are produced by using percentiles, 'hdi' use highest density intervals, while 'graded' creates a graded fan chart of the colors specified with the colorMap property.

- **fanPercentiles** ↑

Sets the percentiles you want to calculate (if the fanDatasets property is representing simulation) or specify the percentiles you have given (if the fanDatasets property is representing already calculated percentiles). Must be given as a double vector. Default is [0.3 0.5 0.7 0.9].

This property is also the default base for the text of the fan legend. (Where the percentiles are given in percent.)

- **fanVariable** ↑

Sets the variable you want to add the fan layers to. Must be given as a string with the variable name. Default is to use the last variable in the variablesToPlot property.

If this input is a cellstr with more than one variable, the 'fanPercentiles' input must be a scalar double. Fan chart will then be added to more than one variable.

- **fanVariables** ↑

If you have the fan layers included in the same dataset as your other plotted variables you can use this property. The input must then be given as 1 x 2 * number of layers cell array with the fan layers names (as strings). I.e. both the upper and lower layers must be given as separate variables.
(Need not be ordered though.)

E.g. {'LowPerc 90%', 'LowPerc 70%', 'UppPerc 90%', 'UppPerc 70%'}

Caution: Must fit the number of percentiles given by the property fanPercentiles (Remember to include both upper and lower bounds!).

Only an input to the method graph(...): Adds the given fan layers to the last variable given by the property variablesToPlot or the variable given by fanVariable property.

- **figureColor** ↑

Color of the figure as a 1x3 double. Default is [1 1 1].

Inherited from superclass NB_GRAPH

- **figureName** ↑

Sets the name of figure (only in MATLAB), default is no name.

Inherited from superclass NB_GRAPH

- **figurePosition** ↑

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

Inherited from superclass NB_GRAPH

- **figureTitle** ↑

Sets if figure titles is wanted on the figures when using the method graphInfoStruct. The fieldnames of the GraphStruct property will be used as figure title. Default is 0 (not include).

If set to a one line char this property can be used for the plotting method graphSubPlots.

Inherited from superclass NB_GRAPH

- **fileFormat** ↑

Sets the save file format. Either 'eps', 'jpg', 'pdf' or 'png'. 'pdf' is default.

Inherited from superclass NB_GRAPH

- **findAxisLimitMethod** ↑

Sets the method used for finding the axis limits, and y-ticks.

- > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
- > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
- > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
- > 4 : Uses the MATLAB algorithm for finding the axis limits.

Inherited from superclass NB_GRAPH

- **flip** ↑

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

Inherited from superclass NB_GRAPH

- **fontName** ↑

Sets the name of font used. Default is 'arial'.

Inherited from superclass NB_GRAPH

- **fontScale** ↑

Sets the parameter that scales all the font sizes of the graphs. Must be scalar. Default is 1 (do not scale).

Inherited from superclass NB_GRAPH

- **fontUnits** ↑

Sets the font units of all the fonts of the graph. Either {'points'} | 'normalized' | 'inches' | 'centimeters'. Default is 'points'.

Caution : If you set the fontUnits property in a method call to the set method, all the font properties set before the fontUnits property will be set in the old fontUnits, while all the font properties set after will be in the new fontUnits.

Caution : Don't use this property in combination with one of the graph styles defined by this class. I.e. 'mpr', 'mpr_white', 'presentation' and 'presentation_white' They will set this property to 'normalized'.

Caution : 'normalized' font units must be between 0 and 1. The normalized units are not the same as the MATLAB normalized units. This normalized units are not only normalized to the axes size, but also across resolution of the screen. (But only vertically)

Inherited from superclass NB_GRAPH

- **graphStyle** ↑

Sets the graphing style of the plots. Give 'mpr' if you want the MPR looking style, or 'presentation' for graphs for the presentation (see nb_Presentation). If you don't want the grey shaded background you can use 'mpr_white' and 'presentation_white' instead.

You can also add your own graph style setting through a .m file. I.e. give the filename (without extension) as a string.

E.g. In the file you can type in something like:

```
set(obj,'titleFontSize',12,'legInterpreter','tex');
```

Caution: If you give this as the first input to the set method it is possible to overrun some of the default settings if that is wanted. E.g. font size of the text, the shading of the plot and so on.

Inherited from superclass NB_GRAPH

- **grid** ↑

Set it to 'on' if grid lines are wanted otherwise set it to 'off'. Default is 'off'.

Inherited from superclass NB_GRAPH

- **gridLineStyle** ↑

Sets the line style of the grid lines. Either '-' , '--' , ':' or '-.' .

Inherited from superclass NB_GRAPH

- **highlight** [↑](#)

If highlighted area between two dates of the graph is wanted set this property.

One highlighted area:

A cell array on the form {'date1', 'date2'}

More highlighted areas:

A nested cell array on the form

{{'date1(1)', 'date2(1)'}, {'date1(2)', 'date2(2)'}, ...}

If plotType is set to 'scatter' scalars can be used instead.

- **highlightColor** [↑](#)

Sets the colors of the background patches. Must be one of the following:

- > A string with the color name to use when plotting (all) the patch(es)
- > A cell array of strings with the color names
- > A cell with 1 x 3 doubles with the RGB color specification.

When given as a cell this property must match the highlight property. I.e. the number of highlighted areas added.

The default color of the highlighted areas is 'light blue'.

- **horizontalLine** [↑](#)

If you want to include some extra horizontal lines, beside the base line, you can set this property. Must be set to a scalar or a double vector with the y-axis value(s) on where to place the horizontal line(s).

Inherited from superclass NB_GRAPH

- **horizontalLineColor** [↑](#)

Sets the color(s) of the given horizontal line(s).

Must either be an M x 3 double with the RGB color(s) or a 1 x M cell array of strings with the color name(s). Where M must be less than the number of plotted horizontal lines.

If less or no color(s) is/are set by this property the default colors for the rest or all the horizontal line(s) is/are [0 0 0], i.e. MATLAB black.

Inherited from superclass NB_GRAPH

- **horizontalLineStyle** [↑](#)

Sets the style(s) of the given horizontal line(s).

Must either be a string or a $1 \times M$ cell array of strings with the style(s). Where M must be less than the number of plotted horizontal lines.

If less or no style(s) is/are set by this property the default lines for the rest or all the horizontal line(s) is/are '-'.

Inherited from superclass NB_GRAPH

- **horizontalLineWidth** [↑](#)

Sets the line width of the horizontal line(s). Must be a scalar. Default is 1.

Inherited from superclass NB_GRAPH

- **language** [↑](#)

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

Inherited from superclass NB_GRAPH

- **legAuto** [↑](#)

'on' | {'off'}. As a string.

> 'on' : The strings given through the fakeLegend and patch properties are automatically added to the legend.

> 'off' : The strings given through the fakeLegend and patch properties are not automatically added to the legend. Which means that you must provide all the legend information through the legends property. The patch descriptions must be given first and the fake legend description must be given last in the legends property. Default.

Inherited from superclass NB_GRAPH

- **legBox** [↑](#)

Set if a box should be drawn around the legend. Either {'on'} | 'off'.

Caution : When removing the box you make it impossible to move it around afterwards.

Inherited from superclass NB_GRAPH

- **legColor** [↑](#)

Sets the color of the background of the box of the legend. Either as 1×3 double with the RGB or as a string). Default is 'none', i.e. transparent.

Inherited from superclass NB_GRAPH

- **legColumnWidth** ↑

Sets the width of the columns of the legend. Default is to let MATLAB find the width itself. If given it must be a scalar with the width of all columns of the legend or a $1 \times \text{legColumns}$ double with the width of each individual column.

Should be between 0 and 1. Use the try and fail method to find out what fits.

Inherited from superclass NB_GRAPH

- **legColumns** ↑

Sets the number of columns of the legends. Must be a scalar.

Inherited from superclass NB_GRAPH

- **legFontColor** ↑

Sets the font color(s) of the legend text. Must either be a 1×3 double or a string with the color name of all legend text objects, or a $M \times 3$ double or a cellstr array with size $1 \times M$ with color names to use of each legend text object.

Inherited from superclass NB_GRAPH

- **legFontSize** ↑

Sets the font size of the legend. Must be a scalar default is 10.

Inherited from superclass NB_GRAPH

- **legInterpreter** ↑

Sets the interpreter of the legend text. Must be a string.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **legLocation** ↑

Sets the location of the legend, must be string. The location can be:

> 'Best' : Same as 'NorthWest'.
> 'NorthWest'
> 'North'
> 'NorthEast'
> 'SouthEast'
> 'South'
> 'SouthWest'
> 'below' : Below the plot (when many subplots, it will place the legend below all of them)
> 'middle' : Could only be use for 2×2 subplot, and then it places the legend between the upper and lower subplots.

Location that only works for the graph() method:

- > 'outsideright' : Legend is placed outside the axes on the right side, and the axes is resized, so the axes and legend does not take up more space than the axes did in the first place. The legend is vertically centered.
- > 'outsiderighttop' : Same as 'outsideright', but placed vertically top.

Inherited from superclass NB_GRAPH

- **legPosition** ↑

Sets the position of the legend. Must be a 1x2 double. Where the first element is the x-axis location and the second is the y-axis location. [xPosition yPosition]

Caution : Both elements must be between 0 and 1. And where we have that [0, 0] will be the bottom left location of the axes and [1, 1] is the top right position of the axes. (This position will be the top left position of the legend itself.)

Caution : This option overruns the legLocation property.

Inherited from superclass NB_GRAPH

- **legReorder** ↑

Set this property to reorder the legend. Either a string with {'default'} | 'inverse' or a double with how to reorder the legend. E.g. if you have 3 legends to plot the default index will be [1,2,3], the inverse ('inv') will be [3,2,1]. If you want to decide that the 3. legend should be first, then the 1. and 2., you can type in [3,1,2].

Caution : If a double is given it must have as many elements as there is plotted legends. I.e. if you give a empty string to one of the legends it will be excluded. Say you provide the property legends as {'s','','t','f'} then the double must have size 1x3.

Inherited from superclass NB_GRAPH

- **legSpace** ↑

The vertical space between the texts of the legend. Must be a scalar. Default is 0.

Inherited from superclass NB_GRAPH

- **legendText** ↑

Sets the legend(s) of the given variable(s). Must be a cell array on the form: {'var1', 'Name', 'var2', 'Name2', ...}. Here we set the legends of the variables 'var1' and 'var2' to 'Name' and 'Name2' respectively. (The rest will be given the variable names as default).

```

To give a legend to a splitted line (second part) give;
{...,'Var1(second)','LegendSplitted',...} (Is case sensitiv)

Caution : legAuto should be set to 'on'. Which is not default.
          This is only important if the patch or fakeLegend
          property is used.

Caution : When given this property will overwrite the legends
          property

Caution : If the variable, scattergroup or candle is not found
          no error will occure!

Caution : If you have used the patch or fakeLegend property these
          can be translated as well with this property

Inherited from superclass NB_GRAPH

- legends ↑

Give the legends of the plot. Must be given as a cell array
of strings.

Default (it depends on the method you use):

> 'graph'           : The variable names are used as the
                      default legends. (Given by the
                      variableToPlot and variableToPlotRight
                      properties)

> 'graphSubPlot'   : The dataset names are used as the
                      default legends. (Given by the
                      dataNames of the DB property.)

> 'graphInfoStruct' : The dataset names are used as the
                      default legends. (Given by the
                      dataNames of the DB property.)

Caution : The ordering of the legends is as follows:

- patch             : See the patch property (only when
                      legAuto is set to 'off')

- variablesToPlot   : Then the all the variablesToPlot
                      variables. When You have splitted
                      lines, i.e. either using the
                      dashedLine property or the
                      lineStyles property, these can be set
                      after all the variablesToPlot. Have
                      in mind that the ordering is kept.

- variablesToPlotRight : Then the comes all the variables
                        provided by the variablesToPlotRight.
                        Then the splitted lines.

- fakeLegend        : Then you can provide the legend text
                      for the fake legend. (only when
                      legAuto is set to 'off')

```

Example:

```
data      = nb_ts.rand('2012',10,2);
plotter = nb_graph_ts(data);
plotter.set('variablesToPlot',{'Var1'},...
            'variablesToPlotRight',{'Var2'},...
            'lineStyles',{'Var1',{'-','2014','--'},...
                         'Var2',{'-','2014','--'},...
            'legends',{'Test','Test (--)','Test2','Test2 (--)'});
plotter.graph()
```

Inherited from superclass NB_GRAPH

- **lineStyles** ↑

Sets the line styles of the given variable(s). Must be a cell array on the form: {'var1', '-' , 'var2', '--', ...}. Here we set the line styles of the variables 'var1' and 'var2' to '-' and '--' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Supported line styles are '-','--','::','.-','---

Caution : For nb_graph_ts and nb_graph_data it is possible to split the plotted line using the following syntax;
{'var1',{'-','2000Q1','--'}} and {'var1',{'-',2,'--'}} respectively

Inherited from superclass NB_GRAPH

- **lineWidth** ↑

Sets the line width of the line plots. Must be a scalar.
Default is 2.5.

Inherited from superclass NB_GRAPH

- **lineWidths** ↑

Sets the line widths of the given variables. Must be a cell array on the form: {'var1', 1, 'var2', 1.5,...}. Here we set the line widths of the variables 'var1' and 'var2' to 1 and 1.5 respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

Inherited from superclass NB_GRAPH

- **localVariables** ↑

A nb_struct with the local variables of the nb_graph object. I.e. a field with name 'test' can be reach with the string input %#test.

Inherited from superclass NB_GRAPH

- **lookUpMatrix** ↑

Sets how the given mnemonics (variable and type names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
```

```
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {  
'mnemonics1','englishDescription1','norwegianDescription1';  
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Inherited from superclass NB_GRAPH

- **mYLim** ↑

Sets the max/min y-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Both or one of them can be set to nan, i.e. the default limits will be used) E.g. [0 6], [nan, 6] or [0, nan].

Caution: If the variablesToPlotRight property is not empty this setting only sets the left y-axis limits.

Only an option for the graphInfoStruct(...) method.

- **markerSize** ↑

Sets the size of the all markers. Must be a scalar. Default is 8.

Inherited from superclass NB_GRAPH

- **markers** ↑

Sets the markers of the given variables. Must be a cell array on the form: {'var1', '^', 'var2', 'o', ...}. Here we set the markers of the variables 'var1' and 'var2' to '^' and 'o' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

See the table below on which markers that are supported.

'+'	: Plus sign
'o'	: Circle
'*'	: Asterisk
'.'	: Point
'x'	: Cross
's'	: Square
'd'	: Diamond
'^'	: Upward-pointing triangle
'v'	: Downward-pointing triangle
'>'	: Right-pointing triangle
'<'	: Left-pointing triangle
'p'	: Five-pointed star (pentagram)
'h'	: Six-pointed star (hexagram)

Inherited from superclass NB_GRAPH

- **missingValues** ↑

Set how to interpret missing observations. Must be a string.
 Either;

```
> 'interpolate' : Linearly interpolate the missing values.

> 'strip'      : Strip the missing values. Should only be
                  used with business days data.

> 'both'       : First strip up until a date given by the
                  property stopStrip and then interpolate the
                  rest of the missing values. If the stopStrip
                  property is not given this will result in
                  the same as the 'strip' option.

%
> 'none'        : No interpolation (default)
```

- **nanAfterDate** [↑](#)

If setted this property would make the graph blank after the provided date, but the x-axis would still keeps its axis limits. Must be a string with the date or an object which of a subclass of the nb_date class.

- **nanBeforeDate** [↑](#)

If setted this property would make the graph blank before the provided date, but the x-axis would still keeps its axis limits. Must be a string with the date or an object which of a subclass of the nb_date class.

- **nanVariables** [↑](#)

Sets the nan option for individual variables. Must be given as a cell. I.e. {'var1', {'2012Q2', '2012Q4'}, ... 'var2', {'2012Q2', '2012Q4'}, ...}. This will make both 'var1' and 'var2' variables blank before '2012Q2' and after '2012Q4' (Not including.) in the given graph.

- **noLabel** [↑](#)

Set it to 1 if no label(s) is/are wanted on the graphs, otherwise set it to 0. Both on the y-axis and x-axis. Default is 0. This is of course only have an effect if the nb_graph object have been given the xLabel or yLabel properties. (These are empty by default.)

Inherited from superclass NB_GRAPH

- **noLegend** [↑](#)

Set it to 1 if no legend is wanted, otherwise set it to 0. Default is 0.

Inherited from superclass NB_GRAPH

- **noTickMarkLabels** [↑](#)

Set to true (1) to remove tick marks and tick marks label of axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTickMarkLabelsLeft** ↑

Set to true (1) to remove tick marks and tick marks label of the left side of the axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTickMarkLabelsRight** ↑

Set to true (1) to remove tick marks and tick marks label of the right side of the axes. Default is false (0).

Inherited from superclass NB_GRAPH

- **noTitle** ↑

Set it to 1 if you don't want title(s) of the graphs, otherwise set it to 0. Default is 0.

Set it to 2 if you want the dataNames{ii} as the title of the graph when using the graph method.

Inherited from superclass NB_GRAPH

- **normalized** ↑

If the font should be normalized to the figure or axes. Either 'figure' or 'axes'.

Inherited from superclass NB_GRAPH

- **numberOfGraphs** ↑

Number of graph produced by the graph methods. Not settable.

Inherited from superclass NB_GRAPH

- **page** ↑

Sets the page of the data object to plot. Only an option for graph() method. Default is [], i.e. plot all pages in separate figures.

Inherited from superclass NB_GRAPH

- **parameters** ↑

A struct with the parameters that can be used in evaluation of expressions in the graphSubPlots and graphInfoStruct methods.

Inherited from superclass NB_GRAPH

- **patch** ↑

Sets the patch property of the object. If set this will add a patch (color fill) between two variables.

Only one patch :

```
{'patchName','var1','var2',color}
```

More patches :

```
{'patchName1','var1Patch1','var2Patch1',color1 ,...  
'patchName2','var1Patch2','var2Patch2',color2,...}
```

Where the the color option(s) must either be a 1 x 3 double with the RGB colors or a string with the color name.

The first input will be the legend text of the patch. I.e. 'patchName', 'patchName1' and 'patchName2' will be the description text included in the legend. (If not the property legAuto is set to 'off'.)

Inherited from superclass NB_GRAPH

- **patchAlpha** [↑](#)

Sets the transparency of the patches. A number between 0 and 1. 1 is opaque, while 0 is fully transparent.

Inherited from superclass NB_GRAPH

- **pdfBook** [↑](#)

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be use in combination with the saveName property.

Inherited from superclass NB_GRAPH

- **plotAspectRatio** [↑](#)

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3, or when '[16,9]' the aspect ratio of the figure is 16 to 9

Inherited from superclass NB_GRAPH

- **plotType** [↑](#)

Sets the plot type. Either:

> 'line' : If line plot(s) is wanted. Default.

> 'stacked' : If stacked bar plot(s) is wanted. Not an option for the graphSubPlots(...) method.

> 'grouped' : If grouped bar plot(s) is wanted.

> 'dec' : If decomposition plot(s) is wanted. Which is

a bar plot with also a line with the sum of the stacked bars. Not an option for the graphSubPlots(...) method.

```

> 'area'      : If area plot(s) is wanted.

> 'candle'    : If candle plot(s) is wanted.

> 'scatter'   : If scatter plot(s) is wanted.

> 'simpleRules' : Can be given if you want graph of the interest rate path compared with the simple rules. (MPR looking graph.) The different variables must have the names:

'QUA_RNFOLIO'      : Interest rate path.
'QUA_TAYLOR'        : Taylor-rule.
'QUA_GROWTHRULE'   : Uses a growth gap measure instead of the output gap in the simple rule.
'QUA_FOREIGNRULE'  : A simple rule that takes foreign variables into account
'QUA_MODELBASEDRULE': A simple rule base on some work of FA. A rule which is robust in different models.

```

You can set which simple rules you want to plot with the property simpleRules and you can graph two different versions of the simple rules using the simpleRulesSecondData property.

Only an option for the graph(...) method.

- **plotTypes** ↑

Sets the plot type of the given variables. Must be a cell array on the form: {'var1', 'line', 'var2', 'grouped', ...}. Here we set the plot type of the variables 'var1' and 'var2' to 'line' and 'grouped' respectively. The variables given must be included in the variablesToPlot or variablesToPlotRight properties.

See the property plotType above on which plot types that are supported.

- **position** ↑

Sets the position of the axes, must be an 1x4 double. [leftMostPoint lowestPoint width height]. Only an option for the graph() method. Default is [0.1 0.1 0.8 0.8].

For the graph method graphSubPlots the position input can be given a 1 x N cell array, where each element is a 1x4 double. N = obj.subPlotSize(1)*obj.subPlotSize(2).

Inherited from superclass NB_GRAPH

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are produced. Must be a string.

Default is to save each graph produced in separate files. Set the pdfBook property to 1 if you want to save all the produced graphs in one pdf file. (To save all figures in one file is only possible for pdf files. I.e. the fileFormat property must be 'pdf'.)

Inherited from superclass NB_GRAPH

- **scatterDates** ↑

Sets the start and end to be used for the scatter plot plotted against the left axes. Must be a nested cell array. The dates can be given as strings or date objects. E.g:

```
{'scatterGroup1',{'startDate1','endDate1'},...  
 'scatterGroup2',{'startDate2','endDate2'},...}
```

Caution : This property must be provided to produce a scatter plot! (Or of course scatterDatesRight)

Be aware : Each date will result in one point in the scatter.

- **scatterDatesRight** ↑

Sets the start and end to be used for the scatter plot plotted against the right axes. Must be a nested cell array. The dates can be given as strings or date objects. E.g:

```
{'scatterGroup1',{'startDate1','endDate1'},...  
 'scatterGroup2',{'startDate2','endDate2'},...}
```

Caution : This property must be provided to produce a scatter plot! (Or of course scatterDates)

Be aware : Each date will result in one point in the scatter.

- **scatterLineStyle** ↑

Sets the scatter line style. Must be string. See 'lineStyles' for supported inputs. (Sets the line style of all scatter plots)

- **scatterVariables** ↑

The variables used for the scatter plot. Must be a 1x2 cellstr array. The first element will be the variable plotted against the x-axis, while the second element will be the variable plotted against the left y-axis. E.g:

```
{'var1','var2'}
```

- **scatterVariablesRight** ↑

The variables used for the scatter plot. Must be a 1x2 cellstr array. The first element will be the variable plotted against the x-axis, while the second element will be the variable plotted against the right y-axis. E.g:

```
{'var1','var2'}
```

- **shading** ↑

The shading option of the axes background:

- 'grey' : Shaded grey background
- 'none' : Background color given by the color property.
- A n x m x 3 double with the background color. n is the number of horizontal pixels, m is the number of vertical pixels and 3 means the RGB colors.

Inherited from superclass NB_GRAPH

- **simpleRules** ↑

Sets the simple rules which will be graphed by the method graph(...) when the plotType property is set to 'simpleRules'. Must be a cell array of strings. See the documentation on the property plotType for more on the simple rules to include.

- **simpleRulesSecondData** ↑

Sets the data of an older version of the simple rules. Only an option of the method graph(...) when the plotType property is set to 'simpleRules'. Must be a string with the name of a excel spreadsheet, a dyn_ts object or an nb_ts object. (.mat file is not supported.) Must include the variables given below (or the variables given by the 'simpleRules' property.):

```
> 'QUA_TAYLOR'      : Taylor-rule.  
> 'QUA_GROWTHRULE'  : Uses a growth gap measure instead of  
                      the output gap in the simple rule.  
> 'QUA_FOREIGNRULE' : A simple rule that takes foreign  
                      variables into account.  
> 'QUA_MODELBASEDRULE' : A simple rule base on some work of  
                          FA. A rule which is robust in  
                          different models.
```

- **spacing** ↑

Sets the x-ticks spacing. Must be a scalar. Refers to the given x-axis tick frequency.

- **startGraph** ↑

Sets the start date of the graph. Must be a string or an object which of a subclass of the nb_date class. If this date is before the start date of the data, the data will be expanded with nan (blank values) for these periods.

- **stopStrip** ↑

Sets the stop date of the graph. Must be a string or an object which of a subclass of the nb_date class.

- **stopUpdate** ↑

Sets a time for when to stop updating the data of this graph, i.e. if the actual time has past this date the data will not be updated. Must be a string on the format 'yyyymmdd', 'yyyymmddhh' or 'yyyymmddhhmm'. E.g. '20121010', '2012101010' or '201210101000'.

Caution: No warning will be provided!

- **subPlotSize** ↑

Sets the number of subplots per figure. Must be a 1 x 2 double with the number of subplot rows as the first element and the number of subplot columns as the second element. Only an option of the graphSubPlots() and graphInfoStruct() methods.

Default is [2, 2].

Inherited from superclass NB_GRAPH

- **subPlotSpecial** ↑

Set it to 1 if you want the 1x2 and 2x1 subplots to better fit for usage in presentations. Default is 0, i.e. use MATLAB default positions.

When set to 1 this class uses the nb_subplotSpecial instead of nb_subplot to find the positions of the subplots.

Inherited from superclass NB_GRAPH

- **subPlotsOptions** ↑

Use this property to set subplot spesific options of each variable while using the the method graphSubPlots(). Each field must be the name of the variable. The options are:

- **yLabel** : The y-axis label.
- **yLim** : Sets the y-axis limits. As a 1x2 double.
- **ySpacing** : Spacing between y-axis tick marks.
- **dashedLine** : The date to start the dashed line for the given variable.

Example:

```
s.Var1 = struct('yLim',[0,1]);  
s.Var2 = struct('yLim',[0,1]);
```

- **sumTo** ↑

Sets a number which the area or the stacked bar plot should sum to. Must be a scalar. I.e. if 100 is given. The sizes of the bars will be the percentage share of the total sum.

Inherited from superclass NB_GRAPH

- **tag** ↑

Used by the nb_graph_subplot class to locate the nb_graph object in the subplot. Should not be used. Use userData instead.

Inherited from superclass NB_GRAPH

- **title** ↑

Sets the title of the plot. Must be a char. Only an option for the graph(...) method.

Inherited from superclass NB_GRAPH

- **titleAlignment** ↑

Sets the figure title text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_GRAPH

- **titleFontSize** ↑

Sets the font size of the titles which is placed above the (sub)plot(s). Must be scalar. Default is 14.

Inherited from superclass NB_GRAPH

- **titleFontWeight** ↑

Sets the font weight of the titles which is placed above the (sub)plot(s). Must be a string. Default is 'bold'.

Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **titleInterpreter** ↑

Sets the interpreter used for the given string given by the title property.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_GRAPH

- **titlePlacement** ↑

Sets the placement of the title. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_GRAPH

- **userData** ↑

User data, can be set to anything you want.

Inherited from superclass NB_GRAPH

- **variablesToPlot** ↑

Sets the variables to plot against the left (or both) axes.
Must be a cell array of strings with the variable names. I.e.
{'var1', 'var2', ...}.

Not an option for the graphInfoStruct(...), which use the
property GraphStruct instead.

Inherited from superclass NB_GRAPH

- **variablesToPlotRight** ↑

Sets the variables to plot against the right axes. Must be
a cell array of strings with the variable names. I.e.
{'var1', 'var2', ...}.

Not an option for the graphInfoStruct(...), which use the
property GraphStruct instead.

Inherited from superclass NB_GRAPH

- **verticalLine** ↑

Sets the date(s) of where to place a vertical line(s).
(Dotted orange line is default). Must be a string or a cell
array of strings with the date(s) for where to place the
vertical line(s). I.e. 'date1' or {'date1','date2',...}

Each element of the cell could also be given as a cell with
two dates, i.e. {'date1', 'date2' }. Then the vertical line
will be placed between the given dates.

If plotType is set to 'scatter' scalars can be used
instead.

- **verticalLineColor** ↑

Sets the color(s) of the given vertical line(s). Must either
be an M x 3 double with the RGB color(s) or a 1 x M cell array
of strings with the color name(s). Where M must be less than
the number of plotted vertical lines.

If less or no color(s) is/are set by this property the default
color(s) for the rest or all the vertical line(s) is/are
[0 0 0]. I.e. MATLAB black.

- **verticalLineLimit** ↑

Sets the y-axis limit(s) of the given vertical line(s). Must
either be a 1 x M cell array of 1 x 2 double with the upper
and lower y-axis limit(s). Where M must be less than the
number of plotted vertical lines.

If less or no limit(s) is/are set by this property the default
limit for the rest or all the vertical line(s) is/are the full
height of the graph.

- **verticalLineStyle** ↑

Sets the line style(s) of the given vertical line(s). Must either be a 1 x M cell array of strings with the style(s). Where M must be less than the number of plotted vertical lines.

If less or no style(s) is/are set by this property the default line style is/are used for the rest or all the vertical line(s) is/are '--'.

- **verticalLineWidth** ↑

Sets the line width of (all) the vertical line(s). Must be a scalar. Default is 1.5.

- **xLabel** ↑

Sets (add) the text of the x-axis label. Must be a string.

Inherited from superclass NB_GRAPH

- **xLabelAlignment** ↑

Sets the x-axis label text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_GRAPH

- **xLabelFontSize** ↑

Sets the font size of the x-axis label. Must be scalar. Default is 12.

Inherited from superclass NB_GRAPH

- **xLabelFontWeight** ↑

Sets the font weight of the x-axis label. Must be string. Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **xLabelInterpreter** ↑

The interpreter used for the given string given by the xlabel property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_GRAPH

- **xLabelPlacement** ↑

Sets the placement of the x-axis label. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_GRAPH

- **xLim** ↑

Sets the x-axis limits of the plot. Must be 1 x 2 double vector, where the first number is the lower limit and the second number is the upper limit. (Both or one of them can be set to nan, i.e. the default limits will be used) E.g. [0 6], [nan, 6] or [0, nan].

Only an option when the plotType property is set to 'scatter'.

- **xScale** ↑

Sets the scale of the x-axis. Either {'linear'} | 'log'.

Only an option when plotType is set to 'scatter'.

- **xTickFrequency** ↑

Sets the frequency of the x-axis tick mark labels. Only necessary if the wanted frequency differs from the data plotted. Must be a string. One of the following

```
> 'yearly'  
> 'semiannually'  
> 'quarterly'  
> 'monthly'  
> 'weekly'  
> 'daily'
```

Caution : It is only possible to use an frequency which is lower then the frequency of the data.

Caution : When the data are of a daily frequency the default is to set the xTickFrequency to 'yearly'.

- **xTickLabelAlignment** ↑

The alignment of the x-axis tick marks labels. {'normal'} | 'middle'.

- **xTickLabelLocation** ↑

The location of the x-axis tick marks labels. Either {'bottom'} | 'top' | 'baseline'. 'baseline' will only work in combination with the xtickLocation property set to a double with the basevalue.

- **xTickLabels** ↑

Sets the x-axis tick mark labels. To translate the default tick mark label 'Var1' and 'Var2' you can use;

```
{'Var1','Label1','Var2','Label2'}
```

If given as a empty cell, default x-axis tick marks will be used, which is default.

This property can be used to create multi-lined x-axis tick mark labels. To do this give a multi-row char to the labels you want to make multi-lined.

Inherited from superclass NB_GRAPH

- **xTickLocation** ↑

The location of the x-axis tick marks. Either {'bottom'} | 'top' | double. If given as a double the tick marks will be placed at this value (where the number represent the y-axis value).

- **xTickRotation** ↑

Sets the rotation of the x-axis tick mark labels. Must be a scalar with the number of degrees the labels should be rotated. Positive angles cause counterclockwise rotation.

- **xTickStart** ↑

Sets the start date of where to start the x-tick mark labels. Must be a string or an object which of a subclass of the nb_date class.

- **yDir** ↑

Sets the direction of the y-axis of the plot. Must be a string. Either 'normal' or 'reverse'. Default is 'normal'.

Caution: If the variablesToPlotRight is not empty this setting only sets the left y-axis direction.

- **yDirRight** ↑

Sets the direction of the right y-axis of the plot. Either 'normal' or 'reverse'. Default is 'normal'. (Only when the variablesToPlotRight property is not empty.)

- **yLabel** ↑

Sets (add) the text of the y-axis label. Must be a string.

Inherited from superclass NB_GRAPH

- **yLabelFontSize** ↑

Sets the font size of the y-axis label. Must be scalar. Default is 12.

Inherited from superclass NB_GRAPH

- **yLabelFontWeight** ↑

Sets the font weight of the y-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_GRAPH

- **yLabelInterpreter** ↑

The interpreter used for the given string given by the xLabel
property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_GRAPH

- **yLabelRight** ↑

Sets the text of the y-axis label. (Only on the right side.)
Must be a string. Takes the same font option as the yLabel
property

Inherited from superclass NB_GRAPH

- **yLim** ↑

Sets the y-axis limits of the plot. Must be 1 x 2 double
vector, where the first number is the lower limit and the
second number is the upper limit. (Both or one of them can be
set to nan, i.e. the default limits will be used) E.g. [0 6],
[nan, 6] or [0, nan].

Caution: If the variablesToPlotRight property is not empty
this setting only sets the left y-axis limits.

Only an option for the graph(...) and graphSubPlots() methods.
(For the graphInfoStruct(...) method use the property
GraphStruct.)

- **yLimRight** ↑

Sets the right y-axis limits of the plot. Must be 1 x 2 double
vector, where the first number is the lower limit and the
second number is the upper limit. (Only when the
variablesToPlotRight property is not empty.) (Both or one of
them can be set to nan, i.e. the default limits will be used)
E.g. [0 6], [nan, 6] or [0, nan].

Only an option for the graph(...) and graphSubPlots() methods.
(For the graphInfoStruct(...) method use the property
GraphStruct.)

- **yOffset** ↑

The y-axis tick mark labels offset from the axes

- **yScale** ↑

Sets the scale of the y-axis. {'linear'} | 'log'.(Both the left and the right axes if nothing is plotted on the right axes.)

- **yScaleRight** ↑

Sets the scale of the right y-axis. {'linear'} | 'log'. (Has only somthing to say if somthing is plotted on the right axes)

- **ySpacing** ↑

Sets the spacing between y-axis tick mark labels of the y-axis. Must be scalar.

Caution: The spacing will be the number of periods between the tick marks labels. The number of periods will follow the frequency of the xTickFrequency property if setted, else it will follow the frequency of the data provided. (Except when dealing with daily data, because then the default xTickFrequency is 'yearly')

Caution: If the variablesToPlotRight property is not empty this property only sets the spacing between ticks of the left y-axis.

- **ySpacingRight** ↑

Sets the spacing between y-axis tick mark labels of the right y-axis. Must be scalar.

Caution: The spacing will be the number of periods between the tick marks labels. The number of periods will follow

► **createFigure** ↑

`createFigure(obj)`

Description:

Create figure to plot in.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_GRAPH

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_graph_ts

Input:

- obj : An object of class nb_graph_ts
- propertyName : A string with the name of the wanted property.

Output:

- propertyValue : The property value of the given property.

Examples:

Get the last axes handle of the nb_graph_ts object. Be aware that all the axes handles are stored in the figurehandle property of the object.

```
axeshandle = obj.get('axeshandle');
```

Get the handle of all the current figures of the nb_graph_ts object.

```
figurehandle = obj.get('figurehandle');
```

See also:

[nb_figure](#), [nb_axes](#), [nb_ts](#)

Written by Kenneth S. Paulsen

► **getCode** ↑

```
[code,numOfGraphs] = getCode(obj,frameTitle,frameSubTitle,...  
footer,source,pageNumber,theme)
```

Description:

Get the latex code when including a graph in a slide object produced by an object of class nb_graph_ts.

This method is called from the nb_Slide class, when making a beamer slide in latex.

Input:

- obj : An object of class nb_graph_ts
- frameTitle : A string with the frame title of the slide.
- frameSubTitle : A string with the frame subtitle of the slide.
- footer : A cellstr with the footers of the slide
- source : A cellstr with the sources of the slide
- pageNumber : Give 1 if the page number should be included.
- theme : The beamer theme used. Default is '' (use default beamer theme).

Output:

- code : The latex code as a char.
- numOfGraphs : The number of graphs produced by the input object of class nb_graph_ts. As an integer.

Examples:

Written by Kenneth S. Paulsen

Inherited from superclass NB_GRAPH

► **getData** ↑

data = getData(obj, zeroLowerBound)

Description:

Get the data of the graph

Input:

- obj : An object of class nb_graph_ts
- zeroLowerBound : Zero lower bound the fan chart of the variables 'QUA_RNFOLIO' and 'QUA_RNFOLIO_LATESTMPR'.

Output:

- data : As an nb_ts object (return as nb_cs if datesToPlot is non-empty)

Example:

```
data = obj.getData();
```

Written by Kenneth S. Paulsen

► **getGenericOptions** ↑

```
options = getGenericOptions(obj)
```

Description:

A static method of nb_graph.

Container with the intersect of options for subclasses of nb_graph.

Input:

- none

Output:

- options : A numSettings x 4 cell array with names in first column, default inputs in second, logical checks in the third, and a function handle with the set function in the fourth.

Examples:

```
options = getGenericOptions(obj);
```

See also:

[set](#), [nb_parseInputs](#)

Written by Per Bjarne Bye

Inherited from superclass NB_GRAPH

► **getPlottedVariables** ↑

```
vars = getPlottedVariables(obj, forLegend)
```

Description:

Get the plotted variables of the graph

Input:

- obj : An object of class nb_graph_ts
- forLegend : true or false (default)

When forLegend is used the variables are listed as needed for the legend, but without fake legends and patches, and duplicates are not removes.

Output:

- vars : As a cellstr

Example:

```
vars = obj.getPlottedVariables();
```

Written by Kenneth S. Paulsen

► **getTSOPTIONS** ↑

```
options = getTSOPTIONS(obj)
```

Description:

Container with the properties specific to nb_graph_ts

Input:

- none

Output:

- options : A numSettings name 4 cell array with names in first column, default inputs in second, logical checks in the third, and a function handle with the set function in the fourth.

Examples:

```
options = getTSOPTIONS(obj);
```

See also:

[set](#), [getGenericOptions](#), [nb_parseInputs](#)

Written by Per Bjarne Bye

► **graph** ↑

```
graph(obj)
```

Description:

Create a graph or more graphs

Graphs all the variables given by the variablesToPlot and the variablesToPlotRight properties in one plot, and does that for all the datasets of the DB property. I.e. one new plot for each dataset (page) of the DB property of the nb_graph_ts object.

Input:

- obj : An object of class nb_graph_ts

Output:

The graph plotted on the screen.

Examples:

```
data = nb_ts([2;1;2],'''2012Q1','Var1');  
obj = nb_graph_ts(data);  
obj.graph();
```

See also:

[nb_graph_ts.set](#)

Written by Kenneth S. Paulsen

► **graphInfoStruct ↑**

```
graphInfoStruct(obj)
```

Description:

Create graphs based on the property GraphStruct. (Or the default GraphStruct given by the method defaultGraphStruct)

This method makes it easy to set up graph packages. For example graphing output from models.

See the documentation NB toolbox for more on this method.

Input:

- obj : An object of class nb_graph_ts, where the property GraphStruct contains the information on how to plot the objects data.

Output:

The wanted graphs plotted on the screen.

Examples:

```
obj.graphInfoStruct();
```

Written by Kenneth S. Paulsen

► graphSubPlots ↑

```
graphSubPlots(obj)
```

Description:

Create graphs of all the variables given in variablesToPlot property, in different subplots. (Each dataset against each other). The number of subplot is given by the property subPlotSize.

Input:

- obj : An object of class nb_graph_ts

Output:

The wanted graphs plotted on the screen.

Examples:

```
data = nb_ts([2 3 2;1 4 5;2 3 2],'', '2012Q1',...
             {'Var1','Var2','Var3'});
obj = nb_graph_ts(data);
obj.graphSubPlots();
```

Written by Kenneth S. Paulsen

► isempty ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_graph_ts object is empty. I.e. if no data is stored in the object. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_graph_ts

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

► merge ↑

```
out = merge(obj,varargin)
```

Description:

Default: This tries to merge the data of plotter objects that uses the graphSubPlots, or the graphInfoStruct.

Caution: All objects must share the exact same variables!

'graph' is given: In this case it will try to merge the data of all nb_graph objects, and concatenate the variableToPlot property. If the property variableToPlot is empty for all objects, it will also be returned as empty, i.e. plot all series in the data.

Caution : Merging of any of the other properties then DB and variableToPlot is not done!

Input:

- obj : An object of class nb_graph, which includes the classes nb_graph_ts, nb_graph_cs and nb_graph_data.

Optional input:

- 'graph' : Give this input to merge the graphs in the way that is described in the description of this method.
- varargin : Each input must be an object of class nb_graph.

Output:

- out : An object of class nb_graph.

Written by Kenneth Sætherhagen Paulsen

Inherited from superclass NB_GRAPH

► **realTimespan** ↑

```
dateString = realTimespan(obj,language,freq)
```

Description:

Get the timespan of the data behind a graph which is not nan or infinite, as a string. On the PPR format.

Input :

- obj : An object of class nb_graph_ts
- language : 'english' or 'norwegian'. 'norwegian' is default
- freq : The wanted frequency of the timespan

Output :

- dateString : A string with the timespan of the graph represented by this object.

Examples:

```
data      = nb_ts([2;1;2],'', '2012Q1','Var1');  
obj      = nb_graph_ts(data);  
dateString = realTimespan(obj);  
dateStringE = realTimespan(obj,'english');
```

Written by Kenneth S. Paulsen

► **resetDataSource** ↑

```
[message,err] = resetDataSource(obj,dataSource,updateProps)
```

Description:

Reset the data source of the nb_graph_ts object.

Input :

- obj : An object of class nb_graph_ts
- dataSource : An nb_ts object with the new data.
- updateProps : If the variablesToPlot should be updated to be equal to dataSource.variables + the startGraph and endGraph properties are set to the startDate and endDate of the new data source.

Can also be 'gui'. Then all properties will be checked

against the new dataset, and if the new dataset does not comply with the properties, the properties will be updated!

Written by Kenneth S. Paulsen

► **saveData** ↑

```
obj = saveData(obj,filename,strip)
```

Description:

Saves the data of the figure

Input:

- obj : An object of class nb_graph_ts
- filename : A string with the saved output name
- strip : - 'on' : Strip all observation dates where all the variables has no value. Default.
 - 'off' : Does not strip all observation dates where all the variables has no value

Example:

```
obj.saveData('test');
```

Written by Kenneth S. Paulsen

► **saveFigure** ↑

```
saveFigure(obj,extraName,format)
```

Description:

Save the figure(s) produced by the nb_graph object to (a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_graph
- extraName : If you want to add some extra name to the saveName property of the nb_graph_data object before saving the file. (If the saveName property of the nb_graph_ts object is empty this will be the full

```
        name of the output file.)  
  
- format      : The format of the saved output. Default is given by  
    the property fileFormat of the nb_graph. Either  
    'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.
```

Output:

The produced figure(s) saved to the wanted formats.

Examples:

```
data = nb_data([2;1;2],'', '1', 'Var1');  
obj = nb_graph_data(data);  
obj.graph();  
saveFigure(obj,'test','pdf');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_GRAPH

► **set ↑**

```
set(obj,varargin)
```

Description:

Set properties of the nb_graph class and its subclasses.

See documentation NB Toolbox or type help('nb_graph') for more on the properties of the class.

Input:

```
- obj       : An object that is a subclass of nb_graph  
- varargin : 'propertyName',PropertyValue,...
```

Output:

No actual output, but the input objects properties will have been set to their new value.

Examples:

```
data = nb_ts([2;1;2],'', '2012Q1', 'Var1');  
obj = nb_graph_ts(data);  
obj.set('startGraph','2012Q1','endGraph','2012Q3');  
obj.set('crop',1);
```

Written by Per Bjarne Bye

Inherited from superclass NB_GRAPH

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct

Input:

- obj : An object of class nb_graph_ts

Output:

- s : A struct

Written by Kenneth Sæterhagen Paulsen

► **timespan** ↑

```
dateString = timespan(obj,language,freq)
```

Description:

Get the timespan of the graph as a string. On the PPR format.

Input :

- obj : An object of class nb_graph_ts
- language : 'english' or 'norwegian'. 'norwegian' is default
- freq : The wanted frequency of the timespan

Output :

- dateString : A string with the timespan of the graph represented by this object.

Examples:

```
data      = nb_ts([2;1;2],'', '2012Q1', 'Var1');  
obj      = nb_graph_ts(data);  
dateString = timespan(obj);  
dateStringE = timespan(obj,'english');
```

Written by Kenneth S. Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the figure

See the update method of the nb_ts classes for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_graph_ts

Output:

- obj : An object of class nb_graph_ts, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

■ **nb_numbering**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_numbering(start,chapter,language)
```

Superclasses:

handle

Description:

A class for numbering graphs used in the nb_graph_package class.

Constructor:

```
obj = nb_numbering(start,chapter,language)
```

Input:

- start : The start number of the numbering of the figures. Must be a double.
- chapter : The chapter of the graph numbering

```
- language : The language of the graph numbering.  
          > 'norwegian' : 'Figur 1.1' or 'Figure 1.1a'.  
          > 'english'   : 'Chart 1.1' or 'Chart 1.1a'.  
  
- bigLetter : Logical that indicates if "number" should be given by  
              letters or numbers.
```

Output

```
- obj       : An object of class nb_numbering
```

Examples:

```
obj = nb_numbering(1,1,'norwegian',false)
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- bigLetter
- chapter
- counter
- language
- letter

- number

- **bigLetter** ↑

Give 1 the numbering should be done with a big letter instead of a number. I.e. 'Figur 1.A' or 'Chart 1.A', instead of 'Figure 1.1' or 'Chart 1.1'.

- **chapter** ↑

The chapter of the graph numbering. As a double.

- **counter** ↑

Indicator of letter counting. Set to 0 if the new graphs should be numbered with letters instead of normal numbering. I.e. 1a, 1b,... Otherwise 1.

- **language** ↑

The language of the graph numbering. As a string.

- **letter** ↑

The current letter of the graph numbering. As a double.

- **number** ↑

The current graph number. As a double.

Methods:

- [char](#)
 - [charData](#)
 - [charNumOnly](#)
 - [charSlide](#)
 - [figNumsAsCell](#)
 - [hold](#)
 - [plus](#)
-

► **char** ↑

```
s = char(obj,table)
```

Description:

Get the graph number represented by the nb_numbering object as a string on the format:

```
> 'norwegian' : 'Figur 1.1' or 'Figur 1.1a'.  
> 'english'   : 'Chart 1.1' or 'Chart 1.1a'.
```

Input:

- obj : An object of class nb_numbering
- table : Indicate if a table is numbered.

Output:

- s : A string on the format 'Figur 1.1', 'Figur 1.1a', 'Chart 1.1', 'Chart 1.1a'.

See also:

[charData](#)

Written by Kenneth Sæterhagen Paulsen

► **charData** ↑

```
s = charData(obj)
```

Description:

Get the graph number represented by the nb_numbering object as a string on the format: 'Data 1.1' or 'Data 1.1a'.

Input:

- obj : An object of class nb_numbering

Output:

- s : A string on the format 'Data 1.1' or 'Data 1.1a'.

Examples:

See also:

[char](#)

Written by Kenneth Sæterhagen Paulsen

► **charNumOnly** ↑

s = charOnly(obj)

Description:

Get the graph number represented by the nb_numbering object as a string on the format: '1.1' or '1.1a'.

Input:

- obj : An object of class nb_numbering

Output:

- s : A string on the format '1.1' or '1.1a'.

See also:

[char](#), [charData](#), [figNumAsCell](#)

Written by Kenneth Sæterhagen Paulsen

► **charSlide** ↑

s = charSlide(obj)

Description:

Get the slide number represented by the nb_numbering object as a string on the format: 'Slide 1.1' or 'Slide 1.1a' in english and 'Lysbilde 1.1' or 'Lysbilde 1.1a' på norsk.

Input:

- obj : An object of class nb_numbering

Output:

- s : A string on the format 'Slide 1.1' or 'Slide 1.1a' in english and 'Lysbilde 1.1' or 'Lysbilde 1.1a' på norsk.

Examples:

See also:

[char](#)

Written by Kenneth Sæterhagen Paulsen

► **figNumsAsCell ↑**

cellOut = figNumsAsCell(obj,len)

Description:

Get incrementing figure numbers as a len x 1 cell.

Input:

- obj : An object of class nb_numbering.
- len : How many graphs/tables/figures you want to number

Output:

- cellOut : A cell with the numbers.

See also:

[char](#), [charData](#), [charNumOnly](#)

Written by Per Bjarne Bye

► **hold ↑**

hold(obj,text)

Description:

Hold the normal graph numbering and start numbering with letters instead. I.e Figur 1.1a, Figur 1.1b,....

Input:

- obj : An object of class nb_numbering
- text : Either 'on' or 'off'

Output:

- obj : The input object of class nb_numbering set to on hold.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

► **plus ↑**

plus(obj)

Description:

Increment the nb_numbering object.

Input:

- obj : An object of class nb_numbering
- num : Number of graphs ahead. As a scalar. Default is 1.

Output:

- obj : The input object incremented with one number (or letter)

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

■ **nb_table_cell**

Go to: [Properties](#) | [Methods](#)

obj = nb_table_cell(data)

Superclasses:

nb_table_data_source, nb_graph_obj, handle,

Description:

A class for displaying data stored in a cell in a table.

Constructor:

obj = nb_table_cell(data)

Input:

- data : An object of class cell

Output:

- obj : An object of class nb_table_cell

See also:

[nb_table_data_source.graph](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- DB
- columnSizes
- factor
- flip
- fontUnits
- lookUpMatrix

- normalized
- position
- table
- titleAlignment
- titlePlacement
- xLabelFontSize
- xLabelPlacement

- **DB** ↑

A nbDataSource object storing the data of the table

Inherited from superclass NB_TABLE_DATA_SOURCE

- **a4Portrait** ↑

Save PDF to A4 portrait format. 0 or 1

Inherited from superclass NB_TABLE_DATA_SOURCE

- **addAdvanced** ↑

Set to false to prevent adding advanced components.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **annotation** ↑

Sets the plotted annotations of the graph.

Must be one or more nb_annotation objects. See the documentation of the class for more. If you give more objects they must be collected in a cell.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **columnSizes** ↑

Set size of each column. As a 1 numCol double.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **columnSpan** ↑

Set columns span of the table. Must be a cell with the same size as the data of the table. Give 2 to make a element span two columns. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **crop** ↑

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

Inherited from superclass NB_TABLE_DATA_SOURCE

- **decimals** ↑

Round numbers to the number of decimals. Default is 4. Can either be an integer or a string with the printed format of the numbers in the table. E.g. 4, '%.4f'. See num2str for more.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **factor** ↑

Set this property to multiply the data with a given factor. Must be a scalar.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figureColor** ↑

Color of the figure as a 1x3 double. Default is [1 1 1].

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figureName** ↑

Sets the name of figure (only in MATLAB), default is no name.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figurePosition** ↑

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **flip** ↑

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontName** ↑

Sets the name of font used. Default is 'arial'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontScale** ↑

Sets the parameter that scales all the font sizes of the graphs. Must be scalar. Default is 1 (do not scale).

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontSize** ↑

Sets the font size of the table, default is 12. Must be a scalar.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontUnits** ↑

Sets the font units of all the fonts of the graph. Either {'points'} | 'normalized' | 'inches' | 'centimeters'. Default is 'points'.

Caution : If you set the fontUnits property in a method call to the set method, all the font properties set before the fontUnits property will be set in the old fontUnits, while all the font properties set after will be in the new fontUnits.

Caution : 'normalized' font units must be between 0 and 1. The normalized units are not the same as the MATLAB normalized units. This normalized units are not only normalized to the axes size, but also across resolution of the screen. (But only vertically)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **horizontalAlignment** ↑

Set the horizontal alignment of each cell of the table. Must be a cell with the same size as the data of the table. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **language** ↑

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **localVariables** ↑

A nb_struct with the local variables of the nb_graph object. I.e. a field with name 'test' can be reach with the string input %#test.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **lookUpMatrix** ↑

Sets how the given mnemonics (variable and type names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {
'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **noLabel** ↑

Set it to 1 if no label(s) is/are wanted on the graphs, otherwise set it to 0. Default is 0. This is of course only have an effect if the nb_table_data_source object have been given the xLabel properties. (These are empty by default.)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **noTitle** ↑

Set it to 1 if you don't want title(s) of the table, otherwise set it to 0. Default is 0.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **normalized** ↑

If the font should be normalized to the figure or axes. Either 'figure' or 'axes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **page** ↑

Sets the page of the data object to table. Default is 1.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **pdfBook** ↑

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be use in combination with the saveName property.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **plotAspectRatio** ↑

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3, or when '[16,9]' the aspect ratio of the figure is 16 to 9

Inherited from superclass NB_TABLE_DATA_SOURCE

- **position** ↑

Sets the position of the axes, must be an 1x4 double array. [leftMostPoint lowestPoint width height]. Only an option for the graph() method. Default is [0.1 0.1 0.8 0.8].

Inherited from superclass NB_TABLE_DATA_SOURCE

- **rowSpan** ↑

Set row span of the table. Must be a cell with the same size as the data of the table. Give 2 to make a element span two rows. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are produced. Must be a string.

Default is to save each graph produced in separate files. Set the pdfBook property to 1 if you want to save all the produced graphs in one pdf file. (To save all figures in one file is only possible for pdf files. I.e. the fileFormat property must be 'pdf'.)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **spacing** ↑

Sets the spacing between the data points displayed in the table. Must be a scalar. Default is 1.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **table** ↑

A nb_table object storing the information of the displayed table

Inherited from superclass NB_TABLE_DATA_SOURCE

- **tag** ↑

Used by the nb_graph_subplot class to locate the nb_graph object in the subplot. Should not be used. Use userData instead.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **template** ↑

Sets the template of the table. See nb_table.stylingPatternsTemplate for the supported templates.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **title** ↑

Sets the title of the plot. Must be a char. Only an option for the graph(...) method.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleAlignment** ↑

Sets the figure title text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleFontSize** ↑

Sets the font size of the titles which is placed above the (sub)plot(s). Must be scalar. Default is 14.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleFontWeight** ↑

Sets the font weight of the titles which is placed above the (sub)plot(s). Must be a string. Default is 'bold'.

Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleInterpreter** ↑

Sets the interpreter used for the given string given by the title property.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titlePlacement** ↑

Sets the placement of the title. {'center'} | 'left' | 'right' | 'lefttaxes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **userData** ↑

User data, can be set to anything you want.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabel** ↑

Sets (add) the text of the x-axis label. Must be a string.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelAlignment** ↑

Sets the x-axis label text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelFontSize** ↑

Sets the font size of the x-axis label. Must be scalar.
Default is 12.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelFontWeight** ↑

Sets the font weight of the x-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelInterpreter** ↑

The interpreter used for the given string given by the xlabel property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelPlacement** ↑

Sets the placement of the x-axis label. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

Methods:

- [get](#)
- [resetDataSource](#)
- [struct](#)
- [getData](#)
- [saveData](#)
- [unstruct](#)
- [getPlottedVariables](#)
- [saveFigure](#)
- [update](#)
- [graph](#)
- [set](#)
- [isempty](#)
- [setTable](#)

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_table_data_source

Input:

- obj : An object of class nb_table_data_source
- propertyName : A string with the name of the wanted property.

Output:

- propertyValue : The property value of the given property.

Examples:

Get the last axes handle of the nb_table_data_source object. Be aware that all the the axes handles are stored in the figurehandle property of the object.

```
axeshandle = obj.get('axeshandle');
```

Get the handle of all the current figures of the nb_table_data_source object.

```
figurehandle = obj.get('figurehandle');
```

See also:

[nb_figure](#), [nb_axes](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **getData ↑**

```
data = getData(obj,zeroLowerBound)
```

Description:

Get the data of the table

Input:

- obj : An object of class nb_table_data_source

Output:

- data : As a nb_cs or nb_cell object.

Example:

```
data = obj.getData();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **getPlottedVariables** ↑

```
vars = getPlottedVariables(obj, forLegend)
```

Description:

Get the variables of the table

Input:

- obj : An object of class nb_table_data_source

Output:

```
- vars : As a cellstr
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **graph** ↑

```
graph(obj)
```

Description:

Plot the table

Input:

- obj : An object of class nb_table_data_source

Output:

The table plotted on the screen.

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_table_data_source object is empty. I.e. if no data is stored in the object. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_table_data_source

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **resetDataSource** ↑

```
[message,err] = resetDataSource(obj,dataSource,updateProps)
```

Description:

Reset the data source of the nb_table_data_source object.

Input:

- obj : An object of class nb_table_data_source

- dataSource : An nb_dataSource object with the new data.

- updateProps : If properties should be updated or not.

Can also be 'gui'. Then all properties will be checked against the new dataset, and if the new dataset does not comply with the properties, the properties will be updated!

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **saveData** ↑

```
obj = saveData(obj,filename,strip)
```

Description:

Saves the data of the figure

Input:

- obj : An object of class nb_table_data_source
- filename : A string with the saved output name, without extension.
- strip : - 'on' : Strip all observation dates where all the variables has no value. Default.
 - 'off' : Does not strip all observation dates where all the variables has no value

Example:

```
obj.saveData('test');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **saveFigure** ↑

```
saveFigure(obj,extraName,format)
```

Description:

Save the figure(s) produced by the nb_graph object to
(a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_table_data_source
- extraName : If you want to add some extra name to the saveName property of the nb_graph_ts object before saving the file. (If the saveName property of the nb_graph_ts object is empty this will be the full name of the output file.)
- format : The format of the saved output. Default is given by the property fileFormat of the nb_graph. Either 'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.

Output:

The produced figure(s) saved to the wanted formats.

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **set** ↑

`set(obj, varargin)`

Description:

Set properties of the nb_table_cell class

Input:

- varargin : Property name property value pairs.

Written by Kenneth Sæterhagen Paulsen

► **setTable** ↑

`setTable(obj, propertyName, PropertyValue)`

Description:

Set underlying table properties, which is of class nb_table.

Input:

- obj : An object of class nb_table_data_source
- propertyName : Name of the property to set.
- PropertyValue : Value of the property to set.

See also:

[nb_table](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **struct** ↑

```
s = struct(obj)
```

Description:

Convert object to struct

Input:

- obj : An object of class nb_table_data

Output:

- s : A struct

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

```
obj = nb_table_cell.unstruct(s)
```

Description:

Convert struct to object

Input:

- s : A struct

Output:

- obj : An object of class nb_table_cell

See also:

[nb_table_cell.struct](#)

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the table

See the update method of the nb_ts, nb_cs and nb_data classes for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_table_data_source

Output:

- obj : An object of class nb_table_data_source, where the data is updated.

Examples:

obj.update();

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

■ nb_table_cs

Go to: [Properties](#) | [Methods](#)

obj = nb_table_cs(data)

Superclasses:

nb_table_data_source, nb_graph_obj, handle,

Description:

A class for displaying time-series data in a table.

Constructor:

obj = nb_table_cs(data)

Input:

- data : An object of class nb_cs

Output:

- obj : An object of class nb_table_cs

See also:

- **[DB](#) ↑**

A nbDataSource object storing the data of the table

Inherited from superclass NB_TABLE_DATA_SOURCE

- **[a4Portrait](#) ↑**

Save PDF to A4 portrait format. 0 or 1

Inherited from superclass NB_TABLE_DATA_SOURCE

- **[addAdvanced](#) ↑**

Set to false to prevent adding advanced components.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **[annotation](#) ↑**

Sets the plotted annotations of the graph.

Must be one or more nb_annotation objects. See the documentation of the class for more. If you give more objects they must be collected in a cell.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **[columnSizes](#) ↑**

Set size of each column. As a 1 numCol double.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **columnSpan** [↑](#)

Set columns span of the table. Must be a cell with the same size as the data of the table. Give 2 to make a element span two columns. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **crop** [↑](#)

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

Inherited from superclass NB_TABLE_DATA_SOURCE

- **decimals** [↑](#)

Round numbers to the number of decimals. Default is 4. Can either be an integer or a string with the printed format of the numbers in the table. E.g. 4, '%.4f'. See num2str for more.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **factor** [↑](#)

Set this property to multiply the data with a given factor. Must be a scalar.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figureColor** [↑](#)

Color of the figure as a 1x3 double. Default is [1 1 1].

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figureName** [↑](#)

Sets the name of figure (only in MATLAB), default is no name.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figurePosition** [↑](#)

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **flip** [↑](#)

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontName** ↑

Sets the name of font used. Default is 'arial'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontScale** ↑

Sets the parameter that scales all the font sizes of the graphs. Must be scalar. Default is 1 (do not scale).

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontSize** ↑

Sets the font size of the table, default is 12. Must be a scalar.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontUnits** ↑

Sets the font units of all the fonts of the graph. Either {'points'} | 'normalized' | 'inches' | 'centimeters'. Default is 'points'.

Caution : If you set the fontUnits property in a method call to the set method, all the font properties set before the fontUnits property will be set in the old fontUnits, while all the font properties set after will be in the new fontUnits.

Caution : 'normalized' font units must be between 0 and 1. The normalized units are not the same as the MATLAB normalized units. This normalized units are not only normalized to the axes size, but also across resolution of the screen. (But only vertically)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **horizontalAlignment** ↑

Set the horizontal alignment of each cell of the table. Must be a cell with the same size as the data of the table. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **language** ↑

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **localVariables** ↑

A nb_struct with the local variables of the nb_graph object. I.e. a field with name 'test' can be reach with the string input %#test.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **lookUpMatrix** ↑

Sets how the given mnemonics (variable and type names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {
'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **noLabel** ↑

Set it to 1 if no label(s) is/are wanted on the graphs, otherwise set it to 0. Default is 0. This is of course only have an effect if the nb_table_data_source object have been given the xLabel properties. (These are empty by default.)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **noTitle** ↑

Set it to 1 if you don't want title(s) of the table, otherwise set it to 0. Default is 0.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **normalized** ↑

If the font should be normalized to the figure or axes. Either 'figure' or 'axes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **page** ↑

Sets the page of the data object to table. Default is 1.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **pdfBook** ↑

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be use in combination with the saveName property.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **plotAspectRatio** ↑

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3, or when '[16,9]' the aspect ratio of the figure is 16 to 9

Inherited from superclass NB_TABLE_DATA_SOURCE

- **position** ↑

Sets the position of the axes, must be an 1x4 double array.
[leftMostPoint lowestPoint width height]. Only an option for
the graph() method. Default is [0.1 0.1 0.8 0.8].

Inherited from superclass NB_TABLE_DATA_SOURCE

- **rowSpan** ↑

Set row span of the table. Must be a cell with the same size
as the data of the table. Give 2 to make a element span two
rows. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are
produced. Must be a string.

Default is to save each graph produced in separate files. Set
the pdfBook property to 1 if you want to save all the produced
graphs in one pdf file. (To save all figures in one file is
only possible for pdf files. I.e. the fileFormat property
must be 'pdf'.)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **spacing** ↑

Sets the spacing between the data points displayed in the table.
Must be a scalar. Default is 1.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **table** ↑

A nb_table object storing the information of the displayed table

Inherited from superclass NB_TABLE_DATA_SOURCE

- **tag** ↑

Used by the nb_graph_subplot class to locate the nb_graph
object in the subplot. Should not be used. Use userData
instead.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **template** ↑

Sets the template of the table. See
nb_table.stylingPatternsTemplate for the supported templates.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **title** ↑

Sets the title of the plot. Must be a char. Only an option
for the graph(...) method.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleAlignment** ↑

Sets the figure title text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleFontSize** ↑

Sets the font size of the titles which is placed above the (sub)plot(s). Must be scalar. Default is 14.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleFontWeight** ↑

Sets the font weight of the titles which is placed above the (sub)plot(s). Must be a string. Default is 'bold'.

Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleInterpreter** ↑

Sets the interpreter used for the given string given by the title property.

> 'latex' : For mathematical expression
> 'tex' : Latex text interpreter,
> 'none' : Do nothing

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titlePlacement** ↑

Sets the placement of the title. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **typesOfTable** ↑

A cellstr with the types to display in the table

- **userData** ↑

User data, can be set to anything you want.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **variablesOfTable** ↑

Sets the variables to be part of the table

- **xLabel** ↑

Sets (add) the text of the x-axis label. Must be a string.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelAlignment** ↑

Sets the x-axis label text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelFontSize** ↑

Sets the font size of the x-axis label. Must be scalar.
Default is 12.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelFontWeight** ↑

Sets the font weight of the x-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelInterpreter** ↑

The interpreter used for the given string given by the xlabel property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelPlacement** ↑

Sets the placement of the x-axis label. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

Methods:

- | | | | | |
|------------|-------------------|-------------------|-----------------------|---------|
| • get | • getData | • getPlottedTypes | • getPlottedVariables | • graph |
| • isempty | • resetDataSource | • saveData | • saveFigure | • set |
| • setTable | • struct | • unstruct | • update | |

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_table_data_source

Input:

```
- obj : An object of class nb_table_data_source  
- propertyName : A string with the name of the wanted property.
```

Output:

```
- PropertyValue : The property value of the given property.
```

Examples:

Get the last axes handle of the nb_table_data_source object. Be aware that all the axes handles are stored in the figurehandle property of the object.

```
axeshandle = obj.get('axeshandle');
```

Get the handle of all the current figures of the nb_table_data_source object.

```
figurehandle = obj.get('figurehandle');
```

See also:

[nb_figure](#), [nb_axes](#)

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **getData** ↑

```
data = getData(obj, zeroLowerBound)
```

Description:

Get the data of the table

Input:

```
- obj : An object of class nb_table_data_source
```

Output:

```
- data : As a nb_cs or nb_cell object.
```

Example:

```
data = obj.getData();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **getPlottedTypes** ↑

```
types = getPlottedTypes(obj)
```

Description:

Get the plotted types of the table

Input:

- obj : An object of class nb_table_cs

Output:

- types : As a cellstr

Example:

```
types = obj.getPlottedTypes();
```

Written by Kenneth S. Paulsen

► **getPlottedVariables** ↑

```
vars = getPlottedVariables(obj,forLegend)
```

Description:

Get the variables of the table

Input:

- obj : An object of class nb_table_data_source

Output:

- vars : As a cellstr

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **graph** ↑

```
graph(obj)
```

Description:

Plot the table

Input:

- obj : An object of class nb_table_data_source

Output:

The table plotted on the screen.

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_table_data_source object is empty. I.e. if no data is stored in the object. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_table_data_source

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **resetDataSource** ↑

```
[message,err] = resetDataSource(obj,dataSource,updateProps)
```

Description:

Reset the data source of the nb_table_data_source object.

Input:

```
- obj : An object of class nb_table_data_source  
- dataSource : An nb_dataSource object with the new data.  
- updateProps : If properties should be updated or not.  
  
Can also be 'gui'. Then all properties will be checked  
against the new dataset, and if the new dataset does not  
comply with the properties, the properties will be  
updated!
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **saveData** ↑

```
obj = saveData(obj,filename,strip)
```

Description:

Saves the data of the figure

Input:

```
- obj : An object of class nb_table_data_source  
- filename : A string with the saved output name, without extension.  
- strip : - 'on' : Strip all observation dates where all the  
variables has no value. Default.  
- 'off' : Does not strip all observation dates where  
all the variables has no value
```

Example:

```
obj.saveData('test');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **saveFigure** ↑

```
saveFigure(obj,extraName,format)
```

Description:

Save the figure(s) produced by the nb_graph object to
(a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_table_data_source
- extraName : If you want to add some extra name to the saveName property of the nb_graph_ts object before saving the file. (If the saveName property of the nb_graph_ts object is empty this will be the full name of the output file.)
- format : The format of the saved output. Default is given by the property fileFormat of the nb_graph. Either 'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.

Output:

The produced figure(s) saved to the wanted formats.

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► set ↑

set(obj, varargin)

Description:

Set properties of the nb_table_cs class

Input:

- varargin : Property name property value pairs.

Written by Kenneth Sæterhagen Paulsen

► setTable ↑

setTable(obj, propertyName, PropertyValue)

Description:

Set underlying table properties, which is of class nb_table.

Input:

- obj : An object of class nb_table_data_source
- propertyName : Name of the property to set.
- PropertyValue : Value of the property to set.

See also:

[nb_table](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct

Input:

- obj : An object of class nb_table_data

Output:

- s : A struct

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

obj = nb_table_cs.unstruct(s)

Description:

Convert struct to object

Input:

- s : A struct

Output:

- obj : An object of class nb_table_cs

See also:

[nb_table_cs.struct](#)

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the table

See the update method of the nb_ts, nb_cs and nb_data classes for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_table_data_source

Output:

- obj : An object of class nb_table_data_source, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

■ **nb_table_data**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_table_data(data)
```

Superclasses:

nb_table_data_source, nb_graph_obj, handle,

Description:

A class for displaying data in a table.

Constructor:

```
obj = nb_table_data(data)
```

Input:

- data : An object of class nb_data

Output:

- obj : An object of class nb_table_data

- [DB](#) ↑

A nbDataSource object storing the data of the table

Inherited from superclass NB_TABLE_DATA_SOURCE

- [a4Portrait](#) ↑

Save PDF to A4 portrait format. 0 or 1

Inherited from superclass NB_TABLE_DATA_SOURCE

- [addAdvanced](#) ↑

Set to false to prevent adding advanced components.

Inherited from superclass NB_TABLE_DATA_SOURCE

- [annotation](#) ↑

Sets the plotted annotations of the graph.

Must be one or more nb_annotation objects. See the documentation of the class for more. If you give more objects they must be collected in a cell.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **columnSizes** [↑](#)

Set size of each column. As a 1 numCol double.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **columnSpan** [↑](#)

Set columns span of the table. Must be a cell with the same size as the data of the table. Give 2 to make a element span two columns. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **crop** [↑](#)

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

Inherited from superclass NB_TABLE_DATA_SOURCE

- **decimals** [↑](#)

Round numbers to the number of decimals. Default is 4. Can either be an integer or a string with the printed format of the numbers in the table. E.g. 4, '%.4f'. See num2str for more.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **endTable** [↑](#)

Sets the end obs of the table. As an integer. If the given obs is after the end obs of the data, the data will be appended with nan values. I.e. the table will be blank for these dates.

- **factor** [↑](#)

Set this property to multiply the data with a given factor. Must be a scalar.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figureColor** [↑](#)

Color of the figure as a 1x3 double. Default is [1 1 1].

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figureName** [↑](#)

Sets the name of figure (only in MATLAB), default is no name.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figurePosition** [↑](#)

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **flip** [↑](#)

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontName** [↑](#)

Sets the name of font used. Default is 'arial'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontScale** [↑](#)

Sets the parameter that scales all the font sizes of the graphs. Must be scalar. Default is 1 (do not scale).

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontSize** [↑](#)

Sets the font size of the table, default is 12. Must be a scalar.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontUnits** [↑](#)

Sets the font units of all the fonts of the graph. Either {'points'} | 'normalized' | 'inches' | 'centimeters'. Default is 'points'.

Caution : If you set the fontUnits property in a method call to the set method, all the font properties set before the fontUnits property will be set in the old fontUnits, while all the font properties set after will be in the new fontUnits.

Caution : 'normalized' font units must be between 0 and 1. The normalized units are not the same as the MATLAB normalized units. This normalized units are not only normalized to the axes size, but also across resolution of the screen. (But only vertically)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **horizontalAlignment** [↑](#)

Set the horizontal alignment of each cell of the table. Must be a cell with the same size as the data of the table. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **language** ↑

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **localVariables** ↑

A nb_struct with the local variables of the nb_graph object. I.e. a field with name 'test' can be reach with the string input %#test.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **lookUpMatrix** ↑

Sets how the given mnemonics (variable and type names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {
'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **noLabel** ↑

Set it to 1 if no label(s) is/are wanted on the graphs, otherwise set it to 0. Default is 0. This is of course only have an effect if the nb_table_data_source object have been given the xLabel properties. (These are empty by default.)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **noTitle** ↑

Set it to 1 if you don't want title(s) of the table, otherwise set it to 0. Default is 0.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **normalized** ↑

If the font should be normalized to the figure or axes. Either 'figure' or 'axes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **observationsOfTable** ↑

A vector with the observations to display in the table, this property will overrun the startTable and endTable properties.

- **page** ↑

Sets the page of the data object to table. Default is 1.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **pdfBook** ↑

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be use in combination with the saveName property.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **plotAspectRatio** ↑

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3, or when '[16,9]' the aspect ratio of the figure is 16 to 9

Inherited from superclass NB_TABLE_DATA_SOURCE

- **position** ↑

Sets the position of the axes, must be an 1x4 double array. [leftMostPoint lowestPoint width height]. Only an option for the graph() method. Default is [0.1 0.1 0.8 0.8].

Inherited from superclass NB_TABLE_DATA_SOURCE

- **rowSpan** ↑

Set row span of the table. Must be a cell with the same size as the data of the table. Give 2 to make a element span two rows. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are produced. Must be a string.

Default is to save each graph produced in separate files. Set the pdfBook property to 1 if you want to save all the produced graphs in one pdf file. (To save all figures in one file is only possible for pdf files. I.e. the fileFormat property must be 'pdf').

Inherited from superclass NB_TABLE_DATA_SOURCE

- **spacing** ↑

Sets the spacing between the data points displayed in the table. Must be a scalar. Default is 1.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **startTable** ↑

Sets the start obs of the graph. As an integer. If this obs is before the start obs of the data, the data will be expanded with nan (blank values) for these periods.

- **table** ↑

A nb_table object storing the information of the displayed table

Inherited from superclass NB_TABLE_DATA_SOURCE

- **tag** ↑

Used by the nb_graph_subplot class to locate the nb_graph object in the subplot. Should not be used. Use userData instead.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **template** ↑

Sets the template of the table. See nb_table.stylingPatternsTemplate for the supported templates.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **title** ↑

Sets the title of the plot. Must be a char. Only an option for the graph(...) method.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleAlignment** ↑

Sets the figure title text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleFontSize** ↑

Sets the font size of the titles which is placed above the (sub)plot(s). Must be scalar. Default is 14.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleFontWeight** ↑

Sets the font weight of the titles which is placed above the (sub)plot(s). Must be a string. Default is 'bold'.

Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleInterpreter** ↑

Sets the interpreter used for the given string given by the title property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titlePlacement** ↑

Sets the placement of the title. {'center'} | 'left' | 'right' | 'lefttaxes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **userData** ↑

User data, can be set to anything you want.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **variablesOfTable** ↑

Sets the variables to be part of the table

- **xLabel** ↑

Sets (add) the text of the x-axis label. Must be a string.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelAlignment** ↑

Sets the x-axis label text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelFontSize** ↑

Sets the font size of the x-axis label. Must be scalar.
Default is 12.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelFontWeight** ↑

Sets the font weight of the x-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelInterpreter** ↑

The interpreter used for the given string given by the xlabel property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelPlacement** ↑

Sets the placement of the x-axis label. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

Methods:

- get
- getData
- getPlottedVariables
- graph
- isempty
- resetDataSource
- saveData
- saveFigure
- set
- setTable
- struct
- unstruct
- update

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_table_data

Input:

- obj : An object of class nb_table_data
- propertyName : A string with the name of the wanted property.

Output:

- propertyValue : The property value of the given property.

Examples:

Get the last axes handle of the nb_table_data object. Be aware that all the the axes handles are stored in the figurehandle property of the object.

```
axeshandle = obj.get('axeshandle');
```

Get the handle of all the current figures of the nb_table_data object.

```
figurehandle = obj.get('figurehandle');
```

See also:

[nb_figure](#), [nb_axes](#)

Written by Kenneth S. Paulsen

► **getData** ↑

```
data = getData(obj, zeroLowerBound)
```

Description:

Get the data of the table

Input:

- obj : An object of class nb_table_data_source

Output:

- data : As a nb_cs or nb_cell object.

Example:

```
data = obj.getData();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **getPlottedVariables** ↑

```
vars = getPlottedVariables(obj, forLegend)
```

Description:

Get the variables of the table

Input:

- obj : An object of class nb_table_data_source

Output:

- vars : As a cellstr

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **graph** ↑

```
graph(obj)
```

Description:

Plot the table

Input:

- obj : An object of class nb_table_data_source

Output:

The table plotted on the screen.

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_table_data_source object is empty. I.e. if no data is stored in the object. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_table_data_source

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **resetDataSource** ↑

```
[message,err] = resetDataSource(obj,dataSource,updateProps)
```

Description:

Reset the data source of the nb_table_data_source object.

Input:

```
- obj : An object of class nb_table_data_source  
- dataSource : An nb_dataSource object with the new data.  
- updateProps : If properties should be updated or not.  
  
Can also be 'gui'. Then all properties will be checked  
against the new dataset, and if the new dataset does not  
comply with the properties, the properties will be  
updated!
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **saveData** ↑

```
obj = saveData(obj,filename,strip)
```

Description:

Saves the data of the figure

Input:

```
- obj : An object of class nb_table_data_source  
- filename : A string with the saved output name, without extension.  
- strip : - 'on' : Strip all observation dates where all the  
variables has no value. Default.  
- 'off' : Does not strip all observation dates where  
all the variables has no value
```

Example:

```
obj.saveData('test');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **saveFigure** ↑

```
saveFigure(obj,extraName,format)
```

Description:

Save the figure(s) produced by the nb_graph object to
(a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_table_data_source
- extraName : If you want to add some extra name to the saveName property of the nb_graph_ts object before saving the file. (If the saveName property of the nb_graph_ts object is empty this will be the full name of the output file.)
- format : The format of the saved output. Default is given by the property fileFormat of the nb_graph. Either 'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.

Output:

The produced figure(s) saved to the wanted formats.

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► set ↑

set(obj, varargin)

Description:

Set properties of the nb_table_data class

Input:

- varargin : Property name property value pairs.

Written by Kenneth Sæterhagen Paulsen

► setTable ↑

setTable(obj, propertyName, PropertyValue)

Description:

Set underlying table properties, which is of class nb_table.

Input:

- obj : An object of class nb_table_data_source
- propertyName : Name of the property to set.
- PropertyValue : Value of the property to set.

See also:

[nb_table](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **struct** ↑

s = struct(obj)

Description:

Convert object to struct

Input:

- obj : An object of class nb_table_data

Output:

- s : A struct

Written by Kenneth Sæterhagen Paulsen

► **unstruct** ↑

obj = nb_table_data.unstruct(s)

Description:

Convert struct to object

Input:

- s : A struct

Output:

- obj : An object of class nb_table_data

See also:

[nb_table_data.struct](#)

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the table

See the update method of the nb_ts, nb_cs and nb_data classes for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_table_data_source

Output:

- obj : An object of class nb_table_data_source, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

■ **nb_table_ts**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_table_ts(data)
```

Superclasses:

nb_table_data_source, nb_graph_obj, handle,

Description:

A class for displaying time-series data in a table.

Constructor:

```
obj = nb_table_ts(data)
```

Input:

- data : An object of class nb_ts

Output:

- obj : An object of class nb_table_ts

See also:

- [DB](#) ↑

A nbDataSource object storing the data of the table

Inherited from superclass NB_TABLE_DATA_SOURCE

- [a4Portrait](#) ↑

Save PDF to A4 portrait format. 0 or 1

Inherited from superclass NB_TABLE_DATA_SOURCE

- [addAdvanced](#) ↑

Set to false to prevent adding advanced components.

Inherited from superclass NB_TABLE_DATA_SOURCE

- [annotation](#) ↑

Sets the plotted annotations of the graph.

Must be one or more nb_annotation objects. See the documentation of the class for more. If you give more objects they must be collected in a cell.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **columnSizes** [↑](#)

Set size of each column. As a 1 numCol double.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **columnSpan** [↑](#)

Set columns span of the table. Must be a cell with the same size as the data of the table. Give 2 to make a element span two columns. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **crop** [↑](#)

Sets the how the figure is saved to .pdf and other figure formats. If 1 is given the output file will be cropped. Default is not to crop (i.e. set to 0).

Inherited from superclass NB_TABLE_DATA_SOURCE

- **datesOfTable** [↑](#)

The dates of the table, as a cellstr. This option will overrun the startTable and endTable properties.

- **decimals** [↑](#)

Round numbers to the number of decimals. Default is 4. Can either be an integer or a string with the printed format of the numbers in the table. E.g. 4, '%.4f'. See num2str for more.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **endTable** [↑](#)

Sets the end date of the table. Either as string or an object which is of a subclass of the nb_date class. If the given date is after the end date of the data, the data will be appended with nan values. I.e. the table will be blank for these dates.

- **factor** [↑](#)

Set this property to multiply the data with a given factor. Must be a scalar.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figureColor** [↑](#)

Color of the figure as a 1x3 double. Default is [1 1 1].

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figureName** ↑

Sets the name of figure (only in MATLAB), default is no name.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **figurePosition** ↑

Position of the figure as a 1x4 double. Default is []. I.e. use the MATLAB default. In characters.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **flip** ↑

For some reason the graph is sometimes flipped and sometimes not. If the graph is flipped use this property to flip it back.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontName** ↑

Sets the name of font used. Default is 'arial'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontScale** ↑

Sets the parameter that scales all the font sizes of the graphs. Must be scalar. Default is 1 (do not scale).

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontSize** ↑

Sets the font size of the table, default is 12. Must be a scalar.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **fontUnits** ↑

Sets the font units of all the fonts of the graph. Either {'points'} | 'normalized' | 'inches' | 'centimeters'. Default is 'points'.

Caution : If you set the fontUnits property in a method call to the set method, all the font properties set before the fontUnits property will be set in the old fontUnits, while all the font properties set after will be in the new fontUnits.

Caution : 'normalized' font units must be between 0 and 1. The normalized units are not the same as the MATLAB normalized units. This normalized units are not only normalized to the axes size, but also across resolution of the screen. (But only vertically)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **horizontalAlignment** ↑

Set the horizontal alignment of each cell of the table. Must be a cell with the same size as the data of the table. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **language** ↑

Sets the language styles of the graphs. Must be a string with either 'norsk' or 'english'. 'english' is default. I.e. axis settings differs between norwegian and english graphs.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **localVariables** ↑

A nb_struct with the local variables of the nb_graph object. I.e. a field with name 'test' can be reach with the string input %#test.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **lookUpMatrix** ↑

Sets how the given mnemonics (variable and type names) should map to different languages. Must be cell array on the form:

```
{'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Or a .m file name, as a string. The .m file must include (and only include) what follows:

```
obj.lookUpMatrix = {
'mnemonics1','englishDescription1','norwegianDescription1';
'mnemonics2','englishDescription2','norwegianDescription2'};
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **noLabel** ↑

Set it to 1 if no label(s) is/are wanted on the graphs, otherwise set it to 0. Default is 0. This is of course only have an effect if the nb_table_data_source object have been given the xLabel properties. (These are empty by default.)

Inherited from superclass NB_TABLE_DATA_SOURCE

- **noTitle** ↑

Set it to 1 if you don't want title(s) of the table, otherwise set it to 0. Default is 0.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **normalized** ↑

If the font should be normalized to the figure or axes. Either 'figure' or 'axes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **page** ↑

Sets the page of the data object to table. Default is 1.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **pdfBook** ↑

Set it to 1 if you want store all the created graphs produced in one pdf file. Must be use in combination with the saveName property.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **plotAspectRatio** ↑

Sets the plot aspect ratio. Either [] or '[4,3]'. Default is [].

When set to '[4,3]' the aspect ratio of the figure is 4 to 3, or when '[16,9]' the aspect ratio of the figure is 16 to 9

Inherited from superclass NB_TABLE_DATA_SOURCE

- **position** ↑

Sets the position of the axes, must be an 1x4 double array. [leftMostPoint lowestPoint width height]. Only an option for the graph() method. Default is [0.1 0.1 0.8 0.8].

Inherited from superclass NB_TABLE_DATA_SOURCE

- **rowSpan** ↑

Set row span of the table. Must be a cell with the same size as the data of the table. Give 2 to make a element span two rows. Empty cell elements are given default values.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **saveName** ↑

Sets the saved file name. If not given, no file(s) is/are produced. Must be a string.

Default is to save each graph produced in separate files. Set the pdfBook property to 1 if you want to save all the produced graphs in one pdf file. (To save all figures in one file is only possible for pdf files. I.e. the fileFormat property must be 'pdf').

Inherited from superclass NB_TABLE_DATA_SOURCE

- **spacing** ↑

Sets the spacing between the data points displayed in the table. Must be a scalar. Default is 1.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **startTable** ↑

Sets the start table of the graph. Must be a string or an object which of a subclass of the nb_date class. If this date is before the start date of the data, the data will be expanded with nan (blank values) for these periods.

- **table** ↑

A nb_table object storing the information of the displayed table

Inherited from superclass NB_TABLE_DATA_SOURCE

- **tag** ↑

Used by the nb_graph_subplot class to locate the nb_graph object in the subplot. Should not be used. Use userData instead.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **template** ↑

Sets the template of the table. See nb_table.stylingPatternsTemplate for the supported templates.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **title** ↑

Sets the title of the plot. Must be a char. Only an option for the graph(...) method.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleAlignment** ↑

Sets the figure title text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleFontSize** ↑

Sets the font size of the titles which is placed above the (sub)plot(s). Must be scalar. Default is 14.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleFontWeight** ↑

Sets the font weight of the titles which is placed above the (sub)plot(s). Must be a string. Default is 'bold'.

Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titleInterpreter** ↑

Sets the interpreter used for the given string given by the title property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **titlePlacement** ↑

Sets the placement of the title. {'center'} | 'left' | 'right' | 'lefttaxes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **userData** ↑

User data, can be set to anything you want.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **variablesOfTable** ↑

Sets the variables to be part of the table

- **xLabel** ↑

Sets (add) the text of the x-axis label. Must be a string.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelAlignment** ↑

Sets the x-axis label text alignment, default is 'center'. You also have 'left' and 'right'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelFontSize** ↑

Sets the font size of the x-axis label. Must be scalar.
Default is 12.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelFontWeight** ↑

Sets the font weight of the x-axis label. Must be string.
Either 'bold', 'normal', 'demi' or 'light'.

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelInterpreter** ↑

The interpreter used for the given string given by the xlabel property.

```
> 'latex' : For mathematical expression  
> 'tex'   : Latex text interpreter,  
> 'none'  : Do nothing
```

Inherited from superclass NB_TABLE_DATA_SOURCE

- **xLabelPlacement** ↑

Sets the placement of the x-axis label. {'center'} | 'left' | 'right' | 'leftaxes'.

Inherited from superclass NB_TABLE_DATA_SOURCE

Methods:

- | | | | | |
|----------------|-------------------|-----------------------|--------------|-----------|
| • get | • getData | • getPlottedVariables | • graph | • isempty |
| • realTimespan | • resetDataSource | • saveData | • saveFigure | • set |
| • setTable | • struct | • timespan | • unstruct | • update |

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get some otherwise non-accessible properties of the nb_table_ts

Input:

- obj : An object of class nb_table_ts
- propertyName : A string with the name of the wanted property.

Output:

- propertyValue : The property value of the given property.

Examples:

Get the last axes handle of the nb_table_ts object. Be aware that all the the axes handles are stored in the figurehandle property of the object.

```
axeshandle = obj.get('axeshandle');
```

Get the handle of all the current figures of the nb_table_ts object.

```
figurehandle = obj.get('figurehandle');
```

See also:

[nb_figure](#), [nb_axes](#)

Written by Kenneth S. Paulsen

► **getData** ↑

```
data = getData(obj, zeroLowerBound)
```

Description:

Get the data of the table

Input:

- obj : An object of class nb_table_data_source

Output:

- data : As a nb_cs or nb_cell object.

Example:

```
data = obj.getData();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **getPlottedVariables** ↑

```
vars = getPlottedVariables(obj, forLegend)
```

Description:

Get the variables of the table

Input:

- obj : An object of class nb_table_data_source

Output:

- vars : As a cellstr

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **graph** ↑

```
graph(obj)
```

Description:

Plot the table

Input:

- obj : An object of class nb_table_data_source

Output:

The table plotted on the screen.

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **isempty** ↑

```
ret = isempty(obj)
```

Description:

Test if an nb_table_data_source object is empty. I.e. if no data is stored in the object. Return 1 if true, otherwise 0.

Input:

- obj : An object of class nb_table_data_source

Output:

- ret : True (1) if the series isempty, false (0) if not

Examples:

```
ret = isempty(obj);
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **realTimespan** ↑

```
dateString = realTimespan(obj,language,freq)
```

Description:

Get the timespan of the data behind a table which is not nan or infinite, as a string. On the PPR format.

Input :

- obj : An object of class nb_table_ts

```
- language : 'english' or 'norwegian'. 'norwegian' is default  
- freq : The wanted frequency of the timespan  
  
Output :  
  
- dateString : A string with the timespan of the graph  
represented by this object.
```

Written by Kenneth S. Paulsen

► **resetDataSource** ↑

```
[message,err] = resetDataSource(obj,dataSource,updateProps)
```

Description:

Reset the data source of the nb_table_data_source object.

Input:

```
- obj : An object of class nb_table_data_source  
- dataSource : An nb_dataSource object with the new data.  
- updateProps : If properties should be updated or not.
```

Can also be 'gui'. Then all properties will be checked
against the new dataset, and if the new dataset does not
comply with the properties, the properties will be
updated!

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **saveData** ↑

```
obj = saveData(obj,filename,strip)
```

Description:

Saves the data of the figure

Input:

```
- obj : An object of class nb_table_data_source  
- filename : A string with the saved output name, without extension.
```

```
- strip      : - 'on'   : Strip all observation dates where all the
                  variables has no value. Default.

                  - 'off'  : Does not strip all observation dates where
                  all the variables has no value
```

Example:

```
obj.saveData('test');
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **saveFigure** ↑

```
saveFigure(obj, extraName, format)
```

Description:

Save the figure(s) produced by the nb_graph object to
(a) file(s) on the wanted format and name(s).

Input:

- obj : An object of class nb_table_data_source
- extraName : If you want to add some extra name to the saveName property of the nb_graph_ts object before saving the file. (If the saveName property of the nb_graph_ts object is empty this will be the full name of the output file.)
- format : The format of the saved output. Default is given by the property fileFormat of the nb_graph. Either 'eps', 'jpg', 'pdf', 'png', 'svg' or 'emf'.

Output:

The produced figure(s) saved to the wanted formats.

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **set** ↑

```
set(obj, varargin)
```

Description:

Set properties of the nb_table_ts class

Input:

- varargin : Property name property value pairs.

Written by Kenneth Sæterhagen Paulsen

► **setTable** ↑

`setTable(obj,propertyName,value)`

Description:

Set underlying table properties, which is of class nb_table.

Input:

- obj : An object of class nb_table_data_source
- propertyName : Name of the property to set.
- propertyValue : Value of the property to set.

See also:

[nb_table](#)

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

► **struct** ↑

`s = struct(obj)`

Description:

Convert object to struct

Input:

- obj : An object of class nb_table_ts

Output:

- s : A struct

Written by Kenneth Sæterhagen Paulsen

► **timespan** ↑

```
dateString = timespan(obj,language,freq)
```

Description:

Get the timespan of the table as a string. On the PPR format.

Input :

- obj : An object of class nb_table_ts
- language : 'english' or 'norwegian'. 'norwegian' is default
- freq : The wanted frequency of the timespan

Output :

- dateString : A string with the timespan of the graph represented by this object.

Written by Kenneth S. Paulsen

► **unstruct** ↑

```
obj = nb_table_ts.unstruct(s)
```

Description:

Convert struct to object

Input:

- s : A struct

Output:

- obj : An object of class nb_table_ts

See also:

[nb_table_ts.struct](#)

Written by Kenneth Sæterhagen Paulsen

► **update** ↑

```
obj = update(obj)
```

Description:

Update the data source of the table

See the update method of the nb_ts, nb_cs and nb_data classes for more on how to make the data of the graph updateable.

Input:

- obj : An object of class nb_table_data_source

Output:

- obj : An object of class nb_table_data_source, where the data is updated.

Examples:

```
obj.update();
```

Written by Kenneth S. Paulsen

Inherited from superclass NB_TABLE_DATA_SOURCE

◆ **nb_combineGraphStructDensityGraphs**

```
plotter = nb_combineGraphStructDensityGraphs(varargin)
```

Description:

Inputs are nb_graph_ts objects where each object uses the fanDatasets property in combination with GraphStruct property.

Input:

- varargin : Every second input starting with the first must be the a string (Used by the legend), and every second element starting with the second element must be an object of class nb_graph_ts.

Output:

- plotter : An object you can use the graphInfoStruct method or the nb_graphInfoStructGUI class on.

Written by Kenneth Sætherhagen Paulsen

◆ **nb_getDataNumbering**

```
[numStr,counter] = nb_getFigureNumbering(graphObj,numberObj,counter)
```

Description:

Help function for numbering graphs.

Caution : numberObj is a nb_numbering object handle, and therefore need
not be returned!

Written by Kenneth Sæterhagen Paulsen

◆ **nb_getFigureNumbering**

```
[numStr,counter] = nb_getFigureNumbering(graphObj,numberObj,counter)
```

Description:

Help function for numbering graphs.

Caution : numberObj is a nb_numbering object handle, and therefore need
not be returned!

Written by Kenneth Sæterhagen Paulsen

◆ **nb_graph_init**

```
obj = nb_graph_init(data)
```

Description:

A function to create a corresponding graph object to the provided data
object

Input:

- data : Either an object of class nb_ts, nb_cs or nb_data.

Output:

- obj : Either an object of class nb_graph_ts, nb_graph_cs and
nb_graph_data

Written by Kenneth Sæterhagen Paulsen

◆ **nb_localFunction**

```
outString = nb_localFunction(obj,inString)
```

Description:

Finds the local function used in a char or a cellstr, i.e. a word starting with %#obj., and substitutes it with the matching method of the provided object.

Input:

- obj : A NB toolbox object.
- inString : A char or a cellstr.

Output:

- outString : A char or a cellstr. (Will match the input)

Written by Kenneth Sæterhagen Paulsen

◆ nb_localVariables

```
outString = nb_localVariables(localVariables,inString)
```

Description:

Finds the local variables used in a char or a cellstr, i.e. a word starting with %#, and substitutes it with the matching field of the localVariables input

Input:

- localVariables : A MATLAB struct or an nb_struct object.
- inString : A char or a cellstr.

Output:

- outString : A char or a cellstr. (Will match the input)

Written by Kenneth Sæterhagen Paulsen and Henrik Halvorsen Hortemo

◆ nb_plots

```
nb_plots(structure,varargin)
plotter = nb_plots(structure,varargin)
```

Description:

Plots a structure of nb_ts objects.

This function plots each variable of each nb_ts objects in separate plots. If the nb_ts objects have more datasets (pages) it will plot these against each other.

This function can be utilized to plot impulse response functions returned by the nb_irf function.

Input:

- structure : A structure of nb_ts objects.

Optional input (...,'propertyName',PropertyValue,...):

- varargin : - See the optional input to the set method of the nb_graph_ts class.

- 'gui' : Give 1 if the one figure with menu to select the graphs is wanted, else 0. Default is 0.

Caution: The saveName property will be disabled.

- 'translate' :

A cellstr array with how to translate the given variables. I.e. {{'modelName1','translation1'},...}

- 'parent' : Parent given to the nb_graphInfoStructGUI class when 'gui' is set to 1. Default is [].

Output:

- plotter : A nb_graph_ts object. Use the graphInfoStruct method to produce graphs.

- If nargout is 0:

Graphs of each variable of each nb_ts objects in seperate plots on the screen. If the nb_ts objects have more datasets (pages) it will plot these against eachother.

Examples:

If you provide the 'saveName' and the 'pdfBook' options all the plotted variables will be saved in one pdf file.

```
nb_plots(structure,'saveName','test','pdfBook',1);
```

Written by Kenneth Sætherhagen Paulsen

◆ nb_saveas

```
nb_saveas(gcf,saveName)
nb_saveas(fig,saveName,format)
nb_saveas(fig,saveName,format,'-noflip')
nb_saveas(fig,saveName,'pdf','nocrop') % Only for pdf and jpg
nb_saveas(fig,saveName,'pdf','-append') % Only for pdf
```

Description:

Saves the provided figureHandle to the provided file format.

Uses the export_fig package and Ghostscript.

Input:

- fig : Handle to the current figure
- saveName : The save file name. With or without extension.
- format : The saved file format:
 - 'pdf' : PDF file using the export_fig
 - 'emf' : EMF using print
 - 'eps' : EPS using print
 - 'png' : PNG file using the export_fig
 - 'dpng' : PNG using print
 - 'svg' :
 - 'jpg' : JPG file using the export_fig
 - 'djpeg' : JPG using print

Optional input:

- '-noflip' : Not flip the saved output.
- '-nocrop' : Don't crop pdf figures.
- '-append' : Append to existing pdf.
- '-a4portrait' : A4 portrait format. Will overrule the other optional inputs.

Output:

- The figure saved to the wanted file format.

Examples:

■ nb_area

Go to: [Properties](#) | [Methods](#)

```
obj = nb_area(xData,yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for making area plots.

The handle have set and get methods as all MATLAB graph handles.

Caution: All the children of this object is of class nb_patch (or line)

Constructor:

```
obj = nb_area(xData,'propertyName',PropertyValue,...)
obj = nb_area(xData,yData,'propertyName',PropertyValue,...)
```

Input:

- xData : The xData of the plotted data. Must be of size; size(yData,1) x 1 or 1 x size(yData,1)
- yData : The yData of the plot. The columns are counted as seperate variables
- varargin : ..., 'propertyName', PropertyValue, ...

Output:

- obj : An object of class nb_area

Examples:

```
obj = nb_area([1,2]); % Provide only y-axis data
obj = nb_area([1,2],[1,2]);
obj = nb_area([1,2],'propertyName',PropertyValue,...)
obj = nb_area([1,2],[1,2],'propertyName',PropertyValue,...)
```

See also:

`area`

Written by Kenneth Sætherhagen Paulsen

Properties:

- `abrupt`
- `accumulate`
- `baseValue`
- `baseline`
- `cData`
- `children`
- `deleteOption`
- `faceAlpha`
- `legendInfo`
- `lineStyle`
- `lineWidth`
- `parent`
- `side`
- `sumTo`
- `visible`
- `xData`
- `yData`

- **abrupt** ↑

Set this property to true to make the areas abruptly finish when given as nan.

- **accumulate** ↑

Set if the areas should be accumulated or not. Default is true.

- **baseValue** ↑

The base value of the area and bar plot. Must be a scalar. Default is 0.

- **baseline** ↑

An nb_horizontalLine handle (object). Use the set and get methods of this handle to change the baseline properties

- **cData** ↑

The color data of the line plotted. Must be of size; `size(yData, 2) x 3` with the RGB colors or a cellstr with size `1 x size(yData, 2)` with the color names.

- **children** ↑

All the handles of the area plot, as patch objects

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **faceAlpha** ↑

Transparency of the patch face. Only the scalar option is supported. A single non-NaN value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible)

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- **lineStyle** ↑

The line style of the edge of the areas. Either a string or a cell array with size as the number of lines to be plotted. {'-' } | '--' | ':' | '-' | 'none' .

- **lineWidth** ↑

The line width of the edge of the area. As a scalar. Default is 1

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes (Which is the default).

- **sumTo** ↑

If given the sum of the bars for each period will sum up to this number (only when style is set to 'stacked'). E.g. if set 100, each bar for each variable will be given as percentage share of the total sum.

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'

- **xData** ↑

The xData of the plotted data. Must be of size; size(yData,1) x 1 or 1 x size(yData,1)

- **yData** ↑

The yData of the plot. The columns are counted as separate variables

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefaultColors](#)
 - [interpretColor](#)
 - [set](#)
-

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow, dataHigh, method, fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get ↑**

propertyValue = get(obj,propertyName)

Description:

Get a property of an object of class nb_area

Input:

- obj : An object of class nb_area
- propertyName : A string with the propertyName

Output:

- `propertyValue` : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the `nb_plotHandle` class.

Get the default colors given the number of plotted variables.

Input:

- `dataSize` : Number of plotted variables.

Output:

- `defaultColors` : The default colors, as a $M \times 3$ double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass `NB_PLOTHANDLE`

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the `nb_plotHandle` class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blå','b'
```

```
> 'red','rÃ,d','r'  
> 'green','grÃ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÃ¥','lb'  
> 'black','svart','k'  
> 'grey','grÃ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÃ¥','hb'  
> 'deep blue','mÃ,rk blÃ¥','db'  
> 'water blue','vannblÃ¥','vb'  
> 'cool grey','kald grÃ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_area. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_area
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_area with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth SÃ¶terhagen Paulsen

■ nb_arrow

Go to: [Properties](#) | [Methods](#)

`nb_lineAnnotation, nb_movableAnnotation, nb_annotation, handle`

Description:

A class for adding arrows to a plot.

Constructor:

```
obj = nb_arrow(varargin)
```

Input:

Optional input ('propertyName', PropertyValue):

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_arrow

Examples:

See also:

[nb_annotation](#), [handle](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth SÃ¶terhagen Paulsen

Properties:

- | | | | | |
|---------------|--------------|--------------|---------------|----------------|
| • ID | • children | • color | • copyOption | • deleteOption |
| • head1Length | • head1Style | • head1Width | • head2Length | • head2Style |
| • head2Width | • lineStyle | • lineWidth | • listeners | • parent |
| • pointer | • selected | • side | • units | • xData |
| • yData | | | | |

- [ID](#) ↑

`nb_arrow/ID` is a property.

- **children** ↑

The children of the handle.

Inherited from superclass `NB_ANNOTATION`

- **color** ↑

The color data of the line plotted. Must be of size;
1 x 3. With the RGB colors. Or a string with the
name of the color. See the method `interpretColor`
of the `nb_plotHandle` class for more on the supported
color names.

- **copyOption** ↑

Set to true if a copy option should be added to the context menu
of annotation object. Default is false.

Inherited from superclass `NB_ANNOTATION`

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be
deleted and all that is plotted by this object are
removed from the figure it is plotted on. If on the other
hand 'only' is given, it will just delete the object

Inherited from superclass `NB_ANNOTATION`

- **head1Length** ↑

Length of first arrowhead. Size in points. As a scalar.
Specify in points.1 point = 1/72 inch. The default
value is 8.

The first arrowhead is located at the start defined by
the point `xData(1)`, `yData(1)`.

- **head1Style** ↑

Style of first arrowhead. As a string. Specify this
property as one of the strings from the following table.

```
> 'none'  
> 'plain'  
> 'ellipse'  
> 'vback1'  
> 'vback2' (default)  
> 'vback3'  
> 'cback1'  
> 'cback2'  
> 'cback3'  
> 'star4'  
> 'rectangle'  
> 'diamond'
```

```
> 'rose'  
> 'hypocycloid'  
> 'astroid'  
> 'deltoid'
```

- **head1Width** ↑

Width of first arrowhead. Specify in points.
1 point = 1/72 inch. As a scalar. The default value is
8.

The first arrowhead is located at the start defined by
the point `xData(1)`, `yData(1)`.

- **head2Length** ↑

Length of second arrowhead. Size in points. As a scalar.
Specify in points. 1 point = 1/72 inch. The default value
is 10.

The second arrowhead is located at the end defined by
the point `xData(2)`, `yData(2)`.

- **head2Style** ↑

Style of second arrowhead. As a string. Specify this
property as one of the strings from the following table.

```
> 'none' (default)  
> 'plain'  
> 'ellipse'  
> 'vback1'  
> 'vback2'  
> 'vback3'  
> 'cback1'  
> 'cback2'  
> 'cback3'  
> 'star4'  
> 'rectangle'  
> 'diamond'  
> 'rose'  
> 'hypocycloid'  
> 'astroid'  
> 'deltoid'
```

- **head2Width** ↑

Width of second arrowhead. Specify in points.
1 point = 1/72 inch. As a scalar. The default value is
10.

The second arrowhead is located at the end defined by
the point `xData(2)`, `yData(2)`.

- **lineStyle** ↑

The line style of the plotted data. Must be a string.
{'-' } | '--' | ':' | '-' | 'none'. '---' is not supported.

- **lineWidth** ↑

The line width of the plotted arrow. As an integer.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **side** ↑

The axes to plot against. 'left' or 'right'. 'left' is default.

- **units** ↑

The coordinates system to plot in. Either {'data'} :
xy-coordinates | 'normalized' : figure coordinates.

- **xData** ↑

The x-axis data. As a 1x2 double. E.g: [x_begin, x_end].

- **yData** ↑

The y-axis data. As a 1x2 double. E.g: [y_begin, y_end].

Methods:

- [set](#)

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_arrow. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_arrow
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_arrow with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_axes

Go to: [Properties](#) | [Methods](#)

```
obj = nb_axes(varargin)
```

Superclasses:

handle

Description:

This is a class for making plot axes.

This class does not supports all the normal axes properties through the set and get methods of this class, but the most important ones.

But it is possible to use the set and get methods of the MATLAB axes class on the properties axesHandle and axesHandleRight of this class after constructing a nb_axes object.

- This class supports y-axes on both sides
- Some extra added functionalites:

```
> Shaded background  
> Set the space between each tick marks of both the  
y-axis and x-axis
```

Caution : This way of making axes is not stable when using the normal MATLAB plotting commands, so I recommend to use the "nb" plotting classes:

```
> nb_area  
> nb_bar  
> nb_hbar  
> nb_highlight  
> nb_horizontalLine  
> nb_line  
> nb_patch  
> nb_pie  
> nb_plot  
> nb_radar  
> nb_scatter  
> nb_plotComb  
> nb_verticalLine
```

I also strongly recommend to use the nb_axes object as the parent of the listet classes above. The default is to use a nb_axes object as the parent for these classes.

The axes will automatically adjust given the children of the nb_axes object. But it is also possible to freeze the axes options if you set the update property to 'off'.

Titles of axes:

You must use the handle you get when intializing the nb_axes object as the parent property of the nb_title class. I.e:

```
> ax = nb_axes();  
    nb_title('A title','parent',ax)  
  
> nb_title('A title') WILL NOT WORK!
```

Lables on the axes:

You must use the handle you get when intializing the nb_axes object as the parent property of the nb_yLabel class. I.e:

```
> ax = nb_axes();  
    nb_yLabel('A y-axis label','parent',ax)  
  
> nb_yLabel('A y-axis label') WILL NOT WORK!
```

It is also possible to decide which axis to place the label on, i.e. 'right' or 'left', by the property side. For more see the documentation of the nb_ylabel class.

The xlabel can be set in the same way as the ylabel, but you do not have the side option.

Constructor:

```

nb_axes
nb_axes('propertyName',PropertyValue,...)
ax = nb_axes('propertyName',PropertyValue,...)

Input:

- varargin : ..., 'propertyName', PropertyValue, ...

Support most the inputs to the MATLAB axes
class for the left axes, but some extra
options is available:

Right axis options:
> 'yDirRight'      : Direction of the axes on
                      the right
> 'yLabelRight'    : The y-axis label of the
                      plot
> 'yLimRight'      : y-axis limit of the right
                      axes

Shaded background options:
> 'shading' : {'none'} or 'grey'

```

Output:

- obj : A nb_axes handle (object). Which can be given as the parent for the nb_* plotting classes

A plotted axes in the current figure or newly made figure

Examples:

```

ax = nb_axes('position',[0.13 0.11 0.775 0.815],...
             'xLim',[0,1],'yLim',[0.1]);

```

same as

```

ax = nb_axes

```

- `yTickCountRightObjects`
- `yTickRightSet`
- `yTickVisible`

- **`UIContextMenu`** ↑

Sets the `uicontextmenu` handle related to the this object

- **`alignAxes`** ↑

Set to a scalar double to align a base value for the left and right axes

- **`annotations`** ↑

A cell with annotation objects

- **`axesHandle`** ↑

A MATLAB axes object (left axes of the plot)

- **`axesHandleRight`** ↑

A MATLAB axes object (right axes of the plot)

- **`axesLabelHandle`** ↑

A MATLAB axes object (Where the axes labels are plotted)

- **`axisVisible`** ↑

If the axis of the plot should be on or off. {'on'} | 'off'

- **children** ↑

All the "nb" plotting objects of the this axes object.

- **color** ↑

{'none'} | ColorSpec ; Color of the axes back planes. Setting this property to none means that the axes is transparent and the figure color shows through. A ColorSpec is a three-element RGB vector or one of the MATLAB predefined names. Note that while the default value is none, the matlabrc.m startup file might set the axes Color to a specific color. If the 'shading' property is given this option will be overrundered.

- **colorMap** ↑

Sets the colormap used by the nb_image class if the object only plotting a image of one page. Must be given as n x 3 double or a one line char with the path to a MAT file containing the colormap. It will also set the colors used for the nb_gradedFanChart class.

For an example of a supported MAT file see:

- ...\\Examples\\Graphics\\colorMapNB.mat

- **dashType** ↑

Either char(173) (dash), char(8211) (en-dash) or char(8212) (em-dash). char(8211) is default.

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **fast** ↑

Set it to fast implementation, but where it may be a loss of functionality.

- **findAxisLimitMethod** ↑

The method used to find the limits of the axes. 1 | 2 | 3 | {4}. Default is to let MATLAB plot function find them

- **fontName** ↑

The font name used on the text of the axes.

- **fontSize** ↑

The font size used on the text of the axes. Only the x-tick and y-tick labels. See also `fontSizeX`

- **fontSizeX** ↑

The font size used on the text of the x-axis. I.e. the x-tick labels. If empty (default) the `fontSize` property is used.

- **fontUnits** ↑

```
{'points'} | 'normalized' | 'inches'  
| 'centimeters' | 'pixels'
```

Font size units. MATLAB uses this property to determine the units used by the `fontSize` property.

`normalized` - Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `fontSize` accordingly.

`pixels`, `inches`, `centimeters`, and `points`: Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

The font weight used on the text of the axes. Only the x-tick and y-tick labels

- **grid** ↑

'on' | {'off'} ; If 'on' grid lines will be added

- **gridLineStyle** ↑

'-' | '--' | ':' | '-.' | 'none'. Line style used to draw grid lines. The line style is a string consisting of a character, in quotes, specifying solid lines (-), dashed lines (--), dotted lines(:), or dash-dot lines (-.).

- **highLighted** ↑

Here will all the highlighted area handles be stored.

- **horizontalLine** ↑

Here will all of the nb_horizontalLine objects of this axes be stored. This will make it possible to automatically fit the horizontal line objects to the axes

- **imageChild** [↑](#)

The nb_image object associated with this axes. See the nb_image class.

- **language** [↑](#)

The number format on th y-axis is different for different languages. Either 'norsk' | {'english'}.

- **legend** [↑](#)

The legend of the axes, given as an nb_legend object.

- **limMode** [↑](#)

{'auto'} | 'manual' . If 'manual' the axis limits will no longer update themself automatically.

- **lineWidth** [↑](#)

Sets the line width of the axes. Default is 0.5.

- **normalized** [↑](#)

Indicate if the font when fontUnits is set to 'normalized' should be normalized to the axes ('axes') or to the figure ('figure'), i.e. the default axes position [0.1 0.1 0.8 0.8]. Default is 'axes'.

- **orientation** [↑](#)

Sets the orientation of the axes. Either 'vertical' (default) | 'horizontal'.

Caution : The y-axes are still the right and the left axes, and the x-axes are still the top bottom axes.

Caution : The properties xTickLabelAlignment, xTickLabelLocation, xTickLocation, and all the properties which sets how the y-axis on the right side are plotted are not supported when this property is set to 'horizontal'.

- **parent** [↑](#)

The parent, as a nb_figure object.

- **plotAxesHandle** ↑

The handle to do the plotting on. Has no axis. (When plotting on the left axes).

- **plotAxesHandleRight** ↑

The handle to do the plotting on. Has no axis. (When plotting on the right axes)

- **plotBoxAspectRatio** ↑

Set the plot box aspect ratio. Must be given as a 1x3 double [ax,ay,az]. Default is empty, which means the aspect ratio is given by the figure aspect ratio.

- **position** ↑

Position of axes. Specifies a rectangle that locates the axes within its parent container (figure or uipanel). The vector is of the form: [left bottom width height], where left and bottom define the distance from the lower-left corner of the container to the lower-left corner of the rectangle. width and height are the dimensions of the rectangle. The Units property specifies the units for all measurements.

Caution: If legend is placed outside the axes with some of the provided location property the axes will scale down accordingly. In this case this property stores the original position. See the axesHandlePosition property to get the corrected position (in normalized uints only)

- **precision** ↑

Sets the precision/format of the rounding of number on the axes.

See the precision input to the nb_num2str function. Default is [], i.e. to call num2str without additional inputs.

- **scaleFactor** ↑

Scale line width with this factor instead of the default scaling. only when scaleLineWidth is set to true.

- **scaleLineWidth** ↑

Scale line width to axes height. true or false (default).

Caution: If you change the height of the axes you need to run an update on the children of the axes to make the line adjust.

- **shading** ↑

The shading option of the axes background:

- 'grey' : Shaded grey background
- 'none' : Background color given by the color property.
- A $n \times m \times 3$ double with the background color. n is the number of horizontal pixels, m is the number of vertical pixels and 3 means the RGB colors.

- **shadingAxes** ↑

Axes of the shading

- **tickDir** ↑

{'in'} | 'out'. Direction of tick marks

- **tickObjects** ↑

Not settable

- **title** ↑

The handle to the title placed right above the axes. An nb_title handle.

- **units** ↑

Units of the position property. Default is 'normalized'.

- **update** ↑

If you want to make it possible to add children to the axes without updating the axes. This could be important for speed, when plotting more object in one axes.
Either {'on'} | 'off'.

- **verticalLine** ↑

Here will all of the nb_verticalLine objects of this axes be stored. This will make it possible to automatically fit the vertical line objects to the axes

- **visible** ↑

{'on'} | 'off'. Sets the visibility of the axes and all its children.

- **xLabel** ↑

A nb_xLabel handle (object) of the y-axis label (both or only left). Use the nb_xLabel command.

- **xLim** ↑

The limit of the x-axis. As a 1x2 double.

- **xLimSet** ↑

Not settable

- **xOffset** ↑

The offset of the x-axis tick marks.

- **xScale** ↑

Sets the scale of the x-axis. {'linear'} | 'log'.

- **xTick** ↑

The tick marks location.

- **xTickLabel** ↑

The labels of the tick marks. Either a cellstr array or a double vector

- **xTickLabelAlignment** ↑

The alignment of the x-axis tick marks labels. {'normal'} | 'middle'

- **xTickLabelLocation** ↑

The location of the x-axis tick marks labels. Either {'bottom'} | 'top' | 'baseline'. 'baseline' will only work in combination with with the xtickLocation property set to a double with the basevalue.

- **xTickLabelObjects** ↑

The text objects of the x-axis tick labels.

- **xTickLabelSet** ↑

Not settable

- **xTickLocation** ↑

The location of the x-axis tick marks. Either {'bottom'} | 'top' | double. If given as a double the tick marks will be placed at this value (where the number represent the y-axis value).

- **xTickRotation** ↑

The rotation of the x tick marks. Specify values of rotation in degrees (positive angles cause counterclockwise rotation).

- **xTickSet** ↑

Not settable

- **xTickVisible** ↑

Sets the visibility of the x-axis tick marks. 1 visible and 0 invisible.

- **yDir** ↑

{'normal'} | 'reverse'. The direction of the y-axis (both or only left)

- **yDirRight** ↑

{'normal'} | 'reverse'. The direction of the y-axis (only right)

- **yLabel** ↑

The nb_yLabel handle (object) of the y-axis labels (only left).

- **yLabelRight** ↑

The nb_yLabel handle (object) of the y-axis labels (only right).

- **yLim** ↑

The limit of the y-axis (both or only left). Default limits is [0 1], on both axes.

- **yLimRight** ↑

The limit of the y-axis (only right). As long as there is not plotted any nb_* plotting objects on this axes this property will not be used, but of course if you set it.

- **yLimRightSet** ↑

Not settable

- **yLimSet** ↑

Not settable

- **yOffset** ↑

The offset of the y-axis tick marks

- **yScale** ↑

Sets the scale of the left y-axis (or both if nothing is plotted on the right axes). {'linear'} | 'log'.

- **yScaleRight** ↑

Sets the scale of the right y-axis. {'linear'} | 'log'.

- **yTick** ↑

The tick marks location (both or only left)

- **yTickLabel** ↑

The labels of the tick marks (both or only left). Either a cellstr array or a double vector

- **yTickLabelObjects** ↑

The text objects of the y-axis tick labels (left)

- **yTickLabelRight** ↑

The labels of the tick marks (only right). Either a cellstr array or a double vector

- **yTickLabelRightObjects** ↑

The text objects of the y-axis tick labels (right)

- **yTickLabelRightSet** ↑

Not settable

- **yTickLabelSet** ↑

Not settable

- **yTickRight** ↑

The tick marks location (only right)

- **yTickRightSet** ↑

Not settable

- **yTickSet** ↑

Not settable

- **yTickVisible** ↑

Sets the visibility of the y-axis tick marks. 1 visible and 0 invisible.

Methods:

- [get](#)
 - [set](#)
-

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_axes

Input:

- obj : An object of class nb_axes
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('color');
```

Written by Kenneth S. Paulsen

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_axes. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_axes
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_axes with the given properties reset

Examples:

```
obj = obj.set('position',[0.1 0.1 0.8 0.8],'xLim',[0,1],...  
'yLim',[0.1]);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_bar

Go to: [Properties](#) | [Methods](#)

```
obj = nb_bar(xData,yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for making bar plots with or without shaded bars.

```
nb_bar(yData)  
nb_bar(xData,yData)  
nb_bar(xData,yData,'propertyName',PropertyValue,...)  
handle = nb_bar(xData,yData,'propertyName',PropertyValue,...)
```

The handle have set and get methods as all MATLAB graph handles.

Caution: All the children of this object is of class nb_patch

Constructor:

```
obj = nb_bar(xData,yData,varargin)
```

Input:

- xData : The xData of the plotted data. Must be of size; size(yData,1) x 1 or 1 x size(yData,1)
- yData : The yData of the plot. The columns are counted as separate variables
- varargin : ..., 'propertyName', PropertyValue, ...

Output

- obj : An object of class nb_bar

Examples:

```
obj = nb_bar([1,2]); % Provide only y-axis data
obj = nb_bar([1,2],[1,2]);
obj = nb_bar([1,2], 'propertyName', PropertyValue, ...)
obj = nb_bar([1,2],[1,2], 'propertyName', PropertyValue, ...)
```

See also:

bar

Written by Kenneth Sæterhagen Paulsen

Properties:

- alpha1
- alpha2
- barWidth
- baseValue
- baseline
- blend
- cData
- children
- deleteOption
- direction
- edgeColor
- fast
- legendInfo
- lineObj
- lineWidth
- parent
- scale
- shadeColor
- shaded
- side
- style
- sumTo
- visible
- xData
- yData

- alpha1 ↑

Sets the alpha blending parameter nr 1 when blend is set to true.

- alpha2 ↑

Sets the alpha blending parameter nr 1 when blend is set to true.

- barWidth ↑

Width of the bars. Must be a scalar.

- baseValue ↑

The base value of the plot. Must be a scalar or a vector with size size(yData,1) x 1.

- **baseline** ↑

A nb_horizontalLine handle (object). Use the set and get methods of this handle to change the baseline properties.

Caution: If baseValue is a vector this property is a nb_line object.

- **blend** ↑

When shaded is used, and this option is set to true, it will do alpha blending with shadeColor instead of shading.

- **cData** ↑

Color of the plotted data. A matrix; size(yData,2) x 3 (RGB color). Or a cellstr with the color names. (With size 1 x size(yData,2))

- **children** ↑

All the handles of the bar plot.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **direction** ↑

The direction of the shading; {'north'} | 'south' | 'east' | 'west'

- **edgeColor** ↑

The color of the edge of the bars. In RGB colors or a string with the color names. Can also be 'none' ; no edgeLine or 'same' ; same color as the base color for each bar. Can also be a cellstr with either the RGB colors or color names with size 1 x size(yData,2).

- **fast** ↑

Is the fast or general algorithm beeing used.

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- **lineObj** ↑

A nb_line handle representing the sum of the stacked bars when 'style' is set to 'dec'. As a line handle.

- **lineStyle** ↑

Sets the line style(s) of the edge of the bars.
Either a string or a cellstr (which must have
the size 1 x size(yData,2)).

- **lineWidth** ↑

The line width of the edge of the bars. Must be a scalar.

- **parent** ↑

The parent axes you wan to plot on, if not given it will
be plotted in a new nb_axes handle. Either a axes or a
nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **scale** ↑

Sets the tightness of the bars plotted. (Stacked)

- **shadeColor** ↑

The color (RGB) the shaded bar plots are
interpolated with. Either a 1x3 double with the
RGB colors or a string with the color name.
Default is [1,1,1]

- **shaded** ↑

Index of which data should be shaded. A matrix with size;
size(yData,1) x 1 or 1 x size(yData,1) or size(yData,1) x
size(yData,2)

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the
parent is of class nb_axes. (Which is the default)

- **style** ↑

'stacked' | {'grouped'} | 'dec'. When 'dec' is given the
bars will be stacked but there will also be plotted a
line with the sum. (It is not possible to use the sumTo
option at the same time)

- **sumTo** ↑

If given the sum of the bars for each period will sum up to this number. (only when style is set to 'stacked')
E.g. if set 100, each bar for each variable will be given as percentage share of the total sum.

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'.

- **xData** ↑

The xData of the plotted data. Must be of size;
size(yData,1) x 1 or 1 x size(yData,1)

- **yData** ↑

The yData of the plot. The columns are counted as separate variables.

Methods:

- findClosestNiceNumber
- findLimitsAlgo
- get
- getDefaultColors
- interpretColor
- set

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                 scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_bar

Input:

- obj : An object of class nb_bar
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors ↑**

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvít','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÅ!terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_bar. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_bar
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_bar with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_barAnnotation

Go to: [Properties](#) | [Methods](#)

`nb_textAnnotation, nb_annotation, handle`

Description:

A class for plotting annotation on bar plots.

Constructor:

```
obj = nb_barAnnotation(varargin)
```

Input:

Optional input ('propertyName', PropertyValue):

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_barAnnotation

Examples:

See also:

`nb_textAnnotation, nb_annotation, handle, nb_graph_ts`
`nb_graph_cs`

Written by Kenneth Sætherhagen Paulsen

Properties:

- `children`
- `color`
- `copyOption`
- `decimals`
- `deleteOption`
- `fontName`
- `fontSize`
- `fontUnits`
- `fontWeight`
- `force`
- `language`
- `listeners`
- `location`
- `normalized`
- `parent`
- `pointer`
- `rotation`
- `selected`
- `space`
- `string`
- `type`

- **`children`** ↑

The children of the handle.

Inherited from superclass `NB_ANNOTATION`

- **`color`** ↑

Color of the text of the annotation. Either a string with the color name or a 1x3 double with the RGB colors.

- **`copyOption`** ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass `NB_ANNOTATION`

- **`decimals`** ↑

The number of decimals wanted on the text. Only when type is set to 'default'.

- **`deleteOption`** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass `NB_ANNOTATION`

- **`fontName`** ↑

Name of the font to use. Must be a string. Default is 'arial'.

Inherited from superclass `NB_TEXTANNOTATION`

- **`fontSize`** ↑

Sets the font size in the units given by the font units property. Must be a scalar. Default is 12.

Inherited from superclass `NB_TEXTANNOTATION`

- **fontUnits** ↑
{'points'} | 'normalized' | 'inches' | 'centimeters' |
'pixels'

Font size units. MATLAB uses this property to determine the units used by the `fontSize` property.

`normalized` - Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `fontSize` accordingly.

`pixels`, `inches`, `centimeters`, and `points`:
Absolute units. 1 point = 1/72 inch.

Inherited from superclass `NB_TEXTANNOTATION`

- **fontWeight** ↑

Weight of text characters. {'normal'} | 'bold' | 'light'
| 'demi'

Inherited from superclass `NB_TEXTANNOTATION`

- **force** ↑

Force the number of decimals. I.e. even integers get zeros as decimals.

- **language** ↑

Sets the language of the text. I.e. how decimal sign should be plotted. Only when the input to the `plot` function is of class `nb_bar`. {'english'} | 'norwegian'.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass `NB_ANNOTATION`

- **location** ↑

Sets the location of the annotation.
{'on'} : Place it on the bars
'top' ; Place it on the top of the bars

- **normalized** ↑

Indicate if the font when `fontUnits` is set to 'normalized' should be normalized to the axes ('axes') or to the figure ('figure'), i.e. the default axes position [0.1 0.1 0.8 0.8].

Inherited from superclass `NB_TEXTANNOTATION`

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **rotation** ↑

The rotation of the text. As a double in degrees.

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **space** ↑

Sets the space between the text and the bar when location is set to top. The scale factor is given as the share of the height of the y-axis. Only an option when location is set to 'top'.

- **string** ↑

Set the text of the bars. Must be a cellstr with same size as the plotted data. Where the rows will be the time periods/case dimension and the columns will be the given variables. I.e. in line with how the data is orginized in nb_ts and the nb_cs classes

E.g: {'2,0','3,0','4,0','5,0'}

- **type** ↑

Sets the how the text on the bars should be created:

- {'default'} : The text represent the contribution
- 'manual' : The text is set manually by the user. See property string (When the string property is set this will be the default value of this property)

Methods:

- **set**

► **set** ↑

set(obj,varargin)

Description:

Sets the properties of an nb_barAnnotation object

Input:

- obj : An object of class nb_drawLine
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output

- obj : An object of class nb_barAnnotation with the wanted properties set.

Examples:

Written by Kenneth Sæterhagen Paulsen

■ nb_candle

Go to: [Properties](#) | [Methods](#)

```
obj = nb_candle(xData,high,low,open,close,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for making bar plots with or without shaded bars.

```
nb_candle(xData,high,low,open,close,...  
          'propertyName',PropertyValue,...)  
handle = nb_candle(xData,high,low,open,close,...  
                    'propertyName',PropertyValue,...)
```

The handle have set and get methods as all MATLAB graph handles.

Caution: All the children of this object is of class nb_patch and nb_line

Constructor:

```
obj = nb_candle(xData,high,low,open,close,varargin)
```

Input:

- xData : The xData of the plotted data. Must be of size; size(high,1) x 1 or 1 x size(high,1)
- high : The highest observation. Must be a double

vector. Can be given as a empty double.

- low : The lowest observation. Must be a double vector.
Can be given as a empty double.
- open : The highest value of the plotted patch. Must be
a double vector. Can be given as a empty double.
- close : The lowest value of the plotted patch. Must be
a double vector. Can be given as a empty double.
- varargin : ..., 'propertyName', PropertyValue, ...

Output

- obj : An object of class nb_candle

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Properties:

- cData
- close
- edgeColor
- indicator
- indicatorLineWidth
- lineWidthStyle
- marker
- shadeColor
- visible
- candleWidth
- deleteOption
- high
- indicatorColor
- indicatorWidth
- lineWidth
- open
- shaded
- xData
- children
- direction
- hLineWidth
- indicatorLineStyle
- legendInfo
- low
- parent
- side

- cData ↑

Color of the plotted patches. A matrix;
1 x 3 (RGB color) or a string with the color
name.

- candleWidth ↑

Width of the candles. Must be a scalar.

- children ↑

All the handles of the bar plot.

- close ↑

The lowest values of the plotted patches. Must be double vector. Must match the open, high and low properties, if they are not empty.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **direction** ↑

The direction of the shading; {'north'} | 'south' | 'east' | 'west'

- **edgeColor** ↑

The color of the edge of the bars. In RGB colors or a string with the color names. Can also be 'none' ; no edgeLine or 'same' ; same color as the base color for each bar. Can also be a cellstr with either the RGB colors or color names with size 1 x size(yData,2).

- **high** ↑

The highest values of the plotted candles. Must be double vector. Must match the close, open and low properties, if they are not empty.

- **hlLineWidth** ↑

The line width of the high and low lines. As a scalar. Default is 2.

- **indicator** ↑

The value for where to plot a vertical line. Can be given as an empty double. Must match the close, open, high and low properties, if they are not empty.

- **indicatorColor** ↑

The color of the indicator line. As a 1 x 3 double or a string with the color name. Default is [0,0,0].

- **indicatorLineStyle** ↑

Sets the indicator line style. Default is '-'.

- **indicatorLineWidth** ↑

The line width of the indicator line. As a scalar. Default is 4.

- **indicatorWidth** ↑

The width of the indicator. The default is to use the same width as provided by the candleWidth property. I.e. when this property is set to [].

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- **lineStyle** ↑

Sets the line style(s) of the edge of the bars. Either a string or a cellstr (which must have the size 1 x size(yData,2)).

- **lineWidth** ↑

The line width of the edge of the bars. Must be a scalar.

- **low** ↑

The lowest values of the plotted candles, Must be double vector. Must match the close, high and open properties, if they are not empty.

- **marker** ↑

Sets the marker of the indicator line. Default is 'none'.

- **open** ↑

The highest values of the plotted patches. Must be double vector. Must match the close, high and low properties, if they are not empty.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **shadeColor** ↑

```
The color (RGB) the shaded bar plots are  
interpolated with. Either a 1x3 double with the  
RGB colors or a string with the color name.  
Default is [1,1,1]
```

- **shaded** ↑

```
Index of which data should be shaded. A vector with size;  
size(open,1) x 1 or 1 x size(open,1).
```

- **side** ↑

```
{'left'} | 'right' ; Which axes to plot on. Only if the  
parent is of class nb_axes. (Which is the default)
```

- **visible** ↑

```
Sets the visibility of the plotted lines. {'on'} | 'off'
```

- **xData** ↑

```
The xData of the plotted data. Must be of size;  
size(high,1) x 1 or 1 x size(high,1)
```

Methods:

- [findClosestNiceNumber](#)
- [findLimitsAlgo](#)
- [get](#)
- [getDefaultsColors](#)
- [interpretColor](#)
- [set](#)

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number,...  
scaleNumber,up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits
when findAxisMethod == 3 is used.

Input:

- **number** : The given number to find a "nice" number close to.
- **scaleNumber** : The scale factor used. I.e. the precision of the algorithm.
- **up** : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► findLimitsAlgo ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_candle

Input:

- obj : An object of class nb_candle
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvít','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_candle. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_candle
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_candle with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ **nb_colorbar**

Go to: [Properties](#) | [Methods](#)

nb_annotation, handle

Description:

A class for adding color bar to a plot (axes).

Constructor:

```
obj = nb_colorbar(varargin)
```

Input:

Optional input ('propertyName', PropertyValue) :

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_colorbar

See also:

[nb_annotation](#), [handle](#), [nb_graph_cs](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- [ID](#)
- [fontName](#)
- [language](#)
- [pointer](#)
- [tickLabelsSet](#)
- [children](#)
- [fontSize](#)
- [listeners](#)
- [selected](#)
- [copyOption](#)
- [fontUnits](#)
- [location](#)
- [space](#)
- [deleteOption](#)
- [fontWeight](#)
- [location](#)
- [strip](#)
- [direction](#)
- [invert](#)
- [parent](#)
- [tickLabels](#)
- [ticks](#)
- [ticksSet](#)

- [ID](#) ↑

`nb_colorbar.ID` is a property.

- [children](#) ↑

The children of the handle.

Inherited from superclass NB_ANNOTATION

- [copyOption](#) ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass NB_ANNOTATION

- [deleteOption](#) ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass NB_ANNOTATION

- [direction](#) ↑

Direction of the color bar. 'normal' or 'reverse'.

- [fontName](#) ↑

Name of the font to use. Must be a string. Default is 'arial'.

Inherited from superclass NB_TEXTANNOTATION

- [fontSize](#) ↑

Sets the font size in the units given by the font units property. Must be a scalar. Default is 12.

Inherited from superclass NB_TEXTANNOTATION

- **fontUnits** ↑
{'points'} | 'normalized' | 'inches' | 'centimeters' |
'pixels'

Font size units. MATLAB uses this property to determine the units used by the `fontSize` property.

`normalized` - Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `fontSize` accordingly.

`pixels`, `inches`, `centimeters`, and `points`:
Absolute units. 1 point = 1/72 inch.

Inherited from superclass `NB_TEXTANNOTATION`

- **fontWeight** ↑

Weight of text characters. {'normal'} | 'bold' | 'light'
| 'demi'

Inherited from superclass `NB_TEXTANNOTATION`

- **invert** ↑

Invert color map when applied to the color bar. `true` or `false`. Default is `false`.

- **language** ↑

Sets the language of the text. I.e. how decimal sign should be plotted. {'english'} | 'norwegian'.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass `NB_ANNOTATION`

- **location** ↑

The location of the color bar. See the MATLAB function `colorbar` for more on the values to choose from. Default is '`eastOutside`'.

- **normalized** ↑

Indicate if the font when `fontUnits` is set to 'normalized' should be normalized to the axes ('`axes`') or to the figure ('`figure`'), i.e. the default axes position [0.1 0.1 0.8 0.8].

Inherited from superclass `NB_TEXTANNOTATION`

- **parent** ↑

The parent as an `nb_axes` object

Inherited from superclass `NB_ANNOTATION`

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **space** ↑

Extra space added between color bar and the assosiated axes.
Positive scalar number.

- **strip** ↑

Strip colors from the color map of the parent to be in the
color bare. Default is to strip [1,1,1] (white). Must be a
N x 3 double.

- **tickLabels** ↑

Tick mark labels, specified as a cell array of character vectors,
a string array, a numeric array, a character vector, or a
categorical array. By default, the colorbar labels the tick
marks with numeric values taken from the data of the imageChild
of the nb_axes the colorbar is attached to. If this property is
empty (no image added to the axes), a default [0,1] scale is
given.

- **tickLabelsSet** ↑

nb_colorbar/tickLabelsSet is a property.

- **ticks** ↑

Tick mark locations, specified as a vector of monotonically
increasing numeric values. The values do not need to be equally
spaced. If you do not want tick marks displayed, then set the
property to the empty vector, [].

- **ticksSet** ↑

nb_colorbar/ticksSet is a property.

Methods:

- [set](#)

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_arrow. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_arrow
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_arrow with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_curlyBrace

Go to: [Properties](#) | [Methods](#)

```
nb_movableAnnotation, nb_lineAnnotation, nb_annotation, handle
```

Description:

A class for adding a curly brace to the plot.

The code for plotting the curly brace is gotten from the drawbrace functionn made by Pål Nærli Sævik.

Constructor:

```
obj = nb_curlyBrace(varargin)
```

Input:

Optional input ('propertyName', PropertyValue) :

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_curlyBrace

See also:

[nb_annotation](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [cData](#)
- [children](#)
- [clipping](#)
- [copyOption](#)
- [deleteOption](#)
- [lineStyle](#)
- [lineWidth](#)
- [listeners](#)
- [marker](#)
- [markerEdgeColor](#)
- [markerFaceColor](#)
- [markerSize](#)
- [parent](#)
- [pointer](#)
- [selected](#)
- [side](#)
- [units](#)
- [width](#)
- [xData](#)
- [yData](#)

- **cData** ↑

The color data of the line plotted. Must be of size;
1 x 3. With the RGB colors. Or a string with the name of
the color. See the method `interpretColor` of the
`nb_plotHandle` class for more on the supported color names.

- **children** ↑

The children of the handle.

Inherited from superclass `NB_ANNOTATION`

- **clipping** ↑

{'on'} | 'off' ; Clipping mode. MATLAB clips lines to the
axes plot box by default. If you set Clipping to off,
lines are displayed outside the axes plot box.

- **copyOption** ↑

Set to true if a copy option should be added to the context menu
of annotation object. Default is false.

Inherited from superclass `NB_ANNOTATION`

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be
deleted and all that is plotted by this object are
removed from the figure it is plotted on. If on the other
hand 'only' is given, it will just delete the object

Inherited from superclass `NB_ANNOTATION`

- **lineStyle** ↑

The line style of the plotted data. Must be a string.
{'-' } | '--' | ':' | '-.' | 'none'. '---' is not
supported.

- **lineWidth** ↑

The line width of the plotted data. As an integer.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **marker** ↑

The markers of the lines. Must be a string. See marker property of the MATLAB line function for more on the options of this property

- **markerEdgeColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'}.

- **markerFaceColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'}.

- **markerSize** ↑

Size of the markers. Must be a integer. Default is 9.

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **side** ↑

The axes to plot against. 'left' or 'right'. 'left' is default.

- **units** ↑

The coordinates system to plot in. Either {'data'} : xy-coordinates | 'normalized' : figure coordinates.

- **width** ↑

Width of the brace. Try and fale method must be used!

- **xData** ↑

The x-axis data. As a 1x2 double.

- **yData** ↑

The y-axis data. As a 1x2 double.

Methods:

- **set**

► **set** ↑

`set(obj,varargin)`

Description:

Sets the properties of an object of class nb_drawLine. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- `obj` : An object of class nb_drawLine
- `varargin` : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- `obj` : The same object of class nb_drawLine with the given properties reset

Examples:

`obj.set('propertyName',PropertyValue,...);`

Written by Kenneth Sæterhagen Paulsen

■ **nb_donut**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_donut(yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for making donut charts in 2D.

This class will make the donut chart automatically fit the axes of the plot.

I recommend to use the nb_* classes for the legend, titles and so on.

Constructor:

```
obj = nb_donut(yData,varargin)
```

Input:

- yData : The data to plot. min(size(yData)) must be 1.

Optional input:

- varargin : 'propertyName',PropertyValue,...

Output:

- obj : An object of class nb_pie (handle).

Examples:

```
nb_donut(yData)
nb_donut(yData,'propertyName',PropertyValue,...)
handle = nb_donut(yData,'propertyName',PropertyValue,...)
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- axisVisible
- bite
- cData
- children
- deleteOption
- edgeColor
- explode
- fontColor
- fontName
- fontSize
- fontUnits
- fontWeight
- innerRadius
- labelHandles
- labels
- labelsExtension
- legendInfo
- lineStyle
- lineWidth
- location
- noLabels
- origoPosition
- parent
- radius
- visible
- yData

- **axisVisible** ↑

Make the axes box visible ('on') or not ('off'). 'on' is default.

- **bite** ↑

A logical array with ones for the slice to bite. I.e. [0,0,1,0]; Must be of size; 1 x nSlices.

- **cData** ↑

The colors of the plotted data. Must be of size nSlices x 3. (Double with the RGB colors), or a cellstr with the color names. Must be of size 1 x nSlices. See the method nb_plotHandle.interpretColor for more on the supported color names.

- **children** ↑

The handles of all the children of the plot.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **edgeColor** ↑

The color of the edge of the pies. Must be of size; 1 x 3. (Double with the RGB colors), or a one line char with the color name. See the method nb_plotHandle.interpretColor for more on the supported color names.

- **explode** ↑

A logical array with ones for the pies to explode. I.e. [0,0,1,0]; Must be of size 1 x nSlices.

- **fontColor** ↑

Color of labels. Must be double with size 1 x 3 (RGB colors), or a string with the name of the color. See the method nb_plotHandle.interpretColor for more on the supported color names.

- **fontName** ↑

Name of the font used. Default is 'arial'.

- **fontSize** ↑

Font size of the text on the plot. Default is 12.

- **fontUnits** ↑

```
{'points'} | 'normalized' | 'inches' |  
'centimeters' | 'pixels'
```

Font size units. MATLAB uses this property to determine the units used by the `fontSize` property.

`normalized` - Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `fontSize` accordingly.

`pixels`, `inches`, `centimeters`, and `points`:
Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

Font weight of the text on the plot. Default is 'normal'.

- **innerRadius** ↑

Sets the relative length of the inner circle of the donut. -0.5 mean that the donut has an inner circle with the same radius as half the outer circle of the donut.

- **labelHandles** ↑

Handles to the labels of the pie plot. As MATLAB text objects.

- **labels** ↑

The labels of the pies, must be a cellstr with `size`; `length(yData)`. If not given the labels will be the shares of each pie in percent.

- **labelsExtension** ↑

If you not give the labels you can set the extension of the labels. Default is '%'. The extension will be added to the value of the data. If '%' is given the data will be in relative shares in percent.

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend.

- **lineStyle** ↑

Line style of the edge.

- **lineWidth** ↑

Line width of the edge.

- **location** ↑

{'west'} | 'east' | 'center'. The location of the pie chart in the current axes.

- **noLabels** ↑

Force there to be no labels of the pies. If yData gives more donuts noLabels will be forced to 1 (true).

- **origoPosition** ↑

Set the origo position. Default is to use the location property. Where 'west' is [-0.5,0], 'center' is [0,0] and 'east' is [0.5,0]. Must either be empty or a 1x2 double.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **radius** ↑

Set the radius of the nb_donut. Default is 1.

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'.

- **yData** ↑

The data to plot. As a nDonuts x nSlices.

Caution: If given as N x 1 it is interpreted as 1 x nSlices.

Methods:

- [findClosestNiceNumber](#)
- [findLimitsAlgo](#)
- [get](#)
- [getDefaultValue](#)
- [interpretColor](#)
- [set](#)

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number,...  
scaleNumber,up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► findLimitsAlgo ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)

```
> 3: Uses the submethod findClosestNiceNumber of  
      the class to decide on the limits. (Also this  
      method have can have problems with data which  
      is not symmetric around the zero line.)  
> 4 : Uses the MATLAB algorithm for finding the  
      axis limits.
```

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_donut

Input:

- obj : An object of class nb_donut
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► interpretColor ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÃ,d','r'  
> 'green','grÃ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÃ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÃ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÃ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colormames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► set ↑

set(obj,varargin)

Description:

Sets the properties of an object of class nb_donut. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_donut
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_donut with the given properties reset

Examples:

obj.set('propertyName',PropertyValue,...);

Written by Kenneth Sæterhagen Paulsen

■ nb_drawCircle

Go to: [Properties](#) | [Methods](#)

[nb_lineAnnotation](#), [nb_movableAnnotation](#), [nb_annotation](#), [handle](#)

Description:

A class for adding a arbitrary circle to a plot using the patch handle class.

Constructor:

```
obj = nb_drawCircle(varargin)
```

Input:

Optional input ('propertyName', PropertyValue):

> You can set some properties of the class.

Output

- obj : An object of class nb_drawPatch

See also:

[nb_annotation](#), [handle](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- children
- clipping
- copyOption
- deleteOption
- edgeColor
- faceColor
- lineStyle
- lineWidth
- listeners
- parent
- pointer
- rData
- selected
- side
- units
- xData
- yData

- **children** [↑](#)

The children of the handle.

Inherited from superclass NB_ANNOTATION

- **clipping** [↑](#)

'on' or 'off'. Clipping to axes rectangle. When Clipping is on, MATLAB does not display any portion of the patch outside the axes rectangle.

- **copyOption** [↑](#)

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass NB_ANNOTATION

- **deleteOption** [↑](#)

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass NB_ANNOTATION

- **edgeColor** ↑

The color of the edge of the rectangle. In RGB colors | 'none' : No edgeLine | 'same' : Same color as the face color | a string with the color name.

- **faceColor** ↑

The RGB color of the face of the rectangle.

Must be a 1 x 3 double with the RGB colors or a string with the color name. See the method interpretColor of the nb_plotHandle class for more on the supported color names.

- **lineStyle** ↑

The line style of the edge of the patch.

- **lineWidth** ↑

The line width of the edge of the patch.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **rData** ↑

Radius at the center of the circle in the y-direction.
Default is 1.

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **units** ↑

The coordinates system to plot in. Either {'data'} :
xy-coordinates | 'normalized' : figure coordinates.

- **xData** ↑

The x-axis data. As a 1x2 double. E.g: [x_begin, x_end].

- **yData** ↑

The y-axis data. As a 1x2 double. E.g: [y_begin, y_end].

Methods:

- **set**

► **set** ↑

`set(obj,varargin)`

Description:

Sets the properties of an object of class nb_drawLine. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- `obj` : An object of class nb_drawLine
- `varargin` : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- `obj` : The same object of class nb_drawLine with the given properties reset

Examples:

`obj.set('propertyName',propertyValue,...);`

Written by Kenneth Sæterhagen Paulsen

■ **nb_drawLine**

Go to: [Properties](#) | [Methods](#)

```
nb_lineAnnotation, nb_annotation, handle
```

Description:

A class for adding a arbitrary line to a plot.

Constructor:

```
obj = nb_drawLine(varargin)
```

Input:

Optional input ('propertyName', PropertyValue):

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_drawLine

Examples:

See also:

[nb_annotation](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- [cData](#)
- [children](#)
- [clipping](#)
- [copyOption](#)
- [deleteOption](#)
- [lineStyle](#)
- [lineWidth](#)
- [listeners](#)
- [marker](#)
- [markerEdgeColor](#)
- [markerFaceColor](#)
- [markerSize](#)
- [parent](#)
- [pointer](#)
- [selected](#)
- [side](#)
- [units](#)
- [xData](#)
- [yData](#)

- **cData** ↑

The color data of the line plotted. Must be of size;
1 x 3. With the RGB colors. Or a string with the name of
the color. See the method `interpretColor` of the
`nb_plotHandle` class for more on the supported color names.

- **children** ↑

The children of the handle.

Inherited from superclass NB_ANNOTATION

- **clipping** ↑

{'on'} | 'off' ; Clipping mode. MATLAB clips lines to the
axes plot box by default. If you set Clipping to off,
lines are displayed outside the axes plot box.

- **copyOption** ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass NB_ANNOTATION

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass NB_ANNOTATION

- **lineStyle** ↑

The line style of the plotted data. Must be a string. {'-' } | '--' | ':' | '-' | 'none'. '---' is not supported.

- **lineWidth** ↑

The line width of the plotted data. As an integer.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **marker** ↑

The markers of the lines. Must be a string. See marker property of the MATLAB line function for more on the options of this property

- **markerEdgeColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'}.

- **markerFaceColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'}.

- **markerSize** ↑

Size of the markers. Must be a integer. Default is 9.

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **side** ↑

The axes to plot against. 'left' or 'right'. 'left' is default.

- **units** ↑

The coordinates system to plot in. Either {'data'} : xy-coordinates | 'normalized' : figure coordinates.

- **xData** ↑

The x-axis data. As a double.

- **yData** ↑

The y-axis data. As a double.

Methods:

- **set**

► **set** ↑

`set(obj,varargin)`

Description:

Sets the properties of an object of class nb_drawLine. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- **obj** : An object of class nb_drawLine
- **varargin** : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_drawLine with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_drawPatch

Go to: [Properties](#) | [Methods](#)

nb_lineAnnotation, nb_movableAnnotation, nb_annotation, handle

Description:

A class for adding a arbitrary patch to a plot using the rectangle handle class.

Constructor:

```
obj = nb_drawPatch(varargin)
```

Input:

Optional input ('propertyName', PropertyValue) :

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_drawPatch

Examples:

See also:

[nb_annotation](#), [handle](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- children
- clipping
- copyOption
- curvature
- deleteOption
- edgeColor
- faceColor
- lineStyle
- lineWidth
- listeners
- parent
- pointer
- position
- selected
- side
- units

- **children** ↑

The children of the handle.

Inherited from superclass NB_ANNOTATION

- **clipping** ↑

'on' or 'off'. Clipping to axes rectangle. When Clipping is on, MATLAB does not display any portion of the patch outside the axes rectangle.

- **copyOption** ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass NB_ANNOTATION

- **curvature** ↑

one- or two-element vector [x,y]. Default is [0,0]

Amount of horizontal and vertical curvature. Specifies the curvature of the rectangle sides, which enables the shape of the rectangle to vary from rectangular to ellipsoidal. The horizontal curvature x is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature y is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of x and y can range from 0 (no curvature) to 1 (maximum curvature). A value of [0,0] creates a rectangle with square sides. A value of [1,1] creates an ellipse. If you specify only one value for Curvature, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass NB_ANNOTATION

- **edgeColor** ↑

The color of the edge of the rectangle. In RGB colors | 'none' : No edgeLine | 'same' : Same color as the face color | a string with the color name.

- **faceColor** ↑

The RGB color of the face of the rectangle.

Must be a 1 x 3 double with the RGB colors or a string with the color name. See the method interpretColor of the nb_plotHandle class for more on the supported color names.

- **lineStyle** ↑

The line style of the edge of the patch.

- **lineWidth** ↑

The line width of the edge of the patch.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **position** ↑

The position of the MATLAB rectangle object.

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **units** ↑

The coordinates system to plot in. Either {'data'} :
xy-coordinates | 'normalized' : figure coordinates.

Methods:

- **set**

► **set** ↑

`set(obj,varargin)`

Description:

Sets the properties of an object of class nb_drawLine. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_drawLine
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_drawLine with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_fanChart

Go to: [Properties](#) | [Methods](#)

```
obj = nb_fanChart(xData,yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for plotting fan chart.

Constructor:

```
nb_fanChart(yData)
nb_fanChart(xData,yData)
nb_fanChart(xData,yData,'PropertyName',PropertyValue,...)
handle = nb_fanChart(xData,yData,'PropertyName',...
                      PropertyValue,...)
```

Input:

- xData : The xData of the plotted data. Must be of size; size(yData,1) x 1 or 1 x size(yData,1)

```
- yData      : The yData of the plot. The columns are counted  
               as different simulations. And on the basis of this  
               data the confidence intervals are calculated.
```

```
- varargin : ...,'propertyName',PropertyValue,...
```

Output

```
- obj       : An object of class nb_fanChart
```

Examples:

```
obj = nb_fanChart(rand(2,100)); % Provide only y-axis data  
obj = nb_fanChart([1,2],rand(2,100));  
obj = nb_fanChart(rand(2,100),'propertyName',PropertyValue,...)  
obj = nb_fanChart([1,2],rand(2,100),'propertyName',...  
                  PropertyValue,...)
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- alpha
- cData
- central
- children
- deleteOption
- legendInfo
- lineWidth
- method
- parent
- percentiles
- side
- visible
- xData
- yData

- **alpha** ↑

Transparency of fan chart. A double between 0 and 1. 0 fully transparent, 1 opaque.

- **cData** ↑

Either double with the RGB color specification for each percentile, or a string with the color specification to use ({'nb'} | 'red' | 'green' | 'yellow' | '')

- **central** ↑

An nb_line object with the mean, if you set this as a string the mean will not be plotted

- **children** ↑

The children of the plot, as MATLAB patch handles.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be deleted and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **legendInfo** ↑

{'off'} : The mean line will not be included in the legend. 'on' : included it in the legend

- **lineWidth** ↑

The line width of center of the fan. See also property center.

- **method** ↑

{'percentiles'} | 'hdi'; Which type of fan chart is going to be made. 'percentiles' are produced by using percentiles, while 'hdi' use highest density intervals

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **percentiles** ↑

The percentiles as 1 x numberOfPercentiles double. E.g:
[.3,.5,.7,.9] (Which is default)

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **visible** ↑

Set the visibility of the fan chart.

- **xData** ↑

The x-axis data. Should be a vector.

- **yData** ↑

Each column of the yData property is counted as one simulation. And on the basis of this data the confidence intervals are calculated.

If this input has more than one page, it will count each page as a seperate variable, and each variable will get its own fan around the central tendency. In this case percentiles property must be set to a 1x1 double.

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefaultColors](#)
 - [interpretColor](#)
 - [set](#)
-

► [findClosestNiceNumber](#) ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► [findLimitsAlgo](#) ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow, dataHigh, method, fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:**See also:**

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► get ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_fanChart

Input:

- obj : An object of class nb_fanChart
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('central');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'
```

```
> 'grey','grÃ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÃ¥','hb'  
> 'deep blue','mÃ¸rk blÃ¥','db'  
> 'water blue','vannblÃ¥','vb'  
> 'cool grey','kald grÃ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_fanChart. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_fanChart
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_fanChart with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_fanLegend

Go to: [Properties](#) | [Methods](#)

```
obj = nb_fanLegend(parent,string,varargin)
```

Description:

This is a class for creating MPR looking legends for the fan charts

Constructor:

```
obj = nb_fanLegend(parent,string,varargin)
```

Input:

- parent : An object of class nb_axes. One of its children must be of class nb_fanChart.
- string : Sets the text over the colored boxes of the MPR looking fan legend, you must give them as a cellstr. Must match the number of percentiles of the graph created by the nb_fanChart object. E.g. {'30%','50%','70%','90%'}). If empty the percentiles of the underling nb_fanChart object will be used.
- varargin : Property name, property value combinations.

Output

- obj : An object of class nb_fanLegend

Examples:

```
fan = nb_fanChart([ones(20,100)*0.5;rand(10,100)],...  
'cData','grey');  
obj = nb_fanLegend(fan.parent,{})
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- | | | | | |
|------------|-------------|----------------|---------------|------------|
| • children | • colors | • deleteOption | • extent | • fontName |
| • fontSize | • fontUnits | • fontWeight | • interpreter | • location |
| • parent | • string | • visible | | |

- **children** ↑

The children of the fan legend. As MATLAB handles.

- **colors** ↑

Colors of the fan layers. As a M X 3 double with the RGB colors. Should not be set.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **extent** ↑

The extent of the fan legend. A 1x2 double with the lower left point.

- **fontName** ↑

The font name to use. As a string. 'arial' is default.

- **fontSize** ↑

The size of the font. As a scalar. Default is 14.

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the fontSize property.

normalized - Interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen fontSize accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

The weight of the font, {'bold'} | 'normal' | 'light'.

- **interpreter** ↑

{'none'} | 'tex' | 'latex'

- **location** ↑

Sets the location of the fan legend. Must be a string or a 1 x 2 double.

Different location supported:

- 'Best' : (same as 'North').)
- 'NorthWest'
- 'North'
- 'NorthEast'
- 'SouthEast'
- 'South'
- 'SouthWest'
- 'outside' : Places the legend outside the axes, one the right side. (If you create subplots, this is the only option which will look good.)

You can also give a 1 x 2 double vector with the location of where to place the legend. First column is the x-axis location and the second column is the y-axis location. Both must be between 0 and 1.

- **parent** ↑

The parent, as a nb_axes handle (object)

- **string** ↑

Text above the squared colorboxes of the legend. As a cellstr. Must match the number of percentiles of the underlying nb_fanChart object. E.g. {'30%', '50%', '70%', '90%'}). If empty the percentiles of the underling nb_fanChart object will be used.

- **visible** ↑

{'on'} | 'off'.

Methods:

- **get**
- **set**

► **get** ↑

```
propertyValue = get(obj, propertyName)
```

Description:

Get a property of an object of class nb_title

Input:

- obj : An object of class nb_title
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_fanLegend. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_fanLegend
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_fanLegend with the given properties reset

Examples:

```
obj.set('propertyName',propertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_figure

Go to: [Properties](#) | [Methods](#)

```
obj = nb_figure(varargin)
```

Superclasses:

handle

Description:

This is a object representing a MATLAB figure. This class extends the MATLAB figure class.

Through the figureHandle property you have all the MATALB functionalities, but you can also store nb_axes objects (not the MATLAB class axes), which again can store nb_bar, nb_pie, nb_radar, nb_plot, nb_area, nb_patch, nb_scatter and nb_plotComb objects.

This class makes it also possible to add a title for the whole figure which will be placed above all the children (axes including text objects). And it makes it possible to add a footer to the figure below all the children (axes including text objects) of the figure. Set the properties figureTitle and footer respectively.

These classes makes it more easy to create nice graphics.

Constructor:

```
obj = nb_figure(varargin)
```

Input:

- varargin : ..., 'propertyName', PropertyValue, ...

Output

- obj : An object of class nb_figure

Examples:

```
nb_figure  
obj = nb_figure()  
obj = nb_figure('propertyName', PropertyValue, ...)
```

See also:

[figure](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- children
- deleteOption
- figureHandle
- figureTitle
- footer
- userData

- **children** ↑

The children of the figure. Must be of class nb_axes.

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be deleted and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **figureHandle** ↑

A MATLAB figure handle.

- **figureTitle** ↑

The title of the figure. Placed above all the figure axes as an nb_figureTitle object.

- **footer** ↑

The footer placed below all the figure axes as an nb_footer object.

- **userData** ↑

User data

Methods:

- get
- getInnerExtent
- set

► **get** ↑

propertyValue = get(obj,propertyName)

Description:

Get a property of an object of class nb_figure

Input:

- obj : An object of class nb_figure
- propertyName : A string with the propertyName

Output:

- `propertyValue` : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **getInnerExtent** ↑

```
extent = getInnerExtent(obj,units)
```

Description:

Get inner extent of all children in a nb_figure object.

Written by Kenneth Sætherhagen Paulsen

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_figure. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- `obj` : An object of class nb_figure
- `varargin` : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- `obj` : The same object of class nb_figure with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_figureTitle

Go to: [Properties](#) | [Methods](#)

```
obj = nb_figureTitle(string,varargin)
```

Superclasses:

handle

Description:

This is a class for making figure title on an nb_figure object.
Placed above all elements of the figure

Constructor:

```
obj = nb_figureTitle(string,varargin)
```

Input:

- string : The figure title, as a string or a char with
the text. If it is a char, each row will be
added as a separate lines.

- varargin : ..., 'propertyName', PropertyValue, ...

Output

- obj : An object of class nb_figureTitle

Examples:

```
nb_figureTitle('A figure title')
ft = nb_figureTitle('A figure title')
ft = nb_figureTitle(char('A figure title','New line'))
ft = nb_figureTitle('A figure title','propertyName',...
    PropertyValue)
```

See also:

[text](#), [nb_footer](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- alignment
- children
- deleteOption
- extent
- fontName
- fontSize
- fontUnits
- fontWeight
- interpreter
- parent
- placement
- position
- string
- visible
- wrap

- [alignment](#) ↑

The figure title text alignment, default is 'left'. You also have 'center' and 'right'.

- **children** ↑

The children of the object. As MATLAB text object(s).

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **extent** ↑

The extent of the figure title object. Specifies a rectangle that locates in the units of the first child of the parent object. The vector is of the form: [left bottom width height], where left and bottom define the distance from the lower-left corner of the container to the lower-left corner of the rectangle. width and height are the dimensions of the rectangle. Allways in normalized units.

- **fontName** ↑

Font name used for the figure title. 'arial' default.

- **fontSize** ↑

Size of the text. Must be a scalar.

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' |
'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the fontSize property.

normalized - Interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen fontSize accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

The footer font weight, either 'bold', 'normal' or 'light'.

- **interpreter** ↑

Latex interpretation is default, set it to 'none' otherwise.

- **parent** ↑

The parent of the this plotting object. Must be a nb_figure object.

- **placement** ↑

Where to place the figure title in the x-axis direction, either 'center', 'right', 'leftaxes' or the default value 'left'.

- **position** ↑

A 1x2 double with the position of the figure title.

- **string** ↑

The figure title text, as a string or a char with the text. If it is a char, each row will be added as a separate line.

- **visible** ↑

Sets the visibility of the radar plot. {'on'} | 'off'

- **wrap** ↑

Wrap text of footer, i.e. make automatic line breaks.

Methods:

- [get](#)
- [set](#)

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_figureTitle

Input:

- obj : An object of class nb_figureTitle
- propertyName : A string with the propertyName

Output:

- `propertyValue` : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► set ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class `nb_figureTitle`. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- `obj` : An object of class `nb_figureTitle`
- `varargin` : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- `obj` : The same object of class `nb_figureTitle` with the given properties reset

Examples:

```
obj.set('propertyName',propertyValue,...);
```

Written by Kenneth SÃ¶terhagen Paulsen

■ nb_footer

Go to: [Properties](#) | [Methods](#)

```
obj = nb_footer(string,varargin)
```

Superclasses:

handle

Description:

This is a class for making footers on an nb_figure object. Placed below all elements of the figure

Constructor:

```
obj = nb_footer(string,varargin)

% Input:
- string : The text of the footer, as a string or a char.
    If it is a char, each row will be added as
    a separate lines.

- varargin : ..., 'propertyName', 'PropertyValue', ...
```

Output

```
- obj : An object of class nb_footer
```

Examples:

```
nb_footer('A footer')
f = nb_footer('A footer')
f = nb_footer(char('A footer','New line'))
f = nb_footer('A footer','propertyName',...
    PropertyValue)
```

Written by Kenneth Sætherhagen Paulsen

Properties:

- alignment
- children
- deleteOption
- extent
- fontName
- fontSize
- fontUnits
- fontWeight
- interpreter
- parent
- placement
- position
- string
- visible
- wrap

- alignment ↑

The footer alignment, default is 'left'. You also have 'center' and 'right'.

- children ↑

The children of the object. As MATLAB text object(s).

- deleteOption ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- extent ↑

The extent of the figure title object. Specifies a rectangle that locates in the units of the first child of the parent object. The vector is of the form: [left bottom width height], where left and bottom define the distance from the lower-left corner of the container to the lower-left corner of the rectangle. width and height are the dimensions of the rectangle. Allways in normalized units.

- **fontName** [↑](#)

Font name used for the footer. 'arial' is default.

- **fontSize** [↑](#)

Size of the text. Must be a scalar.

- **fontUnits** [↑](#)

{'points'} | 'normalized' | 'inches' |
'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the fontSize property.

normalized - Interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen fontSize accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

- **fontWeight** [↑](#)

The footer font weight, either 'bold', 'normal' or 'light'.

- **interpreter** [↑](#)

Latex interpretation is default, set it to 'none' otherwise.

- **parent** [↑](#)

The parent of the plotting object. Must be a nb_figure object.

- **placement** [↑](#)

Where to place the footer in the x-axis direction, either 'center', 'right', 'leftaxes' or the default value 'left'.

- **position** [↑](#)

A 1x2 double with the position of the figure title.

- **string** ↑

The footer text, as a string or a char with the text. If it is a char, each row will be added as a separate lines.

- **visible** ↑

Sets the visibility of the radar plot. {'on'} | 'off'.

- **wrap** ↑

Wrap text of footer, i.e. make automatic line breaks.

Methods:

- **get**
 - **set**
-

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_footer

Input:

- **obj** : An object of class nb_footer
- **propertyName** : A string with the propertyName

Output:

- **propertyValue** : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_footer. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_footer
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_footer with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_gradedFanChart

Go to: [Properties](#) | [Methods](#)

```
obj = nb_gradedFanChart(xData,yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for plotting a graded fan chart.

Caution: Use the nb_colormap or the nb_axes.colorMap property to set colors of the fan. If the colormap specifies too few colors they are used to construct an interpolated colormap.

Constructor:

```
nb_gradedFanChart(yData)
nb_gradedFanChart(xData,yData)
nb_gradedFanChart(xData,yData,'propertyName',PropertyValue,...)
handle = nb_gradedFanChart(xData,yData,'propertyName',...
                           PropertyValue,...)
```

Input:

```

- xData      : The xData of the plotted data. Must be of size;
               size(yData,1) x 1 or 1 x size(yData,1)

- yData      : The yData of the plot. The columns are counted
               as different simulations. And on the basis of this
               data the confidence intervals are calculated.

- varargin : ...,'propertyName',PropertyValue,...
```

Output

```
- obj       : An object of class nb_gradedFanChart
```

Examples:

```

obj = nb_gradedFanChart(rand(2,100)); % Provide only y-axis data
obj = nb_gradedFanChart([1,2],rand(2,100));
obj = nb_gradedFanChart(rand(2,100),'propertyName',PropertyValue,...)
obj = nb_gradedFanChart([1,2],rand(2,100),'propertyName',...
                           PropertyValue,...)
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- alpha
- central
- children
- deleteOption
- legendInfo
- lineWidth
- method
- parent
- side
- style
- visible
- xData
- yData

- **alpha** ↑

Transparency of fan chart. A double between 0 and 1. 0 fully transparent, 1 opaque.

- **central** ↑

An nb_line object with the mean, if you set this as a string the mean will not be plotted

- **children** ↑

The children of the plot, as MATLAB patch handles.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **legendInfo** ↑

{'off'} : The mean line will not be included in the legend. 'on' : included it in the legend

- **lineWidth** ↑

The line width of center of the fan. See also property center.

- **method** ↑

If the the data is all in level use 'level', if one is in level and the rest is in diff to the first column use 'diff'. When set to 'level' the data is sorted and transformed to the format needed when set to 'diff'.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **style** ↑

Either 'patch' and 'line'.

- **visible** ↑

Set the visibility of the fan chart.

- **xData** ↑

The x-axis data. Should be a nObs x 1 vector.

- **yData** ↑

Each column of the yData property is counted as one simulation. As a nObs x nSim.

Caution : If this property is set to nObs x 2 double, it will take the data as the upper and lower limit of the graded fan, and the size of the color map (see nb_axes.colorMap) will decide the number points used for the graded fan chart.

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefaultColors](#)
 - [interpretColor](#)
 - [set](#)
-

► [findClosestNiceNumber](#) ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when `findAxisMethod == 3` is used.

Input:

- `number` : The given number to find a "nice" number close to.
- `scaleNumber` : The scale factor used. I.e. the precision of the algorithm.
- `up` : 1 if rounding up, 0 if rounding down.

Output:

- `niceNumber` : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► [findLimitsAlgo](#) ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow, dataHigh, method, fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:**See also:**

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► get ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_fanChart

Input:

- obj : An object of class nb_fanChart
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('central');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'
```

```
> 'grey','grÃ¥','gr'
> 'purple','lilla','p'
> 'yellow','gul','y'
> 'magenta','m'
> 'white','hvit','w'
> 'cyan','c'
> 'burgundy','burgunder'
> 'sky blue','himmelblÃ¥','hb'
> 'deep blue','mÃ¸rk blÃ¥','db'
> 'water blue','vannblÃ¥','vb'
> 'cool grey','kald grÃ¥','cgr'
> 'sand','s'
> 'pink','rosa','pi'
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_fanChart. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_fanChart
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_fanChart with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_graphPanel

Go to: [Properties](#) | [Methods](#)

```
obj = nb_graphPanel(varargin)
```

Superclasses:

handle

Description:

This is class for creating a graph panel, which will have a resize behavioral to keep the font size fixed proportion to the axes (as nb_axes object) of the panel.

Caution : The panel will be centralized in the figure!

Constructor:

```
obj = nb_graphPanel(aspectRatio varargin)
```

Input:

- aspectRatio : Sets the aspect ratio of the graph panel.
Must be a scalar. Give [], if you want to use the default.
- varargin : ..., 'propertyName', PropertyValue, ...

Output

- obj : An object of class nb_graphPanel

Examples:

```
nb_graphPanel  
obj = nb_graphPanel(aspectRatio)  
obj = nb_graphPanel(aspectRatio,...  
'propertyName', PropertyValue,...)
```

See also:

[nb_figure](#), [nb_axes](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- advanced
- aspectRatio
- children
- deleteOption
- figureHandle
- figureTitle
- footer
- panelHandle
- userData

- **advanced** ↑

Indicate if advanced figure is made.

- **aspectRatio** [↑](#)

Sets the aspect ratio of the graph panel. Default is '[4,3]'

- **children** [↑](#)

The children of the figure. Must be of class nb_axes.

Inherited from superclass NB FIGURE

- **deleteOption** [↑](#)

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

Inherited from superclass NB FIGURE

- **figureHandle** [↑](#)

A MATLAB figure handle.

Inherited from superclass NB FIGURE

- **figureTitle** [↑](#)

The title of the figure. Placed above all the figure axes as an nb_figureTitle object.

Inherited from superclass NB FIGURE

- **footer** [↑](#)

The footer placed below all the figure axes as an nb_footer object.

Inherited from superclass NB FIGURE

- **panelHandle** [↑](#)

Handle to the uipanel object of the nb_graphPanel object.

- **userData** [↑](#)

User data

Inherited from superclass NB FIGURE

Methods:

- [get](#)
- [getInnerExtent](#)
- [set](#)

► **get** [↑](#)

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_figure

Input:

- obj : An object of class nb_figure
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **getInnerExtent** ↑

```
extent = getInnerExtent(obj,units)
```

Description:

Get inner extent of all children in a nb_figure object.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB FIGURE

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_figure. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_figure
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_figure with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_hbar

Go to: [Properties](#) | [Methods](#)

```
obj = nb_hbar(xData,yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for making bar plots with or without shaded bars.

```
nb_hbar(yData)
nb_hbar(xData,yData)
nb_hbar(xData,yData,'PropertyName',PropertyValue,...)
handle = nb_hbar(xData,yData,'PropertyName',PropertyValue,...)
```

The handle have set and get methods as all MATLAB graph handles.

Caution: All the children of this object is of class nb_patch

Constructor:

```
obj = nb_hbar(xData,yData,varargin)
```

Input:

- xData : The xData of the plotted data. Must be of size; size(yData,1) x 1 or 1 x size(yData,1)
- yData : The yData of the plot. The columns are counted as seperate variables
- varargin : ..., 'PropertyName', PropertyValue, ...

Output

- obj : An object of class nb_hbar

Examples:

```
obj = nb_hbar([1,2]); % Provide only y-axis data  
obj = nb_hbar([1,2],[1,2]);  
obj = nb_hbar([1,2],'propertyName',PropertyValue,...)  
obj = nb_hbar([1,2],[1,2],'propertyName',PropertyValue,...)
```

- xData
- yData

- **alpha1** ↑

Sets the alpha blending parameter nr 1 when blend is set to true.

- **alpha2** ↑

Sets the alpha blending parameter nr 1 when blend is set to true.

- **barWidth** ↑

Width of the bars. Must be a scalar.

- **baseValue** ↑

The base value of the plot. Must be a scalar.

- **baseline** ↑

A nb_horizontalLine handle (object). Use the set and get methods of this handle to change the baseline properties

- **blend** ↑

When shaded is used, and this option is set to true, it will do alpha blending with shadeColor instead of shading.

- **cData** ↑

Color of the plotted data. A matrix;
size(yData,2) x 3 (RGB color). Or a cellstr
with the color names. (With size 1 x size(yData,2))

- **children** ↑

All the handles of the bar plot.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be
delete and all that is plotted by this object are removed
from the figure it is plotted on. If on the other hand
'only' is given, it will just delete the object.

- **direction** ↑

The direction of the shading; {'north'} | 'south' |
'east' | 'west'.

- **edgeColor** ↑

The color of the edge of the bars. In RGB colors
or a string with the color names. Can also be
'none' ; no edgeLine or 'same' ; same color as
the base color for each bar. Can also be a
cellstr with either the RGB colors or color
names with size 1 x size(yData,2).

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in
the legend.

- **line** ↑

A nb_line handle representing the sum of the stacked bars
when 'style' is set to 'dec'.

- **lineStyle** ↑

Sets the line style(s) of the edge of the bars.
Either a string or a cellstr (which must have
the size 1 x size(yData,2)).

- **lineWidth** ↑

The line width of the edge of the bars. Must be a scalar.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **scale** ↑

Sets the tightness of the bars plotted. (Stacked)

- **shadeColor** ↑

The color (RGB) the shaded bar plots are interpolated with. Default is white

- **shaded** ↑

Index of which data should be shaded. A matrix with size; size(yData,1) x 1 or 1 x size(yData,1) or size(yData,1) x size(yData,2)

- **side** ↑

From which sides the horizontal bar should start. 'left' or 'right'

- **style** ↑

'stacked' | {'grouped'} | 'dec'. When 'dec' is given the bars will be stacked but there will also be plotted a line with the sum. (It is not possible to use the sumTo option at the same time)

- **sumTo** ↑

If given the sum of the bars for each period will sum up to this number. (only when style is set to 'stacked')
E.g. if set 100, each bar for each variable will be given as percentage share of the total sum.

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'.

- **xData** ↑

The xData of the plotted data. Must be of size; size(yData,1) x 1 or 1 x size(yData,1)

- **yData** ↑

The yData of the plot. The columns are counted as seperate variables.

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefaultColors](#)
 - [interpretColor](#)
 - [set](#)
-

► [findClosestNiceNumber](#) ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when `findAxisMethod == 3` is used.

Input:

- `number` : The given number to find a "nice" number close to.
- `scaleNumber` : The scale factor used. I.e. the precision of the algorithm.
- `up` : 1 if rounding up, 0 if rounding down.

Output:

- `niceNumber` : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► [findLimitsAlgo](#) ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow, dataHigh, method, fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:**See also:**

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► get ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_bar

Input:

- obj : An object of class nb_bar
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nr','g'  
> 'orange','o'  
> 'light blue','lys blÅ','lb'  
> 'black','svart','k'
```

```
> 'grey','grÃ¥','gr'
> 'purple','lilla','p'
> 'yellow','gul','y'
> 'magenta','m'
> 'white','hvit','w'
> 'cyan','c'
> 'burgundy','burgunder'
> 'sky blue','himmelblÃ¥','hb'
> 'deep blue','mÃ¸rk blÃ¥','db'
> 'water blue','vannblÃ¥','vb'
> 'cool grey','kald grÃ¥','cgr'
> 'sand','s'
> 'pink','rosa','pi'
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_bar. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_bar
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_bar with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_highlight

Go to: [Properties](#) | [Methods](#)

```
obj = nb_highlight(xData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

A class for making highlighted colored areas in the background of a plot

The parent of this axes must be a nb_axes handle.

This colored background will automatically adjust to changes in the y-axis limits.

Constructor:

```
obj = nb_highlight(xData,varargin)
```

Input:

- xData : A 1 x 2 double with the x-axis limits of the highlighted area.

Optional input:

- varargin : ..., 'propertyName', PropertyValue, ...

Output

- obj : An object of class nb_highlight

Examples:

```
nb_highlight(xData)
```

```
nb_highlight(xData,'propertyName',PropertyValue,...)
```

```
handle = nb_highlight(xData,'propertyName',PropertyValue,...)
```

See also:

[nb_patch](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- cData • children • deleteOption • legendInfo • parent
- visible • xData

- cData ↑

Must be a 1 x 3 double with the RGB colors or a string with the color name. See the method interpretColor of the nb_plotHandle class for more on the supported color names.

- children ↑

The child of this handle. As a nb_patch handle.

- deleteOption ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- legendInfo ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- parent ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- visible ↑

Sets the visibility of the radar plot. {'on'} | 'off'.

- xData ↑

A 1 x 2 double with the x-axis limits of the highlighted area, or a logical vector with size N x 1. In the case xData is given as a logical vector it will highlight the periods where the elements are true.

Methods:

- findClosestNiceNumber • findLimitsAlgo • get • getDefaultColors
- interpretColor • set

► findClosestNiceNumber ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem

```
    when graphing small number)
> 2: Add some space in both direction of the
y-axis. (The limits will seldom be nice
numbers.)
> 3: Uses the submethod findClosestNiceNumber of
the class to decide on the limits. (Also this
method have can have problems with data which
is not symmetric around the zero line.)
> 4 : Uses the MATLAB algorithm for finding the
axis limits.
```

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_highlight

Input:

- obj : An object of class nb_highlight
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'
```

```
> 'water blue','vannblÅ¥','vb'
> 'cool grey','kald grÅ¥','cgr'
> 'sand','s'
> 'pink','rosa','pi'
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_highlight. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_highlight
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_highlight with the given properties reset

Examples:

```
obj.set('propertyName',propertyValue,...);
```

Written by Kenneth SÃ¶terhagen Paulsen

■ **nb_horizontalLine**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_horizontalLine(yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for making horizontal lines which spans all of the x-axis.

If the parent is a nb_axes object:

- The line will automatically update the length of the line, so it spans all the x-axis.

If the parent is a MATLAB axes handle (object):

- The line will not update itself automatically and you need to use the update() method of the object to make it fit to the axes handle (If it is changed)

Constructor:

```
obj = nb_horizontalLine(yData,varargin)
```

Input:

- yData : The y-axis value to place the horizontal line
- varargin : ..., 'propertyName',PropertyValue, ...

Output

- obj : an object of class nb_horizontalLine

Examples:

```
nb_horizontalLine(yData)
obj = nb_horizontalLine(yData)
obj = nb_horizontalLine(yData,'propertyName',...
                           PropertyValue,...)
```

See also:

[nb_line](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- cData
- children
- deleteOption
- legendInfo
- lineStyle
- lineWidth
- marker
- markerEdgeColor
- markerFaceColor
- markerSize
- parent
- side
- visible
- yData

- **cData** ↑

The color data of the line plotted. Must be of size; 1 x 3 with the RGB colors or a string with the color name.

- **children** ↑

The children of this object. As an nb_line object.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- **lineStyle** ↑

The line style of the plotted data. Either a string or a cell array with size as the number of lines to be plotted. {'-' } | '--' | '---' | ':' | '-' | 'none'

- **lineWidth** ↑

The line width of the plotted data. Must be a scalar.
Default is 1.

- **marker** ↑

The markers of the lines. Either a string or a cell array with size as the number of lines to be plotted. See marker property of the MATLAB line function for more on the options of this property

- **markerEdgeColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **markerFaceColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **markerSize** ↑

Size of the markers. Must be a integer. Default is 9.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'.

- **yData** ↑

A scalar with the y-axis value for where to place the horizontal line.

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefauleColors](#)
 - [interpretColor](#)

-

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number,...  
                                                scaleNumber,up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- **number** : The given number to find a "nice" number close to.
- **scaleNumber** : The scal factor used. I.e. the precision of the algorithm.
- **up** : 1 if rounding up, 0 if rounding down.

Output:

- **niceNumber** : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_horizontalLine

Input:

- obj : An object of class nb_horizontalLine
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvít','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÅ!terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_horizontalLine. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_horizontalLine
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_horizontalLine with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_image

Go to: [Properties](#) | [Methods](#)

```
obj = nb_image(cData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for plotting images.

The handle have set and get methods as all MATLAB graph handles.

Constructor:

```
obj = nb_image(cData,'propertyName',PropertyValue,...)
```

Input:

- cData : The data of the image. Must be a double of size M x N (mapped into the colormap) or M x N x 3 (RGB).

In the case that the parent is of class nb_axes the current colormap can be set by nb_colormap, otherwise use colormap.

```
- varargin : ...,'propertyName',PropertyValue,...
```

Output:

```
- obj : An object of class nb_image
```

Examples:

```
nb_image(rand(5,5));  
obj = nb_image(rand(5,5,3)*255);
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- appendWhite
- cData
- children
- deleteOption
- legendInfo
- parent
- side
- visible

- **appendWhite** ↑

When true, white is added to the colormap property before interpreting the cData. Default is true.

- **cData** ↑

The data of the image. Must be a double of size M x N (mapped into the colormap) or M x N x 3 (RGB).

In the case that the parent is of class nb_axes the current colormap can be set by nb_colormap

- **children** ↑

All the handles of the area plot, as nb_patch objects

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes (Which is the default).

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefaultColors](#)
 - [interpretColor](#)
 - [set](#)
-

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- **number** : The given number to find a "nice" number close to.
- **scaleNumber** : The scale factor used. I.e. the precision of the algorithm.
- **up** : 1 if rounding up, 0 if rounding down.

Output:

- **niceNumber** : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get ↑**

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_area

Input:

- obj : An object of class nb_area
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÅ;terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

set(obj,varargin)

Description:

Sets the properties of an object of class nb_area. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_area
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_area with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_keyEvent

Go to: [Properties](#) | [Methods](#)

The data that get sent when the nb_figure events keyPressed and keyReleased are triggered.

Superclasses:

event.EventData

See also:

[nb_figure](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- Character • EventName • Key • Modifier • Source

- [Character ↑](#)

nb_keyEvent/Character is a property.

- [EventName ↑](#)

event.EventData.EventName – Name of event

```
Documentation for event.EventData.EventName
doc event.EventData.EventName
```

- [Key ↑](#)

nb_keyEvent/Key is a property.

- **Modifier** ↑

nb_keyEvent/Modifier is a property.

- **Source** ↑

event.EventData.Source - Event source

Documentation for event.EventData.Source
doc event.EventData.Source

Methods:

■ **nb_legend**

Go to: [Properties](#) | [Methods](#)

obj = nb_legend(parent, legends, varargin)

Superclasses:

handle, nb_annotation, nb_movableAnnotation

Description:

This is a class for making legend of plots

I strongly recommend to use this class instead of the MATLAB legend command if you use the nb_* plot functions.

Caution : - When the type property of this class is set to 'matlab', the lineStyle '---', will be given as '-'.

- When the 'type' property of this class is set to 'nb' it is not possible to move the legend by click and drag, as the normal MATLAB legend.
- If you create more legends of a plot the first legends will not longer be moveable. (Even if the type property is set to 'MATLAB')

Constructor:

obj = nb_legend(parent, legends, varargin)

Input:

- parent : A nb_axes handle
- legends : A cellstr of the legends of the plot. Say you do not want to plot the legend of a plotted

variable you can type '' at its location in the cellstr, and it will not be shown in the legend.

- varargin : ...,'propertyName',PropertyValue,...

Output:

- obj : An object of class nb_legend (handle)

Examples:

```
nb_legend(ax,legends)
nb_legend(ax,legend,'propertyName',PropertyValue,...)
leg = nb_legend(ax,legend,'propertyName',PropertyValue,...)
```

See also:

[legend](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- | | | | | |
|----------------------------------|--------------------------------|-----------------------------|-------------------------------|------------------------------|
| • box | • children | • color | • columnWidth | • columns |
| • copyOption | • deleteOption | • extent | • fakeLegends | • fast |
| • fontColor | • fontName | • fontSize | • fontUnits | • fontWeight |
| • interpreter | • legends | • listeners | • location | • normalized |
| • objectToNotify | • parent | • pointer | • position | • reorder |
| • selected | • space | • visible | | |

- **box** ↑

If you want a box around the legend or not. 'on' | 'off'.
'on' is default. If you set it to 'off' the movability
of the legend is destroyed

- **children** ↑

The children of the handle.

Inherited from superclass NB_ANNOTATION

- **color** ↑

Background color. Either a string with the color name or
a 1x3 double with the RGB colors. Default is 'none'.

- **columnWidth** ↑

Sets the column width of the legend (Only when dealing
with more than one column). If empty they are try to
adjust to the text.

- **columns** ↑

Number of columns of the legend.

- **copyOption** ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass NB_ANNOTATION

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass NB_ANNOTATION

- **extent** ↑

position rectangle (read-only)

Position and size of the legend. A four-element vector that defines the size and position of the legend:

[left,bottom,width,height]

left and bottom are the x- and y-coordinates of the lower left corner of the text extent. The units are normalized.

- **fakeLegends** ↑

Fake legends added to the legend. Must be given as nb_legendDetails vector with size 1xM.

- **fast** ↑

Indicator if fast legend is tried to be used. If true moving the legend is not possible.

- **fontColor** ↑

Sets the font color(s) of the legend text. Must either be a 1x3 double or a string with the color name of all legend text objects, or a M x 3 double or a cellstr array with size 1 x M with color names to use of each legend text object.

- **fontName** ↑

The font name used for the text of the legend. As a string.

- **fontSize** ↑

Font size of the text in the legend. As a scalar.

- **fontUnits** ↑

```
{'points'} | 'normalized' | 'inches' |  
'centimeters' | 'pixels'
```

Font size units. MATLAB uses this property to determine the units used by the `fontSize` property.

`normalized` - Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `fontSize` accordingly.

`pixels`, `inches`, `centimeters`, and `points`:
Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

Font weight of the text in the legend. As a string.

- **interpreter** ↑

```
{'none'} | 'tex' | 'latex' . See the text properties for  
more.
```

- **legends** ↑

The legends of the plot. Given as a cellstr. Say you don't want to plot the legend of a plotted variable you can type '' at its location in the cellstr, and it will not be shown in the legend.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass `NB_ANNOTATION`

- **location** ↑

The location of the legend; '`west`' | {'`northwest`'} | '`north`' | '`northeast`' | '`east`' | '`southeast`' | '`south`' | '`southwest`' | '`center`' | '`below`' | '`middle`' | '`outsideright`' | '`outsiderighttop`'. When adding a legend to a `nb_pie` plot the '`pie`' option could also be used.

- **normalized** ↑

Indicate if the font when `fontUnits` is set to '`normalized`' should be normalized to the axes ('`axes`') or to the figure ('`figure`'), i.e. the default axes position [0.1 0.1 0.8 0.8].

- **objectToNotify** ↑

Set the object to notify. Must contain the property legPosition. Default is []. Deprecated property!

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object.
When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **position** ↑

Set the position of the legend 1x2 double. I.e;
[xLeftPosition,yLowerPosition]. Only an option when the
type property is set to 'nb'.

- **reorder** ↑

Set this property to reorder the legend. Either
a string with {'default'} | 'inverse' or a
double with how to reorder the legend. E.g. if
you have 3 legends to plot the default index
will be [1,2,3], the inverse ('inv') will be
[3,2,1]. If you want to decide that the 3.
legend should be first, then the 1. and 2., you
can type in [3,1,2].

Caution : If a double is given it must have as
many elements as there is plotted
legends. I.e. if you give an empty
string to one of the legends it will
be excluded. Say you provide the
property legends as {'s','','t','f'}
then the double must have size 1x3.

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **space** ↑

Vertical space between the text in the legend. Must be
scalar. Default is

- **visible** ↑

Sets the visibility of the legend. {'on'} | 'off'.

Methods:

- [get](#)
 - [set](#)
-

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_legend

Input:

- obj : An object of class nb_legend
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_legend. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_legend
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_legend with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_legendDetails

Go to: [Properties](#) | [Methods](#)

```
obj = nb_legendDetails()
```

Description:

This is a class for storing information of how the legend should look.

Constructor:

```
obj = nb_legendDetails()
```

Input:

No inputs.

Output:

- obj : An object of class nb_legendDetails

Examples:

See also:

[nb_legend](#)

nb_legendDetails side is a property.

- **type** ↑

nb_legendDetails/type is a property.

Methods:

■ **nb_line**

Go to: [Properties](#) | [Methods](#)

obj = nb_line(xData,yData,varargin)

Superclasses:

handle, nb_plotHandle

Description:

This is a class for plotting a line. (only 2D)

Extra functionalities:

- The line style '---' is supported.

Caution: Some functionalities of the MATLAB line command is not supported.

Important:

- z-dimension is not supported
- Only possible to plot one line at a time.

Constructor:

obj = nb_line(xData,yData,varargin)

Input:

- xData : The x-axis values of the plotted line. If only one input is given to this constructor it will be interpreted as the yData input. (Then the xData will be 1:size(yData,1)). Must be a double vector.

- yData : The y-axis values of the plotted line. Must be a double vector.

Optional input:

- varargin : ..., 'propertyName', PropertyValue, ...

Output:

- obj : An object of class nb_line

Examples:

```
nb_line([0,2]);
```

same as

```
nb_line([0,1],[0,2]);
```

```
nb_line([0,1],[0,2], 'propertyName', PropertyValue, ...);
```

e.g.

```
nb_line([0,1],[0,2], 'cData', {'red'}, 'lineWidth', 1.5);
```

Return the handle to the plotted line:

```
l = nb_line([0,1],[0,2], 'cData', {'red'}, 'lineWidth', 1.5);
```

Which you can use to set and get properties:

```
l.set('lineWidth', 1);
lw = l.get('lineWidth');
```

See also:

[line](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- [cData](#)
- [children](#)
- [clipping](#)
- [dashLength](#)
- [deleteOption](#)
- [gapLength](#)
- [legendInfo](#)
- [lineStyle](#)
- [lineWidth](#)

- [markerEdgeColor](#)
- [markerFaceColor](#)
- [markerSize](#)
- [parent](#)
- [side](#)
- [visible](#)
- [xData](#)
- [xLim](#)
- [yData](#)
- [yLim](#)

- **cData** ↑

The color data of the line plotted. Must be of size;
1 x 3. With the RGB colors. Or a string with the name
of the color. See the method `interpretColor` of the
nb_plotHandle class for more on the supported color
names.

- **children** ↑

The children of the handle. As line handle(s).

- **clipping** ↑

{'on'} | 'off' ; Clipping mode. MATLAB clips lines to the axes plot box by default. If you set Clipping to off, lines are displayed outside the axes plot box.

- **dashLength** ↑

Lenght of the dashes of the '---' lineStyle.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **gapLength** ↑

Lenght of the gaps of the '---' lineStyle

- **legendInfo** ↑

'off' : Not included in the legend. {'on'} : included in the legend

- **lineStyle** ↑

The line style of the plotted data. Either a string or a cell array with size as the number of lines to be plotted. {'-' } | '--' | '---' | ':' | '-.' | 'none'

- **lineWidth** ↑

The line width of the plotted data. Must be a scalar. Default is 2.5.

- **marker** ↑

The markers of the lines. Either a string or a cell array with size as the number of lines to be plotted. See marker property of the MATLAB line function for more on the options of this property

- **markerEdgeColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **markerFaceColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **markerSize** ↑

Size of the markers. Default is 9.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'.

- **xData** ↑

The x-axis data. As a double vector.

- **xLim** ↑

The x-axis limits as 1x2 double. Default is to use the axes limits (If they are smaller then the data limits, the data limits will be used instead). This property is only used for the line style '---'

- **yData** ↑

The y-axis data. As a double vector.

- **yLim** ↑

The y-axis limits as 1x2 double. Default is to use the axes limits (If they are smaller then the data limits, the data limits will be used instead). This property is only used for the line style '---'

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefaultColors](#)
 - [interpretColor](#)
 - [set](#)
-

► [findClosestNiceNumber](#) ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► [findLimitsAlgo](#) ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow, dataHigh, method, fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:**See also:**

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► get ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_line

Input:

- obj : An object of class nb_line
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nr','g'  
> 'orange','o'  
> 'light blue','lys blÅ','lb'  
> 'black','svart','k'
```

```
> 'grey','grÃ¥','gr'
> 'purple','lilla','p'
> 'yellow','gul','y'
> 'magenta','m'
> 'white','hvit','w'
> 'cyan','c'
> 'burgundy','burgunder'
> 'sky blue','himmelblÃ¥','hb'
> 'deep blue','mÃ¸rk blÃ¥','db'
> 'water blue','vannblÃ¥','vb'
> 'cool grey','kald grÃ¥','cgr'
> 'sand','s'
> 'pink','rosa','pi'
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_line. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_line
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_line with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_mouseOverObjectEvent

Go to: [Properties](#) | [Methods](#)

The data that get sent when a mouseOverObject event is triggered by an object of class nb_notifiesMouseOverObject.

Superclasses:

```
event.EventData
```

See also:

[nb_notifiesMouseOverObject](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- [EventName](#)
- [Source](#)
- [currentPoint](#)
- [h](#)
- [value](#)
- [x](#)
- [y](#)

- [EventName ↑](#)

```
event.EventData.EventName - Name of event

doc `event.EventData.EventName`

- [Source ↑](#)

```
event.EventData.Source - Event source
```

Documentation for `event.EventData.Source`
doc `event.EventData.Source`

- [currentPoint ↑](#)

Current point in axes data units. As a 1x2 double.

- [h ↑](#)

The children index, as an integer

- **value ↑**

The value of the data point the mouse is over. As a scalar double

- **x ↑**

The x-data index, as an integer.

- **y ↑**

The y-data index, as an integer.

Methods:

■ **nb_patch**

Go to: [Properties](#) | [Methods](#)

obj = nb_patch(xData,yData,cData,varargin)

Superclasses:

handle, nb_plotHandle

Description:

This is a class for making patches.

This class makes shaded patches which doesn't return a warning when printed by the export_fig function developed by Oliver Woodford

Caution :

- Not all functionalities of the patch class is supported by this class.
- The transparency options is not supported by the export_fig function when the renderer is set to 'painters' (Which is default for .eps and .pdf files). Use 'openGL'.
- The lighting options is only supported by the renderer 'openGL'
- This class does not support zData.
- Only rectangular patches will be shaded correctly at the moment

Constructor:

```
obj = nb_patch(xData,yData,cData,varargin)
```

Input:

- xData : The x-axis values of the plotted patch. If only one input is given to this constructor it will be interpreted as the yData input. (Then the xData will be 1:size(yData,1)). Must be a double vector.
- yData : The yData of the plot. Must be a double vector.
- cData : The RGB color of the patch, if it has two values the color will be interpolated. The first RGB values will at the bottom of the patch.
Must be a 1 x 3 double (or 2 x 3 double vector when using shading) with the RGB colors or a cellstr with the color names. See the method interpretColor of the nb_plotHandle class for more on the supported color names.

If not provided the color 'black' is used.

Optional input:

- varargin : ..., 'propertyName', PropertyValue, ...

Output

- obj : An object of class nb_patch

Examples:

```
nb_patch(yData)
nb_patch(xData,yData)
nb_patch(xData,yData,cData)
nb_patch(xData,yData,cData,'propertyName',PropertyValue,...)
handle = nb_patch(xData,yData,cData,'propertyName',...
                  PropertyValue,...)
```

See also:

[patch](#), [surface](#), [fill](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- cData
 - children
 - clipping
 - deleteOption
 - direction
 - edgeColor
 - faceAlpha
 - faceLighting
 - legendInfo
 - lineWidth
 - parent
 - side
 - visible
 - xData
 - yData
- **cData** ↑

The RGB color of the patch, if it has two values the color will be interpolated. The first RGB values will at the bottom of the patch.

Must be a 1 x 3 double (or 2 x 3 double vector when using shading) with the RGB colors or a string with the color name. See the method `interpretColor` of the `nb_plotHandle` class for more on the supported color names.

- **children** [↑](#)

All the children (patch and line handles) of the `nb_patch` object

- **clipping** [↑](#)

'on' or 'off'. Clipping to axes rectangle. When Clipping is on, MATLAB does not display any portion of the patch outside the axes rectangle.

- **deleteOption** [↑](#)

{'on'} | 'off' ; Clipping mode. MATLAB clips lines to the axes plot box by default. If you set Clipping to off, lines are displayed outside the axes plot box.

- **direction** [↑](#)

Direction of the shading; {'north'} | 'south' | 'west' | 'east'

- **edgeColor** [↑](#)

The color of the edge of the bars. In RGB colors | 'none' : No edgeLine | 'same' : Same color as the base color for each bar | a string with the color name.

- **faceAlpha** [↑](#)

Transparency of the patch face. Only the scalar option is supported. A single non-NaN value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible)

- **faceLighting** [↑](#)

See the patch properties for more on this option

- **legendInfo** [↑](#)

{'off'} : Not included in the legend. 'on' : included in the legend

- **lineStyle** ↑

The line style of the edge of the patch.

- **lineWidth** ↑

The line width of the edge of the patch.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **visible** ↑

Patch object visibility. 'on' : The patch is visible.
'off' : The patch is not visible, but still exists, and you can query and set its properties.

- **xData** ↑

The x values of the patch. Same as for the MATLAB patch class

- **yData** ↑

The y values of the patch. Same as for the MATLAB patch class

Methods :

- [findClosestNiceNumber](#)
- [findLimitsAlgo](#)
- [get](#)
- [getDefaultColors](#)
- [interpretColor](#)
- [set](#)

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of

the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
> 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

propertyValue = get(obj,propertyName)

Description:

Get a property of an object of class nb_patch

Input:

- obj : An object of class nb_patch
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

propertyValue = obj.get('children');

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

defaultColors = nb_plotHandle.getDefaultColors(dataSize)

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

colors = nb_plotHandle.interpretColor(colors)

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÃ,d','r'  
> 'green','grÃ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÃ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÃ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÃ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colormames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set** ↑

set(obj,varargin)

Description:

Sets the properties of an object of class nb_patch. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_patch
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_patch with the given properties reset

Examples:

obj.set('propertyName',PropertyValue,...);

Written by Kenneth Sæterhagen Paulsen

■ **nb_pie**

Go to: [Properties](#) | [Methods](#)

obj = nb_pie(yData,varargin)

Superclasses:

```
handle, nb_plotHandle
```

Description:

This is a class for making pie charts in 2D.

This class will make the pie chart automatically fit the axes of the plot.

I recommend to use the nb_* classes for the legend, titles and so on.

Constructor:

```
obj = nb_pie(yData,varargin)
```

Input:

- yData : The data to plot. min(size(yData)) must be 1.

Optional input:

- varargin : 'propertyName',PropertyValue,...

Output:

- obj : An object of class nb_pie (handle).

Examples:

```
nb_pie(yData)
nb_pie(yData,'propertyName',PropertyValue,...)
handle = nb_pie(yData,'propertyName',PropertyValue,...)
```

See also:

[pie](#), [pie3](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- axisVisible
- bite
- cData
- children
- deleteOption
- edgeColor
- explode
- fontColor
- fontName
- fontSize
- fontUnits
- fontWeight
- labelHandles
- labels
- labelsExtension
- legendInfo
- lineStyle
- lineWidth
- location
- noLabels
- origoPosition
- parent
- visible
- yData

- axisVisible ↑

Make the axes box visible ('on') or not ('off'). 'on' is default.

- **bite** ↑

A logical array with ones for the pies to bite. I.e. [0,0,1,0]; Must be of size 1 x nSlices.

- **cData** ↑

The colors of the plotted data. Must be of size nSlices x 3. (Double with the RGB colors), or a cellstr with the color names. Must be of size 1 x length(yData). See the method nb_plotHandle.interpretColor for more on the supported color names.

- **children** ↑

The handles of all the children of the plot.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **edgeColor** ↑

The color of the edge of the pies. Must be of size; 1 x 3. (Double with the RGB colors), or a one line char with the color name. See the method nb_plotHandle.interpretColor for more on the supported color names.

- **explode** ↑

A logical array with ones for the pies to explode. I.e. [0,0,1,0]; Must be of size 1 x nSlices.

- **fontColor** ↑

Color of labels. Must be double with size 1 x 3 (RGB colors), or a string with the name of the color. See the method nb_plotHandle.interpretColor for more on the supported color names.

- **fontName** ↑

Name of the font used. Default is 'arial'.

- **fontSize** ↑

Font size of the text on the plot. Default is 12.

- **fontUnits** ↑

```
{'points'} | 'normalized' | 'inches' |  
'centimeters' | 'pixels'
```

Font size units. MATLAB uses this property to determine the units used by the `fontSize` property.

`normalized` - Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `fontSize` accordingly.

`pixels`, `inches`, `centimeters`, and `points`: Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

Font weight of the text on the plot. Default is 'normal'.

- **labelHandles** ↑

Handles to the labels of the pie plot. As MATLAB text objects.

- **labels** ↑

The labels of the pies, must be a `cellstr` with `size`; `length(yData)`. If not given the labels will be the shares of each pie in percent.

- **labelsExtension** ↑

If you not give the labels you can set the extension of the labels. Default is '%'. The extension will be added to the value of the data. If '%' is given the data will be in relative shares in percent.

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend.

- **lineStyle** ↑

Line style of the edge.

- **lineWidth** ↑

Line width of the edge.

- **location** ↑

{'west'} | 'east' | 'center'. The location of the pie chart in the current axes.

- **noLabels** ↑

Force there to be no labels of the pies.

- **origoPosition** ↑

Set the origo position. Default is to use the location property. Where 'west' is [-0.5,0], 'center' is [0,0] and 'east' is [0.5,0]. Must either be empty or a 1x2 double.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'.

- **yData** ↑

The data to plot. Must be a double vector of size 1 x nSlices or nSlices x 1.

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...  
scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- **number** : The given number to find a "nice" number close to.
- **scaleNumber** : The scale factor used. I.e. the precision of the algorithm.
- **up** : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► findLimitsAlgo ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_pie

Input:

- obj : An object of class nb_pie
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvít','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_pie. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_pie
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_pie with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ **nb_plot**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_plot(xData,yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is A class for plotting data by lines (2D). Much the same as the MATLAB plot function, but with some extensions (and some limitation)

Extended functionalitites:

- New line style added '---'. Longer dashed of the dashed line
- Choose the linestyle of all the plotted lines. By a cell.
- Choose the linecolor of all the plotted lines directly to

the class, and not through the default options. By a mx3 double with the RGB colors of the m lines

- Makes it possible to set a nb_axes handle as parent (default). Which makes the plot nicer. It is also possible to add shaded background. See nb_axes for more.

Constructor:

```
nb_plot(yData)
nb_plot(xData,yData)
nb_plot(xData,yData,'propertyName',propertyValue,...)
handle = nb_plot(xData,yData,'propertyName',propertyValue,...)
```

Input:

- xData : The x-axis values of the plotted line. If only one input is given to this constructor it will be interpreted as the yData input. (Then the xData will be 1:size(yData,1))
- yData : The y-axis values of the plotted line. A double matrix. (1. dimension the number of observations and 2. dimension the number of variables.)

Optional input:

- varargin : 'propertyName',propertyValue,...

Output:

- obj : An object of class nb_plot

Examples:

```
nb_plot([0,2]);
```

same as

```
nb_plot([0,1],[0,2;2,3]);
```

```
nb_plot([0,1],[0,2],'propertyName',propertyValue,...);
```

e.g.

```
nb_plot([0,1],[0,2;2,3],'cData',{'red','green'},...
'lineWidth',1.5);
```

Return the handle to the plotted line:

```
l = nb_plot([0,1],[0,2;2,3],'cData',{'red','green'},...
'lineWidth',1.5);
```

Which you can use to set and get properties:

```
l.set('cData',{'black','red'});
lw = l.get('lineWidth');
```

See also:

plot

Written by Kenneth Sæterhagen Paulsen

Properties:

- `cData`
- `children`
- `clipping`
- `deleteOption`
- `legendInfo`
- `lineStyle`
- `lineWidth`
- `marker`
- `markerEdgeColor`
- `markerFaceColor`
- `markerSize`
- `parent`
- `side`
- `visible`
- `xData`
- `yData`

- `cData` ↑

The color data of the line plotted. Must be of size; `size(yData,2) x 3`. With the RGB colors. or a cellstr with the color names. See the method `interpretColor` of the `nb_plotHandle` class for more on the supported color names.

- `children` ↑

The children of the handle. As `nb_line` handles

- `clipping` ↑

{'on'} | 'off' ; Clipping mode. MATLAB clips lines to the axes plot box by default. If you set Clipping to off, lines are displayed outside the axes plot box.

- `deleteOption` ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- `legendInfo` ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- `lineStyle` ↑

The line style of the plotted data. Either a string or a cell array with size as the number of lines to be plotted. {'-' } | '--' | '---' | ':' | '-' | 'none'

- `lineWidth` ↑

The line width of the plotted data. Must be a scalar.
Default is 2.5.

- **marker** ↑

The markers of the lines. Either a string or
a cell array with size as the number of lines
to be plotted. See marker property of the
MATLAB line function for more on the options
of this property

- **markerEdgeColor** ↑

A 1x3 double with the RGB colors | 'none' |
{'auto'} | a string with the color name.

- **markerFaceColor** ↑

A 1x3 double with the RGB colors | 'none' |
{'auto'} | a string with the color name.

- **markerSize** ↑

Size of the markers. Default is 9.

- **parent** ↑

The parent axes you wan to plot on, if not given it will
be plotted in a new nb_axes handle. Either a axes or a
nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the
parent is off class nb_axes. (Which is the default)

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'

- **xData** ↑

The x-axis data. As a double.

- **yData** ↑

The y-axis data. As a double.

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefaultColors](#)
 - [interpretColor](#)

► [findClosestNiceNumber](#) ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- `number` : The given number to find a "nice" number close to.
- `scaleNumber` : The scale factor used. I.e. the precision of the algorithm.
- `up` : 1 if rounding up, 0 if rounding down.

Output:

- `niceNumber` : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► [findLimitsAlgo](#) ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow, dataHigh, method, fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylim : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:**See also:**

Written by Kenneth SÅterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► get ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_plot

Input:

- obj : An object of class nb_plot
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'
```

```
> 'grey','grÃ¥','gr'
> 'purple','lilla','p'
> 'yellow','gul','y'
> 'magenta','m'
> 'white','hvit','w'
> 'cyan','c'
> 'burgundy','burgunder'
> 'sky blue','himmelblÃ¥','hb'
> 'deep blue','mÃ¸rk blÃ¥','db'
> 'water blue','vannblÃ¥','vb'
> 'cool grey','kald grÃ¥','cgr'
> 'sand','s'
> 'pink','rosa','pi'
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_plot. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_plot
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_plot with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_plotBarAtEnd

Go to: [Properties](#) | [Methods](#)

```
obj = nb_plotBarAtEnd(xData,yData,varargin)
```

Superclasses:

handle, nb_plotHandle, nb_plot

Description:

This is A class for plotting data by lines (2D), but then switch to bar plot at the end.

Constructor:

```
nb_plotBarAtEnd(yData)
nb_plotBarAtEnd(xData,yData)
nb_plotBarAtEnd(xData,yData,'PropertyName',PropertyValue,...)
h = nb_plotBarAtEnd(xData,yData,'PropertyName',PropertyValue,...)
```

Input:

- xData : The x-axis values of the plotted line. If only one input is given to this constructor it will be interpreted as the yData input. (Then the xData will be 1:size(yData,1))
- yData : The y-axis values of the plotted line. A double matrix. (1. dimension the number of observations and 2. dimension the number of variables.)

Optional input:

- varargin : 'PropertyName', PropertyValue, ...

Output:

- obj : An object of class nb_plotBarAtEnd

Examples:

```
h = nb_plotBarAtEnd(1:150,rand(150,1),'lineStop',40,'barPeriods',[50,100,150]);
```

- [markerSize](#)
- [xData](#)
- [children](#)
- [legendInfo](#)
- [marker](#)
- [parent](#)
- [yData](#)

- **barPeriods** ↑

The periods for where to plot the bar. E.g 3 or [3,4]

- **cData** ↑

The color data of the line plotted. Must be of size; size(yData,2) x 3. With the RGB colors. or a cellstr with the color names. See the method interpretColor of the nb_plotHandle class for more on the supported color names.

Inherited from superclass NB_PLOT

- **cDataBar** ↑

A string with the color specification to use for the bars
({'nb'} | 'red' | 'green' | 'yellow' | '')

- **children** ↑

The children of the handle. As nb_line handles

Inherited from superclass NB_PLOT

- **clipping** ↑

{'on'} | 'off' ; Clipping mode. MATLAB clips lines to the axes plot box by default. If you set Clipping to off, lines are displayed outside the axes plot box.

Inherited from superclass NB_PLOT

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

Inherited from superclass NB_PLOT

- **endBarWidth** ↑

The width of the bars at the end.

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend

Inherited from superclass NB_PLOT

- **lineStop** ↑

The period that the line should be stopped. E.g. 2.

- **lineStyle** ↑

The line style of the plotted data. Either a string or a cell array with size as the number of lines to be plotted. {'-' } | '--' | '---' | ':' | '-' | 'none'

Inherited from superclass NB_PLOT

- **lineWidth** ↑

The line width of the plotted data. Must be a scalar. Default is 2.5.

Inherited from superclass NB_PLOT

- **marker** ↑

The markers of the lines. Either a string or a cell array with size as the number of lines to be plotted. See marker property of the MATLAB line function for more on the options of this property

Inherited from superclass NB_PLOT

- **markerEdgeColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

Inherited from superclass NB_PLOT

- **markerFaceColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

Inherited from superclass NB_PLOT

- **markerSize** ↑

Size of the markers. Default is 9.

Inherited from superclass NB_PLOT

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **side** ↑

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

Inherited from superclass NB_PLOT

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'

Inherited from superclass NB_PLOT

- **xData** ↑

The x-axis data. As a double.

Inherited from superclass NB_PLOT

- **yData** ↑

The y-axis data. As a double.

Inherited from superclass NB_PLOT

Methods:

- [findClosestNiceNumber](#)
- [findLimitsAlgo](#)
- [get](#)
- [getDefauleColors](#)
- [interpretColor](#)
- [set](#)

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...  
scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► findLimitsAlgo ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:**See also:**

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_fanChart

Input:

- obj : An object of class nb_fanChart
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('central');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvít','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_plot. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_plot
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_plot with the given properties reset

Examples:

```
obj.set('propertyName',propertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ **nb_plotComb**

Go to: [Properties](#) | [Methods](#)

```
obj = nb_plotComb(xData,yData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a class for plotting data with different plot types

The plotypes supported by this function are:

- 'area' : Uses the nb_area class
- 'line' : Uses the nb_plot class
- 'grouped' : Uses the nb_bar class, with the property style

```
        set to 'grouped'  
- 'stacked' : Uses the nb_bar class, with the property style  
        set to 'stacked'
```

Constructor:

```
obj = nb_plotComb(xData,yData,varargin)
```

Input:

- xData : The x-axis values of the plotted line. If only one input is given to this constructor it will be interpreted as the yData input. (Then the xData will be 1:size(yData,1))
- yData : The y-axis values of the plotted line. A double matrix. (1. dimension the number of observations and 2. dimension the number of variables.)

Optional input:

- varargin : 'propertyName',PropertyValue,...

Output:

- obj : An object of class nb_plotComb (handle).

Examples:

```
nb_plotComb([0,2]);
```

same as

```
nb_plotComb([0,1],[0,2;2,3]);
```

```
nb_plotComb([0,1],[0,2],'propertyName',PropertyValue,...);
```

e.g.

```
nb_plotComb([0,1],[0,2;2,3],'types',{'area','line'},...  
'lineWidth',1.5);
```

Return the handle to the plotted line:

```
l = nb_plotComb([0,1],[0,2;2,3],'types',{'area','line'},...  
'lineWidth',1.5);
```

Which you can use to set and get properties:

```
l.set('cData',{'black','red'});  
lw = l.get('lineWidth');
```

Written by Kenneth SÃ¶terhagen Paulsen

Properties:

- abrupt
- alpha1
- alpha2
- barWidth
- baseValue
- baseline
- blend
- cData
- children
- clipping
- deleteOption
- direction
- edgeColor
- edgeLineStyle
- edgeLineWidth
- legendInfo
- lineWidth
- marker
- markerEdgeColor
- markerFaceColor
- markerSize
- parent
- shadeColor
- shaded
- side
- types
- visible
- xData
- yData

- **abrupt** ↑

Set this property to true to make the areas abruptly finish when given as nan.

- **alpha1** ↑

Sets the alpha blending parameter nr 1 when blend is set to true.

- **alpha2** ↑

Sets the alpha blending parameter nr 1 when blend is set to true.

- **barWidth** ↑

Width of the bars. As a scalar. 0.45 is default.

- **baseValue** ↑

The base value of the plot. Must be a scalar or a vector with size size(yData,1) x 1. The last option is not supported if any of the variables are plot as area!

- **baseline** ↑

A nb_horizontalLine handle (object). Use the set and get methods of this handle to change the baseline properties.

Caution: If baseValue is a vector this property is a nb_line object.

- **blend** ↑

When shaded is used, and this option is set to true, it will do alpha blending with shadeColor instead of shading.

- **cData** ↑

The color data of the line plotted. Must be of size; size(yData,2) x 3 with the RGB colors or a cellstr with size 1 x size(yData,2) with the color names.

- **children** ↑

The children of the handle. As nb_plot, nb_bar and nb_area handles (objects)

- **clipping** ↑

{'on'} | 'off' ; Clipping mode. MATLAB clips lines to the axes plot box by default. If you set Clipping to off, lines are displayed outside the axes plot box.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **direction** ↑

The direction of the shading; {'north'} | 'south' | 'east' | 'west' (Only bar plot)

- **edgeColor** ↑

The color of the edge of the bars. In RGB colors | 'none' : No edgeLine | 'same' : Same color as the base color for each bar | a string with the color name.

- **edgeLineStyle** ↑

Line style of the edge of area and bar plots.

- **edgeLineWidth** ↑

Line width of the edge of area and bar plots.

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- **lineStyle** ↑

The line style of the plotted data. Either a string or a cell array with size as the number of lines to be plotted. {'-' } | '--' | '---' | ':' | '-' | 'none'

- **lineWidth** [↑](#)

The line width of the plotted data. Must be a scalar.
Default is 2.5.

- **marker** [↑](#)

The markers of the lines. Either a string or a cell array with size as the number of lines to be plotted. See marker property of the MATLAB line function for more on the options of this property

- **markerEdgeColor** [↑](#)

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **markerFaceColor** [↑](#)

A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **markerSize** [↑](#)

Size of the markers. Must be an integer. Default is 9.

- **parent** [↑](#)

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **shadeColor** [↑](#)

The color the shaded bar plots are interpolated with.
A 1x3 double with the RGB colors | 'none' | {'auto'} | a string with the color name.

- **shaded** [↑](#)

Index of which data should be shaded. A matrix with size; size(yData,1) x 1 , 1 x size(yData,1) or size(yData,1) x number of variables to be plotted as bars

- **side** [↑](#)

{'left'} | 'right' ; Which axes to plot on. Only if the parent is off class nb_axes. (Which is the default)

- **types** ↑

A cell array of the plot type of each column of the property 'yData'. Must have same size as size(yData,2). Supported types : 'line','grouped','stacked' and 'area'.

- **visible** ↑

Sets the visibility of the plotted lines. {'on'} | 'off'.

- **xData** ↑

The x-axis data. As a double.

- **yData** ↑

The y-axis data. As a double.

Methods:

- [findClosestNiceNumber](#)
- [findLimitsAlgo](#)
- [get](#)
- [getDefauleColors](#)
- [interpretColor](#)
- [set](#)

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number,...  
scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Examples:

See also:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_plotComb

Input:

- obj : An object of class nb_plotComb
- propertyName : A string with the propertyName

Output:

- propertyValue : The value of the given property

Examples:

```
propertyValue = obj.get('baseline');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:**See also:**

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÃ¥','b'  
> 'red','rÃ¥d','r'  
> 'green','grÃ¶nn','g'  
> 'orange','o'  
> 'light blue','lys blÃ¥','lb'  
> 'black','svart','k'  
> 'grey','grÃ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÃ¥','hb'  
> 'deep blue','mÃ¥rk blÃ¥','db'  
> 'water blue','vannblÃ¥','vb'  
> 'cool grey','kald grÃ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÃ¶terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set** ↑

```
set(obj,varargin)
```

Description:

Sets the properties of an object of class nb_plotComb. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multple properties could be set with one method call.

Input:

- obj : An object of class nb_plotComb
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_plotComb with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth SÃ¶therhagen Paulsen

■ nb_plotLabels

Go to: [Properties](#) | [Methods](#)

nb_annotation, handle

Description:

A class for plotting labels different types of plots.

Constructor:

```
obj = nb_plotLabels(varargin)
```

Input:

Optional input ('propertyName', PropertyValue) :

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_plotLabels

See also:

[nb_annotation](#), [handle](#), [nb_axes](#)

Written by Kenneth Sætherhagen Paulsen

Properties:

- [children](#)
- [copyOption](#)
- [deleteOption](#)
- [fontName](#)
- [fontUnits](#)
- [formatAll](#)
- [formatCells](#)
- [formatColumns](#)
- [formatRows](#)
- [language](#)
- [listeners](#)
- [normalized](#)
- [parent](#)
- [pointer](#)
- [selected](#)

- **children** ↑

The children of the handle.

Inherited from superclass NB_ANNOTATION

- **copyOption** ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass NB_ANNOTATION

- **deleteOption** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass NB_ANNOTATION

- **fontName** ↑

Name of the font to use. Must be a string. Default is 'arial'.

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the fontSize property.

normalized - Interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen fontSize accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

- **formatAll** ↑

Format of all the labels of this object. As 1 x 1 struct. Will be overwritten by formatColumns, formatRows and formatCells.

- **formatCells** ↑

Internal cell representation of each label. As a cell array of structs. Highest presedence.

- **formatColumns** ↑

Format of selected columns. As a cell array of structs. Will be overwritten by formatRows and formatCells.

- **formatRows** ↑

Format of selected rows. As a cell array of structs. Will be overwritten by formatCells.

- **language** ↑

Sets the language of the text. I.e. how decimal sign should be plotted. {'english'} | 'norwegian'.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **normalized** ↑

Indicate if the font when fontUnits is set to 'normalized' should be normalized to the axes ('axes') or to the figure ('figure'), i.e. the default axes position [0.1 0.1 0.8 0.8].

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object. When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

Methods:

- [set](#)
-

► [set](#) ↑

```
set(obj, varargin)
```

Description:

Set properties of the nb_plotLabels class

Input:

- varargin : Property name property value pairs.

Written by Kenneth S. Paulsen

■ nb_radar

Go to: [Properties](#) | [Methods](#)

```
obj = nb_radar(xData,varargin)
```

Superclasses:

handle, nb_plotHandle

Description:

This is a Class for making radar plots

This class will make the radar plot automatically fit the axes it is plot into.

I recommend to use the nb_* classes for the legend, titles and so on.

Constructor:

```
nb_radar(xData)
nb_radar(xData,'propertyName',propertyValue,...)
handle = nb_radar(xData,'propertyName',propertyValue,...)
```

Input:

- xData : The data to plot. size(xData,1) = number of variables and size(xData,2) = number of observations

Optional input:

- varargin : 'propertyName',propertyValue,...

Output:

- obj : An object of class nb_radar (handle).

Examples:

```
nb_radar(xData)
nb_radar(xData,'propertyName',PropertyValue,...)
handle = nb_radar(xData,'propertyName',PropertyValue,...)
radar = nb_radar([1,2; 2,4; 3,5; 2,1; 3,4; 2,5],...
    'numberOfIsoLines',10);
```

Written by Kenneth Sæterhagen Paulsen

Properties:

- axesColor
- axesLimMax
- axesLimMin
- axesLineWidth
- cData
- deleteOption
- fontColor
- fontName
- fontSize
- fontUnits
- fontWeight
- isoLineColor
- isoLineStyle
- isoLineWidth
- labels
- legendInfo
- lineWidth
- location
- numberOfIsoLines
- parent
- rotate
- scale
- visible
- xData

- axesColor ↑

A 1x3 double with the RGB color or a string with the color name of the axes

- axesLimMax ↑

The axes max limit. Must be a double with size size(xData,1)x1

- axesLimMin ↑

The axes min limit. Must be a double with size size(xData,1)x1

- axesLineWidth ↑

The axes line width. As a scalar.

- cData ↑

The colors of the plotted data. Must be of size; length(xData) x 3. (Double with the RGB colors). Or a cellstr with the color names. Must be of size 1 x length(xData). See the method interpretColor of the nb_plotHandle class for more on the supported color names.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object.

- **fontColor** ↑

The color of the font of the labels. Either a 1x3 double with the color of all the labels or a size(xData,1) x 3 with the color of each label (RGB colors). Can also be a string with the color names to use on all labels or a cellstr with the color names of each label. Size must be 1 x size(xData,1)

- **fontName** ↑

Name of the font used for the labels. As a string. 'arial' is default.

- **fontSize** ↑

Size of the font used for the labels. As a scalar.

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the fontSize property.

normalized - Interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen fontSize accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

- **fontWeight** ↑

Weight of the font used for the labels. As a string. 'normal' is default.

- **isoLineColor** ↑

A 1x3 double with the RGB color or a string with the color name of the isocurves

- **isoLineStyle** ↑

The line style of the isocurves. As a string.

- **isoLineWidth** ↑

The line width of the isocurves. As a scalar.

- **labels** ↑

A cell array with the labels of the plot. Must have the same size as; size(xData,1). Each element of the cell array can consist of char with more lines. I.e.
{'A string',char('In a char','with two lines'),...}

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend

- **lineStyle** ↑

Line style of the plotted data. As a string or a cellstr with size size(xData,2).

- **lineWidth** ↑

Line width of the plotted data. As a double.

- **location** ↑

'west' | 'east' | {'center'}. The location of the plot in the axes.

- **numberOfIsoLines** ↑

The number of isocurves of the radar plot. Must be an integer. Default is 10.

- **parent** ↑

The parent axes you wan to plot on, if not given it will be plotted in a new nb_axes handle. Either a axes or a nb_axes handle (recommended).

Inherited from superclass NB_PLOTHANDLE

- **rotate** ↑

Rotate the radar. In radians. Must be a scalar. Default is 0.

- **scale** ↑

Sets the axes limits, so the radar plot is scaled properly. (Also set the size of the plotted radar). Must be a 1x2 double. Default is [2,1.25].

- **visible** ↑

Sets the visibility of the radar plot. {'on'} | 'off'.

- **xData** ↑

The data to plot. size(xData,1) = number of observations and size(xData,2) = number of variables

Methods:

- [findClosestNiceNumber](#)
 - [findLimitsAlgo](#)
 - [get](#)
 - [getDefauleColors](#)
 - [interpretColor](#)
 - [set](#)
-

► **findClosestNiceNumber** ↑

```
niceNumber = nb_plotHandle.findClosestNiceNumber(number, ...
                                                 scaleNumber, up)
```

Description:

A static method of the nb_plotHandle class.

Find first "nice" number, used for deciding the y-axis limits when findAxisMethod == 3 is used.

Input:

- number : The given number to find a "nice" number close to.
- scaleNumber : The scale factor used. I.e. the precision of the algorithm.
- up : 1 if rounding up, 0 if rounding down.

Output:

- niceNumber : The number which is "nice" and close to the input number.

Examples:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **findLimitsAlgo** ↑

```
ylimit = nb_plotHandle.findLimitsAlgo(dataLow,dataHigh,method,fig)
```

Description:

A static method of the nb_plotHandle class.

Figure out the limits of prepared data by the subclasses of this class

Input:

- dataLow : A double with the lowest values to plot
- dataHigh : A double with the highest values to plot
- method : The method to use when finding the y-axis limits.
 - > 1: Uses the floor and ceil methods. (Give problem when graphing small number)
 - > 2: Add some space in both direction of the y-axis. (The limits will seldom be nice numbers.)
 - > 3: Uses the submethod findClosestNiceNumber of the class to decide on the limits. (Also this method have can have problems with data which is not symmetric around the zero line.)
 - > 4 : Uses the MATLAB algorithm for finding the axis limits.

Output:

- ylimit : The y-axis limits. Given by a 1 x 2 double.
[lowerlimit upperlimit]

Inherited from superclass NB_PLOTHANDLE

► **get** ↑

```
propertyValue = get(obj,propertyName)
```

Description:

Get a property of an object of class nb_radar

Input:

- obj : An object of class nb_radar
- propertyName : A string with the propertyName

Output:

- PropertyValue : The value of the given property

Examples:

```
PropertyValue = obj.get('children');
```

Written by Kenneth S. Paulsen

► **getDefaultColors** ↑

```
defaultColors = nb_plotHandle.getDefaultColors(dataSize)
```

Description:

A static method of the nb_plotHandle class.

Get the default colors given the number of plotted variables.

Input:

- dataSize : Number of plotted variables.

Output:

- defaultColors : The default colors, as a M x 3 double of the RGB colors. M is the number of plotted variables.

Examples:

Written by Kenneth Sæterhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **interpretColor** ↑

```
colors = nb_plotHandle.interpretColor(colors)
```

Description:

A static method of the nb_plotHandle class.

Interpret the colors when given as a cell array of strings

Supported color names are:

```
> 'blue','blÅ¥','b'  
> 'red','rÅ,d','r'  
> 'green','grÅ,nn','g'  
> 'orange','o'  
> 'light blue','lys blÅ¥','lb'  
> 'black','svart','k'  
> 'grey','grÅ¥','gr'  
> 'purple','lilla','p'  
> 'yellow','gul','y'  
> 'magenta','m'  
> 'white','hvit','w'  
> 'cyan','c'  
> 'burgundy','burgunder'  
> 'sky blue','himmelblÅ¥','hb'  
> 'deep blue','mÅ,rk blÅ¥','db'  
> 'water blue','vannblÅ¥','vb'  
> 'cool grey','kald grÅ¥','cgr'  
> 'sand','s'  
> 'pink','rosa','pi'  
> 'turquoise','turkis','t'
```

Input:

- colors : A cellstr with the colornames. E.g. {'red','green'}

Output:

- colors : A M x 3 double with the RGB colors matching the input cellstr. Where M is the length of the input.

Written by Kenneth SÅ;terhagen Paulsen

Inherited from superclass NB_PLOTHANDLE

► **set ↑**

set(obj,varargin)

Description:

Sets the properties of an object of class nb_radar. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- obj : An object of class nb_radar
- varargin : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- obj : The same object of class nb_radar with the given properties reset

Examples:

```
obj.set('propertyName',PropertyValue,...);
```

Written by Kenneth Sæterhagen Paulsen

■ nb_regressLine

Go to: [Properties](#) | [Methods](#)

nb_textAnnotation, nb_annotation, handle

Description:

A class for adding a regression line to a scatter plot.

Constructor:

```
obj = nb_regressLine(varargin)
```

Input:

Optional input ('propertyName', PropertyValue):

> You can set some properties of the class. See the list below.

Output

- obj : An object of class nb_regressLine

Examples:

[nb_annotation](#), [nb_graph_ts](#), [nb_graph_cs](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- `cData`
- `copyOption`
- `fontName`
- `fontWeight`
- `interpreter`
- `listeners`
- `markerFaceColor`
- `parent`
- `positionY`
- `textBackgroundColor`
- `textLineWidth`
- `verticalAlignment`
- `children`
- `decimals`
- `fontSize`
- `horizontalAlignment`
- `lineStyle`
- `marker`
- `markerSize`
- `pointer`
- `selected`
- `textColor`
- `textMargin`
- `clipping`
- `deleteOption`
- `fontUnits`
- `index`
- `lineWidth`
- `markerEdgeColor`
- `normalized`
- `positionX`
- `string`
- `textEdgeColor`
- `textRotation`

- **`cData`** ↑

The color data of the line plotted. Must be of size; nRegLines x 3. With the RGB colors. Or a string with the name of the color. See the method `interpretColor` of the `nb_plotHandle` class for more on the supported color names.

- **`children`** ↑

The children of the handle.

Inherited from superclass `NB_ANNOTATION`

- **`clipping`** ↑

{'on'} | 'off' ; Clipping mode. MATLAB clips lines to the axes plot box by default. If you set Clipping to off, lines are displayed outside the axes plot box.

- **`copyOption`** ↑

Set to true if a copy option should be added to the context menu of annotation object. Default is false.

Inherited from superclass `NB_ANNOTATION`

- **`decimals`** ↑

Number of decimals. Default is 2.

- **`deleteOption`** ↑

{'all'} | 'only'. If 'all' is given the object will be delete and all that is plotted by this object are removed from the figure it is plotted on. If on the other hand 'only' is given, it will just delete the object

Inherited from superclass `NB_ANNOTATION`

- **fontName** ↑

Name of the font to use. Must be a string. Default is 'arial'.

Inherited from superclass NB_TEXTANNOTATION

- **fontSize** ↑

Sets the font size in the units given by the fontUnits property. Must be a scalar. Default is 12.

Inherited from superclass NB_TEXTANNOTATION

- **fontUnits** ↑

{'points'} | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units. MATLAB uses this property to determine the units used by the fontSize property.

normalized - Interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen fontSize accordingly.

pixels, inches, centimeters, and points:
Absolute units. 1 point = 1/72 inch.

Inherited from superclass NB_TEXTANNOTATION

- **fontWeight** ↑

Weight of text characters. {'normal'} | 'bold' | 'light' | 'demi'

Inherited from superclass NB_TEXTANNOTATION

- **horizontalAlignment** ↑

Horizontal alignment of text. Specifies the horizontal justification of the text string. Must be a string.
'left' | 'center' | 'right'.

- **index** ↑

Selects the scatter plot to add the regression line to. I.e. if there is plotted to scatter plots to an axes this property can be set to either 1 or 2. (If <1, 1 is selected. If >2, 2 is selected. In this example)

- **interpreter** ↑

Interpret TeX instructions. Must be a string. 'latex' | {'tex'} | 'none'.

- **lineStyle** ↑

The line style of the plotted data. Must be a string.
{'-' } | '--' | ':' | '-' | 'none'. '---' is not supported.

- **lineWidth** ↑

The line width of the plotted data. As an integer.

- **listeners** ↑

The listeners of the handle.

Inherited from superclass NB_ANNOTATION

- **marker** ↑

The markers of the lines. Must be a string. See marker property of the MATLAB line function for more on the options of this property

- **markerEdgeColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'}.

- **markerFaceColor** ↑

A 1x3 double with the RGB colors | 'none' | {'auto'}.

- **markerSize** ↑

Size of the markers. Must be a integer. Default is 9.

- **normalized** ↑

Indicate if the font when fontUnits is set to 'normalized' should be normalized to the axes ('axes') or to the figure ('figure'), i.e. the default axes position [0.1 0.1 0.8 0.8].

Inherited from superclass NB_TEXTANNOTATION

- **parent** ↑

The parent as an nb_axes object

Inherited from superclass NB_ANNOTATION

- **pointer** ↑

The pointer selected when the mouse is above the object. When not above the object '' is selected.

Inherited from superclass NB_ANNOTATION

- **positionX** ↑

Manually set the x-axis position of the label. Must be a 1 x nRegLines double.

- **positionY** ↑

Manually set the x-axis position of the label. Must be a 1 x nRegLines double.

- **selected** ↑

Indicates if the object is being selected.

Inherited from superclass NB_ANNOTATION

- **string** ↑

Text of regression line label. Default is the regression equation and R^{2} results. Must be a 1 x nRegLines cellstr.

- **textBackgroundColor** ↑

Color of text background rectangle. Must be of size; 1x3. With the RGB colors. Or a string with the name of the color. See the method interpretColor of the nb_plotHandle class for more on the supported color names. Can also be set to 'none'.

- **textColor** ↑

Color of text. Must be of size; 1 x 3. With the RGB colors. Or a string with the name of the color. See the method interpretColor of the nb_plotHandle class for more on the supported color names.

- **textEdgeColor** ↑

Color of edge of text rectangle. Must be of size; 1 x 3. With the RGB colors. Or a string with the name of the color. See the method interpretColor of the nb_plotHandle class for more on the supported color names. Can also be set to 'none'.

- **textLineWidth** ↑

Width of text rectangle edge. Must be a scalar. Default is 0.5.

- **textMargin** ↑

Space around text. A value in pixels that defines the space around the text string, but within the rectangle. Default value is 5 pixels.

- **textRotation** ↑

Text orientation. Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation). Must be a scalar. Default is 0.

- **verticalAlignment** ↑

Vertical alignment of text. Specifies the vertical justification of the text string. Must be a string. {'top'} | 'cap' | 'middle' | 'baseline' | 'bottom'.

Methods:

- **set**

► **set** ↑

`set(obj,varargin)`

Description:

Sets the properties of an object of class nb_drawLine. Give the property name as a string. The input that follows should be the value you want to assign to the property.

Multiple properties could be set with one method call.

Input:

- `obj` : An object of class nb_drawLine
- `varargin` : Every odd input must be a string with the name of the property wanted to be set. Every even input must be the value you want to set the given property to.

Output:

- `obj` : The same object of class nb_drawLine with the given properties reset

Examples:

`obj.set('propertyName',propertyValue,...);`

Written by Kenneth Sæterhagen Paulsen

■ **nb_scatter**
Go to: [Properties](#) | [Methods](#)

`obj = nb_scatter()`

Superclasses:

handle, nb_plotHandle

Description:

Create scatter plot

Constructor:

obj = nb_scatter()

The constructor of the nb_scatter class

Input:

- xData : See below
- yData : See below

Optional inputs:

- varargin : ..., 'propertyName', PropertyValue, ...

Output:

- obj : An object of class nb_scatter

See also:

[scatter](#)

Written by Kenneth Sæterhagen Paulsen

Properties:

- cData
- children
- deleteOption
- legendInfo
- lineWidth
- marker
- markerSize
- parent
- side
- type
- visible
- xData
- yData

- **cData** ↑

Color of the plotted data. A matrix;
size(yData,2) x 3 (RGB color). Or a cellstr
with the color names. (With size 1 x size(yData,2))

- **children** ↑

The children of the object. As MATLAB scatter objects.

- **deleteOption** ↑

'all' | {'only'}. If 'all' is given the object will be
delete and all that is plotted by this object are removed
from the figure it is plotted on. If on the other hand
'only' is given, it will just delete the object.

- **legendInfo** ↑

{'off'} : Not included in the legend. 'on' : included in the legend.

- **lineStyle** ↑
